14. Internationale Tagung Wirtschaftsinformatik (WI 2019)

Tagungsband

Vorwort der Tagungsleitung

Die Internationale Tagungsserie Wirtschaftsinformatik (WI 2019) ist mit ihrer 14. Ausgabe seit über 25 Jahren die größte Wirtschaftsinformatik-Konferenz im deutschsprachigen Raum und ihr Themenfeld hat nichts von seiner ökonomischen und gesellschaftlichen Brisanz verloren. Es scheint im Gegenteil so zu sein, dass erst langsam deutlich wird, wie konsequent Informationstechnologien jeden Aspekt unseres Alltags, ja unserer Existenz, umgestalten. Heute nennen wir diesen Umgestaltungsprozess „Digitalisierung“, und er entspricht bildlich gesehen einer Flamme, von der immer noch nicht klar sein mag, ob sie wärmt oder verbrennt, aber jedem wird klar, dass man sich damit auseinandersetzen muss.

Was bedeutet dies für die Wirtschaftsinformatik als Motor und wissenschaftlicher Unterbau dieses Umgestaltungsprozesses? Der Natur einer Wissenschaft entspricht es, sich nicht auf Ihren Erfolgen auszuruhen, sondern das Erreichte in seinen ökonomischen und gesellschaftlichen Effekten kritisch zu reflektieren, und nach neuen Herausforderungen zu suchen. Aus diesem Grund stellten wir die Konferenz 2019 in Siegen unter das Motto

„Human Practice. Digital Ecologies. Our Future.“

Damit bringen wir das komplexe Geflecht aus menschlicher Praxis und Praktik sowie ganzer digitalen Ökologie zu Ausdruck, das einen starken Einfluss auf unsere gemeinsame Zukunft und die Art wie wir arbeiten, aber vor allem auch leben werden, haben wird.

Mitten in diesem komplexen Geflecht der Digitalisierung erfahren wir, wie unsere Wissenschaftsdisziplin ihre Monopolstellung zu ökonomisch relevanten Digitalisierungsfragen in dem Maße verliert, in dem sich andere Disziplinen mit diesen Konzepten und Effekten stärker auseinandersetzen. Hier finden sich Beispiele von der Politologie über Jura, bis hin zur Verfahrenstechnik und zum Maschinenbau. „Unsere“ Zukunft ist eben nicht nur die Zukunft der Wirtschaftsinformatik an sich, sondern auch die Zukunft der Gestaltung ihrer Beziehung zu anderen Domänen und Wissenschaftsdisziplinen.

Dieses Zusammenwirken der verschiedenen Anwendungsbereiche haben wir versucht in 14 wissenschaftlichen Tracks widerzuspiegeln. Diese reichten von bereits etablierten Tracks wie Unternehmensmodellierung oder IT-Management bis zu den eher neueren Tracks wie Cyber-Physische Systeme, eHealth oder Umweltinformatik. Um die Wirtschaftsinformatik aus den verschiedenen gesellschaftlichen Bereichen zu betrachten, fokussierten die Keynotes der drei Tage auf die Bereiche Industrie (Herr Dr. Robert Zores von der REWE Digital GmbH und Frau Claudia Lensker von der Finanz Informatik GmbH & Co. KG), Wissenschaft (Prof. Dr. Gerhard Fischer von der

University of Colorado Boulder) und Verbraucher (Frau Helga Zander-Hayat von der Verbraucherzentrale NRW e.V.). Die zusätzlichen vier Panels zu Themen wie KI-basierte Digitale Assistenten, Arbeit 4.0 oder DSGVO untermauerten den Gedanken einer vernetzten Wirtschaftsinformatik.

Ergänzt wurde das wissenschaftliche Programm durch drei Special Tracks. Neben dem Praktiker- sowie Student-Track, gab es erstmalig auch einen expliziten Poster- und Demotrack, um vor allem auch NachwuchswissenschaftlerInnen die Möglichkeit zu geben, ihre Arbeiten zu präsentieren. Zusätzlich fand im Vorfeld der Konferenz das Doctorial Consortium, sowie der Workshoptag bestehend aus acht Workshops statt, in denen kontrovers über Dissertationen, aber auch über neue Forschungsbereiche und -themen diskutiert wurde.

Wir freuen uns als Conference Chairs, dass wir insgesamt 765 Teilnehmende in Siegen begrüßen durften, die das Event zu einer großartigen Veranstaltung gemacht haben. Aus den insgesamt 342 Full Paper Submissions wurden am Ende 119 Paper (Akzeptanzrate 34 %) ausgewählt und von den 81 Research-in-Progress Submissions schafften es am Ende 27 (Akzeptanzrate 33 %). Gleichzeitig wurden 25 Poster und 12 Demonstratoren akzeptiert, welche das Programm in zwei interaktiven Sessions ergänzten.

Die Gestaltung des Programms wäre ohne die 42 Track Chairs, die 272 Associate Editors und insgesamt 755 Reviewer nicht möglich gewesen. An dieser Stelle möchten wir uns herzlich für die tatkräftige Unterstützung bedanken. Der vorliegende Tagungsband fasst die Namen aller beteiligten Personen im Begutachtungs- und Auswahlprozess noch einmal zusammen.

Aus den Vorträgen heraus ergab sich eine Vielfalt an Themen, die auch auf den Social Events wie dem zum zweiten Mal stattfindenden Academic Networking Dinner und der erstmals im Format einer Empfangsgala veranstalteten Konferenzdinner mitsamt Poster und Demos zu einem regen Austausch führten.

Unser Dank gilt außerdem den zahlreichen Sponsoren und Freunden der Konferenz, welche durch ihre finanzielle Unterstützung die Konferenz überhaupt erst ermöglichten. Zusätzlich bedanken wir uns bei dem gesamten Organisationsteam, das über mehrere Monate vollen Fokus auf eine erfolgreiche WI 2019 gelegt hatten.

Abschließend bedanken wir uns bei allen Teilnehmenden, die über insgesamt fünf Tage die Wirtschaftsinformatik-Konferenz in Siegen zu einer tollen Veranstaltung gemacht und mit ihrer guten Stimmung die Abendveranstaltungen sowie das Rahmenprogramm Siegen bereichert haben.

Requirements and a Meta Model for Exchanging Additive Manufacturing Capacities

Chiara Freichel[1], Adrian Hofmann[1], Marcus Fischer[1], and Axel Winkelmann[1]

[1] Julius-Maximilians-Universität Würzburg, Lehrstuhl für BWL und Wirtschaftsinformatik, Würzburg, Germany
{chiara.freichel,adrian.hofmann,marcus.fischer,axel.winkelmann}@uni-wuerzburg.de

Abstract. In an environment shaped by digital transformation and globalization, manufacturers face increasing market dynamics, cost pressure, and more sophisticated customer requirements. As this demands flexibility and adaptability, enterprises rely on new solutions for collaboration. A marketplace for production capacities supports companies in reducing order risks and improving responsiveness to changing market conditions. We seek to define requirements for a marketplace that is capable of matching products with production processes. With an initial focus on additive manufacturing, we aim to build a blueprint for similar application scenarios in other industrial contexts. Therefore, we employ a qualitative research based on expert interviews. Our results suggest that a marketplace for production capacities must address various requirements, which can be grouped under the categories of technologies, machines, and products. We further build a conceptual meta model that sets the groundwork for the matching and thus facilitates the implementation of the marketplace in practice.

Keywords: Additive Manufacturing, Market Engineering, Sharing Economy, Sharing Capacities, Two-sided Markets

1 Introduction

In a globalized and digitalized business environment, manufacturers face various challenges that question established strategies and business models. At the center of their business activities, the area of production is influenced by many of the current megatrends, including *Industry 4.0* or *Internet of Things*. They do not only alter production concepts. Enterprises also face more sophisticated customer requirements, increasing competitive pressure, and higher market dynamics. The ability of manufacturers to respond to these changes is mainly determined by their production capacities. On the one hand, the number of orders can exceed available capacities, yielding delays or the non-fulfillment of orders with negative consequences on sales and profits. On the other hand, underutilization imposes the risk of fixed costs that cannot be fully covered. Overcoming the tradeoff between availability and production capacity related costs is frequently perceived as a key factor for the competitiveness of

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

manufacturers [1]. Furthermore, specialization has led to the emergence of supply networks, in which enterprises focus on their core competencies to contribute to and jointly build a complex product or service [2]. This comes with a division of tasks, activities, and responsibilities, which yields direct and indirect interdependencies between market participants and the emergence of single points of failure [3].

To cope with these challenges, enterprises rely on solutions that enable them to adapt to dynamic market conditions by offering or sourcing production capacities to other market participants. This does not only provide enterprises with the opportunity to align capacities with demands, but also fosters collaboration, communication, and the coordination of distributed actors.

Nowadays, complex material flows are supported and controlled by integrated information systems [1]. Most Industry 4.0 scenarios require a seamless integration of processes and information flows based on advanced information and communication technology. Thereby, production planning systems provide enterprises with an integrated database that contains information about available capacities, current delivery times, and future demand [4]. While these systems offer various functionalities for the company-specific management of production capacities, they hardly support transactions between multiple participants that collaborate in a supply network [1].

Against this backdrop, this study[1] seeks to conceptualize a marketplace for production capacities that operationalizes data from multiple manufacturers and yield improvements in various dimensions, such as performance, quality, and costs. Implemented as a central platform, the solution connects to enterprise software of different supply chain participants and allows for superior communication and collaboration. Based on the principles of the *Sharing Economy*, the proposed marketplace matches products with production processes as well as supply and demand. Similar solutions, such as Uber for transportation and Airbnb for housing, have proven effective in various contexts and application scenarios [5, 6]. Due to the complexity of the underlying research problem, we initially focus on the production technology of additive manufacturing. Additive manufacturing is more flexible and subject to less constraints. Hence, it provides the optimal starting point for this research endeavor. It allows us to build a proof of concept and to establish a conceptual foundation for similar solutions that address the requirements of other industries. Our research is guided by the following research questions (RQ):

1. What are the requirements for a marketplace that enables manufacturers to exchange production capacities in the field of additive manufacturing?
2. How can we design a meta model that matches products to production processes and thus facilitate the practical of implementation of a marketplace for production capacities?

---

[1] The study is based on experiences of the research project "DiHP – Dienstleistung für den integrierten Handel mit Produktionskapazitäten" (reference code 02K16C100). It is supported by the BMBF's programme "Technikbasierte Dienstleistungssysteme". Duration: 08/17-08/20.

To answer these RQ, we structure this study as follows: we present related work on platforms and collaborations in supply networks in the subsequent section. We describe the applied research design in Section 3 and present the results of our interview study in Section 4. Subsequently, we integrate our findings and build a meta model for the matching of products and production processes in Section 5. Ultimately, Section 6 concludes this study with a summary of findings, limitations, and future research potentials.

2 Foundations and Related Work

The concept of *Collaboration in Supply Networks* describes networking manufacturers, which has gained tremendous importance in recent years [7]. More sophisticated customer needs, considerable product development costs, and market dynamics yield an increasing pressure on supply networks and require them to realize continuous performance improvements [8]. Effective collaboration can leverage economies of scale, specialization, and integration [9–11]. The ongoing trend of the *Sharing Economy* has already led to a reorganization of a variety of established business activities [12]. Innovative technologies and business models incorporate the principles of this emerging paradigm and change industries by reducing transactions costs and providing easier ways to interact with customers. Thereby, products are increasingly augmented with services, which can be offered and sold based on various business models.

Electronic Commerce (e-commerce) is frequently described as a subclass of *Electronic Business (e-business).* E-business does not only cover the buying and selling of products and services, but also includes internet-based activities, such as customer service or electronic transactions [13]. E-commerce belongs to the e-business paradigm and describes the generation of revenues by initiating, negotiating, or processing business transactions via networks [14]. In 2015, e-commerce revenues amounted to 1,55 trillion US dollars and are currently expected to increase to 3,4 trillion US dollars in 2019 [15–17].

Collaborative Business (c-business) augments e-business or e-commerce with the concept of collaboration. It provides a holistic view on processes and inter-organizational cooperation. The concept uses the notion of end-to-end processes to integrate all participants of a supply network that collaborate and interact via the Internet, EDI, e-portals, or e-marketplaces. Represented by delivery deadlines or demand forecasts, collaborations can yield benefits in various dimension through the exchange of information [18].

Electronic Platforms in e-business can be divided into three types: the concept of *e-procurement* focuses exclusively on electronic purchasing, while *e-shops* pertain to sales activities. Furthermore, *e-marketplaces* provide platforms for the exchange of products and services. Products or services should be offered or requested without charge, but in an organized manner [14]. As of now, there is no marketplace that connects with established enterprise software and allows enterprises to exchange production capacities in order to address demand or supply fluctuations.

Building an e-commerce platform for exchanging additive manufacturing capacities requires profound knowledge about corresponding production processes, configurations, and influence factors. In general, manufacturing defines an industrial or artisanal production process and describes the way in which something is made. The production of components is specified in geometric and material terms [19]. *Additive Manufacturing*, commonly known as 3D printing, is one way of manufacturing. However, additive manufacturing summarizes a variety of manufacturing processes with the aim of producing physical objects on the basis of digital models that are converted into layer models by so-called *slicing*. Additive manufacturing processes add material in layers to obtain a desired object [20–23]. In the past, several techniques have been introduced that differ in regard to the way in which layers are created and connected. Because manufacturing works process oriented and depends upon the used material and machines, the dimensions machines, processes and materials are characterized by significant interdependencies [24].

3 Research Methodology

We employ a qualitative research design based on expert interviews to determine requirements for a marketplace that exchanges additive manufacturing capacities. The chosen design is a result of the limited knowledge on marketplaces for capacity sharing. Hence, we rely on an explorative research approach that integrates the perceptions and opinions of multiple stakeholders with extensive knowledge and experience in the domain of interest. The following section summarizes our research method and elaborates on the selection of interview partners, the design of the semi-structured questionnaires, and the procedures performed for data collection and analysis.

3.1 Selection of Interview Partners

Out of all interview partners four groups of companies and associated experts are defined and interviewed: (1) *potential buyers* of additive manufacturing capacities, (2) *potential sellers* of additive manufacturing capacities, (3) *producers of machines* for additive manufacturing and (4) *platform providers*. The interviewees are required to have knowledge about essential IT and management concepts as well as about the additive manufacturing technology. To select the experts, we first interview various employees of the nine companies to ensure they possess the necessary knowhow.

We interview potential buyers and sellers that already use additive manufacturing, intend to use it in the future, or are interested in buying additive manufacturing capacities. We integrate producers of additive manufacturing machines to evaluate aspects that are relevant for the underlying production processes and platform providers to shed light on requirements that must be addressed when implementing the proposed marketplace in practice.

We use multiple criteria, such as market position, experience in the field of additive manufacturing and e-commerce platforms, and industry and company size for case selection. This leads to a final sample of nine companies with one expert each. It consists of three companies from each of the two groups of potential buyers (buyer A, buyer B, buyer C) and sellers (seller A, seller B, seller C), two manufacturers (manufacturer A, manufacturer B), and one platform operator (platform operator A). There is only one platform operator existing on the market, which can serve as a basis and orientation for our research project. Users of the platform are the key actors on the platform and therefore reflect the most important group for the development of requirements. For this reason, three experts are interviewed there. Machine manufacturers all have similar structures and do not differ as much as the companies using the platform. For this reason, fewer experts are surveyed than in the category of users.

3.2 Questionnaire Design

The interviews are conducted by phone and are based on group-specific semi-structured questionnaires. The questionnaires contain basic information for the interviewees as well as guidelines and questions.

In order to ensure high quality and rigorousness, we operationalize the criteria proposed by [25]. Not included are the criteria *scaling*, *standardization*, and *fairness*, as they are primarily relevant for psychological analysis.

The following section describes the structure of the questionnaires. They are designed in a semi-structured manner, as the interviewees have a basic knowledge of the topics of interest. The interviews are conducted flexibly on the basis of open questions and provide the opportunity to include emerging concepts and ideas [26, 27]. In addition, the questionnaire contains different question types. Besides essential, factual, or direct questions, which address the key topic of this study, so-called *throw-away questions*, introductory, and structuring questions are used to guide the interview progress [28].

Each of the four questionnaires is introduced with a short preamble explaining the goals and scope of this study. In addition to a verbal explanation of the research, we provide information about the recording procedures, anonymity agreements, and data privacy and ask for the interviewees' approval. This is followed by two questions about their educational and work background. Thereby, we ask them to provide general information about their company and their function and responsibilities within it. This allows us to draw conclusions about the quality of their answers and to consider them in subsequent phases of this research.

The second section contains two general questions that introduce the topic and prepare the interviewees for more complex questions. Hence, we ask the interviewees about potential benefits of exchanging additive manufacturing capacities on the one hand, and about possible challenges on the other hand. These questions only serve the flow of discussion and the answers are used to justify this research but are not presented in more detail.

The subsequent part of the questionnaire varies with the expert group. Section three of the questionnaire for manufacturers and platform operators covers the portfolio of additive manufacturing technologies and machines. Questions about selected additive manufacturing methods, models, and production machines as well as about their characteristics are to be answered. In contrast, the third part for platform users includes questions about the buying and selling of capacities. Questions in this section analyze the external and/or internal additive manufacturing capacities used so far as well as their reasons for using a platform in this context.

The fourth section of the questionnaires for manufacturers and platform operators requests information about their machines, such as target groups and industries, applications, and covered product categories. Platform users are further asked about required processes and for characteristics that can be used to distinguish processes and machines.

The fifth part of the questionnaire for platform operators contains questions about the matching of products and additive manufacturing processes. The experts are asked for necessary/unnecessary attributes that must be considered when designing a matching mechanism. The questionnaire for manufacturers does not have a fifth section. Platform users are asked to provide information about the characteristics of additively manufactured products, including their material or size and other aspects.

3.3 Data Collection and Analysis

In order to achieve high-quality results, we describe the employed procedures for data collection and analysis subsequently [29]. Prior to the actual data collection, a pilot study was conducted with two independent researchers. The test confirmed that the questionnaire is understandable, well-structured, and of reasonable length and complexity [28]. As a result, we did not implement any significant changes to the design of the questionnaire.

Despite the various advantages of personal interviews as pointed out by [28], long distances required us to conduct the interviews via phone. The full conversations were documented based on audio recordings.

For data analysis, we followed the process explained in [30]. First, the available audio recordings were transcribed. The transcripts were written literally, the sentence structure was adapted, and filling words were deleted. Finally, we anonymized the transcripts.

The transcripts were then analyzed in order to derive requirements for the matching of products and production processes. For this purpose, the process of content analysis according to [30] was initiated by coding the data. Codes allowed us to break down relevant information to keywords. The coding process was performed by using the MAXQDA Version 18.0.8 software. We initially used the frequencies with which certain words were mentioned in order to determine suitable codes. We sorted the resulting words, consolidated synonyms, and classified sub-codes in subsequent steps. We then formed summarizing categories to group codes with similar meanings. In the next iteration, we controlled whether and to what extent all relevant questions of the guideline were covered by the codes and categories. The results of the categorization provided the basis to derive requirements for matching and sharing additive manufacturing capacities.

4 Requirements for Capacity Exchange

Subsequently, we introduce the requirements for a marketplace for capacity sharing and thereby answer RQ1. In summary, data analysis yielded a total of 371 coded text passages that are relevant for this research and thus suitable for requirements engineering. The passages are grouped into three categories *(1) characteristics of additive manufacturing technologies and machines* (192 occurrences), *(2) characteristics of products to be additively manufactured* (149 occurrences), and *(3) matching products and additive manufacturing technologies* (30 occurrences).

The analysis is carried out by means of a category-based evaluation along the main topics summarized of these three categories [30]. We define requirements for the process of developing the matching and thus exchanging additive manufacturing capacities via an e-commerce platform.

Recent studies identified more than 200 machine types for additive manufacturing on the market [24]. As a basis for expert evaluation and discussion we performed in-depth analysis of literature and actual technical documentation available, which cannot be mapped-out in further detail within the limitations of this paper. However, the findings served as the necessary conceptual foundation of clustering the multitude of additive manufacturing technologies, machine types and suitable characteristics.

Although all manufacturing processes are based on the manufacturing steps already explained, they differ e.g. in terms of how the respective layers are manufactured and bonded and which material is processed.

First of all, it is necessary to examine which additive manufacturing processes can be used for which groups of material.

Requirement 1: Additive manufacturing processes for plastic materials must be evaluated for exchanging manufacturing capacities in a first step, as these are most frequently used in practice.

The first code in category *(1) characteristics of additive manufacturing technologies and machines* contains selected manufacturing technologies represented by subcodes. These were derived on the basis of word frequencies. According to the experts, additive manufacturing processes for plastics are most frequently used in an industrial context. The companies surveyed named the technologies Stereolithography (SLA), Binder Jetting/3D Printing (BJ/3DP), Selective Laser Sintering (SLS), Fused Deposition Modeling (FDM), Multi Jet Fusion/High Speed Sintering (MJF/HSS), Multi Jet Modeling/PolyJet (MJM/PJ) and Digital Light Processing (DLP). Experts have described these as standard technologies. The material group *plastics* represents the largest group of materials for additive manufacturing and is therefore the first category to be considered [24, 31]. Furthermore, the subcode *plastics* in category *(2) characteristics of products to be additively manufactured* implies that buyers A, B and C mainly manufacture plastic products. The focus on the material group *plastics* could thus be decided.

Requirement 2: Additive manufacturing processes for metal materials must be included in a second step due to a high relevance in industrial production.

Following the manufacturing processes for plastics, experts attribute high importance to Selective Laser Melting (SLM) as manufacturing technology for processing metals. Among the interviewees, manufacturer B described the advantages of the SLM process in particular detail: "On the one hand, there is a large variety of materials that can be processed. You can process almost all types of metallics that can be pulverized. On the other hand, the devices are relatively flexible in their settings for different parameters. […] Speed is another aspect. We have some of the fastest devices on the market […] and also have a high build-up rate. This is a very high value, which of course also leaves some potential to be exploited. […] A great advantage is knowing that the speed can be further increased and the quality can be maintained at the same time." This was assigned according to the material group *metals* by means of codes and should be included in further research work due to its relevance. A second requirement arises in relation to the choice of additive manufacturing processes for a matching.

Requirement 3: The characteristic *material* must be considered separately due to various dependencies and specifications.

A total of 45 text passages were coded with the code *material* in category *(1) characteristics of additive manufacturing technologies and machines*. Material is considered by interviewees to be one of the most important parameters of additive manufacturing technologies and machines, which is why it is considered separately. According to manufacturer B, parameter settings, such as device temperatures, depend on the specific material within one group (e.g. metal or plastic). Different material variants or different manufacturers of similar materials do not have to be differentiated at first. Almost all experts emphasize the relevance of quality factors in connection with materials, especially plastics. Material properties include impact resistance, stability, food safety, density and roughness. Furthermore, according to platform operator A, the intended use of the products depends on the selected material: "The difficulty is that it is unclear what certain products are intended to be used for, how durable they have to be, and whether one has to stick to certain specifications, which again depends on the machine or material." In terms of the code *quality*, strength, elongation at break, food safety, heat resistance or biodegradability in this work can be defined as material properties and not as product properties. *Density* was mentioned by manufacturer B and platform operator A as one property of products. This is also regarded as material property.

Requirement 4: The property *material* should be used to link devices to sales offers and purchase requests.

Platform operator A suggests an intense relationship between devices and materials ("processing"). Hence, we must account for them when matching, selling, and exchanging additive manufacturing capacities. The choice of additive manufacturing machines is largely determined by the choice of one or more materials. The property *material* must therefore be related to the purchase order as well as devices. One or more materials can be selected for exactly one purchase request. In return, exactly one sales offer with one or more materials can be offered in the area of sales of additive production capacities, since not all materials to be processed for devices necessarily have to be offered by vendors. Again, one or more materials can be processed by one or more devices. This also results in the following requirement.

Requirement 5: For selling production capacities, it is relevant to specify the materials available in the company.

In the interview with manufacturer B especially, we found that it is important to account for the availability of materials in the company that sells production capacities. This confirms to requirement 4.

Requirement 6: The attribute *quality* is considered in the context of the two characteristics material and layer thickness, since these depend significantly on the material, manufacturing technology, and intended use.

Experts consider quality as an important criterion, but it is dependent on the material, intended use, and technology. Sellers A and B as well as manufacturer B use the term *quality* in relation to materials and manufacturing methods. This has to be considered in the selection of the characteristics in further research work. Manufacturer B concludes correspondingly with regard to an achievable quality in additive manufacturing processes: "There are no welding seams [in additive manufacturing], so that the parts [...] have a higher performance. This makes it more resilient than if it had a welding seam". Buyers A and B use the term *quality* to describe the outer appearance of the product, e.g. its geometry or surface finish. Manufacturer A mentions it in connection with the strength of the product. Seller B also places quality in connection with the intended use of a product. Furthermore, the factor *quality* must be defined differently for different purposes. A prototype, for example, has different quality requirements (high, medium, low) compared to a functional component. Figure 1 illustrates these dependencies.

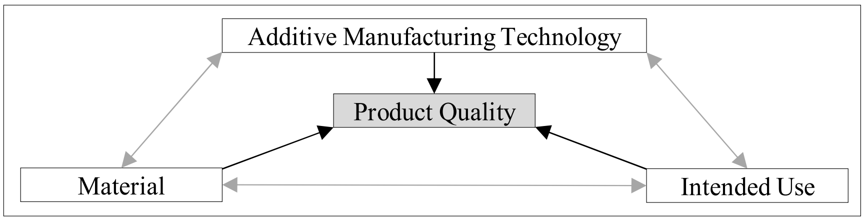

Figure 1. Factors Influencing Product Quality [32]

Within the scope of quality, sellers A, B and C consider it necessary to be aware of the purpose of a product or its category within the meaning of the subcode *product categories*. Often it is not possible to identify which products they manufacture. In this case, a request from the customer is necessary in order to be able to decide which production process is suitable for the respective application of the product in order to achieve the highest possible quality.

In relation to quality it is also necessary to investigate methods for post-processing, such as finishing, painting or assembly, which is represented by another code. In addition to platform operator A, the three groups of sellers named this characteristic. Seller B defines the removal or washing off of support structures in the FDM process as a standard process. Seller A, on the other hand, sees *CNC post-processing* as a necessary standard for increasing surface quality, which they could still not achieve. Seller C emphasizes that the material group *metals* in particular requires post-processing: "There are processes that are very new and more focused on the metal sector. This requires intensive mechanical post-processing, which we cannot do in-house, and therefore we have also made a certain selection there."

Requirement 7: Besides material group and material, multi-color, multi-material, and build volume dimensions/product size are relevant characteristics for matching additive manufacturing technologies and products.

As part of the code *multi-color* and *multi-material* in category *(1) characteristics of additive manufacturing technologies and machines*, the technology MJM/PJ offers the possibility of processing several colors during a production process, even if this is only in limited demand according to seller A. For seller B, the BJ/3DP method also enables multi-color. This confirms the statement that only a small number of procedures offer this functionality. Furthermore, a special feature in the area of plastics according to sellers A and C is the flexible material variety when using the MJM/PJ process. A distinction can be made between soft pressure and fixed pressure. According to the experts surveyed, most devices, with the exception of additional materials for support structures, have no functionality that supports processing more than one material. Platform operator A confirms the request for multi-material on the market. Seller A, on the other hand, experiences a rather low demand for multi-material.

In category *(2) characteristics of products to be additively manufactured* multi-color products are not relevant for buyers A, B and C. However, if this option is offered for a similar price, it would be an interesting option for the experts and thus, according to buyer C, a unique selling point of the products. The color is important for buyer B, as products are then painted, and the color of the base must therefore be accounted for. Similarly, buyer A emphasizes the importance offers that allow him to produce a desired color. This confirms the relevance of this criterion for future research.

Dimensions of the build volume serve as an important differentiator between various machines analyzed in category *(1) characteristics of additive manufacturing technologies and machines*. The space dimensions of the machines of all surveyed experts are smaller than one meter in height, width, and depth. The devices of manufacturer A, seller A, B and C can manufacture components of at least 5 mm in size. Sellers A defined typical sizes between 30 mm and 350 mm. These dimensions can be used as an average. A general statement on additive manufacturing technologies with predominantly larger or smaller dimensions cannot be formulated.

The experts agree that the size of the products for additive manufacturing is relevant for the selection process and can vary strongly. All experts of the group of buyers predominantly manufacture smaller products with approx. 5 mm to 200 mm in height, width and depth. Dimensions between 5 mm and 800 mm were mentioned. Platform operator A emphasized the fact that a product model which did not originally fit into the installation space can be made suitable by rotation or other slicing. In addition, a product that is too large could be manufactured in several parts and then be assembled.

Requirement 8: Production costs and time are one criterion for selecting additive production devices in comparison to conventional production processes and constitute an important requirement for the platform.

Another relevant code of category (1) *characteristics of additive manufacturing technologies and machines* is costs. Buyer B emphasized that by introducing the e-commerce platform, consideration would be given to the purchase of additive manufacturing devices. In addition, according to buyers B and C, the current production costs are one criterion for selecting additive production devices in comparison to conventional production processes. A distinction is also made between additive manufacturing processes with regard to acquisition costs as well as manufacturing and material costs. Manufacturer A describes the FDM process as the most cost-effective. Cost and price mechanisms on the developed platform are not considered in this work as a first analysis, but according to the interviewees they are an important factor, which will be included in further research.

Manufacturers A and B distinguish between machines according to their speed / production time, e.g. influenced by the size of the print head or the number and strength of the lasers in the SLM process. Buyer C considers speed to be an important factor in the purchase of additive manufacturing capacities. The relevance of the delivery time was emphasized according to buyer B: "For us only the delivery time of products is relevant. Of course, it depends on the priority of the order. [Normally we need our products] within two weeks." This was also emphasized in the sense of the code *production time*. Likewise, buyer C attaches importance to a certain speed. No distinction was made for buyer C between production and delivery time. Since production speed is dependent on the used technology, material, and quality in the sense of layer thicknesses and therefore require comprehensive analyses for comparability, separate research should be carried out in this respect.

Requirement 9: There is increasing potential in the application area of additive manufacturing for small series as well as series production. Therefore, the attribute quantity must be included in this analysis.

In a first step, the subcodes *prototypes*, *customized production*, *spare parts*, *small serie*s and *series production* are used to determine the purpose for which additively manufactured products are used. According to the experts, the products are mainly used as prototypes, individual production and spare parts. According to buyers A and C, platform operator A and seller C, there is increasing potential in the area of application of small series and series production. Manufacturer B has evolved from its original focus on prototype types to a manufacturer of additive production equipment for the production of functional components. Buyer B only focuses on individual production, which is in the focus of the company's business model. Both manufacturer A and seller A build spare parts or individual products for their own requirements for additive production machines. Small series and series production are often related to quantities. For example, platform operator A applies small series for quantities of 10 to 100 parts, while buyer A suggests that using additive manufacturing is beneficial even when producing series containing more than 100,000 parts.

Requirement 10: The platform should support application scenarios in different industries.

The subcode *industries* suggests that additive manufacturing is used across industries. The interviewees agree that the automotive industry especially benefits from the use of additive manufacturing. Buyers A, manufacturer B and platform operator A also name the medical, dental, and aviation industries as leading users of additive manufacturing.

5 Meta-Model

Based on the identified requirements, we can define a meta model that supports exchanging production capacities over an e-commerce marketplace. Thereby, *Sales Offers* reflect additive production machines or technologies and *Purchase Enquiries* reflect products. In order to ensure the structured and consistent storage of data and the efficient use of the database, this section introduces a conceptual data model shown and thereby answers RQ2.

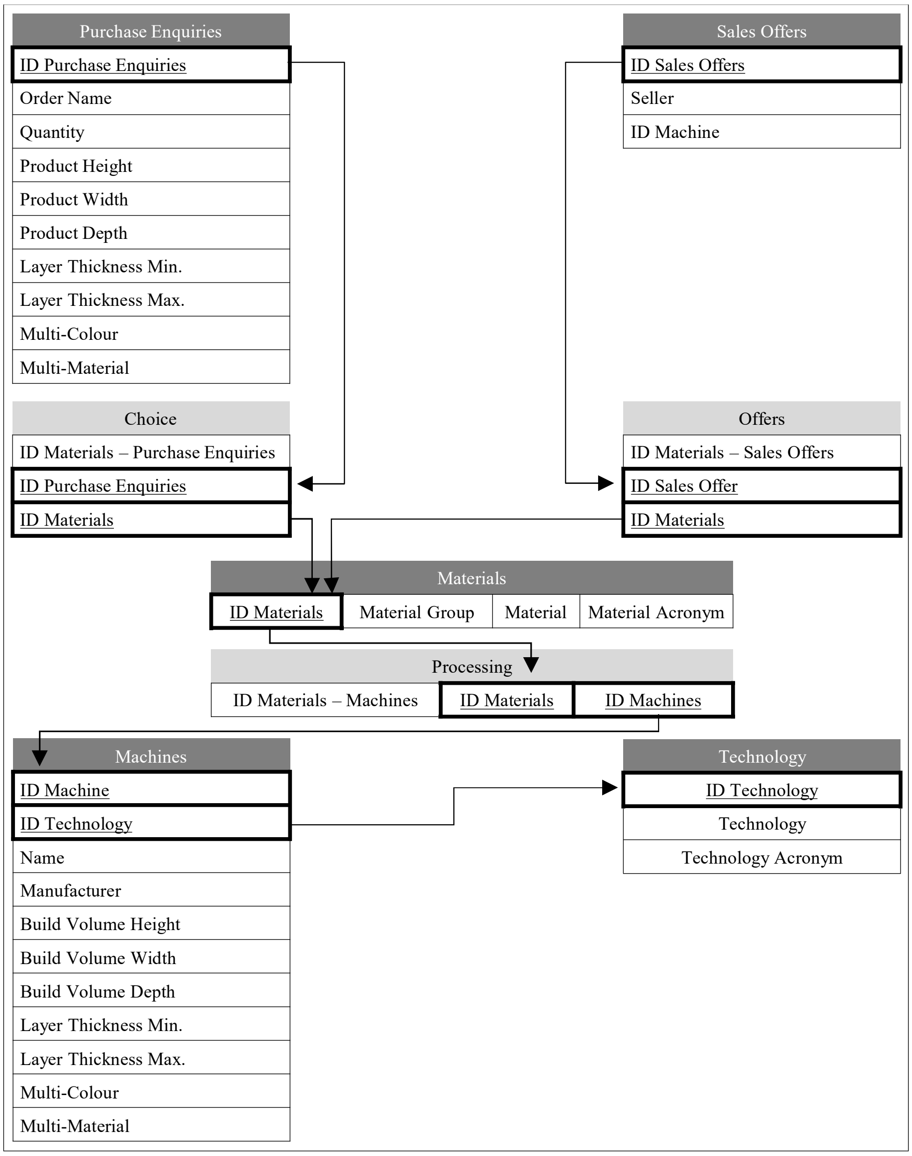

Figure 2. Meta-model for matching products and additive manufacturing technologies

Figure 2 summarizes the resulting model for matching machines with products in a structured collection of tables that are connected through relations. The characteristics of the *Purchase Enquiries* and *Sales Offers* were derived from the developed requirements. The choice of additive manufacturing *Machines* is mainly determined by the choice of *Materials*. These have therefore been added as a separate table and are directly related to *Machines, Purchase Enquiries* and *Sales Offers,* each connected via junction tables (*Processing*, *Choice*, *Offers*). *Materials* can be selected for a *Purchase Enquiry*. In return, a *Sales Offer* with one or more *Materials* can be offered in the area of capacity sales, because not all materials that are processed for devices necessarily have to be offered by vendors. Material properties have to be accounted for in future studies. Again, *Materials* can be processed by *Machines*. The *Machines* have the analyzed attributes and are assigned to *Technologies*.

6 Conclusion

A marketplace for production capacities can significantly contribute to the competitiveness of manufacturers and reduce risks in interwoven supply networks. It supports companies in accomplishing their strategies and business goals, such as a reduction of order risks caused by equipment failure or adaptability in case of changing market demands. Furthermore, they can benefit from synergies, economies of scale, and economies of scope.

This study set out to build the conceptual foundation for a marketplace solution for buyers and sellers of production capacities from the domain of additive manufacturing. Therefore, we sought to develop a catalog of requirements for a workable platform solution (RQ1) as well as to build a meta model that allows the matching of products and production processes in practice (RQ2). To answer RQ1, we conducted a qualitative study based on expert interviews. We questioned experts from nine companies that provided valuable insights from the perspectives of market participants, platform operators, and machine producers. As a result, we derived 10 requirements that can be grouped under the categories of *characteristics of additive manufacturing technologies and machines*, *characteristics of products to be additively manufactured*, as well as *matching products and additive manufacturing technologies*. A marketplace for production capacities must address these requirements to be adopted and to facilitate the expected benefits. To answer RQ2, we integrated our findings and built a meta model that supports the matching of products and production processes. It consists of 8 components and provides a conceptual foundation for the implementation of a matching algorithm in practice. By addressing a white spot in the current IS literature, this study represents a suitable starting point for future research endeavors that aim to examine requirements for exchanging production capacities in other scenarios and industry contexts.

This research is not without limitations. First, it is exploratory by nature and builds upon the perceptions and conclusions of the researcher. Other researchers may have derived different implications and requirements. Second, with only nine participants, our data sample is yet too small to derive a definite set of requirements for exchanging production capacities. Larger studies with more participants are necessary to provide definite evidence on the validity and reliability of our findings. Third, the resulting meta model is of preliminary nature and only provides an initial conceptualization of the marketplace. In future studies, we seek to implement, evaluate, and refine its properties. Future research opportunities lie primarily in transferring our findings to other industries and business scenarios. While its relevance is constantly growing, additive manufacturing only accounts for a small portion of industrial production capacities. As a consequence, future research must incorporate larger industries to realize the full potential of production capacity sharing.

Service Systems, Smart Service Systems and Cyber-Physical Systems—What's the difference? Towards a Unified Terminology

Dominik Martin[1], Robin Hirt[1], and Niklas Kühl[1]

[1] Karlsruhe Institute of Technology (KIT), Karlsruhe Service Research Institute (KSRI), Karlsruhe, Germany
{martin,hirt,kuehl}@kit.edu

Abstract. As businesses and their networks transform towards co-creation, several concepts describing the resulting systems emerge. During the past years, we can observe a rise of the concepts Service Systems, Smart Service Systems and Cyber-Physical Systems. However, distinct definitions are either very broad or contradict each other. As a result, several characteristics appear around these terms, which also miss distinct allocations and relationships to the underlying concepts. Previous research only describes these concepts and related characteristics in an isolated manner. Thus, we perform an inter-disciplinary structured literature review to relate and define the concepts of Service Systems, Smart Service Systems and Cyber-Physical Systems as well as related characteristics. This article can, therefore, serve as a basis for future research endeavors as it delivers a unified terminology.

Keywords: Service System, Smart Service System, Cyber-Physical System, literature review, conceptualization

1 Introduction

As businesses become interconnected, new opportunities and challenges arise for collaboration and co-creation [1, 2]. Different concepts, such as (Smart) Service Systems [3, 4] and Cyber-Physical Systems [5] emerge and strive to allocate, structure and explain phenomena in the field of digitally interconnected systems. However, these concepts are often used synonymously [4, 6] or contradict each other [5, 7]—which can lead to confusion and misunderstandings among practitioners and researchers. As a clear distinction of those concepts and related characteristics fosters the quality of future research, we aim to distinct Service Systems, Smart Service Systems and Cyber-Physical Systems. Thus, we ask the research question of *"How are the concepts Service System, Smart Service System and Cyber-Physical System defined and interrelated?"*. To approach this topic, we perform a structured literature research based on vom Brocke et al. [8] and Cooper [9] to identify commonly used definitions. We consolidate the insights and define each concept on this basis.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Additionally, we aim to derive a conceptualization including the three concepts and ask the additional question: *"Which characteristics are mentioned in the context of the concepts?"*. By applying an open coding approach [10] on 110 identified articles from different disciplines defining the concepts, we identify several characteristics that are mentioned in literature and allocate them accordingly.

We aim to provide distinct definitions of these concepts in order to set a foundation for researchers and practitioners to understand the terms consistently. Based on this, we intend to overcome boundaries to other disciplines and allow for a common understanding as well as, accordingly, to accelerate new research and development in these areas.

The remainder of this article is structured as follows: First, we present theoretical foundations regarding socio-technical systems and system-of-systems. Second, we describe our methodology comprising a literature search followed by an open coding analysis of the identified concept definitions. Third, we analyze all three concepts in isolation and then summarize them through a conceptualization. Fourth, we present a discussion followed by a conclusion.

2 Theoretical Foundations

A system is generally referred to as a "collection of components organized to accomplish a specific function or set of functions" [11, p. 73]. Boulding [12] particularly stresses the system boundaries which delimit a system and determine which parts belong to a system and which to the environment. In an open system, interactions can take place with the environment, whereas in an isolated system no interactions can take place [11]. Interactions can be both the exchange of information (from an Information Systems (IS) viewpoint) [11] and the exchange of mass or energy (from a nature science viewpoint) [13]. Particularly complex open systems consisting of multiple parts that perform complex interactions with each other and with the environment are widely spread in reality [14].

In order to categorize (Smart) Service Systems and Cyber-Physical Systems and form a better understanding of these terminologies, the basic concepts *socio-technical systems* and *system-of-systems* are introduced.

2.1 Socio-technical Systems

The term socio-technical system is often used to describe complex systems consisting of several interacting components [15]. Originally, however, the term was used to describe a set of people and related technologies that are structured in a certain way to produce a specific result [16].

According to Cartelli [17], a socio-technical system consists of two components (subsystems): The technical subsystem represents assets such as machines and equipment, as well as processes and tasks that are responsible for the conversion of input resources into outputs. The social subsystem is made up of people (such as employees) who are structured in groups and have assigned certain roles to operate, control and use the components of the technical subcomponent. Cartelli emphasizes the facet of knowledge, which is "socially constructed and developed in the interactions among people" [17, p. 3], as part of the social subsystem and its value for a socio-technical system.

Both subsystems are "jointly independent, but correlative interacting" [16, p. 17] in order to pursue and adapt to goals in the socio-technical system's environment and are therefore not separable from each other due to their manifold dependencies [15].

2.2 Systems-of-Systems

A system-of-systems has—like a typical system—interdependent components operating together to accomplish a certain common goal [18]. Unlike a typical system, the components of a system-of-systems are themselves systems [18]. According to Maier [19] a system-of-systems is an "assemblages of components that are themselves significantly complex, enough so that they may be regarded as systems and that are assembled into a larger system" [19, p. 269]. However, Maier names two limitations: First, the components must be operationally independent. That is, if a system-of-systems is broken down into its components, they must be able to fulfill their original purpose independently. Second, the component systems can not only work independently of each other, they do so as well. Thus, the subsystems maintain their operational independence continuously. Gideon et al. [18] summarize a system-of-systems as a "system build from independent systems that are managed separately from the larger system" [18, p. 357].

3 Methodology

With the foundations of socio-technical systems and systems-of-systems set, we elaborate on our applied methodology to reconstruct the state of the art of relevant literature. The scope of our literature review is systematized by the taxonomy proposed by vom Brocke et al. [8] and Cooper [9]. This taxonomy consists of six characteristics that distinguish literature reviews—focus, goal, organization, perspective, audience, and coverage—each including specific categories. Some of these categories are mutually exclusive, while for other characteristics several categories can be combined.

The focus of our literature research corresponds to the category research outcomes of the above-mentioned taxonomy. Furthermore, the goal of this article is the aggregation of already existing articles on the concepts Service System, Smart Service System and Cyber-Physical System—as well as their integration. The organization of this article is conceptually structured in order to aggregate the concepts separately. This article takes a neutral perspective. The target audience are scholars who are in need of a clear definition of the concepts as well as their distinction. To provide an appropriate overview of existing research, the literature search covers selected conferences and journals and, therefore, aims to be representative.

We conduct a systematic literature research according to vom Brocke et al. [8] in July 2018. While doing so, we focus on peer-reviewed articles from the field of

Information Systems, Service Science and Computer Science. In order to receive articles elaborating on (Smart) Service Systems and Cyber-Physical System, we use the search query: *"Service System" OR "Smart Service System" OR "Cyber Physical System"*. In a first step, we focus our search on the following selected Information Systems conferences and journals: International Conference on Information Systems (ICIS), European Conference on Information Systems (ECIS), Hawaii International Conference on System Sciences (HICSS), Information Systems Research (ISR), Information Systems Journal (ISJ), Management Information Systems Quarterly (MISQ), Journal of Management Information System (JMIS), European Journal of Information Systems (EJIS) and Business and Information Systems Engineering (BISE).

It is noticeable that the conferences have a much higher proportion of hits (ECIS: 21, ICIS: 14, HICSS: 10) in total than the journals (BISE: 8, MISQ: 2). The journals ISR, ISJ, JMIS and EJIS have no hits at all. In addition, it is recognizable that most of the hits date from the year 2018. Moreover, the number of hits has increased (Figure 1) over the years, which implies a strong relevance in terms of timeliness and strengthens the necessity for a clear nomenclature.

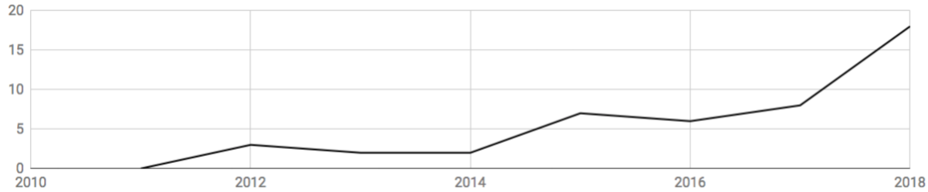

Figure 1. Number of hits in selected IS journals

When analyzing the outcomes, we noticed most of the articles relate to the concept of Service Systems, while in relatively few results the terms Smart Service System or Cyber-Physical System appear. Therefore, we extend our search across all disciplines using the literature database *Web of Science*. We realize that the term Service System plays a dominant role in the IS community, whereas the concept Cyber-Physical System occurs mainly in Computer Science literature. However, the term Smart Service System barely appears in the Web of Science database. Based on these findings, we conduct a Web of Science search for each of the three concepts separately and sort the results by number of citations and thereupon append the first 50 results for each concept to the literature list as well. In a third step, in addition, the outlets from the disciplines Service Science (six outlets with impact factor above 1[1]) and Computer Science (22 outlets with impact factor above 5[1]) are included as well. Thus, we ensure each of the communities in which the concepts are mainly used, are represented in this literature overview accordingly in a balanced manner.

Overall, the applied methodology results in an amount of 354 articles, which are selected by reading the abstract in order to exclude unrelated articles. Through forward

[1] The lower threshold for included outlet's impact factors is derived by the multiplication of the highest impact factor achieved in the specific discipline with a factor of 20 %

and backward search, further relevant articles are identified. By completely reading the remaining articles, all in all 110 relevant articles are selected and analyzed in a final step. All passages containing definitory statements with regard to at least one of the concepts is further analyzed by a coding approach to derive characteristics and interrelations of the considered concepts.

Within this subsequent step, two researchers analyze the concept definitions extracted from the articles using an open coding approach according to Saldaña [10]. With open coding we aim to find recurring characteristics of the individual concepts [10]. At the same time, we try to stay as open and unconstrained as possible in order to identify outstanding and particularly common characteristics from the literature. During this phase, we constantly compare all codes coded by two researchers as well as the underlying concept definitions to cluster passages that pertained to common codes. To substantiate our findings, we further integrate these common codes in order to derive more abstract conjoint categories and to harmonize different views.

4 Results

The results of the literature search and the analysis of the definitions depicted in each article are summarized in this section. In order to provide the reader with a comprehensive picture of the differences and similarities of the definitions, first the concepts are considered individually, before they are compared with each other.

4.1 Service Systems

The concept *Service System* appears most frequently in the results of our conducted literature search. Overall, 64 articles refer to the term Service System. According to Spohrer et al. [3] a Service System comprises *"service providers and service clients working together to coproduce value in complex value chains or networks"* [3, p. 72]. Components of a Service System are *"people, technology, internal and external service systems connected by value propositions, and shared information"* [3, p. 72] and examples include individuals, firms and nations. Based on this article from 2007, Maglio and Spohrer [20] synthesize the definition and formulate: *"Service systems are value-co-creation configurations of people, technology, value propositions connecting internal and external service systems, and shared information (e.g., language, laws, measures, and methods)"* [20, p. 18]. Examples include cities, businesses, nations, as well as individuals as the smallest representative of a service system and world economy as the largest [20].

The majority of articles adopt this definition [4, 7, 21–25], while others phrase it slightly different, but in principle remain faithful to the overall message [26–33]. Besides the more detailed definitions, some authors like Kleinschmidt and Peters [34] and Lintula et al. [35] use shorter and thus less specific descriptions. Böhmann et al. [36], Dörbecker and Böhmann [37] and Li and Peters [38] state that a Service System is a *"socio-technical system that enables value co-creation guided by a value* *proposition"* [36, p. 74], whereas Brust et al. [32] describe it as *"collections of people, technology and interactions"* [32, p. 8].

However, some authors deviate from this common definition and suggest divergent definitions, such as the one proposed in Höckmayr and Roth [39]: *"A service system is composed of multiple entities that interact to co-create value"* [39, p. 3]. Similarly, Motta et al. [40] differs from the common definition and describe a Service System only very abstract as a system which supports business services. Alter [41–44] refers to work systems and defines Service Systems as *"work systems that produce product/services and that may or may not involve co-production by customers and value co-creation"* [41, p. 4], while a work system is a *"system in which human participants and/or machines perform work using information, technology, and other resources to produce products and services for internal or external customers"* [41, p. 4]. Although some authors like Blohm et al. [45], Dörbecker et al. [46] and Matzner and Scholta [47] use the term Service System and name components as well as properties, but avoid defining it.

In conclusion, we also suggest using the definition according to Maglio and Spohrer [20] and Spohrer et al. [3], as it is the most concise and commonly used one, and define Service Systems for this article as *"value-co-creation configurations of people, technology, value propositions connecting internal and external service systems, and shared information (e.g., language, laws, measures, and methods)"* [20, p. 18].

4.2 Smart Service Systems

The concept *Smart Service System* has the lowest number of hits with only 10 represented articles in the searched outlets and databases. This concept is described by Barile and Polese [7], Maglio [4] and Medina-Borja [48] as an extension of the Service System concept containing self-management capabilities. Barile and Polese [7] define: *"Smart service systems may be intended as service systems designed for a wise and interacting management of their assets and goals, capable of self-reconfiguration (or at least of easy inducted re-configuration) in order to perform enduring behavior capable of satisfying all the involved participants in time"* [7, p. 31].

According to Maglio [4], Smart Service Systems are *"capable of self-detection, self-diagnostic, self-corrective, or self-controlled functions through the incorporation of technologies for sensing, actuation, coordination, communication, control, and more"* [4, p. 1]. By automating and self-managing systems, high costs and security risks caused by humans can be reduced, which can lead to improved offers or even new ones [4].

Beverungen et al. [49] state that Smart Service Systems are Service Systems, *"in which smart products are boundary-objects that integrate resources and activities of the involved actors for mutual benefit"* [49, p. 6].

According to the authors Maglio and Lim [50] as well as Medina-Borja [48], such a system is even *"capable of learning, dynamic adaptation, and decision making based upon data received, transmitted, and/or processed to improve its response to a future situation"* [50, p. 2], which can be done by integration of sensing, actuation and communication technologies. In addition, Maglio and Lim [50] describe that big data analytics can contribute to the innovation of Smart Service Systems by *“embedding human knowledge and capabilities in technologies to serve human purposes for effective value co-creation”* [50, p. 3]. Santo et al. [51] also emphasize the capability of such a system to learn and to *“simultaneously optimizing the use of resources and improving the quality of the services provided”* [51, p. 3].

Nevertheless, we recommend using a modification of the definition proposed by Medina-Borja [48] as it is the most detailed and comprehensive and includes most of the characteristics of the other definitions. Furthermore, it delivers a clear demarcation from Service Systems: *“A 'smart' service system is a [Service] [S]ystem capable of learning, dynamic adaptation, and decision making based upon data received, transmitted, and/or processed to improve its response to a future situation. The system does so through self-detection, self-diagnosing, self-correcting, self-monitoring, self-organizing, self-replicating, or self-controlled functions. These capabilities are the result of the incorporation of technologies for sensing, actuation, coordination, communication, control, etc.”* [48, p. 3].

4.3 Cyber-Physical Systems

Hauser et al. [52] state that research on *Cyber-Physical Systems (CPS)* no longer takes place only in the disciplines of electronics and computer science, but also extends to other fields such as IS. Therefore, they describe a CPS as the extension of a legacy system with information technology [52]. Similarly abstract is the definition of Banerjee et al. [53], who describe CPS as *“systems that use the information from the physical environment, and in turn affect the physical environment”* [53, p. 283]. Furthermore, they list examples such as smart electricity grid and unmanned aerial vehicles [53]. Likewise, Gölzer et al. [6] argue that CPS are *“able to communicate with each other, to detect their environment, to interpret available data and to act on the physical world”* [6, p. 1]. They also emphasize the capabilities of self-control and self-optimization [6], while Gruettner et al. [54] describe CPS as *“intelligent networking of people, machines, and industrial processes, which in product components communicate with the production gear by embedded sensors”* [54, p. 1853].

Bradley and Atkins [55] state that CPS *“interface physics-based and digital world models”* [55, p. 60] and emphasize the benefits of integrating physical and computational models.

A formal definition is provided by Burmester et al. [56] describing a CPS as a *“finite state system consisting of several networked components, some of which may be cyber while others are physical”* [56, p. 3].

Akkaya et al. [57] identify the challenges of designing a Cyber-Physical System as *“complexity, heterogeneity, and multidisciplinary nature”* [57, p. 997], but avoid using a distinct definition. In addition, there are some articles that use the term CPS, but neither describe nor define it [58–62]. Other authors give examples such as smart grids [63, 64], Machine-to-Machine communication [65] and data centers [66], but also avoid clear definitions. However, most authors describe CPS basically as a conjunction of computation and physical processes, where there is a mutual influence through observation and control [67–73].

Böhmann et al. [36] build the bridge to Service Systems and explain that the availability of data and automation capabilities provided by Cyber-Physical Systems contribute to Service System innovation. Matzner and Scholta [47] also combine the CPS and Service Systems concepts and define: *"[CPS] are service systems that connect physical and cyber elements through global networks"* [47, p. 0].

Furthermore, Gunes et al. [5] summarize some aspects of different definitions and define CPS as *"complex, multi-disciplinary, physically-aware next generation engineered systems that integrate embedded computing technology (cyberpart) into the physical phenomena"* [5, p. 4244], where integration is achieved by the capabilities of *"observation, communication, and control [...] of the physical system"* [5, p. 4244].

Sanislav and Miclea [74] also recognize the variety of different definitions provided in the existing literature and list several, however, without synthesizing or providing their own.

Ribeiro et al. [75] and Wu et al. [73] emphasize the intelligence of such systems and characterize CPS as *"intelligent systems that are composed of digital virtual/cyber technologies, software, and physical components, and intelligently interact with other systems across information and physical interfaces"* [75, p. 6131]. Sampigethaya and Poovendran [76] consider CPS based on applications in aviation and describe mainly benefits and challenges. Also Sztipanovits et al. [77] and Yao et al. [78] focus mainly on challenges related to the integration of the various computational and physical elements of CPS.

Furthermore, Wan et al. [79] describe some characteristics of CPS such as *"cyber capability in every physical component"* [79, p. 1108], *close integration*, *"dynamically reorganizing/reconfiguring"* [79, p. 1108], and *"high degrees of automation"* [79, p. 1108].

We recommend following the definition of the majority of the authors and, thus, we provide an abstract definition: *"A Cyber-Physical System is an intelligent system connecting the physical and the digital/cyber world through influence and control using sensors and actuators"*.

4.4 Summary

This literature review shows that the concepts Service System, Smart Service System and Cyber-Physical System are not uniformly defined and also that the differentiation is not always clear. While most authors agree on Service Systems, Smart Service Systems and CPS in particular are not clearly defined.

By applying an open coding approach, properties of the examined concepts described in the articles are codified. Codes with similar characteristics are clustered and, thus, grouped together in categories [10]. Overall, we identify five categories of properties the concepts Service System, Smart Service System and Cyber-Physical System have in common. Table 1 depicts five identified categories components, attributes, actions, structure and boundaries. The categories components, attributes, and actions include a set of codes resulting from the different views of the articles being analyzed. We consider the most frequently occurring representatives for these three categories.

Table 1. Conceptualization of (Smart) Service Systems and Cyber-Physical Systems

	Service System	*Smart Service System*	*Cyber-Physical System*
key components	information, people, technology	data, people, technology	cyber part, sensors, actuators
key attributes	interaction, dynamic, adaptive	interaction, adaptive, learning, decision-making	interaction, intelligent, distributed
key actions	value creation	sensing, control	sensing, control
structure	complex, people-centered	complex, self-centered	complex, data-centered
boundaries	open, dynamic	open, dynamic	open, partially dynamic

The key components of all three concepts are frequently mentioned in the definitions within the articles and are also conceptually very clear, especially in the concepts of Service System and Smart Service System. For example, Service Systems and Smart Service systems both include *people* and *technology*, while in terms of Service Systems, the term *information* is very present, data is often referred to in Smart Service Systems. A CPS consists of a *cyber part* that provides computational capabilities, *sensors* collecting data, as well as *actuators*.

A variety of attributes are mentioned across all analyzed articles, however, only the key attributes are listed in Table 1. All three concepts emphasize the *interaction* between components, but also the interaction with the environment. Likewise, the attribute *adaptability* appears for all three concepts, although it is not mentioned as often in CPS definitions as the attribute *distributed*. In addition, the code *dynamic* is very common in Service Systems, while a CPS is particularly described as *intelligent* and Smart Service Systems is capable to *learn* and *make decisions*.

However, a small number of key actions are named, but the ones named are mentioned very frequently. Nearly every article defining a Service System names the goal of *creating value*. For Smart Service Systems and CPS, the actions are not quite as clean, but for both the two most common are *sensing* and *control*.

The structure of all three analyzed systems is described as a complex. In addition, Service Systems focus on people—both as component and user—while Smart Service Systems focus on the system itself and its purpose. CPS are often outlined as data-centered.

All three concepts are considered to be *open* systems. Furthermore, Service Systems and Smart Service Systems are able to change *dynamically*, while for CPS at least the physical part is fixed, but the components of the cyber part can also change dynamically.

5 Discussion

The analysis of the literature on the three concepts shows that Service Systems can be understood as socio-technical systems [29, 36–38, 48, 80]. In addition, a Smart Service Systems is a special kind of a Service System [7, 33, 50, 81]. CPSs, on the other hand, are referred to as a kind of Service System [47], but more often characterized as technical systems [5, 31, 82–84], which can thus be part of a socio-technical and, thus, part of a (Smart) Service System.

The analysis also shows that the need for information in Service Systems is enormous as it acts as a key component. The same applies to data in Smart Service Systems. This data, which can be further processed into information, can be collected by CPS. Thus, by enriching CPS with connectivity capabilities, the need for information / data of (Smart) Service Systems can be met. In addition, intelligent CPS can also serve as a social component to mimic the role of people.

Thus, the concepts Service System, Smart Service System and CPS are closely interlinked and, therefore, have similar characteristics. All concepts emphasize the interaction between humans and technology and the ability for multi-criteria decision-making. This leads to extremely complex and heterogeneous structures that can dynamically adapt over time.

In addition to components such as humans, technology or CPS, however, Service Systems themselves can also be components of Service Systems. This system-of-system property affects all three concepts. Thus, the system boundaries can be extended by parts of the environment, so that other systems arise.

Figure 2 depicts the interrelations of the three considered concepts as well as their connections to socio-technical system and system-of-systems concepts.

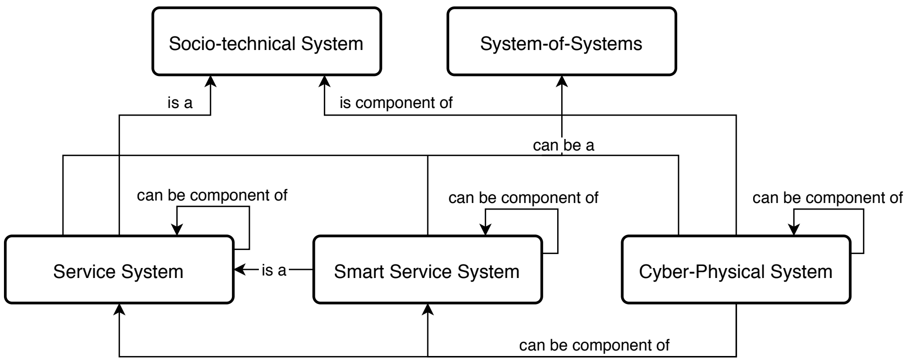

Figure 2. Interrelations of (Smart) Service Systems and Cyber-Physical Systems

6 Conclusion

The concepts of (Smart) Service Systems and Cyber-Physical Systems has been a re-occurring term in research and industry. Aiming for precise definitions, distinctions and similarities, we apply a thorough literature research and review 110 relevant articles. As a result, we show that especially the concepts Smart Service System and Cyber-Physical System are often used in a similar context in different disciplines. The concepts include similar facets and characteristics. However, our research reveals some cases of inconsistent definitions, especially for the concepts of Smart Service Systems and Cyber-Physical Systems. For clarification, we derive suitable definitions from literature and fuse them in a conceptualization. These definitions and concepts may assist researchers in the understanding of the terms and their relationships.

Our work is limited to literature originating mainly from the fields of Information Systems, Service Science and Computer Science community. Furthermore, it can remain subjective as to whether a definition is more suitable than another to understand broader concepts. To address this, we based our research on occurrences in related articles, but cannot account for all articles across all disciplines. Moreover, the identified characteristics are not validated concerning their completeness and meaning within different disciplines. In total, this work sets a foundation for researchers and practitioners to understand the concepts consistently and, accordingly, to push for new research and development in these areas with the same terminology in mind to avoid misunderstandings.

Abstract. Demands for a digitalized, connected, and smart production provide a fertile ground for industrial Internet-of-Things (IIoT) platforms to arise within the manufacturing industry (e.g., Siemens MindSphere, AXOOM Smart Enterprise, FORCAM FORCE). Nevertheless, many companies struggle to successfully kick-off platform ecosystems. Information Systems (IS) literature is of limited help, because insights on managing platform ecosystems are mostly derived from successful examples in the business-to-consumer (B2C) context. To better understand the challenging situation of companies in the emerging IIoT environment, we conducted an in-depth case study at a prospective platform provider. Insights gained through interviews and engagement in the field uncovered a tension between a horizontal platform strategy and vertical integrated solutions as a central challenge for companies aiming to launch an IIoT-platform in the market. By conceptualizing this trade-off, its causes along with related benefits and challenges, we add to existing literature on platform governance and launch strategies.

Keywords: Software Platforms, Industrial Internet-of-Things, CPS Platforms, Platform Development, Exploratory Case Study

1 Introduction

In the course of the ongoing fourth industrial revolution (‘Industry 4.0’), advanced and innovative information and communication technologies (ICT) are being introduced to logistic and manufacturing companies to facilitate more automated and intelligent processes. Within this context, the importance of service-based, real-time enabled cyber physical systems (CPS) was not only identified in theory [1]. In practice, this constitutes in the emergence of a vast number of Industrial Internet of Things (IIoT) platforms, which enable the connection of machines, devices, materials and sensors to lay the foundation for a smart production system [2, 3].

Information systems (IS) researchers have studied the concept of platforms for several years. A common definition is given by Tiwana, who defines a digital platform as “a software-based product or service that serves as a foundation on which outside parties can build complementary products or services” [4, p. 5]. A growing body of research in this field investigated the concept of platforms from different perspectives.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Some studies follow an economic perspective investigating two-sided market characteristics of platforms like network externalities, multi-homing behavior or pricing strategies [5, 6, 7], others focus on technological architectures, open decisions and a platform's innovation potential by efficient value co-creation [8, 9, 10, 11].

Even though we find extensive literature about digital platforms, the applicability in the emerging market of IIoT platforms is limited, as most theories are based on findings from platform ecosystems operating in a business-to-consumer (B2C) context (e.g., web browsers, personal computer and mobile operating systems, video consoles, Facebook, Google search engine etc.) [12, 13, 14, 15]. Business-to-business (B2B) platforms – or B2B products and services in general – differ not only in their technological complexity. Also, different market characteristics such as size, fragmentation, and business relationships entail divergent requirements for platform strategies [e.g., 16]. As market structure shapes a platform's emergence process, the emergence processes observable in the context of Industry 4.0 differ from what has been researched in existing literature. The concept of platform development has also often been studied from a broad industry perspective [17, 18], or with focus on mature platforms [19]. Concerning the start-up phase of a platform, IS researchers agree that most successful platforms emerged from existing products in an evolutionary process [4, 20]. However, literature about this emergence process and involved actions and decisions of the platform owner remains limited.

In practice, we note that many prospective platform owners find themselves in a situation where market demands a vertical (product-oriented) and a horizontal (platform-oriented) strategy simultaneously. Literature has rarely addressed the existence and related challenges of such a hybrid strategy for platform emergence. Instead, literature highlights the difference between products or services and platforms in a sense that strategic decisions being made can have contrasting implications. Thus, managers need to decide early, whether to follow a vertical product or a horizontal platform strategy [4, 21, 22].

The purpose of this study is to gain a deeper understanding of a platform's emergence process from the perspective of a platform owner. More particularly, we focus on the platform owner's trade-off between following a vertical vs. a horizontal approach. To understand why this situation arises and how platform owners deal with this trade-off, we defined the following research questions: *Which factors cause the trade-off between following a vertical vs. a horizontal approach? How do platform owners try to reconcile these contrary requirements and what are benefits or challenges involved?*

In the remainder of this paper, we will first provide a brief overview of this paper's theoretical background. Then, we present the design of our exploratory in-depth case study [23, 24]. In order to answer the research questions defined above, we followed the ideas of engaged scholarships [25] and conducted semi-structured interviews at a medium-sized company currently developing an IIoT platform. Based on our findings, we developed a framework explaining the trade-off's circumstances, resulting strategy chosen by the case company as well as its consequences. Further, we discuss our findings against the background of the platform's B2B context. Finally, we present limitations of the study as well as implications for future work.

2 Theoretical Background

The platform concept has been researched in several fields of studies resulting in different definitions and views on the platform phenomenon [8]. Within IS two strands of literature can be identified [26]. The *market-oriented perspective* emphasizes a platform's characteristic to act as an intermediary between two or multiple sides, whereas researchers following the *technology-oriented perspective* study a platform's architecture and its capabilities to facilitate value co-creation and foster innovation. In theory, only a few researches consider both perspectives within their studies [26], which diminishes applicability of existing theories.

Within this paper, the term platform is used to describe a construct encompassing both platform perspectives. These encompassing platforms correspond to the notion of 'industry platforms' found in the typology of Gawer [20]. Furthermore, it matches the widespread definition by Tiwana, who describes a platform as 'a software-based product or service that serves as a foundation on which outside parties can build complementary products or services' [4, p. 5]. Common examples are the mobile operating systems of Google and Apple. Both platforms provide open application interfaces (APIs) allowing complementors (often referred to as third-party developers) to reuse core functionalities and innovate upon these platforms by developing complementary products and services in form of apps. In addition, Apple and Google offer a marketplace where app developers can sell their apps to end users. Thus, the platforms act as an intermediary between two sides.

2.1 Shifting Towards Horizontally Organized Platform Ecosystems

Literature has acknowledged that more and more markets shift towards a platform-centric market structure. In many cases this shift can be traced back to the digitalization of the industry involved [27, 28]. In addition to the increased software embedding, ubiquity of wireless data networks, IoT and packetization, and the need for deepening specialization are drivers for this transformation [4]. Within affected markets, vertical integrated product offerings get replaced by a layered, modular architecture of digital technologies providing the ground for platforms to rise [18, 27]. In this context, the development and provision of an integrated solution (e.g. from sensor to specific end user application) by a single or small group of firms is referred to as the vertical approach in this paper. In contrast, a company following a horizontal approach decided to focus on a single layer and thus the development of a sophisticated and comprehensive open IIoT platform. From the market perspective, the occurrence of these platforms results in a greater specialization of single firms developing complementary solutions and unlocks an increased pace of innovation in the industry [4, 10].

In this setting, scholars differentiate between *inter*platform and *intra*platform competition. The overall market competition shifted towards a competition between platform ecosystems [28, 29], in which incumbent platforms strengthen their position automatically through network effects [30]. Additionally, high innovation capabilities of an ecosystem make it hard for closed vertical products to compete. In contrary, intraplatform competition refers to the competition between complementors [31]. This competition ensures quality and price regulation [20], even in the common scenario of a market with one leading platform ('Winner-takes-all') [32].

This ecosystem competition requires the management of firms to adopt a new mindset [4]. Stepping into the role of a platform owner means that value creation does no longer happen internally or in few strategic partnerships [33]. The new focus of platform owners is to orchestrate a big, loosely coupled ecosystem of firms for efficient value co-creation [34, 35, 36, 37]. Innovation is not planned anymore, but rather emerges in the ecosystem [4]. Nevertheless, through the provision of appropriate boundary resources [14, 15, 38, 39] or different pricing strategies [6] a platform owner can still foster or hamper the emergence of innovation. Further platform-related management challenges are summarized in the 'Four Levers of Platform Leadership' by Cusumano and Gawer [40]. They include decisions about scope, product technology, relationships with external complementors and internal organization. Referring to these differences, literature highlights the importance of an early and clear management decision, whether to follow a platform strategy or to offer a vertical integrated (product) solution [4, 21, 22]. Otherwise, it 'can result in dangerous strategic confusion' [21, p. 69], as decisions being made in platform competition differ from those, a firm makes while pursuing a product strategy. Nevertheless, other scholars consider a hybrid business model as useful in the transition phase between product and platform business [41], but also acknowledge that especially small firms may not be able to afford such a hybrid strategy [27].

2.2 Platform Emergence from the Perspective of a Platform Owner

For prospective platform owners, it is necessary to detect the shift towards a layered market, determine their role in this ecosystem (platform leader or complementor) and adjust the strategy accordingly [18]. Most successful platforms arise out of a product or service by including a second market side [4]. Thereby, platform potential of a product can be identified by assessing the existence of a second group interested in a cost-effective interaction with existing customers, the potential for cross-side network effects and/or the existence of unexploited long-tails in the prospective market [4]. Others suggest that the following two conditions should be fulfilled: (1) the product, service or technology needs to provide essential functionalities solving an existing problem of an industry and (2) it offers easy-to-use interfaces to develop complementary services [21]. However, adding a second side can also be interpreted as a process of opening the platform and thereby giving up control. This is also reflected in the evolutionary perspective on platforms by Gawer [20], where internal product platforms evolve into industry platforms.

In sum, the theories and strategies provided in literature are not sufficient to understand the specific steps and actions of platform owners during the emergence of platform development. Furthermore, the mostly linear emergence models proposed in literature do not consider, that market demands may require a company to pursue a vertically integrated product strategy and a horizontally platform strategy simultaneously. However, especially in the emerging market for IIoT solutions, the existence of these contrary requirements is a common situation for example for providers of IoT technologies when extending their solutions by complementary software offers.

3 Research Design

To explore the process of platform emergence from the perspective of a platform owner, we conducted a single case study [23, 24]. Considering the complexity of a platform's emergence process, it is reasonable to study the phenomenon in its real-life context. Therefore, we did not only conduct semi-structured interviews, but also gained valuable insights through engagement in the field [25]. Furthermore, the 'how' and 'why' research questions confirm the suitability of a case study research approach, which was conducted in an exploratory manner [24]. In this sense, the case study is also designed to reveal yet unknown events and challenges in the process of platform development to later build theory upon [23]. Overall, the case study was carried out in an iterative process of data collection and analysis [23, 24, 42].

The case company being studied (referred to as *HardwareProvider* in the following) is a medium-sized, young company based in Germany. As many other players in the field, the company's background lays in the hardware business [43], so that a software platform was primarily developed as a value-added service for their customers from the manufacturing and logistic industry. The platform should be designed open to raise an ecosystem around it and thereby foster innovation. Thus, the case company is currently facing the tension between following a vertically integrated product strategy and a horizontally open platform strategy. In this regard, *HardwareProvider* is an interesting case for two reasons. First, being in an early stage of its platform development allows observing strategical decisions while being made. Second, the limited business maturity and the company's small size simplify the otherwise very complex environment of an IIoT platform.

For **data collection**, we relied on primary and secondary data. We conducted seven semi-structured expert interviews with employees having a key role in the development of the company's platform offer [44]. Table 1 provides an overview of the interviewee's job responsibilities, date of interviews and the interview length. The respective interview partners (IP) got informed about the interview and its purpose beforehand. In the manner of an iterative study design, questions in the first interviews were rather broad to get an overview of the platform emergence and interview partners for further interviews [42]. In general, topics covered during the interviews included not only the technical development, but also strategical decision making related to platform design, marketing and related partnerships. Due to the fact, that each interview partner had a different role in the process of platform development, not every interviewee was asked the same questions. Besides interviews, additional primary and secondary data was accessible due to our engagement in the field over a period of five months. As our single case study at *HardwareProvider* follows the ideas of engaged scholarship [25], informal conversations and collaboration with key stakeholders from the case company took already place in an early stage to build a practical pre-understanding, formulate relevant research questions and design the study accordingly. In a later stage, additional data sources like marketing material, internal product roadmaps and project documentation, were used to validate findings from the interviews. Furthermore, the attendance of internal and external meetings and workshops allowed us to include perspectives from additional stakeholders not being interviewed directly (e.g. partners and customers).

Table 1. Summary of interviews (ID, date, interviewee, length)

ID	*Date*	*Interviewee position*	*Length*
IP1	19.06.18	Founder and managing director of *HardwareProvider*	50 min
IP2	21.06.18	Managing director of *HardwareProvider*	36 min
IP3	10.07.18	Head of project engineering	48 min
IP4	17.07.18	Head of development	55 min
IP5	18.07.18	Product and project manager	41 min
IP6	20.07.18	Sales and partner manager	49 min
IP7	25.07.18	Founder and managing director of *HardwareProvider* (follow-up)	39 min

For **data analysis**, we applied procedures of the grounded theory methodology [42, 45, 46]. We used the bottom-up coding technique to analyze qualitative data and find theoretical concepts. In a first step of open coding, we associated about 340 concepts to more than 450 interview quotes. Then, we grouped codes by defining emerging (sub-)categories (Table 2). During axial coding, we adapted the *Six C* coding family to relate identified categories to each other [47]. Furthermore, we wrote theoretical memos to record ideas raised during coding [42]. As a last step, we applied selective coding to establish the core category and identify all relevant categories to describe the phenomenon in more detail and to build a theoretical model.

Table 2. Illustration of coding scheme

Interview statement[1]	**Concepts**	**Categories**
"The past has shown that we did not do completely wrong, when following a project-driven development strategy. Because we knew, that the market needed the feature or this functionality[1,2]*. We could develop the feature in cooperation with the customer from industry*[2]*. Thus, also tap into a lot know-how*[2,3]*. But we also tried to develop new functionalities independently, which was also driven out of a new product management department*[4]*." [IP5]*	1. Minimizing risk through customer-oriented feature development 2. Cooperative feature development with customer 3. Building up know-how through cooperative development 4. New product management department	▪ Sources of platform features ▪ Project-driven development ▪ Independent feature development

4 Results and Interpretation

Within our analysis we did not only gain a deeper understanding of *HardwareProvider's* journey of becoming a platform provider, but we also identified the trade-off between horizontal and vertical platform development as a major issue faced by a platform owner during platform emergence. Therefore, we further studied the issue by investigating context, causes, (pre-)conditions, undertaken strategy and consequences. The established model is depicted in Figure 1 and will be discussed in the following.

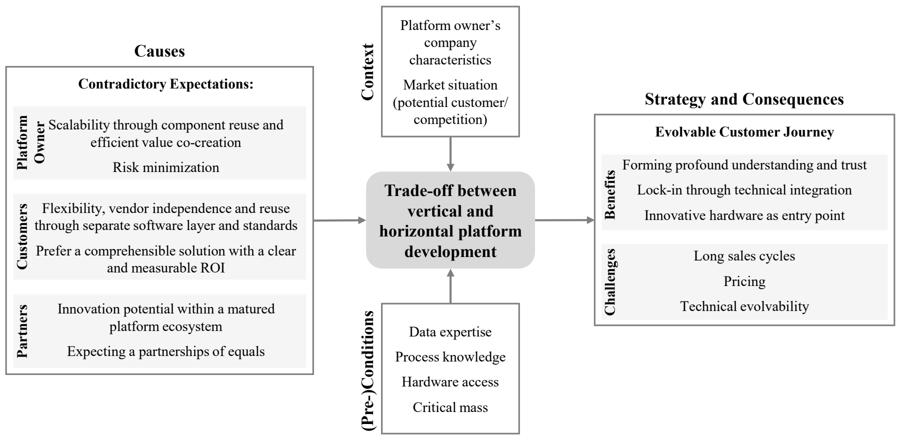

Figure 1. The challenging platform development environment

4.1 Emergence of the Horizontal vs. Vertical Trade-off

The case study helped to understand the circumstances, which brought the prospective platform owner into the trade-off between vertical product and horizontal platform development. The overall situation appears rather complex, though we defined three clusters shaping this trade-off.

Causes: The emergence of the trade-off is driven by anticipated consequences of internal and external stakeholders. On the one hand, the *platform owner*, especially members of the development and project management team, would benefit from focusing on a generic horizontal approach. Such an approach allows for more scalable project business through component reuse, as well as the possibility for efficient value co-creation by the customers themselves or external partners. On the other hand, customer-oriented implementations of vertical end-to-end use cases minimize the risk of implementing features not required by the market and simplifies marketing and sales.

From the *customer perspective*, a comprehensive, company-wide open platform for its data may be desirable as it can be used to set standards. Thus, flexibility and vendor independence for the implementation of vertical use cases can be achieved. This would in turn strengthen the customer's position in future purchasing processes: *'But the [customer's] strategy was, to not be dependent on a specific manufacturer, but to establish a layered model, in which vendors of every layer [e.g. hardware, software,* *application] can be easily replaced.'* [IP3] However, although big players and a few progressive medium-sized companies already recognized the potential of a horizontally, layered architecture, many customers, especially employees from operational departments, prefer use-case oriented solutions with a clear and measurable Return-on-Investment (ROI). Especially in manufacturing companies these stakeholders have an important role, as an interview partner mentioned: *'There were mainly the production managers, who wanted that a specific use case is tailored and targeted well-functioning. And as with any manufacturing company, production [departments] have a prominent position and weight […].'* [IP3]

Lastly, *potential partners* have contradictory expectations as well. While a horizontally matured platform approach would provide them with a fertile ground for innovation, they still expect a close partnership of equals with shared product portfolio often requiring partner-specific vertical use-case implementations. Although these contradictory partner requirements are mainly attributed to the variety of partner types, even within single partner companies, expectations contradict to a certain degree.

Context: The trade-off must be seen in the context it emerged in. On the one hand, the popularity of trends like 'Industry 4.0' or concepts of the 'Smart Factory' not only raised interest for innovative solutions, but also had a positive impact on the customers' or potential partners' willingness to invest. On the other hand, companies in the production and logistics industry are still rather conservative. That is, management staff often belongs to elderly generations lacking a well-versed technological understanding, thus struggling to recognize technological potential. This requires educational work, which in turn is easier when selling vertical end-to-end solutions. Furthermore, the market is flooded by a high number of (I)IoT platforms. In this context, potential customers get confused and a critical attitude towards the platform term is clearly noticeable, as it was pictured by an interview partner: *'[…] there are platforms like sand by the sea. If you go to the customer and you use the word platform, then most say: Please leave immediately, I can't, I really can't hear this [word] anymore.' [IP2]* Hence, a clear value proposition in form of an implemented vertical end-to-end use case is even more important for those customers.

However, not only the target market caused the trade-off being faced, but also the current situation of the platform owner. Conducting interviews at *HardwareProvider* it became clear, that especially the company characteristics like age, size and background are closely intertwined with the trade-off. To begin with, limited resources in the development, sales, partner management as well as the product and project engineering department intensify the trade-off, because a simultaneous realization of both concepts is not feasible. As the company was only founded a few years ago, it had only a small potential to exploit existing (hardware) customer base for upselling. In addition, due to a limited brand recognition, customers expect close customer contact, commitment by the platform owner and a clear value proposition: *'Well, as a company with our name [little prominence] and without any other relationships, we don't have the opportunity to just bluntly sell a platform, which may not have such a huge added value yet, because there are only few applications on it.'* [IP1]

Also for *HardwareProvider,* such a close collaboration is desirable, as they can acquire relevant domain and process knowledge. Lastly, the company went through a transformation of the business focus as it was operating in the hardware sector before. The shift towards software business was challenging as the company lacked not only technical expertise in this field, but also experience concerning software sales processes and partnerships. By offering vertical end-to-end solutions combining software platform and own hardware products, *HardwareProvider* can leverage their existing resources to obtain a competitive advantage: *'[…] that we had a great deal of know-how in the field of [this type of] data and we were able to develop the right platform for it. […] That is, I need to differentiate my offer by knowing the data well, understand related use cases and then having a platform for it.'* [IP2]

(Pre-)Conditions: To pursue either of the two approaches a set of conditions need to be fulfilled. A vertical end-to-end solution requires access to hardware components as well as expertise about the created data (transportation, structure, content). In this context, one interview partner explained, why interface standards are only of limited use: '*[...] but if you are able to understand it - that is a different problem. The standardization of [data] transportation […] is relatively easy. And this is, what most concentrate on, when implementing standard interfaces. And the other [aspects] are often forgotten. Things like content structure. But even if the content is clear, then you still have things like units and coordinate systems. […] standard definitions leave questions, for example how certain information like battery status is communicated. That isn't standardized. And every supplier does it a bit different. Thus, it is not completely standardized anymore.'* [IP4] In addition, process knowledge is necessary to identify relevant use cases for implementation. While for the implementation of vertical use cases mostly specific data expertise is required, for successfully following the horizontal approach an even broader data expertise is necessary. Furthermore, a critical mass is relevant for making reasonable investments in the development of platform related features like an app store, user management, interface management, or automatic licenses.

4.2 Resulting Strategy and Consequences

Being confronted with this trade-off, *HardwareProvider* established a strategy to combine the two approaches by pursuing an **evolvable customer journey**. Thereby, the concept of a customer journey describes different stages of the actual purchasing cycle, as well as the relation to previous and future purchase experiences [48]. We denote the customer journey as evolvable, because of the customer's shift of interests: from requiring a vertical integrated solution towards requesting horizontal platform characteristics.

Starting with small, timely restricted projects as a proof-of-concept, *HardwareProvider's* customers in most cases focus on the underlying hardware technology. At this stage, the software platform is only seen as a complementary service to implement specific, vertical end-to-end use cases. Generic platform features like device management, user management, or generic standard interface implementations are used rarely within these proof-of-concepts. After a successful proof-of-concept, the customer decides to stay with the technology in form of a permanent hardware installation. Although this entails the installation of more hardware components in many cases, the scope of software features being used remains mostly the same. However, ensuing customer workshops often result in the identification of further projects. These projects consider not only the implementation of the similar use cases at other sites. Instead, identified use cases increasingly exploit platform characteristics of *HardwareProviders* software components. This is, customers' requirements develop more towards use cases utilizing the platform's standard interfaces to connect external data sources, for integration with existing systems or to connect with other external services on top. Furthermore, cross-cutting use cases depend on the scalability of a platform's architecture.

Benefits: Following such an evolvable customer journey approach has several benefits for *HardwareProvider*. First, it allows the company to exploit its innovative hardware technology and existent expertise by using it as an entry point for launching a more sustainable platform business-model at the customer. Furthermore, this step-by-step approach is the foundation for involved stakeholders at the customer site to develop a deeper understanding concerning the technology and its potential. By also building trust in *HardwareProvider* as a technology vendor, these stakeholders serve as internal promoters for follow-up projects. In general, customer investments in platform adoption and training for software usage, as well as already implemented use cases, including customization and integration with other IT systems, entail a certain lock-in effect. This was also summarized by one interview partner: '*And once [...] you anchored yourself horizontally with other systems, then it is very difficult to lose that position again. This way, you can establish yourself very well and thereby make yourself interesting for follow-up business [...].'* [IP5]

Challenges: In the first place, small proof-of-concept projects, including continuous consulting services and close collaboration, are not profitable. This evolving approach results in long sales cycles requiring *HardwareProvider* to make big investments in the technology not being covered by current revenues.

From a technical perspective, the chosen approach cannot be realized as seamlessly as it may be assumed. This is, further use cases are not just implemented by activating additional features on the platform. For example, an increased scalability required by later use case extensions (e.g., additional data sources) causes changes in the infrastructure. An interview partner outlines the reason for having two different versions: *'For this scalability, which is that this cluster is functioning, it requires a minimum of three servers. Without that, it doesn't make sense. And not every customer wants to put up three servers, if it is not needed. Thus, we also have another mode, which operates on only one server.'* [IP4] Further technical challenges include version management and security aspects related to network integration.

Lastly, *HardwareProvider* faces challenges concerning pricing. At first glance, a mixed offering (hardware plus software) may allow for more flexibility in cost allocation. However, in reality, the combination of one-time hardware costs and recurring software costs associated with an uncertainty about future software development and usage poses a problem. One strategy to solve this problem is the modularization of platform features. Thereby, value-based vs. cost-based pricing considerations as well as questions about feature granularity (e.g., statistic module vs. single charts) and licenses control mechanisms arise.

5 Discussion

Findings of the conducted case study shed light on a platform owner's challenging situation during early platform development. While the previous chapter explained our observations in more detail, we now discuss findings in the context of extant platform literature. We find that the emergence of the identified trade-off, which was rarely addressed in the literature so far, is attributable to characteristics specific to the B2B market. Especially, the complexity of B2B solutions, length of sales processes, bargaining power of customers, as well as the market fragmentation resulting in a lack of standardization, causes the differences to findings of existing literature, which are mostly based on examples from the B2C context [12, 13, 14, 15, 49].

Results of this case study further show, that, initially, customers in this market are mostly interested in single vertical end-to-end solutions for certain use cases. Thus, indirect network effects as a central and valuable mechanism of platforms do not occur because customers do not value the availability of other use cases on the platform. Consequently, the well-researched chicken-and-egg problem is less relevant in this context [32]. Nevertheless, customers expect a flexible and open solution to be able to develop further applications in their own IT departments or jointly with other third-party developers. Hence, platform-specific design principles (modularity, stable interfaces) and provision of boundary resources (documentation, developer communities etc.) are still relevant aspects to consider for the case company [14, 31].

Analyzing the case company's situation and chosen strategy, we provide insights to the prominent research question examining a company's decision to follow a platform strategy in the complex B2B market, considering differences between a horizontal and a vertical strategy [4, 21, 22]. In particular, we outlined the need for a hybrid strategy caused by anticipated consequences for internal and external stakeholder. Furthermore, this work also contributes to theory dealing with 'make-or-join' decisions being made by companies in emerging platform markets, that is, the decision whether to implement a new platform or to join an existing platform ecosystem [50]. Due to a complex and vast market situation, the immature state (in terms of technology and customer base) of existing platforms in the market, as well as the inability of these solutions to serve specific technical requirements (e.g. real-time and scalability), the case company decided to pursue a 'make' strategy.

This paper also adds to literature researching platform development from a market perspective. Unlike the assumption of a homogenous shift towards a horizontal market architecture [27], the results of this case study reveal, that in B2B markets, this transition from vertical integrated products towards a horizontally layered architecture can happen for every customer individually on different points in time. As a result, a company striving for platform ownership needs to provide a hybrid solution first. By describing *HardwareProvider's* hybrid strategy utilizing an evolvable customer journey approach, this paper presents a possible solution for this situation. We also outline the benefit of this strategy as yielding strong lock-in effects through investments by the customers for user education and technical system integration. Due to the complexity of B2B products, these investments are bigger, switching costs are higher and lock-in effects are stronger compared to those of B2C platforms. Thus, we consider it as unlikely, that the prominent ‘Winner takes all’ mechanisms [32] will apply in this context. Rather we expect the market to be composed of several niche platforms being linked with each other.

Our study also contributes to practice: By breaking down the current situation of a real company in this field, our work reveals important aspects and challenges to consider when working on a business model in an emerging B2B platform market. However, practitioners should consider, that results presented here are derived from a case study at a start-up and thus may not apply to established companies to the same extent [cf. 50, 51].

6 Conclusion

The purpose of our exploratory case study was to deepen the understanding of prospective platform owners’ situation in the context of Industry 4.0. Thereby, we derived novel insights about the early stage of platform development and the challenging trade-off between following a vertical product strategy or the implementation of a horizontal platform business model. We not only presented the identified circumstances fueling this challenging situation, but also outlined the platform owner’s approach of pursuing an evolvable customer journey as one strategy to counteract this trade-off. Although this strategy yields strong benefits like customer lock-in, it still includes business and product related challenges.

However, our study is also subject to several *limitations* laying the foundation for *future work*. Conducting a single case study allowed us to gain in-depth understanding of the company’s situation in the complex emerging IIoT market. Nevertheless, the generalization of findings is restricted. Furthermore, we want to point out, that the long-term success of the presented strategy undertaken by the case company could not be evaluated, as the platform is still in a very early stage. To overcome these limitations, we suggest multiple, long-term case studies also addressing differences in platform type (e.g., edge vs. cloud or platform for equipment supplier vs. for equipment operator) and platform owner’s characteristics (background, size, age) while evaluating findings. Lastly, presented results focus on the technical development and design of the platform. Besides that, building an ecosystem is a key aspect of successful platforms. While the onboarding process of customers has been addressed in more detail, onboarding of the supply side was not in the focus of this work. However, in the course of this exploratory case study we came across interesting aspects differing from extant literature (e.g., partner acquisition, motivation, collaboration). Thus, we call for future work further investigating partner management strategies in the context of IIoT platforms and hope that our work can provide a helpful starting point.

Machine Learning und Complex Event Processing: Effiziente Echtzeitauswertung am Beispiel Smart Factory

Jonas Wanner[1], Christopher Wissuchek[1], Christian Janiesch[1]

[1] Julius-Maximilians-Universität Würzburg, Würzburg, Germany
{jonas.wanner, christian.janiesch}@uni-wuerzburg.de,
christopher.wissuchek@gmail.com

Abstract. Durch die Verbindung zwischen physischen Maschinenteilen und digitalen Services werden mit Cyber-physischen Systemen in Smart Factories viele datenbasierte Optimierungen möglich. Ein wichtiger Bestandteil dieser sogenannten Smart Factories kann die Technologie Complex Event Processing (CEP) sein. CEP erlaubt Echtzeitauswertungen komplexer Events, i. S. v. kombinierten Datenwerten aus unterschiedlichen Quellen. Damit können u. a. anomale Prozessabläufe identifiziert und lokalisiert werden. Eine aktuelle Beschränkung der Wirkungsfähigkeit ist die hauptsächlich deklarative und reaktive Implementierung von CEP. Eine Erweiterung um Ansätze aus dem Machine Learning (ML) ist daher vielversprechend. Es fehlt jedoch an einer aktuellen Übersicht zu Verbindungen von CEP und ML innerhalb der Forschung sowie deren Transferfähigkeit auf Smart Factories. Unser Beitrag liefert (1) eine Synthese der bislang erforschten CEP-ML-Kombinationen, wobei sich Supervised Learning als überwiegender Kombinationsansatz zeigt, und (2) eine Übertragung der Potenziale für die Verwendung in Smart Factories. Hier zeigten sich reaktive Maßnahmen als bisheriger Forschungsschwerpunkt.

Keywords: Machine Learning; Complex Event Processing; Real-time Event Processing; Smart Factory; Literature Review

1 Einleitung

Die nutzbare Datenmenge in der modernen Industrie steigt stetig an [1]. Inzwischen beschränkt sich die Nutzung der Analysepotenziale nicht nur auf historische Datenbestände, sondern verstärkt auf die Auswertung von Echtzeitdaten. Dies erlaubt eine situationsabhängige und dynamische Entscheidungsfindung [2]. Ein Realisierungsansatz dafür kann Complex Event Processing (CEP) sein, ein Technologie-Paradigma zur Verarbeitung kontinuierlicher Datenströme auf Basis von Ereignissen [3].

Gerade in Smart Factories lassen sich mit dieser Technologie Einsparungen durch die Echtzeitauswertung von Sensordaten erzielen [4]. Trotz der großen Potenziale von CEP existiert jedoch eine fundamentale Einschränkung: CEP verarbeitet und analysiert Ereignisse auf Basis manuell vorspezifizierter, deklarativer Regeln [5, 6]. Durch die regelbasierte Umsetzung [6] ist eine Proaktivität schwierig umsetzbar. Ebenso erfordert

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

der reaktive Charakter teure manuelle Identifikations- und Implementierungsprozesse [7].

Forscher aus der Domäne des CEP greifen infolgedessen zuletzt verstärkt auf Machine Learning (ML) zurück, um die (teure) deklarative Natur von CEP zu verändern und zu verbessern [8-12]. ML ist ein Ansatz, in dem Computersysteme automatisiert auf Basis von Algorithmen aus Erfahrung lernen [13].

Zusammenfassend sollen die aktuellen CEP-Restriktionen durch geeignete ML-Möglichkeiten aufgeweicht und wenn möglich ganz gegenstandslos werden. Der Fokus dieser Arbeit liegt dabei auf der Anwendbarkeit in Cyber-physischen Systemen moderner Smart Factories. Es lassen sich damit zwei Forschungsfragen ableiten:

(1) *Welche ML-Verfahren werden in Kombination mit CEP eingesetzt und wie sind diese zu systematisieren?*
(2) *Welche Potenziale leiten sich aus dem Einsatz von ML im CEP von Industriefertigungsanlagen in Smart Factories ab?*

Zur Beantwortung der Forschungsfragen ist dieser Beitrag wie folgt aufgebaut: In Kapitel 2 wird ein Überblick zu den theoretischen Grundlagen von Smart Factories, CEP und ML gegeben. Kapitel 3 erläutert die angewendete Forschungsmethodik. Kapitel 4 beantwortet Forschungsfrage (1) auf Basis einer literaturgestützten Taxonomie zur Lokalisierung potenzieller Anwendungsmöglichkeiten. Die erlangten Erkenntnisse werden anschließend innerhalb von Kapitel 5 zur Beantwortung von Forschungsfrage (2) auf Herausforderungen und Verbesserungspotenziale für Anlagen in Smart Factories übertragen. In Kapitel 6 erfolgt eine kritische Stellungnahme zu den erarbeiteten Erkenntnissen. Ebenso werden erkannte Forschungslücken aufgezeigt. Die Arbeit schließt mit einem Fazit.

2 Smart Factories, CEP und ML

Cyber-physische Systeme und Smart Factories. Die zentralen Produktionsfaktoren der Industrie 4.0 sind Informations- und Kommunikationstechnologien [14]. Sie werden dazu genutzt Cyber-physische Systeme (CPS) zu entwickeln. Dabei handelt es sich u. a. um Objekte, Gebäude oder Produktionsanlagen, die durch eingebettete Systeme kommunikationsfähig werden und ihre Umgebung mittels verbundener Sensorik erfassen können. Sie sind vernetzbar und offenbaren über echtzeitfähige Messungen von Ereignissen (sog. Events) neue Optimierungs- und Automatisierungspotenziale [14].

Complex Event Processing. Eine Möglichkeit der Nutzenmachung dieser Events ist CEP, ein Technologie-Paradigma zur Echtzeitverarbeitung kontinuierlicher Ereignis-Datenströme [3]. Die CEP-Referenz-Architektur besteht aus drei Komponenten. Der (1) *Event Producer* überträgt die gesammelten Events an den (2) *Event Processor*, die zentrale Verarbeitungseinheit. Dieser verarbeitet Events regelbasierend auf Basis manuell und deklarativ zu definierender Agenten zur Erkennung anomalen Verhaltens [7]. Die Verbesserung der Fähigkeiten dieser sogenannten *Event Processing Agents* durch ML ist der Fokus des vorliegenden Beitrags. Nach der Verarbeitung werden die Ergebnisse an festgelegte (3) *Event Consumer* übergeben, welche die Ereignisbehandlung übernehmen [2, 15].

ML-Verfahren. Die bisherigen CEP-Einschränkungen sollen durch Möglichkeiten des ML verbessert werden. Dies erlaubt die automatisierte CEP-Regelbildung für bekannte und ggf. unbekannte Anomalien. Zum Beispiel könnte eine zu definierende, Schwellenwert-basierte Filterung durch eine ML-trainierte Klassifikation ersetzt werden. ML bietet dazu unterschiedliche Verfahren zur Schulung von Algorithmen. *Supervised Learning* umschreibt einen Lernansatz, bei welchem Inputs bewusst vordefinierten Outputs zugeordnet werden. Durch die Übergabe der Input-/ Output-Paare zu Trainingszwecken kann die Maschine künftig neue Fälle automatisiert zuordnen [16-18]. Diese können weiter in Klassifizierungs- und Regressionsansätze unterkategorisiert werden. Beim *Unsupervised Learning* wird auf die Übergabe der Input-/ Output-Paare verzichtet. Der verwendete Algorithmus erhält ausschließlich Inputs. Als Ziel gilt das Erkennen bisher unentdeckter Muster [17, 19, 20]. Hier wird i. d. R. mit Clustering und Dimensionsreduktion gearbeitet. Das *Reinforcement Learning* ist ein weiterer Lernansatz zum Verstehen und zur Automatisierung von zielgerichtetem Lernen und Entscheidungsfindungsprozessen [21]. Durch Versuch und Irrtum in Kombination mit Belohnungen wird ein Lernagent geschult, sodass er je nach angenommenen Zuständen und Aktionen Belohnungen maximiert [18, 22, 23].

3 Methodisches Vorgehen

Zur Beantwortung der Forschungsfragen wurde das Rahmenwerk zur strukturierten Literaturrecherche nach vom Brocke et al. [24] verwendet.

Rechercheumfang. Der festzulegende Rechercheumfang basiert auf der Taxonomie nach Cooper [25]. Als Fokus gelten *Forschungsergebnisse* und *Anwendungen*. Das Ziel ist die *Integration* der Forschungsbereiche ML und CEP. Es wird eine *neutrale Darstellung* mit *repräsentativer Abdeckung* gewählt. Die Ergebnisse selbst werden *konzeptionell* zur Beantwortung der Forschungsfragen organisiert. Als Zielgruppe haben wir *spezialisierte Forscher* aus den Bereichen von ML und oder CEP sowie *allgemeine Forscher* aus der Wirtschaftsinformatik bestimmt.

Konzeptualisierung. Das Suchergebnis muss ein Verfahren aus der Domäne des ML im CEP einsetzen und auf Anwendungen in Smart Factories übertragbar sein.

Literatursuche. Bei der *Datenbankauswahl* wurden sieben Datenbanken aus den Bereichen der Informatik und Betriebswirtschaftslehre gewählt (vgl. *Abbildung 1*). Für die *Keyword-Suche* wurden gängige Begriffe aus dem CEP genutzt (Kurzform: *Event & Processing | -driven*) und mit dem engl. Oberbegriff „Machine Learning“ verbunden.[1]

[1] Eine Übersicht der definierten Suchterme je wissenschaftlicher Datenbank sowie die vollständigen Referenzen zu Tabelle 1 können im digitalen Anhang abgerufen werden unter: https://bit.ly/2qSdhP8.

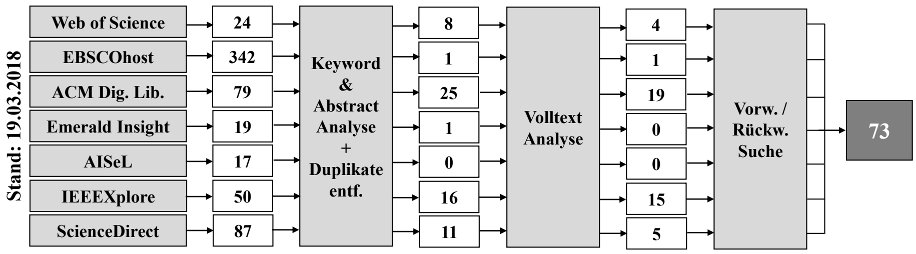

Abbildung 1: Prozess der Literatursuche

Es wurden im ersten Schritt 618 potentiell relevante Werke identifiziert. Nach der Analyse aller Werke bzgl. Titel, Abstract, Keywords und Duplikaten konnten 62 relevante Publikationen ermittelt werden. Die Volltextanalyse reduzierte die Anzahl auf 44. Ein Gros an Suchergebnisse fand sich in informatiknahen Datenbanken (*IEEEXplore* und *ACM Digital Library*). Letztere publiziert u. a. Beiträge der für das Thema hoch relevanten Konferenz Distributed Event-Based Systems (DEBS). Die *Rückwärtssuche* wurde auf Basis der extrahierten Quellen aus den Werken durchgeführt, die *Vorwärtssuche* über Google-Scholar-Zitationsdaten. Dies führte zu weiteren 29 Ergebnissen, sodass insgesamt 73 Beiträge gefunden werden konnten.

4 Auswertung der Literaturanalyse

Ergebnis der Synthese. Die Synthese (vgl. *Abbildung 2*) zeigt, dass das Lernparadigma *Supervised Learning* im CEP dominiert (n=46). Der Großteil der Arbeiten behandelt dabei den algorithmischen Ansatz der *Klassifizierung* (n=23).

Das Lernparadigma *Unsupervised Learning* findet hingegen weniger Anwendung (n=6). *Clustering* zeigt sich hier als dominanter Ansatz (n=5), wobei ein Beitrag einen *dimensionsreduktionsbasierten Ansatz* verfolgt.

Beliebter ist die Kombination (Englisch: *Combined Learning*) aus *Unsupervised* und *Supervised Learning* (n=13). Die meisten Autoren (n=12) nutzen hierbei eine Verbindung aus *Clustering* und *Klassifikation*. Ein Ansatz behandelt *Clustering* erweitert um ein *probabilistisches Modell* (n=1).

Reinforcement Learning für CEP wurde bisher nicht beachtet und scheint damit potentieller möglicher Gegenstand weiterer Forschung. Weitere alternative Ansätze, welche sich nicht in das gewählte Klassifikationsschema einordnen ließen, wurden unter *Weitere Beiträge* (n=8) aufgelistet. Beispiele finden sich mit Algorithmen aus der Data Mining Domäne [26] oder Eigenentwicklungen wie bei Margara et al. [27] mit deren Windows Learner.

Zeitliche Entwicklung. Die Forschungsdomäne kann als jung bezeichnet werden mit dem frühsten Beitrag aus dem Jahr 2007 [28]. Über die Folgejahre zeigt sich ein steigendes Forschungsinteresse mit Höhepunkten in den vergangenen Jahren 2016 (n=18) und 2017 (n=17). Das Jahr 2018 ist nicht vollständig erfasst. Diese Tendenz verdeutlicht die Aktualität und Themenrelevanz sowie die verschiedenartigen Anwendungsmöglichkeiten des ML im CEP.

Auf Ebene der Lernparadigmen ist festzustellen, dass anfangs vor allem *Supervised Learning* betrachtet wurde. Hierbei lag der Fokus zunächst auf Klassifizierungsansätzen. Ab dem Jahr 2013 findet eine Diversifikation statt. Weitere Ansätze, wie bspw. regressionsbasierte Verfahren, finden vermehrt Betrachtung. Dennoch bleiben Klassifikationsverfahren durchgehend dominant. *Unsupervised Learning* ist in der CEP-Forschung hingegen (bisher) unterrepräsentiert. Die erste Publikation aus dem Jahr 2010 verfolgt einen dimensionsreduktionsbasierten Ansatz. Ab 2013 werden vereinzelt Clustering-basierte Beiträge veröffentlicht, wobei das Maximum im Jahr 2017 (n=2) liegt. Ein stärkeres Interesse zeigt sich bei der *Kombination* beider Paradigmen. Nach nur einer Publikation im Jahr 2014, finden sich 2016 fünf und 2017 sieben Beiträge.

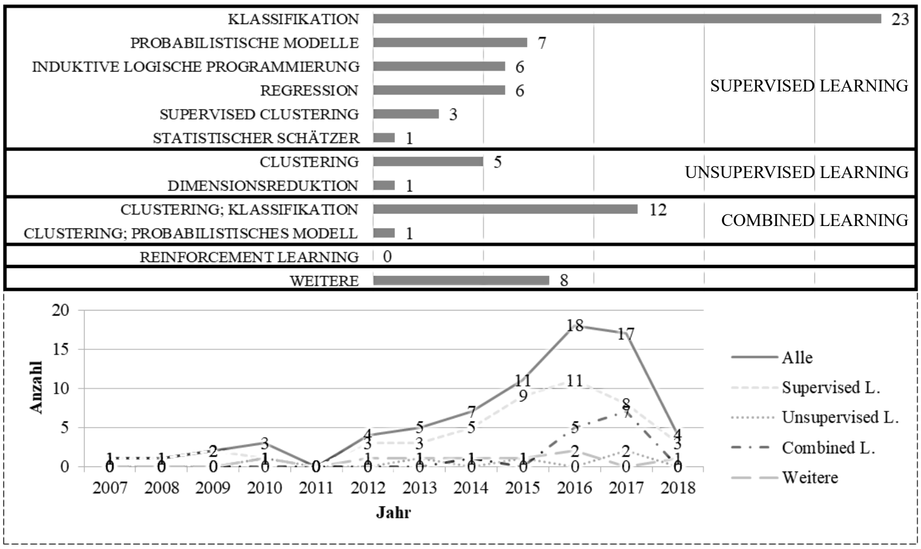

Abbildung 2: Zuordnung der Beiträge zu den ML-Lernparadigmen

Fazit. Im CEP findet überwiegend *Supervised Learning* Anwendung. Dies lässt sich aufgrund des reaktiven Charakters in Kombination mit historischen Eventdaten erklären. *Unsupervised Learning* wird dementsprechend meist in *Kombination* eingesetzt. Damit lassen sich Vorteile aus beiden Paradigmen nutzen, wobei hierbei weiterer Forschungsbedarf besteht. Eine fundierte Eignungsprüfung des Ansatzes *Reinforcement Learning* für CEP fehlt hingegen. Es zeigt sich aus der historischen Analyse, dass die Forschung im Bereich CEP und ML an Wirkungskraft gewinnt und nicht nur punktuell einzelne Verfahren betrachtet. Es ist vielmehr ein Trend zu erkennen, dass verschiedene Verfahren kombiniert werden, um einen erkennbaren Mehrwert in der Echtzeitverarbeitung von Events zu schaffen.

5 Anwendungspotenziale in Smart Factories

5.1 Zielbereiche von Produktionsanlagen

Aus betriebswirtschaftlicher Perspektive bestehen in Produktionsanlagen vier Zielbereiche [29]: Kosten, Qualität, Zeit und Flexibilität. Unter *Kosten* wird mehrheitlich die bestmögliche Allokation der eigenen Ressourcen verstanden. *Qualität* umschreibt die Annahme und Schätzung einer Übereinkunft des Produkts mit den eigenen Zielvorgaben basierend auf dem Produktionsprozess. *Zeit* definiert sich als Quelle eines Wettbewerbsvorteils i. S. v. Ansätzen wie Just-in-time und als fundamentale Messinstanz für die Produktionsperformance. *Flexibilität* beinhaltet die Fähigkeit eines Industrieherstellers, sein Produktionssystem effizient zu verändern – sowohl hinsichtlich der Produktvielfalt als auch der Herstellmenge [30].

Dieselben Zielbereiche bestehen auch in Smart Factories [4]. Durch den Einsatz von CPS und der verbundenen Infrastruktur sollen potenzielle Verbesserungen in allen vier Bereichen realisierbar sein [4]. Um Potenziale durch die Kombination aus CEP und ML aufzuzeigen, wird im nachfolgenden Kapitel von derartigen Industrieanlagen ausgegangen.

5.2 Synthese potenzieller Lösungsansätze durch CEP und ML

Synthese. Auf Basis der Rechercheergebnisse lassen sich sowohl reaktive als auch proaktive Einsatzpotenziale für Smart Factories erkennen. Wie in *Tabelle 1* ersichtlich überwiegen Forschungsbemühungen zu reaktiven Möglichkeiten. Ebenso sind die in *Abbildung 2* unter *Weitere* aufgeführten Beiträge ausschließlich auf reaktive Maßnahmen gerichtet. Aus Platzgründen wurde jedoch auf die Aufnahme in *Tabelle 1* verzichtet, zumal es sich weitestgehend um Spezialfälle handelt oder kein spezifischer Algorithmus genannt wird. Ein Hinweis zu weiteren Details findet sich in Fußnote 1.

Reaktive Maßnahmen. Reaktive Maßnahmen von CEP in Kombination mit ML sollen effizientere Abläufe für Fehler- bzw. Schadensfälle ermöglichen. Dies erlaubt die Aufbereitung wichtiger Informationen für die Fehlerlokalisierung und -behebung. Bei Beginn des CEP-Monitorings in Industrieanlagen sind allerdings i. d. R. nicht alle Störfälle bekannt. Eine Fortschreibung der Mustererkennung ist daher essentiell. Dies erfordert eine manuelle Identifizierung neuer Anomalien. Die Aufgabe impliziert hohes technisches Wissen, bei vertiefender Domänenkenntnis [5, 6]. Eine Unterstützung kann ML bieten. Damit werden im Idealfall bisher unbekannte Eventmuster vollautomatisch aufdeckbar und für die Zukunft aufbereitet [28, 59].

Einen direkten Anwendungsbezug in Smart Factories bietet der Ansatz von Metz et al. [35]. Sie nutzen Produktionsdaten in Kombination mit Prozessdaten, um mit Hilfe einer ML-Komponente neue Regeln über Entscheidungsbäume zu klassifizieren und diese für die CEP-Einheit zu nutzen. Ebenso findet sich der Einsatz von Kamerasystemen und bildverarbeitenden Sensoren in Produktionsprozessen [42]. Diese bieten wertvolle Informationen für Smart Factories, um eine präzisere Mustererkennung und -adaption zu realisieren.

Tabelle 1: Potenziale beim Einsatz von CEP und ML in Smart Factories (für die vollständige Einordnung aller analysierten Quellen vgl. Fußnote 1)

Lernparadigma	ML-Ansatz	Algorithmus	Reaktive Maßnahmen (∑=39) ∑	Beispiel	Proaktive Maßnahmen (∑=35) ∑	Beispiel
Supervised Learning	Klassifikation	Support Vector Machine	4	[31]	1	[32]
		Shapelet-basierte Algorithmen	2	[33]	3	[34]
		Entscheidungsbäume	2	[35]	2	[36]
		Künstlich neuronale Netze	4	[12]	1	[37]
		Sliding Window, Aggressive and Pessimist Classifier	1	[38]	0	
		Markov Model	1	[7]	1	[39]
		Diskriminanzanalyse	3	[12]	0	
		K-nearest Neighbors	1	[31]	0	
		Naive Bayes	1	[31]	1	[36]
		FURIA	3	[40]	0	
	Probabilistisches Modell	Bayessche Netzwerke	0		6	[36]
		Markov Model	1	[41]	0	
		Conditional Density Estimation	0		1	[42]
	Induktive logische Program.	Eigenentwicklung	6	[43]	0	
	Regression	Support Vector Regression	0		3	[44]

		Adaptive Moving Window Regression	0		2	[45]
	Supervised Clustering	k-Means Adaption	0		1	[46]
		Eigenentwicklung	1	[47]	1	[48]
	Statistischer Schätzer	Discrete Kalman Filter	1	[6]	0	
Unsupervised Learning	Clustering	Density-based Clustering	2	[49]	0	
		Complete-link and Single-link Clustering	1	[50]	0	
		Fixed-width Clustering	1	[51]	0	
		k-Means	1	[5]	0	
	Dimensionsreduktion	Principal Component Analysis	1	[52]	0	
Combined Learning	Clustering; Klassifikation	k-Means; Markov Model	0		8	[53]
		k-Means; Gaussian Mixture Model	1	[54]	0	
		Hierarchical Clustering; Entscheidungsbäume; k-Means; Naive Bayes, SVM	0		1	[55]
		Unspezifizierter Clustering-Algorithmus; Naive Bayes	1	[56]	0	
	Clustering; Probabilistisches Modell; Topic Mining	Density-based Clustering; Bag-of-words; Markov Model	0		1	[57]
	Clustering; Klassifikation; Kollaboratives Filtern	k-Means; Complementary Naive Bayes; ALSWR	0		1	[58]

Darüber hinaus werden Sensornetze in Kombination mit Klassifizierungsalgorithmen genutzt [38]. Die Erkennung anomalen Verhaltens erfolgt dabei über Analysen von Events aus Druck-, Vibrations-, Temperatur- und Näherungssensoren [60]. Auch Ansätze aus weiteren Forschungsbereichen zeigen Potenzial für die Problemlösung auf. Einige der Autoren [41, 43] setzen auf Videoüberwachungs-Datensätze, um Aktivitäts- bzw. Eventmuster zu erlernen. Hierbei wird bis auf eine Ausnahme einer Markov-Model-Verwendung in [41] auf Induktive Logische Programmierung gesetzt. Die Anwendung erfolgt allerdings außerhalb von Smart Factories, ist aber potenziell übertragbar.

Weitere Autoren [40, 56] nutzen Beschleunigungssensor-basierte Ereignisströme, um automatisiert Bewegungsmuster von Personen zu erkennen. Für das ML wird bei [40] eine Klassifizierung mittels des Fuzzy Unordered Rule Induction Algorithm (FURIA) verwendet. [56] nutzen hingegen eine Kombination aus Clustering und Klassifikation auf Basis von Naive Bayes und eines unspezifizierten Clustering-Ansatzes. In produktionsspezifischen Szenarien bietet dies jeweils u. a. die Möglichkeit zur Überwachung und Steuerung von industriellen Roboterarmen [61]. Eine manuelle Implementierung der Bewegungsprofile als Events in einem CEP-System wäre dagegen mit großem zeitlichem Aufwand und hoher technischer Expertise (Kosten) verbunden.

Ein weiteres Anwendungsfeld ist die Netzwerksicherheit. Durch den Einsatz von CPS werden neue Cyber-Angriffsflächen eröffnet, welche eine Betriebsstörung oder Produktionsausfälle verursachen können [62]. Zur Prävention resultierender Zeitverluste und Kosten setzen [6, 26] auf CEP-basierte Intrusion Detection Systeme, welche um ML-Komponenten erweitert werden. [6] nutzen hierfür Discrete Kalman Filters, wohingegen [26] eine Kombination aus Markov Logic und Data Mining Ansätzen einsetzen. In beiden Fällen wird eine dynamische und adaptive Anpassung der Angriffsmuster möglich ohne die Notwendigkeit von manuellen Eingriffen und wiederkehrender, aufwändiger Nacharbeitung.

Durch die aufgezeigten Maßnahmen werden primär die manuelle Überwachungstätigkeit und die Implementierung von deklarativen Regeln im CEP-System entfallen. Dies resultiert in einer Verbesserung der Reaktivität in Produktionsstätten und spart *Zeit* und *Kosten* ein.

Proaktive Maßnahmen. Zukünftige Events werden im CEP standardmäßig nicht berücksichtigt [42]. Eine proaktive und frühe Reaktion auf Events erhöht jedoch den Geschäftswert des Systems [32]. Mit der Erweiterung um ML lässt sich dies auch im CEP-Umfeld erreichen. Damit werden Vorhersagen und proaktives Handeln auf Basis historischer Eventdaten durch Schwellenbereiche möglich.

[42] setzen auf ein Conditional Density Estimation trainiertes ML-CEP-System, welches Eventdaten von Kamerasystemen und Sensoren erhält. Der Produktionsdurchlauf wird in Echtzeit auf anormale Veränderungen geprüft und mit Eintrittswahrscheinlichkeiten abgeglichen. Dieselbe Aufgabe findet sich als zentrales Thema der ACM DEBS 2017 Grand Challenge [53]. Zur Datenvorverarbeitung galt es Events auf Basis diskreter Zustände (z. B. Temperatur oder Druck der Produktionsmaschine) durch einen Clustering-Algorithmus zu gruppieren. Daraufhin musste ein Markov-Modell trainiert werden, um Eintrittswahrscheinlichkeiten von Anomalien in Echtzeit

zu berechnen. In allen Lösungsansätzen wurde mit Zustandsübergängen zwischen den Clustern gearbeitet. Das System benachrichtigt den Mitarbeiter sobald die Wahrscheinlichkeit über einem definierten Schwellenwert liegt.

[34] zeigen mit Hilfe eines Shapelet-basierten Ansatzes, dass sich die Vorhersagefähigkeit mit dem automatisieren Lernen von Regeln kombinieren lässt. Ein alternativer Ansatz [36] zielt auf die einheitliche Verwendung eines proaktiven Architekturstandards im industriellen Umfeld ab. Mit Hilfe eines Bayesschen Netzes und einer verbundenen Klassifizierung anhand von Entscheidungsbäumen werden in diesem Beispiel Probleme Zeit-terminierter Wartungsvorgänge unabhängig vom tatsächlichen Maschinenzustand angegangen. Durch eine CEP-Kombination mit einer ML-gestützten Echtzeitanalyse wird der Austausch bei faktischer Notwendigkeit eines Ersatzteils in Abhängigkeit der verbleibenden Lebensdauer angezeigt. Dies erlaubt eine entsprechende Optimierung des Wartungsintervalls.

Weitere Einsatzszenarien finden sich einerseits für intra-logistische Materialbewegungen wie der gezielten Überwachung von Förderbändern [63] sowie andererseits für extra-logistische Materialbewegungen wie z. B. im Straßenverkehr [8, 64, 65]. Dabei werden Eventdaten kontinuierlich über Sensoren, Kamerasystemen oder Induktionsschleifen erfasst, übertragen und zur Vorhersage u. a. von Verkehrsstaus herangezogen. [8] setzen dazu auf eine Adaptive Moving Window Regression, um ein kontinuierliches Lernen des CEP-Systems zu sichern. [64]. [65] nutzen hingegen Bayessche Netze, um probabilistische Complex Events vorherzusagen.

Die Proaktivität der aufgezeigten Ansätze führt vorrangig zur Optimierung der *Auslastung* der Fertigungs-, Wartungs- und Warenflussprozesse. Ebenso resultieren daraus *Kosteneinsparungen* durch proaktiv reduzierte Wartungsprozesse.

6 Diskussion und Fazit

Diskussion. Die unternommene Untersuchung zeigt, dass ein Einsatz von ML großes Potenzial für CEP besitzt. [66] bestätigen dies und bezeichnen den Einsatz von ML als bedeutenden Fortschritt in der Echtzeitauswertung von Events. Trotz der Bedeutung für die Forschungsdomäne fehlte bislang eine umfassende Betrachtung der unterschiedlichen Kombinationsansätze.

Auf Basis der durchgeführten Literaturrecherche konnte festgestellt werden, dass bei der Erweiterung von CEP um ML primär Supervised-Learning-Ansätze eingesetzt werden. Über die letzten Jahre finden sich aber vermehrt Kombinationen aus Supervised- und Unsupervised-Learning-Ansätzen. Dies birgt großes Potenzial für die Umsetzung proaktiven Verhaltens. Reinforcement Learning und weitere Alternativen sind hingegen kaum untersucht worden. Zukünftige Forschung könnte hier ansetzen, um bspw. die Wirksamkeit von belohnungsorientierten Ansätzen für das CEP zu untersuchen. Reinforcement Learning wird bereits in Multi-Agenten-Systemen verwendet. Da Event Processing Agents konzeptionell als autonome Agenten eines umfassenderen Event Processing Networks betrachten werden, liegt es nahe, die Wirksamkeit dieses Ansatzes auch in diesem Umfeld zu untersuchen.

In einer zweiten Synthese wurden mögliche Einsatzpotenziale von ML in CEP für Smart Factories betrachtet. Für die betriebswirtschaftlichen Zielbereiche von Kosten, Zeit, Flexibilität und Qualität ergaben sich sowohl (1) reaktive als auch (2) proaktive Verbesserungsansätze. Das Potenzial wird überwiegend in der Reduzierung der Zeit (d. h. in Bezug auf bessere Maschinenauslastung) und der Kosten (d. h. in Bezug auf Automatisierungsansätze) gesehen und adressiert. Bisherige Forschung zielte primär auf reaktive Maßnahmen ab, wobei gerade in den letzten beiden Jahren verstärkt auch proaktive Maßnahmen erforscht wurde.

Die Literaturanalyse zeigt, dass für reaktive Maßnahmen in Smart Factories vornehmlich auf Supervised Learning zurückgegriffen wird. Es handelt sich dabei insbesondere auf SVMs und künstlich neuronale Netze aus dem Bereich der Klassifizierung. Ansätze aus dem Unsupervised Learning sind bislang unterrepräsentiert, wobei jedoch erste Testversuche erfolgt sind. Combined Learning wiederum scheint für reaktive Maßnahmen hinsichtlich der fehlenden Verwendung vergleichsweise unbrauchbar. Dies steht im Gegensatz zu proaktiven Maßnahmen. Hier wird zunehmend mit Ansätzen aus dem Combined Learning gearbeitet. Primär erscheint eine Verbindung aus k-Means und dem Markov Model erfolgsversprechend. Auch Anwendungen aus dem Supervised Learning finden sich. Dabei werden überwiegend Bayessche Netze aus dem Bereich der probabilistischen Modelle eingesetzt. Ansätze aus dem Unsupervised Learning bestehen hingegen keine, was deren fehlende Eignung nahelegt.

Fazit und Ausblick. Aktuell werden einige Anwendungen für die kontinuierliche Echtzeitauswertung von Events auf CEP-Basis erprobt. Gerade im Umfeld von Smart Factories zeigen sich erste Umsetzungen primär in reaktiven Bereichen, wie der informationsgestützten Reparatur im Fehlerfall. Auch in Bezug auf Big Data werden Kombinationen aus CEP und ML als erfolgsversprechend angesehen [67]. Der Trend geht hierbei zu probabilistischen bzw. ungewissen Eventmodellen. Im Gegensatz zu deterministischen Eventmodellen sind dabei nicht alle Attribute bekannt oder mit Ungenauigkeiten versehen [67]. Erste Lösungsansätze fokussieren Bayessche und Markov-Netze allerdings mit bisher mäßigem Erfolg [68].

Zukünftige Forschung könnte hier ansetzen und über neue Ansätze wie bspw. das Online Machine Learning [69] weitere Verbesserungen erreichen. Beim Online ML steht die automatische Generierung der vormals manuell spezifizierten deklarativen CEP-Abfragen im Mittelpunkt, um sowohl eine verbesserte Eventerkennung und -verarbeitung zu erreichen als auch um Kosten zu sparen. Auch die Kombination von CEP mit Ansätzen aus dem Reinforcement Learning ist wie oben beschrieben vielversprechend. Gerade für Smart Factories kann im Hinblick auf die Optimierung der Maschinenlauffähigkeit und für das damit verbundenen Wartungsmanagement eine Verbesserung erfolgen. Dies lässt sich insbesondere durch präskriptive Analyse prognostizieren, wobei hier nicht die Maschine als Einzelkomponente betrachtet werden sollte, sondern die jeweils beste betriebswirtschaftliche Entscheidung im Gesamtunternehmenskontext [70].

Förderhinweis

Dieses Forschungs- und Entwicklungsprojekt wird mit Mitteln des Bayerischen Staatsministeriums für Wirtschaft, Landesentwicklung und Energie (StMWi) innerhalb des Förderprogramms "Informations- und Kommunikationstechnik" (Kennzeichen IUK536/003) gefördert und vom Projektträger VDI+VDE Innovation + Technik GmbH betreut.

Sensor retrofit for a coffee machine as condition monitoring and predictive maintenance use case

Peter Burggräf[1], Johannes Wagner[1], Benjamin Koke[1], Kailashnath Manoharan[1]

[1] University of Siegen, Mechanical Engineering, Siegen, Germany
{peter.burggräf,johannes.wagner,benjamin.koke}@uni-siegen.de

Abstract. The concept of Industry 4.0 provides promising approaches to reduce downtime and increase overall equipment efficiency in manufacturing processes through interconnected devices in the industrial internet of things (IIoT). As the procurement of new IIoT-ready machines is costly, the retrofit of old machines can be an idea worth exploring. In this paper, we designed a simple experiment setup using affordable sensors and a coffee machine (due to the absence of machinery) to measure grinding vibrations and to predict the last coffee before grinder no-load. Microsoft Azure Machine Learning Studio was used to deploy machine learning techniques in order train prediction models. While prediction accuracy in this experiment was non-satisfactory, our results nonetheless indicate that retrofit is indeed a proper approach to make an older machine park smart, provided that sensors (especially their sample rate) are suitable for the application.

Keywords: Condition Monitoring, Machine Learning, Retrofit, Industry 4.0, Internet of Things

1 Introduction

With the rise of the concept of Industry 4.0 and the advent of data analytics and machine learning, **condition monitoring** to understand machine status and detect faults is considered as an important research topic [1]. In Industry 4.0, manufacturing systems include numerous sensors and interconnected devices (so-called cyber-physical systems) that form the industrial internet of things (IIoT) and facilitate the collection of large amounts of data. Data Analytics helps manufacturing firms to get actionable insights resulting in smarter decisions and better business outcomes [2]. The implementation of Machine Learning (ML) and Big Data may drive the next wave of innovation and may soon prove to be an unavoidable tactical move in achieving higher levels of optimization [3]. Some authors even argue that ML will play a major role in managerial decision-making [4].
Enabling communication and data collection in established manufacturing shop-floors, however, requires extensive capital investment in new machinery and IT infrastructure, which may prove to be a burden for small and medium-sized enterprises (SMEs). One alternative is the retrofit of older machines with sensor kits to collect machine data to

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

gain valuable insights. The purpose of this paper is to demonstrate the ease of retrofit initiatives by presenting an experiment setup using an affordable sensor kit and a coffee machine. The experiment involves detection of shifts in vibration frequency when the bean container runs empty to predict the last coffee. The remainder of this paper is structured as follows: first, we present relevant literature background for ML. Second, we present the experiment and results. Third, we present a discussion of the quality of results. Lastly, a conclusion and future outlook is presented.

2 Literature

ML analyses past data and makes predictions as well as decisions based on it. The machine learns to create its own logics and solutions with or without any form of human intervention [3]. There are different types of ML techniques relevant for real time scenario in a condition monitoring system. Supervised learning approaches use defined input-output tuples and require extensive training in order to make predictions for the future while unsupervised learning acts on information without pre-labeled output [5]. Classification and regression problems are the most frequently used methods in supervised learning whereas k-means clustering, auto-encoders and anomaly detection are popular in unsupervised learning [6].

Regression algorithms that are most commonly used in the domain of vibration monitoring studies include: Linear Regression [7] identifies a relation between dependent and independent variables. Bayesian Linear Regression [8] uses probability distributions rather than point estimates on generally small datasets. Neural Network Regression [9] approximate nonlinear functions of their inputs by adapting weights. Boosted Decision Tree Regression [10] creates a prediction model in the form of an ensemble of weak prediction models. With Decision Forest Regression [11], labeled set of inputs learn a general mapping which associates previously unseen independent test data with their correct continuous prediction.

As the experiment is designed as regression problem, the experiment setup (see next section) will focus on the use of regression algorithms.

3 Experiment

3.1 Setup

This experiment serves to approximate manufacturing condition monitoring by equipping a coffee machine with sensors. It is assumed that the same process applies to regular industrial applications in smart factories. Figure 1 shows the steps involved in the IoT Condition Monitoring use case of the coffee machine.

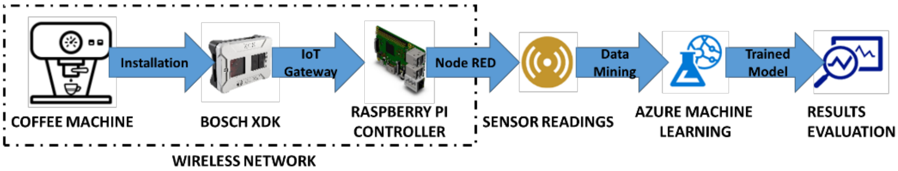

Figure 1. Coffee Machine IoT Use Case

A Bosch XDK device was mounted on the casing atop the bean grinder. Various sensor measurements (x, y and z acceleration, temperature, light, humidity, air pressure and orientation) were taken and sent to a Raspberry Pi via Wi-Fi. To reduce the amount of null measurements (machine idle), a threshold was set and measurements performed for 60 seconds. Using Node-RED, the data are transferred from the Raspberry Pi to a local server as comma-separated value (CSV) files. The CSV files were manually uploaded to **Microsoft Azure Machine Learning Studio** where data analytics and ML took place.

The raw dataset consisted of 49443 instances and 11 unique features (8 sensor measurements and 3 time stamps). The data was split into 70 percent for the training set and 30 percent for the testing. Since the dataset had over 95 percent of samples in abundant class (Idle Condition of Coffee Machine) and less than 5 percent being the rare class (Coffee Intake), it was essential to resample the training and testing datasets. Synthetic Minority Oversampling technique was used to increase the size of the rare class. Another major challenge in data preprocessing is to resolve dataset imbalance. Joining data is another complex process in the initial data preparation due to large number of missing values. Those were cleaned using Replace With Median and Probabilistic PCA (principal component analysis) approaches. Boosted Decision Tree Regression, Two-class Neural Network, Decision Forest and Bayesian Linear Regression models were trained and scored in this experiment using the feature **magnitude of vibration** as scored labels. For model testing, we deployed the model as Excel web service and provided time stamps for a typical intake cycle as input variables.

3.2 Results

With an accuracy of 62.06% (as measured by the coefficient of determination), Boosted Decision Tree Regression outperformed the other algorithms for this particular dataset. The performance of the learning algorithm strongly relies on the nature of the dataset. Other algorithms have also performed well and could be feasible options as they display accuracy slightly above 50%. When using these algorithms in regression models, slight changes in conditions between different datasets lead to wide temporal variations in the weights associated with individual features. So different temporal datasets lead to the vastly different relative importance of features, which makes the analysis of trends difficult.

4 Discussion

Good accuracy for trained models depend on several factors such as the algorithm selection, feature selection, quality, sensibility and size of data. In a classifier, 50% accuracy is considered as random guessing whereas in regression, 50% accuracy can be considered good or bad depending on the data. For the given experiment, the dataset consisted of 2472 useful data points (5%, see section 3.1). A regular coffee intake cycle held around 600 data points (average). Thus, predicting a cycle with 62% accuracy results in 228 inaccurate data points. To detect minor shifts in vibration frequency, the accuracy of 62.06% must therefore be considered non-satisfactory.

An explanation for this deficit can be found upon closer examination of the gathered data. The time stamps reveal that there is an average of 1 and a maximum of 2 measurements per second which seems to be insufficient to properly represent higher-frequency vibrations.

5 Conclusion

In this paper, we described an experiment setup to demonstrate the ease of machine retrofit for Industry 4.0 compatibility. We attempted to predict the last coffee before coffee bean depletion by collecting vibration data from a coffee machine using a Bosch XDK sensor kit and deploying ML algorithms on Microsoft Azure.

The experiment results indicate that while algorithm selection for this experiment can be considered satisfactory, data collected from this sensor are not accurate enough for this application. Using a different type of accelerometer (e.g. piezo resistive) in combination with a microcontroller with sufficiently high sample rate might help in getting better results for this use case. Therefore, as a next step, we will re-attempt the experiment using improved data acquisition. Nonetheless, we believe that this experiment highlighted that there is efficiency potential for manufacturing in retrofitting old machines through the advancement of ML and IIoT.

Abstract. Eine Herausforderung bei der Implementierung des industriellen Internet of Things (IIoT) besteht darin, Mehrwerte in Wertschöpfungsketten zu identifizieren, um darauf aufbauend Lösungen nutzerzentriert zu gestalten. Dieser Beitrag stellt das Forschungsprojekt FreshIndex vor, bei dem diese Herausforderung durch eine Kombination aus Stakeholder-Analyse und User-Centered-Design-Methoden adressiert wurde. Ziel des Projekts ist es, eine IIoT-basierte Lösung zum Monitoring der Kühlkette in der Lebensmittelindustrie zu entwickeln. Hierzu ist es wichtig zu wissen, welche Nutzer/-innen mit den Daten in Berührung kommen und welche Erfahrungen, Fähigkeiten, Anforderungen und Wünsche sie mitbringen. Die Berücksichtigung dieser Aspekte ist relevant für den Erfolg der Konzeption, Implementierung und des Betriebs eines IIoT-Systems. So können nützliche und handhabbare Produktideen generiert und Anwendungen gestaltet werden, die von Mitarbeiter/-innen und Konsument/-innen angenommen werden. IIoT schließt somit die lokale Verwendbarkeit von Daten entlang der Wertschöpfungskette ein und beschränkt sich nicht auf zentrale Verfügbarkeit von Daten.

Keywords: Stakeholder-Analyse, User-Centered Design, IIoT (Industrial Internet of Things), EPCIS (Electronic Product Code Information Services).

1 Einleitung

Bei der Betrachtung des Internet of Things (IoT), insbesondere beim industriellen Internet of Things (IIoT) wird häufig eine ausschließlich technologische Sichtweise verwendet, wie z. B. von Gubbi et al. [1–3]. Dabei sind es die Nutzer/-innen, die ihren Input in das IIoT-System einbringen, mit den Daten arbeiten und von den Ergebnissen profitieren können. Um IIoT-Systeme mitarbeiter- und kundenorientiert zu gestalten, muss der lokale, sozio-technische Kontext erhoben werden [4]. In dieser Studie zeigen wir exemplarisch an einem IIoT-Projekt zur Dokumentation der Kühlkette von Fleisch, wie eine Stakeholder-Analyse durchgeführt und damit nutzerzentrierte Lösungen entwickelt werden können. Das Projekt, in dem die Analyse durchgeführt wurde, adres-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

siert die akute gesellschaftliche Herausforderung der Reduzierung von Lebensmittelabfällen. Jüngsten Studien zufolge werden in der EU jährlich Nahrungsmittel im Wert von 143 Milliarden Euro weggeworfen [5]. Ein wesentlicher Teil der Abfälle entsteht entlang der immer komplexer werdenden Lieferkette durch Nichterfüllung der Qualitäts- und Sicherheitsanforderungen, Verzögerungen im Prozess oder Ablauf des Verfallsdatums ohne Verkauf oder Verbrauch der Ware [6]. Im Jahr 2015 verabschiedete die UN-Generalversammlung Ziele für eine nachhaltige Entwicklung bis 2030, die eine Verpflichtung zur Halbierung der Nahrungsmittelverschwendung pro Kopf beinhalteten [7]. Ziel des Projektes ist die Entwicklung eines dynamischen Haltbarkeitskriteriums für Lebensmittel. Dazu werden die bestehenden EPCIS (Electronic Product Code Information Services) [8] um Informationen zu Lagerbedingungen und Produktqualität entlang der gesamten Wertschöpfungskette erweitert. In der Wertschöpfungskette von Lebensmitteln entstehen eine Vielzahl von Sensordaten. Die Temperaturüberwachung ist die wichtigste Anforderung beim Management einer Kühlkette. Das IIoT bietet neue Möglichkeiten, die Temperatur von Produkten digital zu verfolgen. Durch eine dynamische Anpassung des Haltbarkeitsdatums bei Übererfüllung der Kühlanforderungen, kann die vorzeitige Entsorgung von Lebensmitteln deutlich reduziert werden. Digitale Plattformen verbessern den Datenaustausch zwischen den involvierten Unternehmen und Endverbraucher/-innen und bringen damit zusätzliche Transparenz und Sicherheit. Um IIoT nutzstiftend verwenden zu können, muss jedoch der lokale Kontext der Informationserzeugung, -verarbeitung und -nutzung berücksichtigt werden.

2 Angewendete Methoden zur Analyse der Anforderungen

Im Rahmen der Forschungs- und Entwicklungsarbeit wird aktuell mit den verschiedenen, für den Projekterfolg relevanten Akteuren eine Anforderungsanalyse durchgeführt. Hierzu muss die, zunächst trivial erscheinende Frage geklärt werden, welche Stakeholder bei der Produktion, Distribution und Konsumption von den Daten der Kühlkette beteiligt sind. Da die verschiedenen Stakeholder unterschiedliche Ansprüche an die IIoT-Lösung haben und das Themenfeld noch neu ist, wurden im ersten Schritt qualitative Erhebungen durchgeführt. Dabei erfolgte die Auswahl der Interviewpartner/-innen auf Basis des Schneeballsystems, sowie einer ergänzenden, unternehmensübergreifenden Analyse des Wertschöpfungsprozesses.

2.1 Stakeholder-Analyse

Im Zuge der Stakeholder-Analyse wurde eine detaillierte Stakeholder-Übersicht ausgearbeitet, die einen Überblick darüber gibt, welche Personen potenzielle Nutzer/-innen sein könnten [Abbildung 1]. Der Begriff Stakeholder wurde gewählt, da es zunächst noch herauszufinden gilt, wer zukünftig Nutzer/-in der Frischedaten sein wird. Die Übersicht ist in englischer Sprache, da das Projekt im internationalen Kontext stattfindet. Diejenigen Stakeholder, die im Fokus des Projekts stehen und für dessen Umsetzung erforderlich sind, wurden im innersten Kreis platziert. Weitere Stakeholder, die im Rahmen des Projekts erforscht werden, aber für die Projektziele nicht erforderlich sind, befinden sich im mittleren Kreis. Die Stakeholder, die im Projekt nicht untersucht werden, befinden sich im äußeren Kreis. Dies können Stakeholder sein, die nicht direkt in den Prozess eingebunden sind, aber den Erfolg des Produktes in der Zukunft beeinflussen können. Es ist wichtig sie zu analysieren, aber erst zu einem späteren Zeitpunkt.

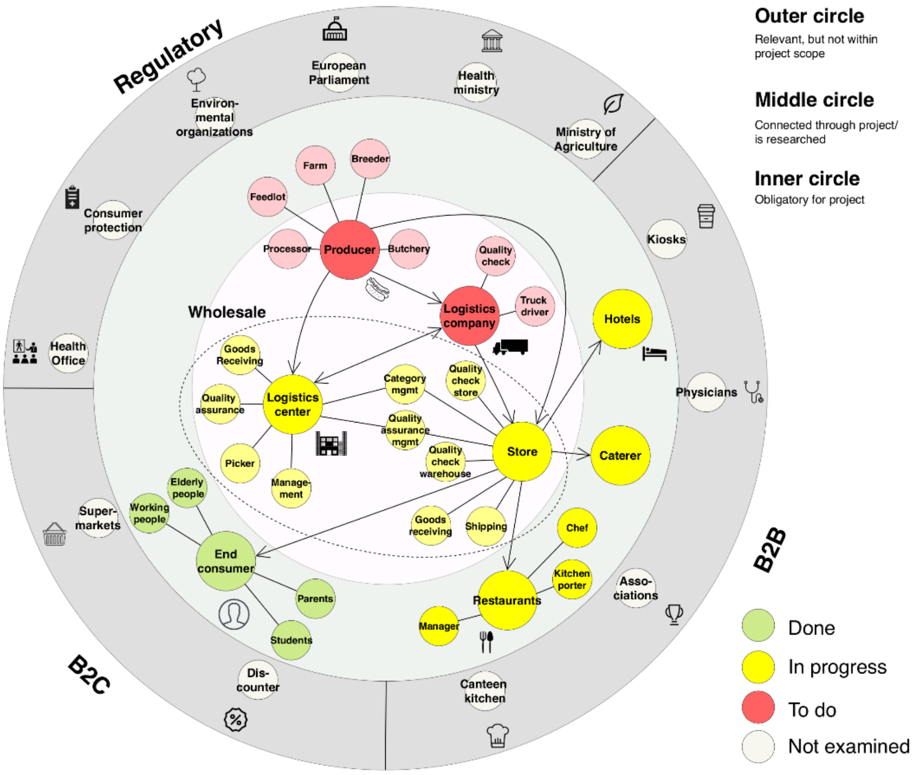

Abbildung 1: Stakeholder-Übersicht

Anschließend wurden die Stakeholder durch Pfeile in der Reihenfolge ihres Auftretens in der Wertschöpfungskette miteinander verbunden. Dies hilft, den Prozess lückenlos zu betrachten, einschließlich aller Schnittstellen und beteiligten Personen. Weitere Stakeholder wurden auch durch Empfehlungen der Interviewteilnehmer identifiziert. Die Stakeholder-Übersicht bietet eine Möglichkeit, mit Projektmitgliedern sowie mit Externen über die Relevanz bestimmter Stakeholder zu diskutieren. Sie hilft, einen Fokus zu setzen, aber auch Interessensgruppen, die nicht im Zentrum des Projekts stehen, in Zukunft nicht zu vergessen. Darüber hinaus ist sie ein lebendiges Instrument, das iterativ weiterwachsen kann und soll. Wenn ein neuer Stakeholder in den Erhebungen identifiziert wird, wird er in der Stakeholder-Übersicht platziert und muss so direkt im Projektkontext bewertet werden. Mit Ampelfarben, die signalisieren welche Bereiche untersucht wurden, hilft sie auch, den Überblick über To-Dos zu behalten.

2.2 Qualitative Forschung

Basierend auf der Stakeholder-Übersicht haben wir die Stakeholder mit Methoden aus dem User-Centered Design, wie Site Visit, Contextual Inquiry und semistrukturierte Interviews untersucht, um den jeweiligen Kontext der IIoT-Infrastruktur qualitativ zu erforschen [9]. Ziel der Forschung war es Personas und Kontextszenarien zu generieren, die Aufschluss über ihre Tätigkeit, Bildung, Erfahrung, IT-Nutzung, Ziele, Prozessintegration und Wünsche an dynamische Frischedaten geben. Dies hilft, die Bedürfnisse der möglichen zukünftigen Nutzer/-innen zu verstehen. Für jeden Stakeholder wurden geeignete Methoden zur Erhebung seiner Anforderungen gewählt. Im Bereich der Endverbraucher/-innen wurden 22 qualitative Interviews entlang semistrukturierter Leitfäden geführt. Endverbraucher/-innen kommen in sehr unterschiedlichem Kontext mit dem Thema Frische in Kontakt. Diese Unterschiede galt es hier zu erheben. Mitarbeiter/-innen hingegen befassen sich in einem ganz bestimmten Kontext mit Frische. Im Rahmen von Beobachtungen mit Fotodokumentation im Großhandel wurden Einblicke in die Arbeitsplatzgestaltung und -prozesse von Mitarbeiter/-innen gewährt, die Aufschluss über die Arbeitskontexte gaben. Anschließend wurden Interviews mit 11 Mitarbeiter/-innen geführt, die in unterschiedlichen Kontexten des Bereichs Frische arbeiten. Im B2B-Kundensegment HoReCa (Hotels, Restaurants und Caterer), der Hauptzielgruppe des Großhandels gab ebenfalls die Kombination von 6 Interviews mit Beobachtungen, erweiterte Einblicke in den Arbeitskontext. Produzenten und Logistikunternehmen ziehen den geringsten Nutzen aus Frischedaten der zurückliegenden Wertschöpfungskette und zeigten sich daher weniger interessiert, an der Forschung für dieses Produkt teilzunehmen. Für weitere Projekte bedeutet dies, dass diejenigen Stakeholder, die nicht so offensichtlich von der IIoT-Lösung profitieren, früh einbezogen werden müssen, da auch sie für den Erfolg relevant und schwieriger zu motivieren sind. Mittels qualitativer Inhaltsanalyse wurden die Erhebungen ausgewertet und Personas generiert. Ein Design-Thinking-Workshop mit weiteren Teilnehmern aus der Wertschöpfungskette findet am 25. September 2018 statt. Die Personas werden dort diskutiert und mit neuen Ideen ergänzt. So können verschiedene Sichtweisen zu den Stakeholdern erhoben und die ersten Ergebnisse verifiziert werden. Darüber hinaus werden dort Lösungsansätze in einem kreativen Umfeld erarbeitet. Im nächsten Schritt werden die Erkenntnisse über die potenziellen Nutzer/-innen zusammengefasst. Die Lösungsansätze werden hinsichtlich ihrer Potenziale und Realisierbarkeit bewertet und für die nutzerorientierte Prototypentwicklung verwendet.

Towards a Framework for Predictive Maintenance Strategies in Mechanical Engineering – A Method-Oriented Literature Analysis

Nina Wiedemann[1], Friedemann Kammler[1], Andreas Varwig[1], and Oliver Thomas[1]

[1] University of Osnabrück, Osnabrück, Germany
{nwiedemann,fkammler,anvarwig,othomas}@uni-osnabrueck.de

Abstract. Industrial machines are amongst Germany's main export products and contribute to the increasing revenue of Mechanical Engineering. However, in the course of globalization, services for such machines have become costly and inflexible due to long distances between vendors and customers. Consequently, companies seek to avoid unexpected failures and long down times by the development of data-based "smart" service solutions, including Predictive Maintenance (PM). In contrast to reactive or preventive measures, PM refers to the proactive planning of required maintenance services based on data sampled from the machinery. Although PM has been conceptualized decades ago and various methods have been proposed ever since, there is no standard strategy. By analyzing existing literature, we shed light on the knowledge base in PM. We provide an overview of methods and discuss their respective context, including preconditions and applications. Our work constitutes a first step towards a framework that guides the implementation of PM-strategies.

Keywords: Predictive Maintenance, Service Strategies, Predictive Analytics, Literature Review, Mechanical Engineering

1 Motivation

Mechanical Engineering is a leading industry in Germany that generates most of its turnover on international markets. However, the traditional product business is under pressure of global competition, that also spreads to other revenue streams such as the spare part business [1]. In response, companies start to transform their business strategies, offering supplementary services or even "servitizing" aspects of the product business [2-3]. A key challenge to the gain in profitability of repair and maintenance activities are costs involved with the unexpected failure of machines in distant countries, e.g. high traveling expenses as well as opportunity costs resulting from long down times. Digital technologies offer improvements to this situation, since they allow for the remote identification of current and upcoming service needs.

One strategy is the analysis of sensor data from installed machines, in order to diagnose degradation and to predict the remaining useful lifetime. Such concepts contribute to the vision of "Predictive Maintenance" (PM), aiming to avoid both

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

unexpected failures of machines, as well as the opportunity losses of only partially worn spare parts [4-5]. In recent years, companies of various fields have started to implement PM systems, but often the proposed strategies are highly individual, focusing on a specific application scenario. The field of PM is thus very diverse, comprising a range of complex methods that is unstructured and difficult to grasp for non-experts. Therefore, we believe that research is required to facilitate the implementation of a PM strategy, in particular to unify and standardize existing approaches. In this contribution, we aim to provide a consolidated methodical overview based on an extensive literature study, in order to build a framework for PM methods in a next step.

2 Design and Results of our Study

We have conducted a structured literature study on articles addressing Predictive Maintenance in respect to the guidelines of Webster & Watson [6]. We firstly focused on articles in reputable information systems (IS) journals according to the A, B and C categories of the VHB-Jourqual3-ranking. However, PM articles are often highly methodical and are therefore also published in other domains. Thus, we complemented a general query via the paper hosts Google Scholar, Sciencedirect and Scopus, narrowing the extensive results to the 200 most relevant articles. During both reviews, we used the search term "Predictive Maintenance". By the analysis of title, abstract and keywords, we retrieved and categorized 87 relevant articles that describe concepts, methods or applications of predictive maintenance strategies.

Our literature study yields information on research trends in the field of PM. When the topic emerged around 1960, articles were highly conceptual, but over the years this focus increasingly shifted towards methodical and applicational papers. In particular, this became evident in the analysis of utilized data, where 16 of the 21 papers published before 1998 (76%) did not rely their contributions on any data. Apparently, PM research experienced a paradigm shift then, with only 8% articles after 1998 testing their strategies on neither real nor simulated data. In the last ten years, more than half of the publications deal with real data and thus with actual use cases, indicating that now PM has advanced from a conceptual challenge to a feasible business strategy. We believe that this development has been strongly encouraged by the advancement of methods. Fig. 1 presents the result of our methodological classification of the literature, which is an overview of identified method groups, their subclasses and specific methods. For a long time, only functional approaches that model the degradation process of a unit over time have been employed. From 1990 on, the methodical spectrum enlarged. As in other fields, we identified the increasing popularity of Machine Learning and Data Science for PM purposes. The interest in such methods can be linked to parallel advances in hardware that enabled the efficient use of methods such as Artificial Neural Networks (ANNs). By now, research employing reliability functions accounts for 32% of our literature base, whereas ANNs have reached 23%, followed by modern Time Series Analysis (15%).

Further, the analysis provides first insights on the context of application, benefits and drawbacks of each method. Firstly, the articles describe utilizable methods for

Figure 1. Overview of methods employed in Predictive Maintenance articles

particular tasks: For example, classification methods such as ANNs or Decision Trees are well suited for a simple status classification or failure recognition [7-8], [9]. If the residual life or future malfunctions should be predicted, a method that incorporates temporal information is required (e.g. Regression Analysis [10], Markov Models [11], [12] or Kalman Filtering [13-14]). Secondly, the method is highly dependent on the properties of the data. The analysis of event logs for instance can be conducted by text mining methods as in [15-17]. Similarly, image processing can now be performed efficiently by Convolutional Neural Networks (CNNs). [18] and [19] apply CNNs on thermographic images for failure recognition. But not only does the general data format influence the choice of method, other features such as scale or the proportion of outliers must be considered. Filtering methods might be necessary to smooth the data before further processing. For example, Yiwei et al. include Kalman filtering in their framework to track an aircraft's health state [20]. Another selection criterion can be the transparency of the inner mechanism of a method. For example, imagine that sensors are installed throughout a machine, and its failure is being predicted based on the data received. In order to execute maintenance tasks quickly, it would be helpful to isolate particular sensors that identify root causes of the problem. Consequently, methods providing high transparency during the information retrieval (e.g. Decision Trees) might be preferred in such scenarios, in contrast to ANNs which are often referred to as black boxes. Because of this, but also considering the problem of overfitting in complex function approximations such as ANNs, it is important to be aware of multiple methods and carefully compare "trending" with simple approaches.

3 Discussion

Our study exemplifies insights on methodology from the literature review, with more decision criteria yet to be analyzed, such as the industry or the relevance of runtime performance. Considering the plurality of influences and the diversity of use cases, it can already be concluded that this large variety of methods is inevitable. Nevertheless, it is crucial to shed light on the smorgasbord of methods. Our literature study does not cover all research extensively, but provides a structured overview of a multitude of methods and exemplary studies. We regard this as a suitable starting point to a framework for future PM implementations. However, the methodological point of view is not sufficient, but must be embedded in a holistic service and business model. The application scenario, including production, the exact execution of maintenance work and involved costs must be considered as well. PM necessitates high flexibility and cooperation between service providers and customers. Thus, we see further research need in the implementation of use cases and required information systems as well as the elaboration of new business strategies.

The ongoing research aims at the extensive classification of methods. We strive for the development of an information hub that allows for the requirements-based recommendation and choice of methods. This way, we hope the structured report on existing concepts and methods constitutes a first step to lower existing barriers for investing in PM, and enables more companies to seize the opportunity of innovative data-driven service strategies.

Abstract. This paper addresses the challenge of a systematic requirement-oriented configuration and selection of cyber physical systems (CPS) for SMEs. As the key technologies of realizing the digitalization and interconnection of production processes, manufacturing companies have realized the potential benefits brought by CPS. However, due to the complexity and fast development of CPS technology, it is difficult for SMEs, which lack expertise and financial resources, to select the appropriate CPS technologies meeting both functional and financial requirements. To overcome the issue, an online matching platform is developed to let SMEs express their needs and assist them conceptualize the individual CPS. This paper presents the matching methodology of the matching platform, which can not only match technical characteristics but also evaluate economic potentials. Then, it was demonstrated by a tracking and tracing use case in the end-of-line assembly of a small-sized German electric automobile manufacturer.

Keywords: cyber physical systems, matching, evaluation, SMEs

1 Introduction

Faced with the growing digitalization trend, manufacturing companies have realized the potential benefits of adopting cyber-physical systems (CPS) in their production processes. The function of CPS is characterized by the connection of physical and computational entities usually with feedback loops, which enables higher efficiency and flexibility in production monitoring and control [1-5]. However, due to lack of overview of all available CPS technology in the market and technical expertise, it lasts especially for SMEs a long time until CPS are conceptualized and implemented. In this

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

paper, a matching platform aimed at SMEs is developed and demonstrated, which supports the requirement-oriented selection of CPS.

2 State of the Art

In the literature, there are no specific methods but several general methods, which can be adopted to conceptualize CPS such as the guideline to design and construct technical systems and products (VDI 2221) [6]. However, it focuses a new development of technical systems, while implementation of CPS is usually a retrofit of existing infrastructure and a selection of available solutions. Thus, frame conditions and matching methodology need to be supplemented. Value benefit analysis and technical-economic evaluation method according to VDI 2225 [7–10] can contribute to functional or economic evaluation of CPS technologies. However, they fail in considering the two aspects in one framework. Therefore, a combined methodology to match technical features and evaluate economic potentials of CPS needs to be developed.

3 Development of CPS Matching Methodology

In this chapter, the developed CPS matching methodology including functional matching logic and economic evaluation model is presented. The methodology is then implemented in an online CPS matching platform: goo.gl/UmV7n8. The CPS matching platform will be introduced in more details through the case study in Chapter 4.

3.1 Functional Matching Logic

The approach to match user requirements and CPS technology functions is developed according to the VDI guideline 2221 [6] (see Figure 1). CPS technologies are broken down into six categories (actuators, sensors, transmission technologies, IT-Infrastructure, data processing, and HMI) to structure the components of CPS [11]. The functional fulfilment of available CPS technologies is assessed by a structural evaluation scheme containing all requirement specifications with a grading from 0 to 4 (see Figure 1) [12]. It enables user requirements and CPS technologies to be evaluated in a uniform scale, so that the matching of a CPS technology (or technology combinations) and requirements can be easily identified.

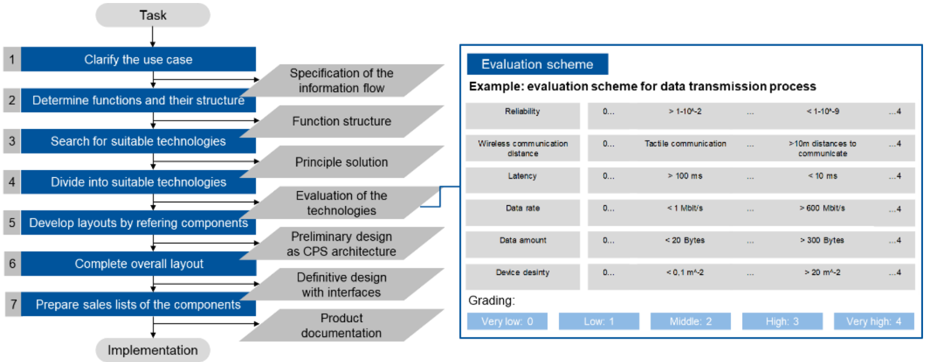

Figure 1. The overview of matching process and evaluation scheme for CPS functional fitting

3.2 Economic Evaluation Model

After a functional fitting, the matching platform can further assist user companies with economic evaluation of CPS solutions. A model of Return on CPS (RoCPS) is developed specifically to quantify the potential profits by CPS applications, which is defined in Formula (1) with reference to the method of Return on Investment [13].

$$\mathrm{RoCPS} = \sum_{i=0}^{n} \frac{p_i}{(1+r_i)^i} \Big/ \sum_{i=0}^{n} \frac{c_i}{(1+r_i)^i} \tag{1}$$

p_i is the total profit in period i, c_i is the total cost in period i, r_i is the discount rate in the period i, n is number of periods. The value of RoCPS indicates how much return can be gained after adopting CPS compared with its implementation costs. In the matching platform, a universal template sheet for cost and profit estimation is provided, in which all cost drivers and benefit types are identified and monetization rules are given, thus facilitating non-experts to make assessment (see more in [14] about our research work).

4 Application of the CPS Matching Platform

The developed matching platform was applied to conceptualize a CPS solution at a small-sized German EV manufacturer. The SME wishes to track the order status during the end-of-line assembly by a wireless identification and localization of the initial chassis place and the final mounting place, in order to bring more transparency in intralogistics.

Firstly, the production manager of the SME chose the use case type on the matching platform. Following information processes of the use case were suggested by the platform: identification, localization, raw data transmission, raw data processing, information transmission and data storage. Among them the identification, localization and data transmission are the mayor challenging selection task to construct the CPS.

Secondly, the matching platform asked the production manager to fill out a requirement catalog for each information process. The requirement specifications in the catalog are derived from the evaluation scheme introduced in 3.1. For this tracking and tracing

case, the resolution of the localization within less than one meter, the data rate larger than 1 Mbit/s and a scalable IT-infrastructure are some most decisive requirements. Thirdly, the matching platform automatically filtered the suitable solutions, because all CPS technology specifications stored in the platform have been assessed in advance with the identic evaluation scheme as the requirement specifications (see Figure 2). In analogy to the morphological box [11], the platform can also generate CPS technology combinations, which fulfills the requirements of all information processes. Now the production manager can either take the optimal combination suggested by the platform or combine the technologies by himself and compare the functional fulfillment based on the grading.
Finally, the RoCPS was calculated with the given calculation sheet and the profitability of CPS concepts was evaluated. Figure 2 shows that the first CPS concept suitable for the use case consists of RTLS and LTE; the second concept suggests 5G as the transmission technology. Since the use of mobile communication systems in production requires a base station and customized networks, which is an expensive option, the SME decided to choose Bluetooth connections via Beacons by self-combination.

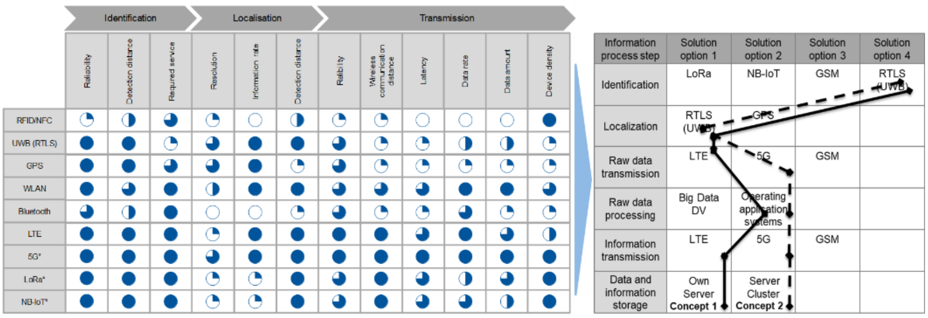

Figure 2. Two CPS concepts suggested by the matching platform for the use case

5 Summary and Outlook

This paper developed a matching platform for SMEs to select appropriate CPS solutions from both functional and economical perspectives. It was demonstrated by a small-sized German EV manufacturer, supporting them in CPS selection for tracking and tracing during the end-of-line assembly. The matching platform bridges the gap between inexperienced users and CPS suppliers, which can promote the digitalization transformation of SMEs. In future, it is expected to be optimized by more uses of public.

Abstract. Shared mobility services for passenger transportation become increasingly popular all over the world. As services like carsharing are already well-established and well-accepted, ridepooling services are at their early stage and currently within first implementations. The most critical success factor of such services is the customer acceptance. We investigate the acceptance of 115 German questionnaire respondents using and extending the Technology Acceptance Model. Results indicate that the success factors of the developed model serve as useful predictors of the behavioral intention to use ridepooling services. Perceived compatibility was identified to have the strongest impact whereas perceived ease of use and perceived safety are not relevant for accepting ridepooling services. Based on these findings, our paper provides management implications and recommendations to improve acceptance and success of ridepooling services in Germany.

Keywords: Ridepooling, Passenger Transportation, Urban Mobility, Technology Acceptance Model, Structural Equation Modeling.

1 Introduction and Motivation

Urban areas are confronted with a multitude of challenges as high emissions, poor air quality, fossil fuel dependency, traffic volume, and congestion [1]. With increasing consciousness for sustainability and environmental responsibility, the need for innovative solutions tackling these problems is emerging. As a consequence, the sharing economy has been arisen from the idea that sharing a good or a service is often more advantageous than owning it as resource inefficiencies are reduced. Regarding passenger transportation, rideservices depict a possibility for individuals to share a car or a trip in different modes. Supported by technological developments and the digitalization of processes, companies are able to offer reliable modes of dynamic on-demand rideservices; concurrently, customers can participate easily through the use of immediate communication with connected mobile devices [1-3]. In this way, the

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

information system (IS) domain can be characterized as enabler for digital economies and corresponding digital services as well as business models [4].

The most recent development of digitally supported rideservices is ridepooling (also referred to as shared ridehailing). Using big (geo) data analytics approaches together with intelligent algorithms, passengers are aggregated to groups and allocated to the best option of available vehicles in real-time and on-demand. Thereby, multiple passengers share a ride in the same vehicle to increase transport efficiency. Recent studies from New York City demonstrate ridepooling's efficiency, as it was shown that the traffic volume can be significantly reduced when using high-capacity ridepooling instead of individual taxi services [2, 5]. Due to this positive impact, ridepooling becomes of increasingly interest to cities worldwide. In Germany, potential ridepooling providers are planning to offer this service in order to take advantage of the untapped potential. Except of overcoming the legal barriers, the acceptance of ridepooling services is a critical factor for being successful in the long term. It represents the first step in the adaption process and results in actual usage. Especially in the early stages of innovation development, its investigation is of high relevance because a modification of the service is still possible based on changed customers' needs and requirements [6].

In the literature, the acceptance of innovations has been already investigated by different models regarding various contexts [7]. With the help of hypothesis-testing studies, pertinent factors for these acceptance models have been identified. The most used and established model is the Technology Acceptance Model (TAM) [8]. With regard to the ridepooling context neither a model nor success factors have been studied yet. To address this research gap, we investigate the customer acceptance using TAM as basic theory and extending it in order to fit the research field of ridepooling services. The following research question guides our examination:

RQ: Which constructs influence the customer acceptance of ridepooling?

To answer this question, the article is structured as follows: first, the background is explained containing urban mobility, TAM, and related literature. The methodology covering the hypothesis development, the study description, and the results build the third section. In the fourth section, obtained results are discussed and the contributions of our approach are highlighted. Recommendations, limitations, and further research are elaborated in the fifth section. At last, we complete our article with conclusions.

2 Research Background

2.1 Urban Mobility, New Mobility Services, and Ridepooling

As an outcome of numerous individuals' decisions, urban mobility describes passenger movements within the city environment. Regarding the travel behavior, passengers decide upon vehicle ownership, individual or collective transportation, and mode of transport (e.g., car, bike, feet, tram, etc.). In contrast to private vehicle ownership, people are able to choose Mobility-as-a-Service (MaaS) (e.g., bus, taxi, carsharing, bikesharing, mass transit, etc.) to carry out daily activities. The individuals' decisions are affected by several key factors which are dynamic and interacting [9]:

- *demographic trends* – population (e.g., age, growth, density), licensed drivers;
- *transportation options* – private vehicles, carsharing, mass transit, taxi;
- *infrastructure* – road network, traffic management systems;
- *user preferences* – social mobility preferences, residence;
- *transportation costs* – fuel, transit, parking, ownership costs; and
- *macroeconomic facts* – economic growth, global warming, employment, pollution.

Besides these factors, technological developments influence the way people move, as they address economic, ecological, and societal problems within people's environment [10]. This results in new mobility concepts, respectively new mobility services (NMS) as subcategory of MaaS. Emerging technologies – such as digitalization, high-speed computing, location data, accurate sensors, wireless connectivity, social media expansion, and new usage-based pricing schemes – serve as enabler for NMS [9]. Thereby, NMS represent potential solutions to allow for a more convenient, efficient, and flexible transportation for different individual purposes of travelling. NMS contribute to a mobility evolution because they incrementally change the travel behavior towards a multimodal and less car-centric system, particularly in urban areas. They dissolve the boundaries of what is owned and shared [9]. Present trends take a stronger shift towards sharing with a special focus on sustainability [11]. As the use of shared transportation modes partially substitutes private car ownership, the number of cars on and off the road can be reduced. Consequently, traffic density, travel costs and time, fuel consumption per person, and air pollution are reduced [12, 13]. One reason for choosing NMS instead of owning a car is the problem of missing parking space in urban areas. Compared to public transportation, NMS have the advantage of high flexibility, especially regarding point-to-point service. In addition, short waiting times and easy payment methods are further benefits [14]. The following list gives an overview of the latest NMS including a brief explanation [15]:

- *Carsharing*: Users pay money based on the used time or distance for renting a car (variants: business-to-consumer or consumer-to-consumer; station-based or free-floating).
- *Carpooling* or *Ridesharing*: A vehicle is used by individuals who take a ride at the same time in the same car from and to similar destinations. The matching is done by an intermediary company or by an informal system of the users.
- *Ridehailing*: Determining the trip's start and end point, a passenger demands a transport service offered by companies or individuals.
- *Ridepooling* or *Shared Ridehaling*: Users hail a shuttle to designated pick-up points near their location. Passengers with similar routes are matched and transported together in one vehicle.

The most recent development regarding NMS is the shared travelling respectively pooling of users with overlapping routes. Thus, customers share the costs of the trip resulting in prices between taxi and mass transit charges. Exemplary services are *uberPOOL*, *Lyft Line*, and *MOIA*. The concept of ridepooling comprises that users hail shuttles via an app and get on the shuttle at designated pick-up points near their location. An algorithm optimizes each vehicle's route in terms of travel time and capacity to enable shared trips with overlapping routes. As a result, the number of cars and thereby road traffic's negative impacts can be reduced significantly. Dealing with the urban mobility in an American context, a study by Alonso-Mora et al. [2] predicts that 99% of the taxi demand in New York City could be served by 25% of the utilized vehicles if using high capacity ridepooling. Due to the economic, environmental, and societal advantages, ridepooling offers a high potential to different target groups. Besides competition and political issues, an important barrier to overcome appears to be the acceptance and the conclusive usage by the population.

2.2 Technology Acceptance Model

Consumer acceptance can be defined as the "relatively enduring cognitive and affective perceptual orientation of an individual" [8]. Thereby, the acceptance process of individuals depends on the tradeoff between benefit and effort of using an innovation or technology [16]. Investigating these psychology processes causing special human behavior is complex and difficult [17]. For solving this problem, lots of social-psychological models have been developed in the last decades to explain and predict technology acceptance as well as usage of individuals [18].

In scientific literature, the most popular cited model for that is TAM [8]. TAM is an adaption of the Theory of Reasoned Action (TRA) which was originally developed by Fishbein and Ajzen [19] to predict human behavior [20]. Davis [21] and Davis et al. [22] adopted TRA to the acceptance research in IS contexts and used it as a basic theory to explain the relationship between the individual's reaction of using a technology, the intention, and the actual usage of it [23]. For that it utilizes behavioral intention to use (BI) to predict actual behavior and focuses on the identification of relevant factors for adopting an innovation or technology [24]. TAM can also be transformed into a measurement of customer acceptance in other varieties of settings and technologies like internet banking, mobile service, online tax service, or teacher's technology usage which has been investigated by several researchers (e.g., [6], [20], [25]). Both models, TRA and TAM, are based on individual beliefs which determine and affect its attitude towards a technology in a given situation [26]. Beliefs are defined as "the person's subjective probability that performing the target behavior will result in salient consequence" [21]. These beliefs are the internal psychological variables, for instance, the individuals' characteristics in the models. They function as mediators of all external variables like individuals' characteristics which also may affect the usage of an innovation [27]. Therefore, they have an indirect effect on the BI [21]. In TAM, these beliefs consist of the two factors perceived usefulness (PU) and perceived ease of use (PEOU) which have a relationship to each other. At TRA, attitude towards use (ATU) and subjective norm (SN) represent the beliefs [28]. In addition, TAM represents the motivational variables which lead to the actual system usage. They reflect a tendency which is built directly at the beginning of being in contact with the innovation. This enables researchers to test the innovation in an early stage [21]. Because of the mentioned descriptions, we make use of TAM in combination with constructs of the TRA in order to measure the acceptance factors of ridepooling.

2.3 Related Research

Chowdhury and Ceder [29] provide a literature overview of public transport studies analyzing willingness to ride as well as the related acceptance. Investigations on the acceptance of NMS are not contained within the review. However, there are some studies that deal with the different carsharing variants and their acceptance. Ohta et al. [30] present an article that examines the acceptance of carsharing in Japan. As result, the attitude to conduct carsharing for car-owners was low and the BI was quite high for non-owners. People living in urban areas had a greater acceptance for carsharing than rural inhabitants. Dütschke and Peters [31] conduct an empirical analysis on sustainable modes of transport like carsharing and electric vehicles. As a result, perceived compatibility (PC) was the most influencing factor towards ATU carsharing across all sociodemographic groups. Fleury et al. [32] examine the acceptance of corporate carsharing in France based on the Unified Theory of Acceptance and Use of Technology (UTAUT) framework. The most important dimension in determining behavioral intentions about corporate carsharing was effort expectancy. Besides, the added perceived environmental friendliness had only a small effect on behavioral intentions, mediated by performance expectancy. Another quantitative study by Efthymiou et al. [33] investigate the factors affecting the adoption of carsharing systems by young drivers. Further, Cheng et al. [34] examine the motivation of users to participate on a carsharing platform.

Regarding ridesharing, Giang et al. [26] investigate the customers' BI such services. The authors ascertained the positive effect of ATU ridesharing applications on BI them based on a Vietnamese study. Results demonstrate that PU and PEOU had positive influence on attitude toward ridesharing behaviors. The constructs ATU, SN, and perceived behavior control further played critical roles in predicting the BI ridesharing applications. Another article by Wang et al. [35] investigate the customers' BI such services extending TAM on the new constructs personal innovativeness, environmental awareness, and perceived risk (PR). Results demonstrate that these constructs were positively associated with customers' BI ridesharing services. On the other hand, PR was negatively associated with the BI as well as PU. Further, personal innovativeness was negatively related to PR. Other quantitative analyses are for instance Delhomme and Gheorghiu [36], who conduct a French study of users and non-users, or Wright et al. [37], who focus on the acceptance of a ridesharing-platform.

Concerning acceptance analyses on ridehailing or ridepooling, literature lacks using common applications of theories like TAM, TRA, or others. To the best of our knowledge, no article focuses on the acceptance of these services itself. There exist only short surveys revealing that around 79% of the ridehailing-users would use ridepooling, depending on factors like costs and number of passengers extracted from a Brazilian study [38]. Clewlow and Mishra [15] investigate the adoption and use of ridehailing services in San Francisco. Studies on the acceptance of apps or platforms for ridehailing services are more frequent, as for instance, Tan et al. [39] or Ruangkanjanases and Chayanee [40]. For ridepooling service apps or platforms, no scientific studies are existent. Thus, ridepooling is a quite new concept which currently starts being implemented and has not been addressed in acceptance studies so far.

3 Methodology

3.1 Hypothesis Development

One of the goals of TAM is the quantification of the influence of behavioral intentions on actual systems usage. Measuring the actual system usage is in most contexts difficult, especially if the acceptance of a system is investigated which is still at its early stage of implementation, such as ridepooling [41]. The actual system usage is influenced by the BI a technology. It measures the strength "of one's willingness to exert effort while performing certain behaviors" [41]. By a high degree of accuracy, the actual system usage can be very well approximated by behavioral intentions which a lot of studies already found out in different contexts [17]. According to the TRA, behavioral intention is the direct factor of the appropriate behavior [25]. Furthermore, it is more suitable "for a survey-based research", because beliefs can be measured at the same time [27]. Based on this relationship, we choose the BI ridepooling as the dependent variable in our approach. BI is directly influenced by ATU. It describes "the degree to which using a technology is positively or negatively valued by an individual" [42]. According to the NMS context, Giang et al. [26] explore the positive effect of ATU ridesharing applications on BI. In view of these findings regarding ridepooling services it can be hypothesized:

H1: ATU has a significant positive effect on the BI ridepooling services.

ATU does not only represent the main antecedent of BI but also functions as the key mediator between it and the other influencing factors [43]. According to the TRA, attitude will be developed by individual beliefs. These beliefs arise through learning processes and consequently affect attitudes [27]. Therefore, a better understanding of ridepooling may lead to a superior ATU ridepooling and consequently to a higher acceptance. These beliefs are represented by the constructs of PU and PEOU. Therefore, the following hypotheses can be derived:

H2: PU has a significant positive effect on ATU ridepooling services.

H3: PU has a significant positive effect on BI ridepooling services.

According to TAM, PEOU is another driver of ATU and represents also a crucial belief [7]. This term addresses the complexity degree of an innovation "to which (…) [it] is perceived as relatively difficult to understand and use" [16]. In a ridepooling context, the mobile application to order the service should work without errors, its functions should be instinctively understandable, and the user should be able to choose between different payment methods. Besides, the amount of effort must be in a proportionate relation to the usage. Therefore, the following hypothesis can be developed:

H4: PEOU has a significant positive effect on ATU ridepooling services.

Apart from the direct effect of PEOU on ATU, Davis [16] found the indirect effect via PU. The easier the innovation is perceived to be, the higher seems its usefulness in the case that more effort can be put into other activities. Therefore, the advantage of PU on ATU would be weakened by the uneasiness to use [16]. For this reason, the following hypothesis can be derived:

H5: PEOU has a significant positive effect on PU of ridepooling services.

According to the diffusion theory of Rogers [44] several factors are responsible for the adaptation of innovations. Being quite similar to the belief concept of TAM, it proposes PC as one of the core factors for customer acceptance of new technologies [45]. It can be defined as “the degree to which an innovation is perceived as being consistent with the existing values, needs and past experiences of the potential adopters” [41]. In the literature, lots of studies discovered the high importance of compatibility for measuring and explaining technology acceptance behavior. For example, Schierz et al. [8] already found the positive effect of PC on ATU, PU, and BI a technology. Based on these studies the following hypotheses can be developed:

H6: PC has a significant positive effect on the PU of ridepooling services.

H7: PC has a significant positive effect on the ATU ridepooling services.

H8: PC has a significant positive effect on the BI ridepooling services.

Apart from reaching benefits of using new technologies (e.g., PU and PEOU), it is still hard to evaluate the unknown [8]. As new technologies are uncertain in their outcomes, they seem to be riskier for customers [46]. Especially when it comes to transportation modes, feelings of safety are associated with PR that is why the selection of transportation modes is dependent on perceived safety (PS). That is why PS is a relevant issue in the car context regarding the acceptance which Osswald et al. [6] confirmed in their study. They defined this construct “as the degree to which an individual believes that using a system will affect his or her well-being” [6]. It addresses the capability of an individual to estimate the situation as being dangerous or safe. Regarding to the context of ridepooling services, the element of safety exemplarily includes the estimation of the driver’s ability and trustworthiness [6]. Another safety problem might be the traveling with unfamiliar passengers [29]. Therefore, we construct the following hypothesis:

H9: PS has a significant positive effect on the ATU ridepooling services.

Especially at the beginning of a diffusion or development of an innovation, the social context plays a major role within the adaptation process. The influence of the social context is represented by the factor SN which can be “defined person’s perception that most people who are important to him think he should or should not perform the behavior in question” [19]. Already Davis et al. [22] suggested to further research the relationship between TAM and the effect of social influences on usage behavior. That is why the following hypothesis can be set:

H10: SN has a significant positive effect on the BI ridepooling services.

3.2 Description of Our Study

Primary data was collected through an online-survey. We shared our questionnaire to German participants only. Therefore, the complete questionnaire was translated into German before. To generate high response rates in different areas, the survey was spread over social media, forums, and via e-mail using our existing network on transportation research. We conducted our examination in the first half of March 2018.

Our questionnaire begins with a short definition of ridepooling services to ensure similar knowledge of the respondents. The measurement items base on different applications and were modified to suit the research context of ridepooling services. We adapted the items for the construct ATU from Cheng et al. [34] and Delhomme and Gheorghui [36]. Items for PU and PEOU were adapted from Davis [16]. SN was adapted from Madigan et al. [18]. Items for the constructs PC and BI were taken and adapted from Schierz et al. [8]. As described, we added the construct PS to our model, adapting the items from the study of Osswald et al. [6]. For instance, we asked questions about concerns with unfamiliar passengers or trust into the driver of a ridepooling vehicle. For measuring the items, a seven-point Likert scale was used, ranging from 1 ("strongly disagree") to 7 ("strongly agree"). The underlying codebook is presented in Table 1.

Regarding demographics, 115 respondents took part in the survey, whereas 48 (42%) were female and 66 (57%) were male. Regarding the age, 94 participants responded to the group of 20-29 years old, representing 70% of our total data set, 15 people (13%) were between 30-39 years. In terms of their profession, 48 were students (42%) and 48 employees (42%). We asked some general questions about the usage of ridepooling services in the past and relevant factors for the future. The additional questions could be answered on a multiple selection with an open text field. 77 (67%) of the participants have already heard of ridepooling services. 91 out of 115 people surveyed (79%) did not used ridepooling services in the past. We asked also about the (possible) purposes to use a ridepooling services. Most frequently, participants would use ridepooling to drive to a train station or airport (mentioned 74 times) and to drive to a nightclub in their leisure time (mentioned 70 times).

Table 1. Presentation of underlying Codebook

Constructs	*Items*	*Constructs*	*Items*
ATU 1	More comfortable mode of transportation	PC 1	Usage depends on transportation possibilities
ATU 2	Independence of movement	PC 2	Usage fits lifestyle
ATU 3	Pleasant service	PC 3	Preferring of ridepooling services
ATU 4	Advantageousness of usage	PEOU 1	Easy execution of the steps to usage
ATU 5	Good idea to use	PEOU 2	Precise and comprehensible interaction
BI 1	Usage in contrast to other transportation modes	PEOU 3	Easy usage
BI 2	Probability of usage in the future	PEOU 4	Learning would be easy
BI 3	Willingness of usage in the future	PS 1	Dangerous usage
BI 4	Intention of usage in the future	PS 2	Ride with unfamiliar passengers
SN 1	Importance by family and friends	PS 3	Trust in the driver
SN 2	Good idea by family and fiends	PU 1	Useful mode of transportation
SN 3	Recommendation by family and friends	PU 2	Simplification of the transport
		PU 3	Fast transport possible
SN 4	Usage by family and friends	PU 4	Improvement of the transportation selection
Notes:	ATU: Attitude towards Use; BI: Behavioral Intention to Use; SN: Subjective Norm; PC: Perceived Compatibility; PEOU: Perceived Ease of Use; PS: Perceived Safety; PU: Perceived Usefulness		

3.3 Results

We performed Structural Equation Modeling with the help of the software package *SmartPLS* (version 3.2.7). For validating the reflective measurement models the indicator reliability must be given. This is proven by a factor analysis which tests if more than 50% of the variance of an indicator can be traced back to the associated latent variable. The indicator can remain in the dataset if the factor loadings are above 0.5 [47]. The factor analysis show factor loadings above the critical value for all indicators except of two. In consequence, we dropped SN 4 and PC 2 for our investigations. Our scale reliability tests found Cronbach´s alpha values greater or equal 0.7. Therefore, we found an acceptable internal consistency [48]. Table 2 shows the mean values, the standard deviations (Std. Dev.), and the discriminant validity analysis of our model. We compared the roots square of average variance extracted (AVE) values and the correlations between the constructs [49]. The diagonal elements in bold face in Table 2 represent the square root of AVE values. All of them are larger than the correlations among constructs. In result, convergent and discriminant validity are verified [50].

Table 2. Mean Values, Std. Dev., and Discriminant Validity of the Structural Equation Model

Construct	Mean	Std. Dev.	ATU	BI	PC	PEOU	PS	PU	SN
ATU	4.73	1.40	**.899**						
BI	4.41	1.69	.800	**.894**					
PC	3.93	1.63	.747	.814	**.905**				
PEOU	5.58	1.27	.453	.477	.518	**.904**			
PS	5.57	1.16	.428	.479	.411	.394	**.872**		
PU	4.27	1.45	.841	.783	.792	.475	.401	**.862**	
SN	4.70	1.37	.697	.664	.566	.441	.403	.662	**.951**

In support of H1, there is a positive significant, but moderate influence of ATU ridepooling services on BI them (β=0.29; p<0.001). Moreover, the path coefficient of β=0.65, (p<0.001), points to a strong positive relationship between PU of ridepooling services and the ATU them. Thus, H2 can be affirmed. Regarding H3, even though the structural link from PU to BI ridepooling services is still positive (β=0.09; $p\geq$0.1), no significant relationship can be proved. In addition, the results do not provide significant evidence for the effects of PEOU of ridepooling services on ATU them (β= 0.01; $p\geq$0.1) and on PU (β=0.09; $p\geq$0.1). As result, H4 and H5 are not supported. The strongest significant influence is found at PC of ridepooling services on PU of them with a beta of 0.75 and a p-value<0.001, as hypothesized and supported in H6. Furthermore, a positive influence reveals PC on ATU ridepooling services (β=0.19; p<0.01) so that H7 can also be supported. As hypothesized in H8, with a path coefficient of β=0.44, PC has a positive impact on BI ridepooling services (p<0.001) and is therefore supported. The hypothesized significant effect of ridepooling services' PS on the ATU them was found to be nonsignificant (β=0.08; $p\geq$0.1), thus H9 is rejected. The hypothesized assumption of the influence of SN on BI ridepooling services (H10) can be confirmed to be significant (β=0.16; p<0.1). Due to these results, H1, H2, H6, H7, H8, and H10 can be accepted, whereas H3, H4, H5, and H9 need to be rejected.

Apart from investigating the path coefficients, the quality of the endogenous variables must be checked as well. The construct of PU of ridepooling services is explained by its exogenous variables of adjusted $R^2= 0.63$. ATU ridepooling services as well as BI them are quite similar: the former shows an explanatory power of adjusted $R^2=0.72$; the second of adjusted $R^2=0.75$. With regard to the definition, these results are satisfactory. Figure 1 summarizes the results of our path analysis presented before.

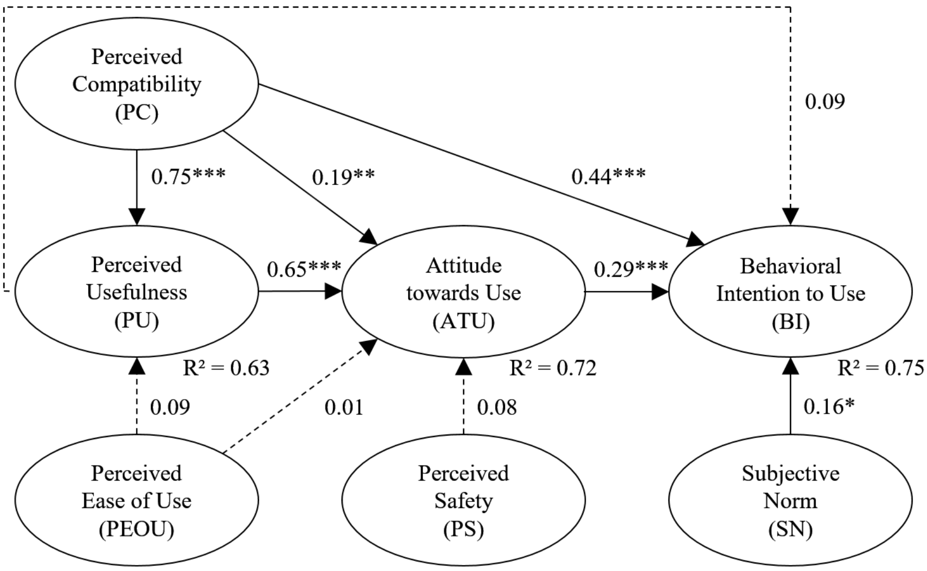

Figure 1. Results of the Path Analysis
*Notes:*p<0.1; **p<0.01; ***p<0.001; n=115; Dotted lines represent insignificant paths*

4 Discussion and Contributions

The insignificant direct influence of PU on BI (H3) is quite unexpected as this relationship has been confirmed in the literature many times in other contexts. For instance, Wang et al. [35] who analyzes the customers' BI ridesharing found a significant positive relationship between PU on BI. Regarding the ridesharing context, the service is seen as useful and has therefore, in contrast to ridepooling, an influence on BI. PU represents a fundamental driver of BI and counts therefore to the key constructs of the TAM [51]. However, a possible reason could be that the majority of respondents have not yet used ridepooling services. Under certain circumstances, it may be not the usefulness but the experience and its accompanying pleasure that is a reason for participating in such a concept. The journey in a modern and appealing vehicle with a slight cost disadvantage compared to conventional mass transport could be an explanation for this. According to these results, the direct relationship cannot be transferred to the ridepooling context with the empirical data of our study. Consequently, the mentioned direct effect of beliefs on BI ridepooling services cannot be affirmed. In addition, Lee et al. [41] found ten non-significant and even 17 not applicable relationships of in total 101 investigated studies in their literature review. This refers to the fact that there are also other studies with the same inexplicable results.

In contrary to that, the role of PEOU in the TAM is already critically discussed in the literature. Many researchers question this construct as a fixed component in the TAM due to the existence of many controversy studies regarding the unstable measurement of PEOU. Therefore, rejecting H4 and H5 is not quite unexpected. PEOU of ridepooling has no significant influence on PU and ATU of ridepooling. In contrast to our results, Giang et al. [26] found a significant relationship of PEOU on ATU in a ridesharing contexts. Lee et al. [41] summarized that there are 13 non-significant and 19 not applicable relationships between PEOU and PU as well as 24 non-significant and 19 not applicable relationships between PEOU and BI. This result already shows the doubtfulness of this construct [41]. According to Subramanian [52] the low or not existing importance of PEOU on the acceptance process arises at innovations which are intuitively easy to use, so this factor has no impact on this process any more. This argumentation comes along with the mean value of 5.58 for PEOU (see Table 2) which is the highest of all constructs and therefore an indicator for the easiness to use ridepooling services. Moreover, literature often mentions that the impact of PU on ATU is stronger than PEOU on ATU. This points out the subordinate role of PEOU in the TAM [6, 26]. This can also be confirmed in our study as PU is the more important construct for predicting the ATU ridepooling services. Therefore, the construct of PEOU plays a subordinate role for explaining the acceptance of ridepooling services.

By rejecting H9, it was shown that the introduced variable of PS is not relevant for the acceptance process, or to be more precise on the ATU in a ridepooling context. A possible reason for this not significant relationship is that the journey with instructed drivers or other passengers is not considered unsafe as shared transportation means or MaaS are already used and therefore has no influence on the acceptance of ridepooling. This stands in contrast to the findings of Agatz et al. [53], who state that factors as security and safety must be ensured.

Concluding, the model and its connections can be largely confirmed. Most of the extended TAM variables contribute to the prediction of BI ridepooling services. As a core variable of TRA, SN is identified as having a low influence on BI ridepooling services and therefore contributes to a better prediction of its acceptance. This is in line with the findings of Giang et al. [26] who found a significant positive relationship between SN and BI. As already suggested, this extension should be a core variable in the model, in particular regarding innovations with unexperienced users. In addition, the high relevance of PC in the context of ridepooling services has been identified. Thus, for accepting ridepooling services, the technology and service itself must be compatible to the individual lifestyle. These strong effects observed in the data suggest to include this construct as a permanent factor in the TAM regarding the context of ridepooling services. Also, the influence of PEOU and PU deviated from expectations in some cases because the data was too inconsistent for accepting H3, H4, and H5. As a result, the suggestion of the available theory cannot be totally confirmed by the empirical data. This gives cause to rethink their roles in the model especially in the context of ridepooling services.

5 Recommendations, Limitations, and Future Research

The results indicate a stronger preferred use of ridepooling services for leisure activities, while daily commuter trips are not the main objective of such services. Respondents do not seem to have any problems regarding the handling of the service, as they evaluated PEOU very high. Scientific research suggests, that perceived behavioral control has a positive influence on the adoption of innovations [54]. As the general acceptance of ridepooling services is existent, providers must ensure the availability and reliability of the booking process as well as the service itself. Therefore, the level of travel costs as well as the use of ecologically friendly vehicles play a crucial role for the success of a ridepooling service provider.

Since ridepooling is, especially in Germany, a rather new mobility concept, relatively little information for customers about this concept exists. With greater awareness and more practical implementations, ridepooling's acceptance might be different. As our study focuses on Germany, comparative studies across other countries or cultures can be conducted to identify similarities or differences. In order to achieve better predictive results, the contextual factors and external variables as for example gender, income, system characteristics, design features, and personality traits which are neglected in our research can be also included. According to Davis [16], they have a direct effect on PU and PEOU. In addition, some of the correlations among our constructs are very high as presented in Table 2, e.g., PU and ATU with a correlation of 0.841. Possible explanation of this could be a lacking differentiation of the constructs and the corresponding items. To counteract this points, future research can base on other items or other theories, as for instance UTAUT by Venkatesh et al. [23], since moderating variables are included in the analysis. Future research can also replicate the same study after a period of time in order to identify differences caused by more ridepooling providers or more experience with ridepooling services. Thus, a longitudinal study is recommended, ideally with an evenly distributed sample of participants. In this way, it can be measured whether potential customers will accept, adopt, and actually use ridepooling services.

6 Conclusions

Our paper gives insights regarding the customer acceptance of ridepooling services which support the society's shift towards a digital and shared economy using various IS solutions. As this field of research is still underdeveloped in the literature, our study addresses this research gap to satisfy the increasing interest and importance of this topic in practice. The TAM with its core determinants was used in combination with constructs of the TRA. To fit the research context of ridepooling services, it was extended by the constructs PC and PS. The results of the analysis show that BI ridepooling services is well explained by the developed model. Unexpectedly, the relationship between PU of ridepooling services as well as the BI them plays only a subordinate role. In addition, the results do not provide significant evidence for the impact of PEOU and PS on ATU ridepooling services. In contrary to that, the high relevance of PC for predicting the acceptance of ridepooling services has been identified as it has the most significant impact of BI them. This finding shows that the acceptance process of ridepooling services has already started. The trend of ridepooling is getting adopted by Germans as well. Therefore, companies must tackle this challenge to exploit the high potential this market offers. Analysis have revealed that companies can increase their acceptance, for instance, using electric vehicles or offering low costs.

julian.reisch@deutschebahn.com

Abstract: In railway scheduling, the planning of time supplements is crucial to the robustness of the resulting timetable. Time supplements as a means to accommodate for train delays are often distributed according to operation rules and based on experience. A part of the project for strategic schedule optimization at *DB Netze* aims at improving the supplements distribution through learning of structures of delay propagation and transmission from historical railway operation data. The work at hand focuses on delay transmissions between trains. It employs correlations and correlation network analysis to identify and analyze these knock-on delays and to develop logical precedence orders of trains at certain operation points which can in turn be used in a sequential calculation of single train delay propagation. Furthermore, it endeavors to establish a basis to identify strongly connected groups of trains and stations, thus forming relevant subnets for further analysis.

Keywords: data analytics, correlation network analysis, delay management, rail transportation, railway timetabling

1 Introduction

The German railway network is with a total of about 38,000 track kilometers the largest in Europe. The complexity of the timetabling process arises from three conflicting objectives that need to be balanced out. First, the capacity on the infrastructure, that is, allocation of trains to tracks, is to be maximized. Secondly, trains should operate with reasonably tight schedules and thirdly, the timetable must be robust against minor disruptions.

This paper contributes to a research project that aims at optimizing the third aspect, the robustness, meaning that the number of trains and also the traveling times are fixed. One way to cope with minor disruptions and hence improve robustness is to include slack in the timetable, that is time supplements. The trade-off between scheduling slack to achieve robustness against unforeseen events and the goal to realize a schedule as

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

efficient as possible and to operate as many trains as possible is evident. To improve upon this trade-off by identifying optimization potentials within the current distribution of supplements is the greater goal.

The project this work is part of is structured in the following way: First, we analyze delay propagation through the network of train operations. Clearly, if a train is delayed at a certain station, then this delay might still have an impact on the amount of delay in its next operation point. Moreover, delay may also be transmitted from one train to another. This happens for manifold reasons, e.g. passenger transits, track blockage and so forth. We implement a correlation network to detect the most important inter-train interdependencies. Then, in the second part of the project, we model delay propagation probabilistically, but only within one train operation and through the formerly detected interdependencies between trains. This gives us the possibility to see what happens, if the probabilities for a delay change, e.g. if trains always depart on time and so on. Furthermore, this model will be the basis of an optimization task, which will be the third and last part of our project. We will apply algorithms that modify the distribution of time supplements and check whether delays might propagate less, thus yielding a marginally increased punctuality.

The work at hand contributes to this project in the following way: We develop and deploy a novel approach to modeling railway train interdependencies with respect to the propagation and absorption of delays. As [1] have presented in their comprehensive survey, railway data analytics can benefit from employing *Big Data* methods. With a focus on scalability for the included development task, our paper explores and selects procedures and tests them on an exemplary large data set from German railway operations. This enables us to detect which trains have a dependency significant enough so that it should be included in the delay propagation model. Furthermore, the delay networks approach yields us the crucial trains and stations where a delay has a huge impact on many other trains in the network. It will prove wise to first optimize the punctuality of these trains, for instance in an initial solution of a future optimization algorithm.

The outline of this paper will be as follows. In Section 2 we introduce the data from railway operations and motivate our choice of data selection. We then give a brief insight in how we clean our data with respect to outliers, missing values and seasonality. What is next, we present our model for delay transmission. More precisely, we analyze the influence of the absolute value of delays of one train to the change of delay of a succeeding train. In Section 3, we start by discussing two measurements of this influence, namely the Pearson and the Kendall correlation coefficient. This gives rise to a delay transmission network that utilizes these measurements as weights on the edges of a network graph model. Section 4 ends with an analysis of a select example and the validation of the overall results. Finally, we give a short conclusion in Section 5.

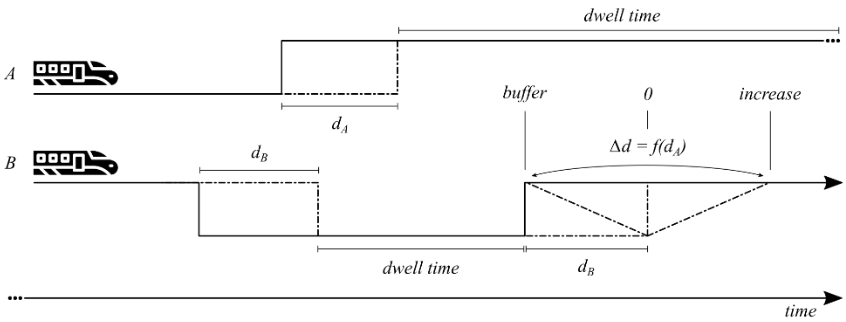

Figure 1. Model for delay transmission between two trains. Train A arrives with a delay d_A and train B with d_B. The change in delay upon departure of train B is ranged between *buffer*, where $\Delta d = -d_B$, no change, where $\Delta d = 0$, and *increase*, in which case Δd.
Source: own compilation.

2 Methods

We focus on the effects of the total delay of an arriving train on the ability of any departing train to reduce prior delay by using up time buffer or the necessity to build-up additional delay. Figure 1 illustrates this idea. We denote the *total delay upon arrival* as d and the *change in delay* as Δd. The suspected relationship can be expressed by $\Delta d_{Dep} = f(d_{Arr}) := \Theta \cdot d_{Arr}$, where Θ is an arbitrary function which yields a measure of association.

2.1 Data Selection: Region and Traffic Type

As an example, for our analysis, we choose the long-distance train network in the south western region of Germany where we deal with two major railway corridors. The first one is from Basel to Frankfurt and the other one from Stuttgart to Cologne. These corridors meet in Mannheim, where a transfer is possible as the different long-distance train lines are synchronized there. This synchronization is the first reason to choose this region as we expect interdependencies of the long-distance trains there. Furthermore, the two corridors are highly frequented so that the capacities are fully saturated, and an optimization of slack is helpful. We discretize the corridors by flag stops and omit signals which do not involve a regular stop. Accordingly, this study focuses on the southern part of the first corridor with stations *Offenburg (RO)*, *Baden-Baden (RBB)*, *Karlsruhe (RK)*, and *Mannheim (RM)*, the latter two being the cities with the second and third largest population in Baden-Württemberg, whereas the former stations are stereotypical for smaller sized cities. A large variety of train types is moving along the German railway network. We generally distinguish between regular and irregular and long- and short-range passenger trains and freight trains. Since this work's approach is to analyze regular train encounters with a focus on temporal precedence, and since freight traffic behaves structurally irregular, this work will abstract from freight trains and solely consider regularly running passenger trains - both long and short distance.

2.2 Data Cleaning: Outliers, Missing Data, STL

Before the actual data analysis can be performed, data must be cleaned and, if necessary, transformed[1]. The data preparation procedure for the work at hand comprises of the following key activities: *outlier detection and removal*, *handling of missing data* and, finally, *correction for trend and seasonality*.

Outliers. The univariate distribution of the total delay of a train and the change in delay cannot generally be expected to be symmetric. Positive delays occur more frequently than negative ones. The latter would imply that a train runs faster than necessary to maintain punctuality, which is inefficient and generally unwanted, whereas positive delay is an unwanted though inevitable phenomenon. Analyses of train delays of passenger trains in the Netherlands [2, 3] showed right-skewed distributions of delay across trains. In fact, delays for railway trains are commonly modeled as log-normal, exponential, Weibull, or gamma distributed random variables [4]. In our data, the same asymmetry can be observed (see Table 1). Accordingly, the empirical distributions of our random variables are skewed, and their location parameters and moments shifted unevenly. Hence, symmetrical outlier detection methods, like Tukey's fences [5], will falsely classify extreme observations on the heavy tailed side of the distribution as outliers and fail to detect outliers on the steep side. For this, [6] used the *medcouple* (MC) measure to adjust Tukey's fences for skewness. The medcouple, as proposed in [7], is a robust and efficient measure for skewness with a contamination breakdown barrier as high as 25%[2]. It can be calculated in $O(n \log n)$ time. Thus, MC is a best compromise between robustness, complexity and skewness detection performance. For un-skewed distributions, both the basic and adjusted method yield the same results. However, if the data distribution is skewed, then the adjusted boxplot method accounts for the skewness, even in the case of contamination due to the presence of far outliers.

	$[S > 0.05]$	$[-0.05 \leq S \leq 0.05]$	$[S < -0.05]$
Total delay	3104	2965	247
Change in delay	1969	3328	1056

Table 1. Number of trains, which are either right-skewed, symmetrical, or left-skewed. The skewness S was measured by means of the medcouple, showing that the majority of trains show exhibit right-skewness or approximate symmetry for both d and Δd.

Using this method *13.95%* of all cases were marked as outliers caused by either of our interesting variables. Out of all observations for the delay upon arrival *5.87%* and for

[1] Technologies like *bootstrapping* exist, where these preparation steps are not necessary, however, we expect them not to scale well.

[2] In 8 the asymptotic breakdown point of an estimator T is derived as $\epsilon^* = \epsilon^*(F_0, T) = inf\{\epsilon \mid b(\epsilon; X, T) = \infty\}$, where ε is the amount of deviant (i.e. contaminated) data, b the bias function, and ε* the minimum level of for which the estimate bias becomes infinite.

change in delay *8.34%* where marked as outliers both of which lie well within the breakdown range of MC.

Missing Data. Based on expert knowledge, many occurrences of missing observations in the dataset have been rectified prior to the import into the *RDBMS*[3]. However, missing values for both variables persist. In order to decide upon the correct means of dealing with missing values, first, the cause of their absence must be identified. In data mining, three mechanisms of missing data are distinguished: *missing at random* (MAR), *missing completely at random* (MCAR), *missing not at random* (MNAR) [9]. If the occurrence of missing values is completely unrelated to the manifestations of the variable itself and other observed data, the underlying mechanism is MCAR and can be considered as *ignorable* [10]. The occurrence of missing values in the data seems unrelated to other relevant variables in the data set and is due to the lack of contradicting evidence assumed to be caused by MCAR. MCAR with as low occurrence rates (*3.26%* of the values for *delay upon arrival* and *4.95%* of the values for *change in delay*) as in the present data can be treated with the *complete-case* method, by which only complete observations will be regarded in the analysis[4].

Trend & Seasonality. We can identify systematic differences in delays and the delay

differences between days of the week. On average, the total delay upon arrival at an operation point peaks on Fridays. Analogously, the ability to reduce delay seems to

[3] Relational Database Management System: *Maria DB* (https://mariadb.org/).

[4] We have added binary dummies, representing missingness in the total delay and in the change in delay, and then checked, whether they are correlated with each other and with the original values. Furthermore, we have performed a pairwise contingency test for the dummies and cardinal variables (train type, source station), and only found evidence for a, though significant, rather weak association between them (*Cramér's v* $\leq .30$). We found that missingness for the total delay and change in delay are strongly connected ($\rho = .782$). In most occurrences of missingness in either variable the other was missing as well, which supports the use of the complete case method. At the same time, missingness appears to be virtually unrelated to the absolute values of the delay variables.

decrease (see Table 2). The Wilcoxon rank sum test to compare medians of unpaired samples shows that the daily means are significantly shifted[5]. In addition, temporary rescheduling might lead to a-cyclical local and global trends, which must be addressed. To model the described trends and weekly patterns, we use an additive component model. The decomposition is achieved using a combined approach called *seasonal-trend decomposition procedure based on LOESS* (STL), as presented in [11].

2.3 Data Engineering: Cumulated Delay, Train Encounters

As the change in delay of a train after its departure shall be analyzed, data rows which constitute a departure process are merged in order to obtain the cumulated *change in delay*. Furthermore, as this study focuses on associations between train delays at specified operation points and at specific times, encounters of one train with another are obtained by matching the time of arrival of an incoming train with the time of departure the departing train at an operation point. Lastly, relevant and valid subsets must be selected with respect to the size of the resulting sub-samples.

Cumulative Change in Delay. The process of a train arriving and departing at an operation point is established as a sequence of events connected by activities called an *activity-event network* ([12, 13], similarly). A simplified version of such a network is depicted in Figure 2. The nodes in the graph represent signal passing events and links between event nodes indicate the transitions from one activity to the other, e.g. the train moving from signal to signal. Each transition can result in a change in delay Δd. The total delay d of a train i upon arrival can be represented as the difference between its scheduled time of arrival $\hat{t}^{a}_{i}$ and its actual time of arrival t^{a}_{i}, at that time: $d_i(\hat{t}^{a}_{i}) = t^{a}_{i} - \hat{t}^{a}_{i}$ This approach is rather straightforward and the resulting delay indiscriminately encompasses primary and secondary delays, which the train in question has accumulated during its course up until arriving at the respective operation point. The change in delay during the train's departure follows a slightly more complex pattern. As the reader can see in Figure 2, a change in delay can be the result of transitions (2) or (3) simultaneously. The delay change during one transition from t_k to t_j, $\Delta d_i(t_k,t_j)$, can be calculated as $\Delta d_i(t_k,t_j) = d(t_k) - d(t_j)$. For the work at hand, it is considered negligible which transition causes the build-up or decrease in delay, given that it is induced by the delayed arrival of another train. We accept the possibility for causes of the change in delay (e.g. passengers boarding and alighting), however, abstract from it. Because there is a systematic element in how the change in delay is distributed across phases, only the combination of all phases is considered. For simplicity, in this work a linear combination, i.e. the sum, will be applied: $\Delta d_i(t_k, t_{k-n}) = \sum_{j=1}^{n} \Delta d_i(t_k, t_{k-j})$, where $n \in \mathrm{N} \wedge n < k$ Putting the above equations together and simplifying yields the *cumulated change in delay*: $\Delta d_i(t_k,t_{k-n}) = d(t_k) - d(t_{k-n})$.

[5] As can be guessed from Table 2, the medians for Fridays and Saturdays as well as Wednesdays and Thursday are not significantly different.

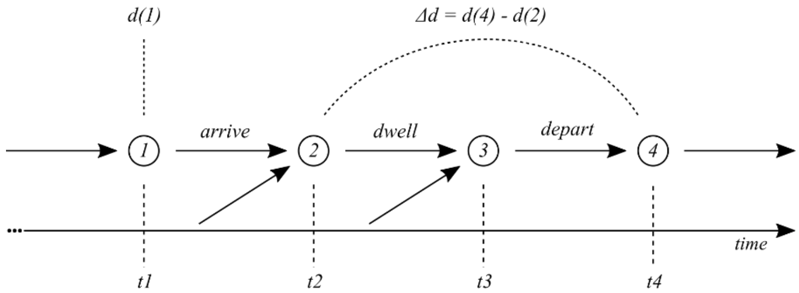

Figure 2. In (1) the train leaves the section prior to the station and enters its area. The train then arrives at the platform/station track (2) and leaves the platform in (3). In (4) the train leaves the station area for the next section. Between events (2) and (3) the train dwells at the platform for boarding and alighting or a conductor change etc. Source: own compilation based on [13].

Train Encounters. Extracting actual train encounters is an important preparatory step for the analysis. The following gives a concise definition of what is meant by the term *encounter*: For the purpose of this work, the arrival of one train *i* and the departure of a train *j* are considered an encounter, if the target operation point of *i* equals the start operation point of *j*, and, if the actual arrival time of i, t_i^a, was less than 10 minutes before the time of departure of j, t_j^a. Following this understanding, encounters imply temporal precedence, e.g. it is logically assumed that a train can only pass its delay on to trains, which depart at a later time, and never to trains that have already left the operation point. This assumption generally holds, however, the opposite direction is not inconceivable, as the dispatcher may always take action to create a situation in which one train passes its delay on to a preceding train and thus works as a time forwarding transmitter. In the further analysis, this inversion does not constitute an encounter.

Exclusion of Small Sub-Samples. For this paper, we consider only pairs of trains which have a minimum number of *30* encounters, using the method presented in [14] to determine exact sample sizes. These sizes depend on pre-estimated correlation coefficients, which are determined either through expert knowledge or prior research. For this work, the overall correlation between the d and Δd serves as an estimate for the expected magnitude of ρ and τ.

3 Constructing the Delay Transmission Network

3.1 Pearson's Product-Moment Correlation Coefficient ρ

For continuous variables which are at least interval-scaled *Pearson's product moment correlation coefficient* is a measure of choice. It gives the change in a random variable X which coincides with an increase or a decrease in another variable Y and vice-versa.

The coefficient is defined for the interval [−1,+1] and measures the strength and direction of a linear association between two variables. A negative sign indicates an anti-proportional relationship and a greater absolute value implies stronger association between the variables. If the coefficient is equal to 0, the two features do not exhibit any *linear* relationship. However, a non-linear function to describe their relationship might still exist [15]. The product-moment correlation coefficient for random variables X and Y is given by $\rho(X,Y) = \frac{\sum_{i=1}^{n}(x_i-\overline{x})\cdot(y_i-\overline{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\overline{x})^2}\cdot\sqrt{\sum_{i=1}^{n}(y_i-\overline{y})^2}}$ where x and y are realizations of the variables. Thus, the interpretation of the calculated coefficients is rather straightforward: Let $X = d^k_{ij}$ denote the absolute delay upon arrival of a train i at a station k in an encounter with a train j. Furthermore, let $Y = \Delta d^k_{ij}$ signify the change in delay of that train j in an encounter with the preceding train i. Then $\rho(X,Y)$ gives the amount of time by which Δd^k_{ij} would increase or decrease, if d^k_{ij} were to be increased or decreased by one second. In other words, ρ is the extent to which the delay of train i proportionally influences the aggregate delay build-up (or reduction) of train j during dwelling and/or departure. $\rho(X,Y) = 1$ means that an increase or a decrease by one second of delay in train i fully translates into an increase or a decrease in the change in delay by that same amount and $\rho(X,Y) = -1$ means the exact opposite.

3.2 Kendall's Rank Correlation Coefficient τ

For ordinal variables, *Kendall's rank correlation coefficient* is an appropriate measure. Its interpretation is very similar to Pearson's coefficient, however, it does not measure the linear relationship between two features, but whether both variables share the number of discordances, instead. We use a modified version of the coefficient, *tau-b*, which accounts for rank ties. The rank correlation coefficient τ_b, corrected for the bilateral presence of ties is defined as $\tau_b(X,Y) = \frac{S}{\sqrt{\left(\frac{n(n-1)}{2}-T_X\right)}\cdot\sqrt{\left(\frac{n(n-1)}{2}-T_Y\right)}}$ where T_X and T_Y denote the number of ties in the rank pairs of X and Y (in adaptation of the formula given in [16]). In this paper, Kendall's τ will serve as a verification instrument for Pearson's coefficient, as it is non-parametric and, other than ρ, is resilient even in the presence of far outliers [17].

3.3 Graph Theory & Network Analysis

This paper employs elements of graph theory and network analysis to further analyze relationships between trains. While a multitude of applications for network analysis in exploratory data analysis exists, if the network properties of the available data are evident [18], this toolbox has also found use in areas where graphical structures in the underlying data are less ostensible. Examples can be found in qualitative studies where covariates to an interesting outcome might exhibit multiple moderation effects [19], and, for some time now, in genetics where network-graphs are created based on correlations as a similarity measure for gene-expression states ([20, 21]). The foundation of a network structure is a graph G which comprises of *vertices* and *edges*. If two vertices are connected by an edge, they are called *adjacent*. Hence, G can be represented by its *adjacency matrix* $A_G = [a_{ij}]$ in which each a_{ij} represents the number of connections between two nodes i and j. Every graph H with vertices and edges from G restricted by the adjacency matrix A_G is a *subgraph* of G. A network is a graph-based structure and its interpretation specific to the application-domain – the *network graph*. It is formed from *nodes* (vertices) which are connected through *links* (edges) and extends the graph model with additional attributes for vertices and edges. A typical addition in the network context is the assignment of weights w_{ij} to each link. A *weight matrix* W_G would have the same shape as the adjacency matrix of the underlying graph. A network, in which the links have weights of arbitrary value, is called a *weighted* network. If links in the network connect ordered pairs of nodes exclusively, then the network (graph) is *directed* [22].

3.4 Constructing the Delay Transmission Network

The proposed network is based on a graph consisting of a set of vertices ($v_i \in V$) which each represent a respective train (number). Relationships between trains are expressed through a set of directed links $e_{ij} \in E\ \forall\ (v_i, v_j) \in (V, V)$ in the network graph. These directed links represent the dependency of the target node's change in delay from the source node's total delay. Weights in the constructed network are based on the correlation coefficients. In the constructed network graph, link weights are interpreted as similarities or the relative closeness between adjacent nodes. Hence, on the one hand, while negative weights are not generally inconceivable (for example [23]), they are implausible in the current application context. Negative values for the correlation coefficients, on the other hand, are very plausible, and must be dealt with prior to performing the network analysis. Otherwise, the resulting negative and positive weights might bias weighted and distance-based network measures. The application of soft-thresholding produces weights for the proposed network. In this work they are obtained based on the arithmetic means of the correlation coefficients γ: Let γ be the mean of the correlation coefficients ρ and τ and let exist an arbitrary number $\lambda \in <$ then the weight w_{ij} for the link connecting the nodes i and j is given by $w_{ij}^{p} = |\gamma(v_i, v_j)|^{\lambda}$. The resulting values fit the interval *[0,1[,* thus, preserving information on the strength of the respective correlation. Additionally, the exponent λ is included. Performing this operation from the Tukey-ladder of power-transformations [5] adds the ability to reduce tail weights in the coefficients' distributions.

3.5 Measuring Network Properties

In this paper, we use the node *strength* as an indicator for the importance of a node. The node strength respects the strength of ties with other nodes in the network and calculates as the sum of link weights [24]. Of particular interest for this paper is the out-strength $D_{in}(p_k) = \sum_{i \neq k} w_{ik}$ and in-strength $D_{out}(p_k) = \sum_{i \neq k} w_{ki}$ – analogous to the degree-measures.

An adequate means to identify possible moderation-effects, which certain trains might have, is betweenness centrality (C_B) as detailed in [25]. It can be considered a measures of a node's overall connectedness with the network[6]. The betweenness $b_{ij}(p_k)$ of a node k with respect to two other nodes i and j is defined as the ratio of the number of paths between i and j which contain k, and the number of all paths connecting i and j: $b_{ij}(p_k) = \frac{1}{g_{ij}} \times g_{ij}(p_k)$. *Betweenness Centrality* (BC) is the sum of a node's betweenness for all node pairs formed from the $n - 1$ other nodes in the network: $C_B(p_k) = \sum_{i=1}^{n} \sum_{j \in [1,i[} b_{ij}(p_k)$

4 Evaluation

In the following section, we take a look at some select examples and evaluate the approach. We have implemented it using *GNU-R*[7]. Furthermore, we have used *Gephi* and *Inkscape* for visualizations.

4.1 Results

In the subset around the four selected operation points, we can observe the following data as follows.

Number of Trains by Operation Point. Figure 2 shows the number of trains arriving

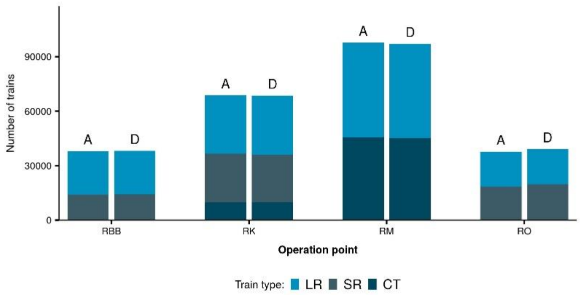

Figure 2. Number of trains arriving (A) at and departing (D) from the selected operation points. Source: own compilation.

and departing at the respective operation points and the distribution of different train types. As was expected, *Mannheim* and *Karlsruhe* handle much more than twice as much traffic as the two smaller operation points.

[6] The concept of betweenness was originally used as a measure of a person's ability to influence a group. A high betweenness would mean that a person is able to control the flow of information in the network.

[7] To name the central libraries: *reshape2*, *RMySQL*, *dplyr*, *broom* (data handling); *robustbase*, *stlplus* (outlier removal, detrending, de-seasonalization); *igraph* (network modeling); *ggplot2* (visualization).

Number of Encounters by Operation Point. Accordingly, we were able to extract encounters, as presented in Figure 3. The smaller operation points, *RO* and *RBB*, on the one hand, show a similar distribution having most trains being involved in well less than 1000 encounters. The larger operation points, *RM* and *RK*, on the other hand, appear to be very different. The *Mannheim* plot looks like a scaled version of that of the former two. At *RK*, most trains have even fewer encounters than in the smaller operation points, and at the same time, very few trains have a great number of encounters. This would appear to be a result of regular strong peaks in the number of arriving and departing trains.

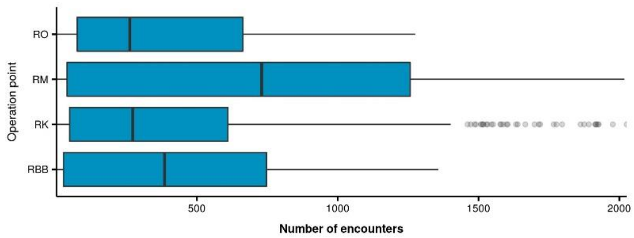

Figure 3. Number of encounters by train at the selected operation points. Given is the count of all encounters a train is involved in (as both arriving and departing). Source: own compilation.

Correlation Coefficients. The Kendall and Pearson correlation coefficients' distributions show similar patterns, with the median indicating a weak negative correlation. Both have a cluster in the weak to medium positive correlation range. In Figure 4, these train couples appear as outliers on the right side of the scale. However, Kendall's τ doesn't reach the extremes of the scale $(-1,1)$ as much as ρ does.

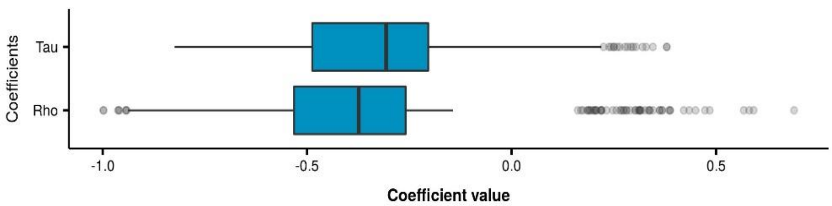

Figure 4. Comparison of the two correlation measures. Source: own compilation.

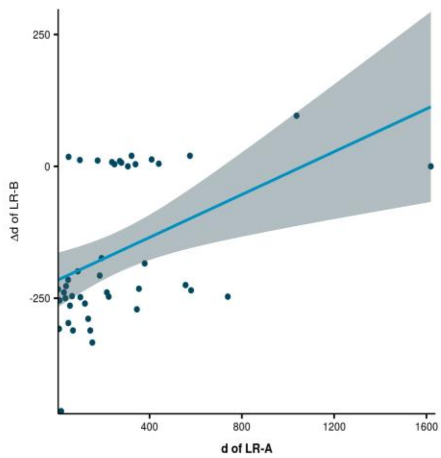
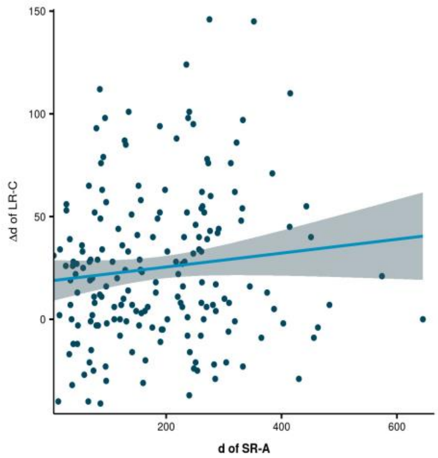
4.2 Examples

To test the approach, the described network was constructed for the *Mannheim* operation point. As for the link weights, we regard only significant correlation coefficients for τ (with $\alpha = 0.05$) and with maximum CI range of 0.3 for ρ. The resulting density distribution is almost Gaussian with a mean of -0.12. There are several strongly connected trains for which an increase in delay upon arrival in one train coincides with an increase in the change in delay in the other. In Figure 6, the relationship between different trains is presented. There clearly exists a positive relationship between delay



(a) LR-A on LR-B



(b) SR-A on LR-C

Figure 5. Scatter plot for encounters of trains with positive correlation in *Mannheim*. LR:= long-distance train; SR:= regional train. Source: own compilation.

upon arrival and the change in delay. Figure 5 (a) plots the total delay of long-distance passenger train $LR\text{-}A$ against the change in delay of another long-distance passenger train $LR\text{-}B$. Figure 5 (b) plots the delay of a regional train $SR\text{-}A$ against the delay change of a long-distance passenger train $LR\text{-}C$. Both situations seem plausible. The trains' respective planned arrival and departure in each coupling are at least 7 minutes apart, qualifying as a connection. While the correlation between the trains in pair (a) is relatively strong by comparison, that in (b) finds week support, as the dots are rather unevenly distributed. It is possible, nonetheless, that the correlation in (b) is due to a feeder train relationship, i.e. that $SR\text{-}A$ is a feeder for $LR\text{-}C$. Table 3 represents the network characteristics of our examples. The out-strength of all long-distance passenger trains is in the 3rd and 4th quartile (median: 0.32) of the strength distribution for $Mannheim$ and can be considered as medium to highly influential for this operation point. Most trains, which exhibit strong outgoing links, are long-distance passenger trains as well. $LR\text{-}A$ is also a highly influential train; however, it has incoming links. Yet, it is the only train with a link to $LR\text{-}B$, which is the target of only one incoming edge. This example is remarkable, as $LR\text{-}B$, on many days, has no change in delay, at all. On other days, it reduces delay, probably prompted by its own delays. However, its ability to decrease delay seems to be negatively related to the total delay of $LR\text{-}A$. Similarly, $LR\text{-}C$'s change in delay is correlated only with the total delay of $SR\text{-}A$. However, the latter exhibits a higher in-strength and little out-strength. In the respective figure, we can ascertain that the correlation is rather weak ($\rho = .123$ and $\tau = .195$), yet significant.

	Out-Strength	In-Strength	Out-Degree	In-Degree	Betweenness
LR-A	0.68	0.48	3.00	2.00	0.00
LR-B	0.51	0.30	2.00	1.00	0.00
SR-A	0.16	0.57	2.00	2.00	0.00
LR-C	0.65	0.16	2.00	1.00	0.00

Table 3. Exemplary trains and their network characteristics.

Betweenness values are generally very small. With means at *.012* and *.031* and maximum values at *.17* and *.005*, moderation effects for the delay transmission appear negligible. This seems to be due to the fact, that the network is not well connected. The observable formation of cliques indicates that the transmission of delays is restricted to certain "areas" of times during the day.

4.3 Validation

To validate the results, we have extracted a sub-sample from the train encounters by randomly selecting *70%* of all encounters of each pair of trains. This serves as the training set on which we perform the analysis, as described above. The remaining *30%* serve

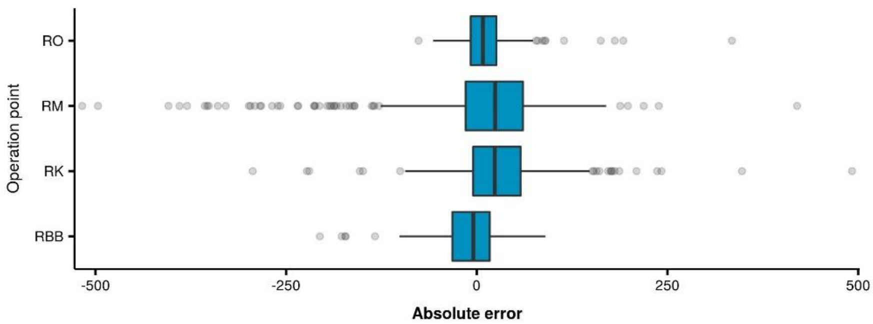


Figure 8. Boxplots for the distribution of differences for predicted vs. observed Δd for each pair of trains at the respective stop (10%-trimmed). Predictions were obtained by multiplying the total delay of the incoming trains with the estimated Pearson correlation coefficients.

as our test set. Figure 8 shows the distributions of differences at the four focal operation points. As can be seen, the larger operation points *Mannheim* and *Karlsruhe* exhibit slightly higher errors for all train pairs (i.e. lower accuracy) and higher variance in means than the smaller ones. However, the means are kurtotically centered around a gravity center close to zero. The overall *mean squared error* (MSE) for the predicted *Δd* is *149,999.59* (vs. *265,952.12* with mean values). Many of the individual models perform very poorly, however, some perform well - with the best R^2 of *70.70%.*

5 Discussion & Conclusions

As was stated, as of now, no distinction is made between secondary and primary delays. This is simply due to the fact, that recognizing true secondary delay build up, would go beyond the scope of the research task completed in this work. Discerning primary and secondary delays requires additional modeling, an approach that is discussed further in this section. Furthermore, our understanding of negative correlation coefficients is somewhat inconclusive. A working hypothesis is that negative correlations indicate discontinuities in the development of the change in delay, such as train order swaps; such that up to a certain arrival delay, transmission occurs until a threshold is reach, when transmission decreased towards *0*. The correlation coefficient might then be negative. In addition, further sophistication in the data preparation process or just broadening the data selection might consolidate interpretability and facilitate a better understanding. In the work at hand, an approach for the analysis of train delay propagation was demonstrated. As a result, train interactions can be determined for selected railway networks. These will be used as inputs at subsequent project stages, where we plan to use these inputs to retrieve a computation order for a by-train-optimization of time supplements. Further validation and verification will be part of further project stages. This involves expert evaluations and the inclusion of information on passenger movements, which has not been available to us, so far.

What is the impact of company specific adjustments on the acceptance and diffusion of logistic standards?

Daniel Neuß[1], Samuel Pfister[1], Adrian Hofmann[1], and Axel Winkelmann[1]

[1] Julius-Maximilians-Universitaet, Chair of Business Management and Business Information Systems, Wuerzburg, Germany

Abstract. Transportation Networks and Logistics 4.0 work on the basis of integrated systems. These systems are enabled by standards which are widely used for the communication between IT-Systems. Due to individual requirements, standards are customized by companies. The extent of individualization has not yet been investigated. Therefore, we applied an empirical analysis on two mature logistic communication standards to identify the standard-application gap by calculating the interoperability between the applied standards. Within these results, we expand the standardization theory by simulating the network effects and the standard diffusion and quantify the impact of the company specific individualization of logistic standards. The identified findings help to improve the standard diffusion model and to improve the development of logistic standards.

Keywords: network effects, standardization, standard deviation, diffusion, logistic standards

1 Introduction

Global supply chains work with integrated logistics systems [1]. This integration offers several performance benefits [2], and is necessary for concepts like Industry 4.0 [3]. To accomplish a certain level of integration, standardization is necessary [4], [5]. Standards therefore have economic advantages like positive network externalities [6], [7] economics of scale [8] and the reduction of transaction costs [9], which are widely discussed theories. Theoretical research on standards deals to a large extent with network effects. Participants benefit from the advantages if the number of participants increases [10], [11]. Specifically, this means that the benefit for a standard user grows stronger if more actors implement the standard. This is combined in the standardization model from Weitzel et al. where the adoption decision is taken as soon as the advantages exceed the costs [11]. Consequently, the decision to introduce a standard is strongly linked to the expectation of how the other actors in the corresponding environment (e.g. within a certain industry) decide, which is known as the standardization problem. In conclusion, the adoption of a standard is more influenced by the anticipated diffusion than on

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

its actual direct benefit, i.e. its quality [11]. In the theoretical concepts of standardization, deviations have not yet been taken into account. This is based on the assumption that a standard is either not or fully implemented, and then becomes perfectly interoperable (and thus compatible). This simplifying assumption leads to a significant theory-practice gap. Therefore, we want to address the hypothesis that there is a direct impact on the standardization deviation, e.g. network effects, due to an interoperability gap.

In this article, we want to close this gap by extending the standardization model developed by Weitzel et al. Therefore, we introduce the interoperability metric from Zhu and Whu [12] and apply it with real data to derive the real interoperability of EANCOM D.96A standard messages. This mature and widely used standard defines several communication massages which are used in different parts of the supply chain. In the next step, we simulate the impact of this metric on the diffusion of the standards and network effects to conclude with an outlook of our future research.

2 Implications of company specific standard adjustments on network effects

Interoperability describes the agreement which exists if, for example, two business partners use the same standard. In practice, this results in different variants, which means that only a certain part of the defined data elements is used and, if necessary, individually defined elements are added. The incompatibilities are eliminated by bilateral coordination within the implementation of the standard. Interoperability measures the extent to which the data elements of two instances overlap (1) [12]. It describes the interoperability values I_{ij} between two actors i and j, where D_i is the set of data elements required by user i. The interoperability values in this paper are calculated from approximately fifty thousand messages of EANCOM standards and result in the arithmetic mean for orders 0.7842 (ORDERS D.96A) and shipping notifications (DESADV D.96A) of 0.8684. The messages were provided and anonymized by an IT service provider. To investigate the impact of the interoperability on to network effects and therefore on the further adaptation of standards, we use the network model by Weitzel et al. [11] and extend it by including the loss of efficiency produced by a lower interoperability.

$$I_{ij} = \frac{|D_i \cap D_j|}{\sqrt{|D_i||D_j|}} \tag{1}$$

The net gain of the whole network can be calculated as coordination efficiency (CE) which is the sum of the *ex post* network benefits of each actor E_i in a network with n actors, where c_{ij} is the direct network effect if the standard is used between actor i and j when the standard is fully interoperable (2). I_{ij} describes the interoperability of the standard between the actors, x_j is a binary variable that indicates whether j uses the standard and K_i represents the cost for an actor i to introduce the standard.

Table 1. Parameters used for the simulation

	Standard	*Model*	n	$\mu(c)$	$\sigma(c)$	$\mu(K)$	$\sigma(K)$	$\mu(I)$	$\sigma(I)$	$\tilde{I}$
S1	*(ideal)*	Base model	20	1000	200	variable	1000	1	0	1
S2	DESADV	Without I-Anticipation	20	1000	200	variable	1000	0.8684	0.0608	1
S3	DESADV	With I-Anticipation	20	1000	200	variable	1000	0.8684	0.0608	0.8684
S4	ORDERS	Without I-Anticipation	20	1000	200	variable	1000	0.7842	0.0866	1
S5	ORDERS	With I-Anticipation	20	1000	200	variable	1000	0.7842	0.0866	0.7842

$$CE = \sum_{i=1}^{n} E_i \qquad \text{with} \qquad E_i = \sum_{\substack{j=1 \\ j \neq i}}^{n} c_{ij} I_{ij}^2 x_j - K_i \tag{2}$$

To decide if an actor adopts the standard (and therefore the value of x_j), an *ex-ante* calculation of the benefit can be used by each actor. The benefit has to be estimated since the actors don't know in advance who will adopt the standard (3). Here p_{ij} is the probability that actor i estimates for actor j to adapt the standard. ϕ_j is the number of j' s communication partners. In this first simulation we assume a full-density network, hence $\phi_i = n - 1$. To further evaluate the effects of interoperability we examine the effects of the actors knowing of interoperability losses (I-anticipation). In this case $\tilde{I} = I$, otherwise $\tilde{I} = 1$.

$$\tilde{E}_i = \sum_{\substack{j=1 \\ j \neq i}}^{n} c_{ij} \tilde{I}_{ij}^2 p_{ij} - K_i \qquad \text{with} \qquad p_{ij} = \frac{c_{ji} \tilde{I}_{ji}^2 \phi_j - K_j}{c_{ji} \phi_j} \tag{3}$$

If the expected benefit $\tilde{E}_i > 0$, then actor i will implement the standard and $x_i = 1$. The results of the simulation are shown in Figure 1. Due to the possibility of an actor falsely estimating network effects that exceed the standardization cost, it is possible that the standard is adopted by not enough actors to fully utilize network effects, which leads to a negative net gain of the network. This is referred to as the *standardization gap.* It can be seen, that a lower interoperability impacts the network effects. If the cost for the introduction of the standard is low enough, there is no difference whether I-Anticipation is used or not. It should be noted that, even though standard adoption is higher at lower costs when the actors do not anticipate the interoperability, the standardization gap is more severe without I-Anticipation.

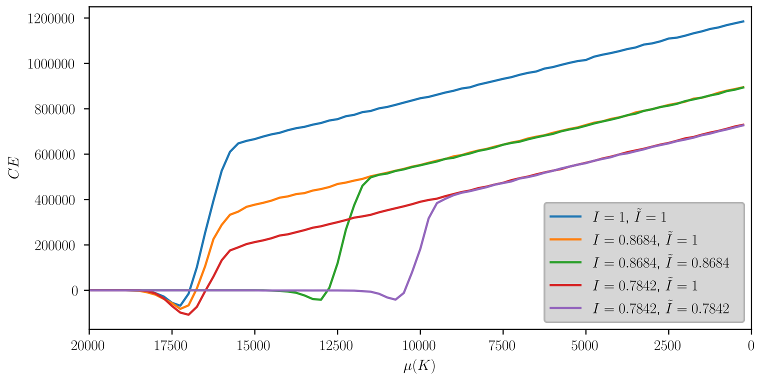

Figure 1. Simulated network effects

3 Conclusion and future work

Within the first simulation we could prove the effect of the interoperability on the standardization gap. In addition, we simulated the scenario with *I*-Anticipation and without. Therefore, we can conclude three major findings.

First, we can prove the hypothesis, that the individual and collectively achieved net benefit effects from a standard introduction with decreasing interoperability are constantly being reduced. Deviations in standards can lead to more or less severe economic losses. The **second** finding is that with medium to low standardization costs, it can provide economic sense to keep the actors unaware of possible interoperability losses. The area in which such a disinformation strategy offers a higher networkwide benefit increases as the expected interoperability decreases. However, in the case of medium-high cost, it is more advantageous for the actors to anticipate interoperability and therefore decide against a standard introduction. In the case of very low or high standardization cost, both strategies achieve identical results (i.e. no or complete standardization). The standardization gap can be divided into a centralization gap that has already been extensively researched and an interoperability gap that is shown for the first time in this paper and depends on the level of anticipated interoperability. This additional gap delays the diffusion of a standard, since the actors only consider an introduction if the cost of standardization is significantly lower, which concludes the **third finding.**

In conclusion there are two main points for further research. First, we want to expand the simulation to different standards to gather more practical insights on the deviation and use them for the simulation. In addition, we want to focus on the company and industry specific standardization gap. In the second step, we want to take the model extensions based on Weitzel et al. into account. These include, for example, the parallel availability of several standards with different interoperability factors, diffusion paths, different network topologies ($\phi_i \leq \text{n} - 1$) or several periods of time in which actors can subsequently make their individual decisions. Nevertheless, it is already clear from this study that losses in interoperability have a lot of theoretical implications for the theories of standardization, standard diffusion and network effects.

Robust Route Planning in Intermodal Urban Traffic

Matthias Ruß, Gunther Gust, and Dirk Neumann

University of Freiburg, Information Systems Research, Freiburg, Germany
{matthias.russ,gunther.gust,dirk.neumann}@ is.uni-freiburg.de

Abstract. Passengers value reliable travel times but are often faced with delays in intermodal urban traffic. To improve their mobility experience, we propose a robust route planning tool that provides routes guaranteeing a certain probability of on-time arrival and satisfying additional constraints. The constraints can limit the number of transfers, time-dependent trip costs and other relevant resources. To find such routes, we extend the time-dependent reliable shortest path problem by adding constraints on time-dependent and stochastic edge weights. An exact solution method based on multi-objective A* search is proposed to solve this problem. By applying our algorithm to a showcase featuring an actual city, we hope to answer relevant questions for policy-makers and contribute to smarter mobility in the future.

Keywords: Urban Mobility, Travel Time Reliability, Constrained Shortest Path Problem, Multi-Objective A* Search

1 Introduction

Urban transport passengers value reliable travel times [1]. However, travel times in urban transport are uncertain due to a range of factors such as the traffic situation or infrastructure defects. A robust route planning tool that takes reliability into account can therefore help to improve passengers' mobility experience in cities and enable smarter mobility. However, current tools typically don't consider reliability and base their advice on deterministic public transport schedules and expected car travel times.

Our contribution is the development of a route planner that finds robust routes in intermodal urban traffic. We define a network model that reflects intermodal specifics such as uncertain travel times that vary over time and a flexible set of constraints. These constraints can limit the number of transfers, time-dependent trip costs and other resources. Subsequently, we extend the work of Chen et al. [2] and develop an exact algorithm based on multi-objective A* search [3] that finds robust routes satisfying the constraints. Reliability is reflected by setting a minimum probability for on-time arrival.

2 Related Work

Reliable route planning is a stochastic shortest path problem [4] in a network with time-dependent travel times [5]. Many variants of this problem exist. Firstly, paths defined

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

a priori can be distinguished from adaptive decision rules that define a successor based on realized arrival times [5]. We focus on a priori paths, which are more practical than complex decision rules. Secondly, many optimization criteria were proposed, e.g., expected time [5, 6], a combination of expected time and variance [7], worst- [8] and best-case time [9] as well as criteria based on on-time arrival probability [10, 11].

Limiting cost or walking time creates a constrained problem. In its well-studied deterministic version [12] it is NP-complete [13] and can include waiting in some variants [14]. It was recently extended to the stochastic case [15, 16].

Main solution approaches for the unconstrained problem include mixed integer programming [11, 15, 17] and label-correcting algorithms [2, 9, 10, 18]. For example, Chen et al. [2] use an A* search approach to find a shortest path with on-time arrival guarantees and also apply it to a weighted combination of time and cost.

The constrained problem has been addressed with mixed integer programming to minimize expected time [15] and with genetic algorithms to maximize on-time arrival probability [16], both assuming constant weights. Building on Chen et al. [2], our contribution is to develop an exact solution method for the problem with on-time arrival guarantees, applicable to constant as well as time-dependent and stochastic weights.

3 Problem Definition

We use a weighted multi-layer digraph $G = (N, E, L, \Omega, D, W)$ to model intermodal networks. Locations are represented by nodes $i \in N$ and passengers can travel between locations on directed edges $(i, j) \in E \subseteq N \times N$. Each node belongs to a layer $l \in L$ that corresponds to a transport mode, e.g., walking or a train line. Edges within a layer represent travel using that mode and edges between layers model transfers.

Departures and arrivals at nodes are assumed to happen at discrete times t within a finite time horizon $\Omega = \{0, 1, \dots, t_{max}\}$ and travel times are described by discrete random variables. To reflect time-dependence, functions $D_{ij}(t)$ assign such random variables to each edge (i, j) depending on the time $t \in \Omega$ at which it is used. In addition, each edge is labeled with time-dependent discrete random variables $W_{ijk}(t), k \in \{1, \dots, K\}$ representing a diverse set of non-negative weights such as distance or (time-dependent) fees.

Finding robust routes translates into a discrete and stochastic optimization problem:

$$\max_{p, t_{start}} \quad t_{start} \tag{1}$$

$$s.t. \quad P\left(T_d^p(t_{start}) \leq t_{target}\right) \geq \alpha \tag{2}$$

$$P\left(C_{dk}^p(t_{start}) \leq c_k\right) = 1, \forall k \in \{1, \dots, K\} \tag{3}$$

$$t_{start} \in \Omega, \;\; p \in SP_{od} \tag{4}$$

The goal is to find a path p in the set of simple paths SP_{od} from origin $o \in N$ to destination $d \in N$ that leaves the origin at the latest possible time t_{start} and reaches the destination before or at a given time $t_{target} \in \Omega$ with a probability of at least α while satisfying additional constraints on, e.g., the number of transfers, cost or walking time.

The random variable $T_i^p(t)$ in (2) describes the arrival time at node i if starting at time t along path $p = (o, \dots, i, j, \dots d)$. With $T_o^p(t) = t$, it is calculated as follows:

$$T_j^p(t) = T_i^p(t) + D_{ij}(T_i^p(t)), \quad \forall j \in p \backslash o \tag{5}$$

In (3), accumulated weights, described by time-dependent random variables $C_{ik}^p(t)$, $\forall k \in K$ are limited to c_k. With $C_k^p(t) = 0, \forall k \in K$, they are calculated as follows:

$$C_{jk}^p(t) = C_{ik}^p(t) + W_{ijk}(T_i^p(t)), \quad \forall j \in p \backslash o, \forall k \in \{1, \dots, K\} \tag{6}$$

The sums of random variables in (5) and (6) can be calculated using time-dependent convolution. For example, the probability of reaching node j on path p at time w is calculated as follows:

$$P\big(T_j^p(t) = w\big) = \sum_{v \in \Omega, v \leq w} P\big(T_i^p(t) = v\big) P\big(D_{ij}(v) = w - v\big), \forall\, w \in \Omega \tag{7}$$

This requires a sufficiently large time horizon and the assumption of independent edge travel times along paths. However, for scheduled modes, travel times are likely dependent. For example, a train that is delayed on one trip segment might try to get back on schedule on the subsequent segment by driving at top speed. To reflect such dependencies and still maintain the independence assumption, we represent entire journeys on one transportation line with a single edge. The travel time on that edge includes waiting before boarding and total time on board.

Waiting at nodes is often not allowed [2, 18]. However, it can improve the solution in the constrained problem: for example, waiting for congestion charges to drop after rush hour can allow passengers with a limited budget to use a faster mode of transport and thus accelerate their journey. We call this *strategic* waiting, as it is voluntary and thus distinguished from *transfer* waiting, i.e., waiting for a scheduled vehicle. We introduce strategic waiting by replacing $T_i^p(t)$ in (5) and (6) with a random variable $S_i^p(T_i^p(t), s_i)$ representing arrival time after strategic waiting. It depends on the original arrival time $T_i^p(t)$ and waiting parameter $s_i \in \Omega, \forall i \in N$. s_i is an additional decision variable and models that the passenger waits until s_i if arriving before s_i.

4 Solution Approach

We will build on the work of Chen et al. [2], who iteratively solve the closely related forward problem in which t_{start} is fixed and t_{target} is minimized. After several iterations with different starting times, a solution to the original problem is found.

The forward problem will be converted to a multi-objective problem by turning the weight constraints into objective functions. The set of non-dominated solutions to this associated multi-objective problem contains a solution to the constrained problem [19].

To find the non-dominated solutions, we will generalize the A* approach in [2] and apply multi-objective A* search [3]. A* search is defined for additive attributes, but can be extended to convolutions if they are order-preserving [20]. Given two paths p_1, p_2 from o to a node $i \in N \backslash o$ with p_1 dominating p_2 and any path p_3 starting at i, the order-preserving property (OPP) implies that the extended path $p_1 p_3$ dominates the extended path $p_2 p_3$. Given the OPP, dominated paths can be pruned in the algorithm.

Without constraints, the OPP holds if distributions are FIFO[1] [2]. As this is not always true with constraints and general weight functions, we will define conditions for which the OPP holds and structure our proofs along three hypotheses:

- The OPP holds for FIFO travel times and non-decreasing, deterministic weights.
- For deterministic weights that are non-decreasing until time t' and decrease afterwards (e.g., a congestion charge during rush-hour), strategic waiting parameters can be set such that the combined waiting and travel times satisfy the OPP.
- The OPP holds for time-dependent stochastic weights if $t' > t$ implies for all edges that $W_{ijk}(t) \leq W_{ijk}(t'), \forall k \in K$ regarding first-order stochastic dominance (FSD)[2].

5 Next Steps and Expected Contributions

So far, this research in progress has defined the constrained time-dependent reliable shortest path problem with time-dependent and stochastic weights to model robust route planning in urban intermodal traffic. In addition, we outlined an exact solution method.

We will continue to implement this approach and support it with required proofs. Numerical experiments will be conducted to evaluate the algorithm's speed given different network sizes and problem setups. This will include a comparison with the less complex unconstrained problem that was solved within seconds for real-world instances [2]. Furthermore, solutions will be benchmarked against deterministic routing advice. Finally, we plan to set up a showcase for an actual city with travel times sampled from, e.g., real-time public transport data or car trajectories. We expect that this will help to answer important questions for policy-makers such as:

- Which measures are most effective for improving reliability? For example, how does the effect of increasing train reliability compare to that of higher trip frequencies?
- How does reliability affect mode choice? And can mode choice be effectively influenced by improving the reliability of certain modes (e.g., bus or bike sharing)?

By answering these questions, we hope to make a significant contribution to smarter urban mobility in the future.

Work System Modeling Method with Different Levels of Specificity and Rigor for Different Stakeholder Purposes

Steven Alter[1] and Dominik Bork[2]

Abstract. This paper proposes a modeling method (the work system modeling method - WSMM) that addresses key issues related to enterprise and process modeling. Those issues lead to modeling method requirements that call for relaxing common assumptions about the nature of modeling methods and related modeling languages and metamodels. A summary of work system theory (WST) and the work system method (WSM) provides background for understanding WSMM. A design space for modeling positions most applications of WSM in relation to seven purposes of modeling that call for successively more formal approaches. WSMM is presented in relation to the seven purposes, thereby extending WSM in new directions. A final section summarizes how WSMM addresses the issues and requirements from the introduction, explains how coherence is maintained within WSMM, and identifies areas for future research.

Keywords: modeling method, modeling language, work system method, work system theory

1 Overcoming Problems in Enterprise and Process Modeling

Prominent researchers argue from various backgrounds that modeling methods for enterprise and process modeling have not achieved their full potential and need to be extended or augmented to make them more usable by broader user groups. This paper's approach to modeling methods addresses important issues that they mention:

- A Dagstuhl seminar [1] emphasized how differing stakeholder needs call for different approaches to enterprise modeling (EM). That seminar led to a *BISE* research note by EM community leaders [2] that encourages moving EM from an expert discipline towards "grass roots modeling" and "modeling for the masses." Their future research agenda includes "softened requirements to completeness, coherence and rigor".
- Six of seven process modeling problems discussed in [3] are relevant here: 1) aiming for one model that suits all purposes, 2) straightjacketing smaller interactive processes into one monolithic model, 3) using static hierarchical decomposition as the only abstraction mechanism, 4) modeling humans as if they are machines doing

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

a single task, 5) being vague about vagueness, 6) abstracting [away] from the things that really matter [to stakeholders].

- [4] calls for "overcoming tendencies to view diagrammatic modeling methods and languages" as "stable, even standardized, artefacts that establish some commonly agreed way of describing a 'system under study,' [which] implies that all stakeholders work on the same level of abstraction and specificity."

Related research on modeling method usage (e.g., [5, 6]) and model comprehension (e.g., [7–9]) illuminates major issues. Many modelers do not apply modeling methods as intended by their designers, frequently using only a subset of the syntactic concepts provided [10]. Modeling methods often do not fit modelers' aptitudes, knowledge, and purposes [11, 12]. [13] notes that the "lack of intuitiveness of diagrammatic representations and the complementary role of text-based representations has been underlined in recent research." Cognitive load [14] for stakeholders becomes increasingly important as unfamiliar symbols and icons proliferate. [13] also mentions lack of flexibility in process models, dilemmas of control, and excessive prescriptiveness. Uncertainty and variability related to accidents, mistakes, and intentional workarounds bring further challenges for modeling methods.

Requirements for a More Flexible Modeling Method. This paper pursues four requirements by presenting a modeling method that relaxes many common assumptions that are obstacles to dealing with those issues about modeling and modeling methods.

1. The modeling method should respect stakeholder diversity related to knowledge, beliefs, and roles, thereby making it usable both by business professionals working individually and in collaboration and by IT professionals pursuing model-driven development or code generation. (cf. [5]).
2. A modeling method can include different modeling techniques for different stakeholder purposes related to the same situation (contrary to the view in [15] that a modeling method can have only one modeling technique that combines a single modeling language and a modeling procedure).
3. With different modeling techniques for different purposes, a modeling method can use different modeling languages based on different metamodels. In relation to domain-specific conceptual modeling (cf., [16]), this approach assumes that intersubjective understanding between stakeholders might not require a single metamodel for processes, services, enterprises, goals, and so on.
4. The representation of a model might or might not use diagrams with rigorously defined notation and syntax (e. g., BPMN, ArchiMate) or might use such diagrams for some purposes but not for others.

Acceptance of multiple techniques, modeling languages, and metamodels within a modeling method leads to challenges about maintaining coherence across different models produced by different stakeholders for different purposes. Our approach to coherence within a modeling method is to require use of a single overarching metaphor that applies to all modeling techniques of the modeling method. According to [17, p. 138], a modeling method metaphor defines a specific perspective taken by the modeler while observing the reality and mapping the relevant aspects to the modeling language at hand, thereby creating a model representation of the reality. Ideally that metaphor should help in bridging gaps between modelers and practitioners who often visualize situations from different viewpoints. The invariance of the single overarching metaphor ensures that all modeling techniques contribute to an overall goal, even if they employ different levels of detail and expressiveness. Differences between the models will be revealed in stakeholders' personal understandings and collaborative discussions.

A Work System Modeling Method. This paper extends several decades of effort related to the work system method (WSM), a flexible systems analysis and design approach based on an informal type of modeling and problem-solving designed to help business professionals visualize work systems and collaborate more effectively with IT professionals [18–21]. Many hundreds of MBA and Executive MBA students have used various versions of WSM templates that guided their production of management briefings about improving real world work systems. Those templates contain many modeling techniques that have never been expressed as a formal modeling language (cf. [22]). For example, none is based on an explicit metamodel or operationalized along a procedure.

Research Goal and Organization. This paper explains how a work system modeling method (WSMM) based on WSM, WST, and a central work system metaphor satisfies the four requirements above. WST and WSM provide a plausible starting point for developing WSMM because their spirit is aligned with the "modeling for the masses" vision in [2] and because an enterprise is a set of interacting work systems.

Building on our previous work [23], this paper provides contributions in several areas by showing that WSMM could help modelers and users apply a range of modeling techniques to situations that seem difficult to address without relaxing assumptions such as use of a single modeling technique, a formal modeling language, and diagrammatic notation. WSMM is a step toward a modeling tool that can be implemented using existing metamodeling platforms such as ADOxx. Reflection on WSMM's form and assumptions might help researchers and practitioners wishing to revise or design modeling methods including those for domain-specific conceptual modeling. It might contribute to reflection on how modeling standards such as BPMN, EPC, and ArchiMate can be adapted to address needs of broader audiences. It also might show a path for formalized extensions of less structured contexts such as those addressed by Checkland's soft systems methodology [24].

The next section summarizes WST and WSM to introduce the central work system metaphor. A two-dimensional design space for modeling methods illustrates the context of WSM. One dimension traverses seven purposes of modeling that require a range of modeling techniques from quite informal to highly formal (cf. [22]). A second dimension represents different degrees of specificity in content, appearance, and usage. The subsequent section illustrates the scope of WSMM using an example that emphasizes modeling techniques and related metamodels. A final section summarizes how WSMM addresses the requirements mentioned above, explains how WSMM maintains coherence across models built for different purposes, and identifies challenges for future research.

2 Thinking of Systems in Organizations as “Work Systems”

This section provides background related to the work system method (WSM), an informal modeling approach that to date has not been guided by a metamodel and that does not produce specifications in the sense of enterprise modeling.

Work system basics. A work system is a system in which human participants and/or machines perform processes and activities using information, technology, and other resources to produce product/services for internal and/or external customers. The and/or in the definition implies that work systems can be sociotechnical (with human participants) or totally automated. A work system operates within an environment that matters (e.g., national and organizational culture, policies, history, competitive situation, demographics, technological change, other stakeholders, and so on). Work systems rely on human, informational, and technical infrastructure that is shared with other work systems. Work systems should support enterprise and departmental strategies. The definition of work system specifies that work system is a very general case that includes many special cases such as information systems, supply chains, service systems, projects, and totally automated work systems. For example, an IS is a work system most of whose activities are devoted to processing information. Supply chains are work systems that extend across multiple organizations to provide resources for other organizations. Projects are work systems that produce specific product/services and then go out of existence. An enterprise or organization is a series of interacting work systems.

WST, the theoretical basis of WSM, consists of three parts: 1) the definition of work system, 2) the work system framework, and 3) the work system life cycle model, which is not discussed here. This paper makes direct use of the definition and of the work system framework (Figure 1), which outlines elements of even a rudimentary understanding of a work system’s form, function, and environment as the work system exists during a time interval when its structure is basically static. Emphasizing business rather than IT concerns, this framework covers situations that might not have a well-defined business process and might not be IT-intensive. Processes and activities, participants, information, and technologies are viewed as completely within the work system. Customers and product/services may be partially inside and partially outside because customers often participate in work systems. A common limit to modeling precision is that human participants in work systems may make errors and may pursue adaptations and workarounds instead of following prescribed procedures. Furthermore, processes fall along a dimension from unstructured to structured [25], starting with largely unstructured creative processes (such as many design and management processes) that have no pre-specified sequence, may involve extensive iteration, and therefore are not amenable to detailed, high precision modeling.

Work system method. WSM is a semi-formal systems analysis and design approach that was developed over several decades to help business professionals visualize work systems in their own organizations and collaborate more effectively with IT professionals. To date, almost all use of WSM has applied work system analysis templates that outline how to proceed from aspects of a work system’s structure and performance toward producing a preliminary recommendation about how to improve the work system. The templates include some questions that require textual answers, others that require filling out formatted tables, and others that invite users to include swimlane diagrams, Pareto charts, or other diagrams if they have appropriate software.

While details differ, every version of WSM is organized around the following: 1) identify the smallest work system that has the problem or opportunity; 2) summarize the “as-is” work system using a work system snapshot (example in Table 2), a stylized one page summary; 3) evaluate work system operation using measures of performance, key incidents, social relations, and other factors; 4) drill down further as necessary; 5) propose changes by producing a work system snapshot of a proposed “to be” work system that will probably perform better; 6) describe likely performance improvements.

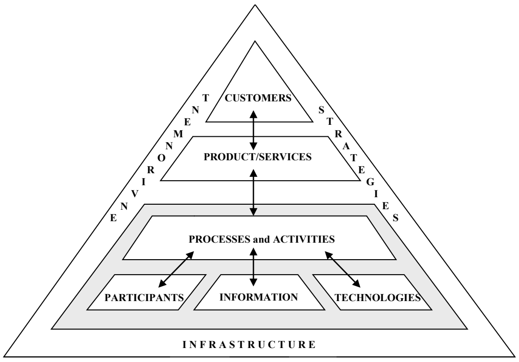

Figure 1. Work system framework [19, 20]

3 Framework for Visualizing Modeling Methods

We agree with the view in [2] that “not all knowledge should be represented as a formal model” and that it is important to find “the right balance of representational forms,” including formal and informal models. A clear discussion of this entire topic requires a foundation such as the framework in [15] by which a modeling method is a composition of a *modeling language*, *modeling procedure*, and *mechanisms & algorithms*. A modeling language, the backbone of a modeling method, is composed of three components: syntax (the concepts provided by a modeling language, including their valid combinations), semantics (the meaning of the concepts), and notation (the graphical representation of the concepts). The combination of a modeling language with a modeling procedure is referred to as a *modeling technique*.

An alternative perspective on modeling methods. Facilitating modeling by diverse stakeholders calls for relaxing the requirement in [15] that all stakeholders and purposes must be accommodated using a single modeling technique, i.e. one modeling language and one modeling procedure. Relaxing that requirement avoids cognitive overload from increasing metamodel complexity due to adding concepts to separate modeling techniques when diverse stakeholder needs and purposes call for them. Thereby, the cognitive load of each single modeling technique is minimized by maintaining the overall expressiveness of the modeling method.

An alternative view of modeling methods starts with a modeling method design space. The ideas explained next are equally applicable to design spaces based on the work system metaphor or other central metaphors such as systems in general, sociotechnical systems, actor networks, activity theory, and viable systems.

3.1 Design Space for Modeling Methods and Modeling Techniques

Figure 2 represents a design space for modeling methods and modeling techniques related to a core metaphor. A key goal of the design space is accommodating a range of stakeholder purposes, shown as P1 through P7. Technique specificity is the extent to which a technique defines exactly what to include, what to ignore, and how to proceed. Techniques with low specificity tend to be flexible but at the cost of providing relatively little conceptual or procedural guidance. The reverse applies as well.

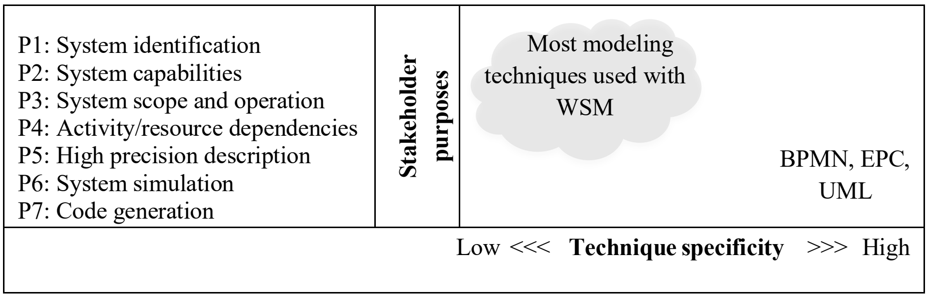

Figure 2. Design Space for Modeling Methods and Modeling Techniques

The shaded area represents the positioning of most of the modeling techniques that WSM users have applied. Most of those techniques focus on topics such as work system *scope and operation*, and *activity/resource dependencies*. Those techniques are relatively low in specificity compared to techniques that might be used for high precision description, system simulation, or code generation. Instead of accepting the assumption that WSMM would include only one technique, this paper assumes that WSMM could include techniques anywhere in the design space provided that those techniques genuinely fit with the overarching metaphor and stakeholder purposes.

4 Work System Modeling Method

WSMM expands WSM greatly by recognizing a wide range of stakeholder purposes and different degrees of specificity for different stakeholders that all use the central work system metaphor. WSMM provides a broader scope of modeling to help various users understand the situation and decide how to improve it. WSMM uses simpler metamodels for informal and intuitive visualization of work systems and more precise and expressive metamodels for helping decision makers identify and select among possible changes and for helping software developers produce or improve software.

WSMM is a highly adaptable method organized around a set of modeling techniques based on a work system metaphor. That range of techniques should be available where required by a range of stakeholders who may encounter situations that resist being modeled within restrictions that are often viewed as essential to conceptual modeling. Our WSMM test case is a hiring system. Similar test cases could be constructed for work systems in production, sales, accounting, software development, and so on.

Managers of an engineering firm are concerned that their current work system for finding, interviewing, and hiring job applicants takes too long, wastes too much effort in interviews, and seems to hire too many engineers whose contributions to engineering projects are disappointing. Some managers believe that a better online human resources (HR) portal would help. Others believe that the problems lie elsewhere.

4.1 Modeling Techniques within WSMM

WSMM should include modeling techniques that support different stakeholder purposes identified in Figure 2. The following discussion uses the hiring example to illustrate the scope of an initial version of WSMM in relation to purposes P1 through P7, but not to show all imaginable modeling techniques that might be included eventually, and certainly not to go into a lengthy explanation of specific techniques.

P1: Identification of the work system. Simply naming the work system of interest with a verb phrase such as *"finding, interviewing, and hiring applicants"* often avoids confusion with people thinking that the technology (e.g., the online HR portal) is the primary object of the improvement effort. Clarity in that regard makes sure that the project is viewed as much more than a software project that produces software. P1 makes no attempt to describe the work system's behavior and structure and does not call for a specific procedure. The metamodel consists of one concept: *Work System.*

Table 1. Two illustrations of lists of capabilities (P2) for the hiring example

Table 1a: Simple list of capabilities	Table 1b: List of capabilities with performance or service level expectations
• defining parameters of the position • publicizing the position • prioritizing applications	• defining parameters for a position, responding within 3 days of request • publicizing the position, advertising in at least five bulletin boards • prioritizing applications, responding within three days of due date

P2: Capabilities of the work system. The hiring work system has capabilities that can be included as a service catalog explanation for the P1 work system description. Those capabilities might be described using a list of verb phrases such as those in Table 1a. A slightly more complete description of capabilities might include performance or service level expectations for each capability in Table 1b. A minimalist metamodel for P2 includes the concepts *Work System* and *Capability* and a slightly more detailed metamodel would add *Performance expectation* or *Service level.* The P2 capabilities lists in Table 1 are simple in form. Again, a specific procedure is not employed.

Researchers focusing on capability driven-development have used a more rigorous notion of capability, e.g., the 15 concepts in the capability-related metamodel in [26].

P3. Scope and general operation of the work system. With P3, the stakeholder wants to clarify the scope of the work system (based on P1) and to attain an overview of its general operation without going into great detail. Table 2 illustrates P3 in the form of a "work system snapshot", a modeling technique for describing a work system's scope and general operation. This is a formatted one-page summary of a work system in terms of the six central elements of the work system framework. Those six elements provide an easily used description that helps in defining the boundaries and contents of the work system that has the problem or opportunity at hand.

Table 2. Illustration related to P3: A work system snapshot of a hiring work system

Customers	Product/Services
• Hiring manager • Larger organization (which will have the applicant as a colleague) • HR manager (who will analyze the nature of applications)	• Applications (which may be used for subsequent analysis) • Job offers • Rejection letters • Hiring of the applicant

Major Processes and Activities	
• **Hiring manager** submits request for new hire within existing budget • **Staffing coordinator** defines the parameters of the new position. • **Staffing coordinator** publicizes position. • **Applicants** submit job applications. • **Staffing coordinator** selects shortlisted applicants. • **Hiring manager** identifies applicants to interview.	• **Staffing coordinator** sets up interviews. • **Hiring manager** and **other interviewers** perform interviews. • **Hiring manager** and **other interviewers** provide feedback from the interviews. • **Hiring manager** makes hiring decisions. • **Staffing assistant** sends offer letters or rejections. • Successful **applicant** accepts or rejects job offer or negotiates further.

Participants	Information		Technologies
• Hiring managers • Staffing coordinator • Applicants • Staffing assistant • Other interviewers	• Job requisition • Job description • Advertisements • Job applications • Cover letters • Resumes	• Short list of applicants • Information and impressions from the interviews • Job offers • Rejection letters	• HR portal for communicating with applicants • Word processor • Telephones • Email

Work system snapshots increase syntactic expressiveness through a metamodel with seven concepts: *Work System, Customer*, *Product/Service*, *Activity*, *Participant*, *Information*, and *Technology*. Cardinalities in the metamodel express internal consistency rules for the snapshot, e.g., each product/service must be received and used by at least one customer group. The type of one-page tabular representation in Table 2 helps in visualizing a work system's scope by focusing on its core components. There is no need for a modeling procedure for producing this type of table. Note that customers may be work system participants, as in custom software development.

P4. Resources used and produced by specific activities. While a work system snapshot such as Table 2 is useful for discussing a work system's purpose and scope, many stakeholders need a deeper understanding of which resources are used and produced by each activity. Tables in the form of Table 3 are more useful for clarifying operational details by listing selected activities of a work system snapshot along with selected types of resources that are used and/or produced by those activities.

Table 3. Illustration of P4: Selected resources used by a subset of Table 2 activities

Activity	Actors	Information used, created, updated, or deleted	Technology	Trigger	Pre-conditions	Post-conditions and product/ services produced
Submit request for new hire.	Hiring manager	Hiring budget Job requisition	HR portal	Need for new employee	Sufficient hiring budget	Job requisition exists
Define parame-ters of the job.	Staffing coordina-tor	Job requisition Job description Hiring policies	Word processor, HR portal	Job requisi-tion	Job requisition	Job description
Publicize the job opening	Staffing coordina-tor	Experience with advertising media, Advertisement	HR portal, Web site for selected media	Job requisite-ion, Job descript-tion	Job requisition, Job description	Advertisement displayed on websites
Submit applica-tion	Applicant	Job description, Cover letter, Job application, Resume	HR portal	Advertise ment displayed on websites	Advertiseme nt displayed on websites	Receipt of cover letter, job application, and resume

Various metamodels can be the basis of Table 3. A minimalist metamodel for P4 would include *Work System, Activity, and Resource*. It would treat all but the first column in Table 3 as resources that are used by the activities. Saying that actors are "used" by activities may sound strange, but it fits with the way some managers use the term resource in planning and management. For modeling this provides a symmetrical way to handle human, informational, and technological resources. A more expressive metamodel might include all of the column headings in Table 3. An even more expressive metamodel presented in [27] contains over 50 concepts that identify other associations between activities and resources, such as which business rules affect customer-facing activities. Those increasingly elaborate metamodels move toward the level of specificity that programmers need, e.g., in identifying resources that are used or produced. The resulting models are still somewhat informal since the concepts are introduced with natural language.

P5. High precision description of the work system. Existing diagrammatic modeling techniques address many typical needs for understanding how the work system components are structured and how the work system operates. For example, it is easy to represent activity sequence and branching logic using BPMN diagrams with activities in swimlanes for different participant roles (see Figure 3, which also applies to P6). While analysts might prefer a full version of BPMN, business stakeholders might prefer a simpler, restricted version of BPMN based on a minimalist metamodel whose concepts are limited to *Event*, *Activity*, *Gateway*, and *Sequence Flow*. That would suffice for diagramming activities in Tables 2 and 3 even though it would require implicit handling of branching logic for situations such as when an applicant is rejected. Similarly, entity-relationship diagrams and ArchiMate's application and technology layers could be used for P5 level descriptions of data structures and interactions between hardware and software. Thus, a high precision description of the work system needs to use modeling techniques that are not associated with WSM or WST but would be important to include in WSMM if it is to address needs of P5, P6, and P7.

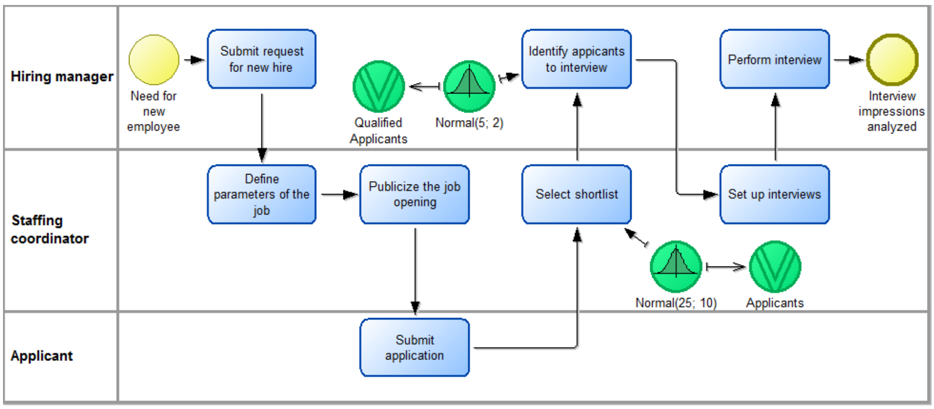

Figure 3. Part of a model supporting a P6 simulation of the hiring process

P6. Simulation of the work system's key processes. Some stakeholders may want to execute simulations to support deeper analysis of the "as-is" work system and deciding on the best of several possible future "to-be" work systems. For example, it might be useful to simulate the workload of different actors depending on the number of applicants, number of interviewers, and other factors. A simulation model could apply an extended BPMN metamodel that adds simulation-specific concepts such as *Statistical Distribution*, and *Random Generators* (the green elements in Figure 3), plus attributes such as transition conditions, probabilities, quantity, cost, and time. Figure 3 illustrates how those concepts might be added to a BPMN model for the hiring example.

P7. Code generation. Figure 2 mentioned code generation because it is a central concern of many researchers in the modeling community. WSMM supports the effort to create understandings and artifacts that are needed in model-driven development but does not attempt to bridge the final gap between understandings and code.

5 Discussion and Conclusions

This paper was inspired by recently published concerns of leading researchers regarding current limitations of enterprise and process modeling. Its goal was to characterize a practical modeling method that applies a central work system metaphor and can be used by stakeholders with different purposes and different levels of technical expertise. WSMM's approach to modeling methods relaxes widely accepted assumptions concerning the nature of modeling methods. That approach positions modeling methods and modeling techniques in a design space that traverses seven types of purposes that had not been articulated in that manner previously and that assumes different levels of technique specificity might be applied for any of those purposes.

We conclude with three topics: whether the four requirements for WSMM were met, how coherence is maintained, and areas for future research.

5.1 Satisfying Four Requirements for WSMM

WSMM satisfies the four requirements identified as the outset. 1) In contrast with most modeling methods, it respects stakeholder diversity by recognizing that different stakeholder purposes may generate different needs for expressiveness, rigor, and completeness. 2) It includes multiple modeling techniques, as shown in the previous section. 3) It can use multiple modeling languages based on different metamodels, but all related to the same work system metaphor. 4) It includes diagrams where needed by stakeholders, e.g., for P5 and P6, but does not require diagrams for other purposes.

Similarly, WSMM addresses other issues mentioned at the outset. WSMM conforms with the willingness in [2] to soften requirements for completeness, coherence, and rigor to achieve broader and more effective usage of modeling. In relation to process modeling problems discussed in [3]: 1) WSMM assumes that different users with different purposes will prefer models with different characteristics; 2) WSMM does not straitjacket processes into one monolithic model; 3) WSMM does not use static decomposition; 4) WSMM does not treat people as machines doing a single task; 5) WSMM is clear about vagueness in its recognition of unstructured and semi-structured processes, adaptations, and workarounds; 6) WSMM is designed to help people improve work systems and does not abstract away from things that matter, such as performance. In relation to issues from [4], WSMM assumes that stakeholders will work at different levels of abstraction and specificity and that their needs may not be satisfied by a specific modeling language.

5.2 Coherence within WSMM

The challenge of coherence in WSMM can be viewed as making sure that WSMM is more than just an assemblage of techniques. At minimum, the use of metamodels that all build on the same core metaphor (the work system) should facilitate production of consistent models for different purposes. For example, a P2 model of capabilities should create a logical constraint on a P3 model that summarizes the work system scope and operation that enacts those capabilities. P3 processes and activities become the basis for the activities in P4 models, and so on.

A larger question is whether WSMM would help business professionals understand work systems for their own purposes while also helping them collaborate with IT professionals with different world views. The use of different metamodels developed for different purposes reduces the likelihood of an automatic way to zoom between the various modeling techniques. However, the progression of the different stakeholder purposes (P1 through P7) outlines a path for communicating between stakeholders who have different purposes. P1 names the work system in the form of the verb phrase. All stakeholders should be able to rally around creating or improving that work system. P2 and P3 support relatively informal understandings of the work system's content, capabilities, and scope. A software engineer in a work system improvement project needs to understand levels P1, P2, or P3 to communicate effectively with business professionals about topics other than isolated details, and also to make it less likely that software will miss basic issues. P4 covers details that business professionals need to verify and that IT professionals need to understand to produce software. Both business and IT professionals might have their own needs for delving into detailed process models, data models, or technical interface models created for P5. In all cases, knowledge of models for P1 through P4 will help in understanding both details and significance of models for P5. Only specialists will pursue P6 and P7, and it would be difficult for them to do that well without understanding models for P3 and P4.

Much of coherence across the various modeling techniques in WSMM needs to be achieved through looking at models and communicating with other stakeholders. From a general standpoint, the different techniques are completely independent and their purposes might not follow the linear and successive nature as proposed for WSMM. Therefore, a technical realization is not always necessary or feasible and needs to be decided individually for each modeling method and its modeling techniques.

5.3 Areas for Future Research

WSMM could help modelers and users apply a range of valuable modeling techniques to situations that seem difficult to address convincingly without relaxing widely held assumptions about the singular nature of modeling methods and modeling languages. Here are some of the research opportunities that represent next steps:

Exploring general implications of the WSMM vision. This paper showed how relaxing common assumptions about modeling methods enables comprehensive visualization of complex systems such as work systems. We do not know where synergies and conflicts between this view and more established views might take us.

Challenging, extending, and/or validating these ideas requires iterations of discussion, feedback, and possibly revision.

Implementation of a widely accessible WSMM toolkit. This paper focused on explaining ideas rather than illustrating technical implementations. In a parallel effort we demonstrated technical feasibility of implementing WSMM by using ADOxx, a widely used metamodeling development and configuration platform for implementing modeling methods that is available through OMiLAB (the Open Models Laboratory), an open community for the conceptualization of modeling methods [28, 29]. ADOxx provides capabilities that can be used to implement all of the metamodels mentioned in this paper plus all of the modeling techniques found in existing Microsoft Word analysis templates used by MBA and EMBA students in recent years. For example, we created a blank work system snapshot in ADOxx and filled in the details from Table 2. ADOxx also can support other work system modeling techniques such as those related to conformance to sociotechnical principles, anticipation of workarounds, customer responsibilities for specific work system activities, and the value of product/services to specific customer groups. Further work and experience with ADOxx is required to identify the most convenient ways to use its modeling capabilities across the many topics in existing WSM templates and other topics based on new metamodels.

Replication for other test cases. Many aspects of this paper, such as the dimensions of the design space in Figure 2, superimposed a rigorous modeling viewpoint on top of useful but less rigorous ideas associated with WSM as it has existed to date. The same type of exercise should be attempted for other sets of ideas, such as general systems theory, sociotechnical theory, actor network theory, soft system methodology, and so on. That would require experts in those areas of theory and practice to identify modeling techniques that are used or could be used, to specify underlying metamodels, and to explore the possibility of producing modeling methods that researchers and practitioners in those areas would find useful.

Further development of the research stream related to WSM, WST, and extensions. The development of WSM started several decades ago with a focus on issues related to P3 and with little or no attempt at rigor other than trying to define terms and encourage organized thinking about work systems that involved IT. The ideas that became WSM and WST evolved gradually. A first book on WSM appeared in 2006; a first version of a work system metamodel in 2010 as an extension of the core ideas; a first article articulating WST appeared in 2013.

The current research extends that stream of research in many directions. It overcomes the limiting assumption that the research was mostly centered around what Figure 2 would call a P3 analysis by business professionals. It eliminates an outdated assumption of a single work system metamodel that needs to be highly detailed (and that until recently was updated incrementally). The new approach is potentially much more valuable because it calls for many alternative metamodels based on the same central metaphor but designed for different purposes.

This paper described metamodels for six of the seven purposes in Figure 2 and noted that different metamodels with different degrees of specificity could be applied for most of those purposes. Length limitations prevented including diagrams of the metamodels. Follow-on research should look at work system-related metamodels in substantial detail, showing them as diagrams, and most importantly, explaining the stakeholder issues that would call for greater syntactic and semantic expressiveness related to specific issues. That research would contrast incremental extensions at each level based on well-known stakeholder concerns (e.g., related to different types of information, product/service offerings, value for customers, application of encapsulated services, and various types of interactions with other work systems) with the combination of more unstructured relationships among modeling techniques.

Resolving Inconsistencies in Declarative Process Models based on Culpability Measurement

Carl Corea, Matthias Deisen, and Patrick Delfmann

Institute for Information System Research, University of Koblenz-Landau, Germany
{ccorea,mdeisen,delfmann}@uni-koblenz.de

Abstract. Contrary to traditional process models, declarative process models define a set of declarative constraints to specify the behavior which a process should adhere to. In the scope of process mining, declarative process discovery aims to derive such constraint sets from event logs. Here, a problem for current discovery techniques is that of inconsistency. That is, dependent of certain event log characteristics, the derived constraint set may contain contradictory constraints. This in turn however makes the discovered model unusable, as contradictory constraints make it impossible to execute declarative process models, thus hampering previous process discovery efforts. In this work, we present an approach for resolving inconsistencies in declarative process models, based on methods from the scientific field of inconsistency measurement. We introduce our approach algorithm and evaluate its feasibility with data sets of the BPI Challenge 2017.

Keywords: Declarative Process Models, Inconsistency Resolution, Declare

1 Introduction

Process Discovery is a key part of Process Mining and comprises techniques for the automated derivation of process models [18, 20]. The creation of processes models is performed by the means of discovery algorithms and techniques, which are applied to entail process models based on observed behaviour, for example that in event logs [6, 17]. Recent efforts have been directed towards so-called declarative process models [17]. Where procedural process models provide an imperative description of how exactly company processes should be performed, declarative process models consist of a set of constraints, that must not be violated. Hence, contrary to the explicitly confined process execution in procedural process models, process execution in declarative process models is all allowed behaviour within the set of constraints.

As the declarative constraint set defines how processes can be executed, the quality of this set is of central importance to companies, in order to ensure a correct and compliant process execution. A potential problem here is that of inconsistency [6]. That is, the set of constraints must not contain any contradictory constraints, as this can make it impossible to perform the process such that it satisfies the set of declarative constraints, i.e. the declarative process model cannot be executed. Ensuring the

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

consistency of declarative process models in the scope of process discovery is widely recognized as a challenging task [6, 8, 15]. In cases of inconsistency, methods are needed to provide an analysis and (semi-) automated resolution capabilities, as a manual analysis and resolution is not feasible in practice due to the potential size of declarative process models.

In this paper, we describe an approach that can automatically resolve inconsistencies in declarative process models. The approach applies quantitative measures from the scientific field of inconsistency measurement [10]. Such measures allow to assign a numerical value to individual constraints, with the informal meaning that a higher value reflects a higher degree of inconsistency. In result, this quantitative assessment is used to pin-point and delete causes of inconsistency in the declarative process model while ensuring a low amount of information loss. We implemented our approach and conducted an evaluation of data sets of the Business Process Intelligence Challenge 2017.

The remainder of this work is structured as follows. In Section 2, we provide a motivational example and introduce preliminaries. Next, Section 3 introduces our approach algorithm to resolve inconsistencies in declarative process models. The evaluation of our implemented algorithm is presented in Section 4. Last, we discuss our approach in the context of related work in Section 5 and conclude in Section 6. As a design choice, we base our approach on the Declare formalisms, which is a widely acknowledged modelling language for declarative process models [6, 12, 17]. Our approach can however be extended to arbitrary declarative process modelling languages as defined subsequently.

2 Background

This section provides an example for the necessity of resolving inconsistencies in declarative process models. Also, prerequisites for the Declare modelling language and culpability measurement are introduced.

2.1 Declare Modelling Language and Motivational Example

Declarative process models can be defined as a set of constraints, modelling the allowed behaviour that processes should adhere to.

Definition 1 (Declarative Process Model). A declarative process model is a tuple $\boldsymbol{M} = (\boldsymbol{A}, \boldsymbol{T}, \boldsymbol{C})$, where $\boldsymbol{A}$ is a set of *tasks*, $\boldsymbol{T}$ is a set of pre-defined constraint *templates*, and $\boldsymbol{C}$ is the set of actual *constraints*, which instantiate the template elements in $\boldsymbol{T}$ with activities in $\boldsymbol{A}$.

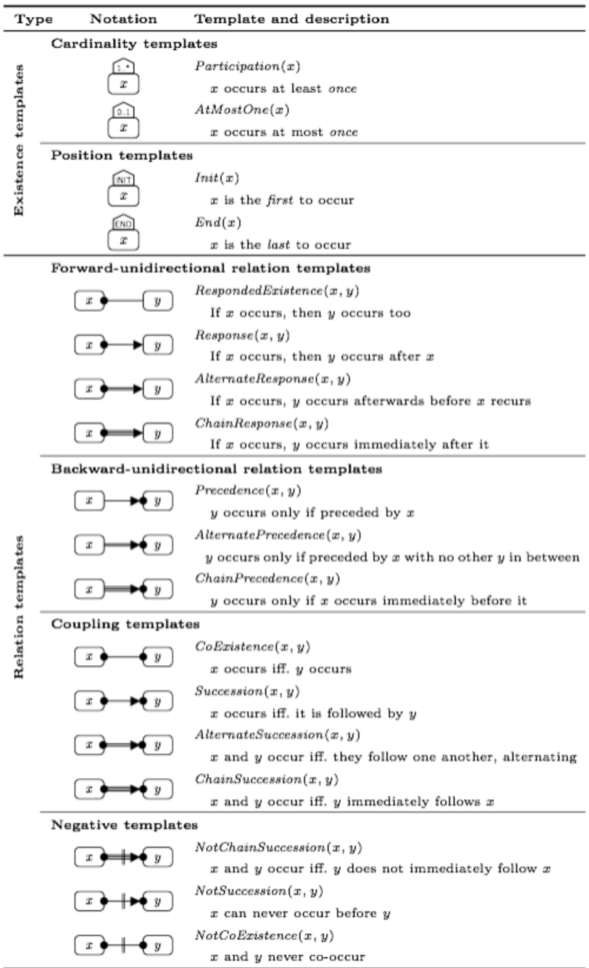
In this paper, we consider Declare, which is a popular declarative modelling language based on a set of constraint templates. Such templates can be used to define declarative constraints by passing tasks as parameters. For instance, the template *init(x)* indicates that every process instance must start with a task x. Declare can be used to define the *relationships* between two individual tasks, by the means of so-called relationship templates, each taking two input parameters. For example, *Response(x,y)* indicates that for any process instance, if *x* occurs, then later *y* must occur. The template *ChainResponse(x,y)* denotes that for any process instance, if *x* occurs, then *y* must occur *immediately* after *x*, i.e., a directly follows relation. Due to space limitations, we ommit a further detailed discussion of all relationship templates. An overview and a short description is provided in Figure 1. Please see [6, 17] for a further discussion.

The template relationships can be hierarchically ordered. Figure 2 shows the subsumption hierarchy of relational Declare templates considered in this work. For example, a *ChainResponse* between tasks *a* and *b* is also a *Response* between *a* and *b*.

Three important templates for the remainder of our discussion are the so-called *negative* relationship templates *NotCoExistence(x,y)*, *NotSuccession(x,y)* and *NotChainSuccession(x,y)*. *NotCoExistence(x,y)* states that tasks *x* and *y* must never appear in the same process instance. *NotSuccession(x,y)* states that *y* must never occur after *x* in a process instance (regardless of how many tasks are in-between *x* and *y*). *NotChainSuccession(x,y)* states that *y* must not *directly* follow *x* for any process instance. These three negative templates can cause inconsistency of the overall declarative process model in combination with other templates. For example, *ChainSuccession(a,b)* and *NotChainSuccession(a,b)* must not appear simultaneously in the same constraint set, as this is a logical contradiction. As the set of Declare templates is pre-defined, it is possible investigate which combinations of templates can cause inconsistencies. Here we distinguish between three types of Declare inconsistencies, namely *trivial inconsistencies*, *generalization-based inconsistencies* and *path-based inconsistencies*.

- **Trivial Inconsistencies.** We define trivial inconsistencies as the co-existence of any negative constraint and its direct complement, i.e. with the same parameters, in the same constraint set. That is, any constraint-set with the templates *CoExistence(x,y)* and *NotCoExistence(x,y)*, OR, *Succession(x,y)* and *NotSuccession(x,y)*, OR, *ChainSuccession(x,y)* and *NotChainSuccession(x,y)* is trivially inconsistent.

- **Generalization-based Inconsistencies.** The subsumption hierarchy entails that generalization relations can also impose inconsistencies in combination with negative templates. For instance, every *ChainSuccession(x,y)* is also a *Succession* between *x* and *y*. Therefore, the two constraints *ChainSuccession(x,y)* and *NotSuccession(x,y)* are contradictory to each other. Based on the subsumption hierarchy shown in Figure 2, all possible combinations of generalization-based inconsistencies can be defined. Intuitively, *NotCoExistence(x,y)* contradicts all other (non-negative) templates with the parameters *x* and *y*, as any possible occurrence of both *x,y* contradicts the *NotCoExistence* of *x* and *y*. *NotSuccession(x,y)* contradicts *Precedence(x,y), Succession(x,y), Response(x,y)* and all inheriting template types. Last, *NotChainSuccession(x,y)* contradicts *ChainPrecedence(x,y), ChainSuccession(x,y)* and *ChainResponse(x,y)*.



Type	Notation	Template and description
Existence templates		**Cardinality templates**
		Participation(x) — x occurs at least *once*
		AtMostOne(x) — x occurs at most *once*
		Position templates
		Init(x) — x is the *first* to occur
		End(x) — x is the *last* to occur
Relation templates		**Forward-unidirectional relation templates**
		RespondedExistence(x, y) — If x occurs, then y occurs too
		Response(x, y) — If x occurs, then y occurs after x
		AlternateResponse(x, y) — If x occurs, y occurs afterwards before x recurs
		ChainResponse(x, y) — If x occurs, y occurs immediately after it
		Backward-unidirectional relation templates
		Precedence(x, y) — y occurs only if preceded by x
		AlternatePrecedence(x, y) — y occurs only if preceded by x with no other y in between
		ChainPrecedence(x, y) — y occurs only if x occurs immediately before it
		Coupling templates
		CoExistence(x, y) — x occurs iff. y occurs
		Succession(x, y) — x occurs iff. it is followed by y
		AlternateSuccession(x, y) — x and y occur iff. they follow one another, alternating
		ChainSuccession(x, y) — x and y occur iff. y immediately follows x
		Negative templates
		NotChainSuccession(x, y) — x and y occur iff. y does not immediately follow x
		NotSuccession(x, y) — x can never occur before y
		NotCoExistence(x, y) — x and y never co-occur

Figure 1. Overview of Declare templates (Taken from [6])

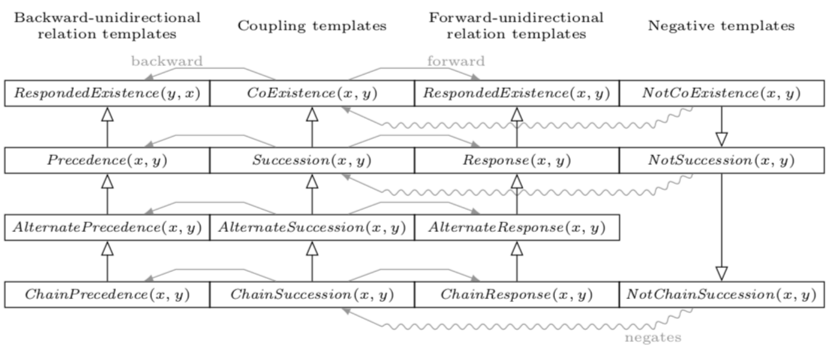


Figure 2. Declare Subsumption Hierarchy (Taken from [6])

- **Path-based Inconsistencies.** So far, we have only discussed the relation of templates with identical parameter signature, e.g. *(x,y)* for both templates. However, *transitive* relations between individual constraints must also be considered. Consider a declarative constraint set consisting of *ChainSuccession(a,b), ChainSuccession(b,c)* and *NotSuccession(a,c)*. The first two constraints state that for every process instance, *a* must directly be followed by *b*. Accordingly, *b* must be directly followed by *c*. Yet, the constraint *NotSuccession(a,c)* demands that *a* must never occur before *c* in the same process instance. Thus, the demands of the first two constraints are contradictory with *NotSuccession(a,c)*. Therefore, inconsistency can occur between groups of templates even if they don't have the same parameters. The definition of path-based inconsistencies will be further discussed in Section 3 based on the definition of so-called *task entailment graphs*.

To clarify, consider the following declarative process model D_1 based on Declare.

ChainSuccession(a,b)	*(i)*	*Response(b,d)*	*(vi)*
NotChainSuccession(a,b)	*(ii)*	*ChainResponse(d,e)*	*(vii)*
NotSuccession(a,b)	*(iii)*	*ChainResponse(e,c)*	*(viii)*
ChainSuccession(b,c)	*(iv)*	*ChainResponse(a,b)*	*(ix)*
NotSuccession(a,c)	*(v)*		

Figure 3. Exemplary Declare model D_1

First, the constraint set in Figure 3 has a trivial inconsistency, as *(i) ChainSuccession(a,b)* and *(ii) NotChainSuccession(a,b)* is contradictory. Also, there are generalization-based inconsistencies. *NotSuccession(a,b)* also entails *NotChainSuccession(a,b)*, therefore, line *(iii)* contradicts line *(i)*. This also yields a conflict between line (iii) and line (ix). Next, the constraints in lines *(i)* and *(iv)* constrain the tasks *abc* as a valid process instance. This path is in contradiction to *(v) NotSuccession(a,c)*, thus a path-based inconsistency. Also, the constraints in line *(i), (vi), (vii)* and *(viii)* define the sequence *abdec* as a valid process instance, which constitutes a path-based inconsistency to *(v) NotSuccession(a,c)*. Path-based inconsistencies also arise for *(ix)*, *(vi), (vii), (viii)* with *(v)*, and (ix), (iv) with (v).

The question may arise how a constraint set such as in Figure 3 can even exist in the first place. Following Di Ciccio et al. (2017), Declare models are mostly automatedly generated in the scope of declarative process discovery. A central problem here are certain completeness characterictics in the underlying event logs. Recording errors or irregularities in process execution can lead to incomplete or distorted logs. To cope with such problems, most declarative process discovery algorithms introduce the notion of a *support factor*, that is, a parameter defining the fraction of traces in which a discovered template must occur in, in order to accept it in the resulting declarative constraint set [6]. Due to the mentioned problems of log completeness, it can make sense to lower this support factor. However, while this increases the amount of constraints, this does not ensure that these constraints are consistent in relation to each other. Thus, methods for post-evaluation in process discovery are needed to ensure that the returned constraint set is consistent.

2.2 Culpability Measurement

A scientific field concerned with the analysis of inconsistent information is the field of Inconsistency Measurement, cf. Grant and Martinez (2018). Here, a central object of study are quantitative measures, which allow to assign a numerical value to (elements of) a constraint set, with the informal meaning that a higher value reflects a higher degree of inconsistency, cf. Thimm (2016) for a survey.

A core notion of our approach are *culpability measures*, which are a type of mentioned quantitative measures [5]. Informally, culpability assesses the degree of blame that an individual constraint carries in the context of the overall inconsistency of the constraint set [11]. Let $\mathfrak{D}$ be the set of all declare constraint sets, and $\mathfrak{C}$ the set of individual constraints in a set $\in \mathfrak{D}$. Then, a culpability measure $\mathcal{C}$ is a function

$$\mathcal{C}: \mathfrak{D} \times \mathfrak{C} \rightarrow [0, \infty) \tag{1}$$

which assigns a non-negative real value to a mapping of a declare constraint set and an individual constraint. An example is the so-called $C_{\#}$ measure [11] which assesses the culpability of a constraint γ for a constraint set $\boldsymbol{D}$ via

$$C_{\#}(\boldsymbol{D}, \gamma) = | \, m \in \boldsymbol{MIS}(\boldsymbol{D}) \mid \gamma \in m \, | \tag{2}$$

This measure is based on so-called minimal inconsistent subsets of the constraint set $\boldsymbol{D}$. Given a constraint set $\boldsymbol{D}$, the minimal inconsistent subsets (***MIS***) of $\boldsymbol{D}$ are defined via

$$\boldsymbol{MIS}(\boldsymbol{D}) = \{\boldsymbol{D'} \subseteq \boldsymbol{D} \mid \boldsymbol{D'} \textit{ is inconsistent and minimal in terms of set inclusion}\} \tag{3}$$

This definition of minimal inconsistent subsets can be used to find inconsistencies in declarative constraint sets. We revisit the exemplary constraint set D_1 from Figure 3. Figure 4 shows the minimal inconsistent subsets of D_1.

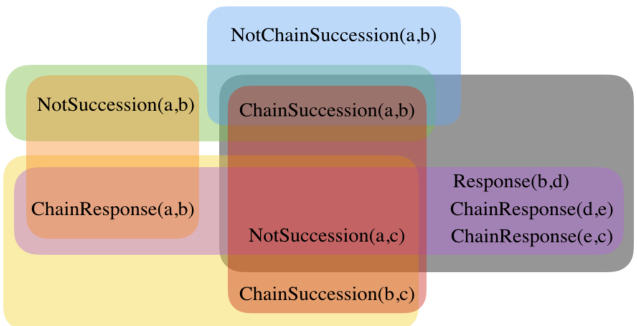

Figure 4. Minimal Inconsistent Subsets for Example D_1 from Figure 3

Based on these ***MIS***, the $C_{\#}$ measure counts the number of minimal inconsistent subsets that a constraint γ belongs to. Applying the $C_{\#}$ measure for the ***MIS*** shown in Figure 4 results in the quantification shown in Figure 5.

C#(D1, ChainSuccesion(a,b))	*= 4*	*C#(D1, Response(b,d))*	*= 2*
C#(D1, NotChainSuccession(a,b))	*= 1*	*C#(D1, ChainResponse(d,e))*	*= 2*
C#(D1, NotSuccession(a,b))	*= 2*	*C#(D1, ChainResponse(e,c))*	*= 2*
C#(D1, ChainSuccession(b,c))	*= 2*	*C#(D1, ChainResponse(a,b))*	*= 3*
C#(D1, NotSuccession(a,c))	*= 4*		

Figure 5. Constraint Culpability for Example D_1 from Figure 3

As a driver for inconsistency resolution, the authors in [5] introduced the notion of a *culpability ranking*, which orders the constraints by their degree of culpability. For the quantification shown in Figure 5, this leads to the following ranking

$$\langle i, v, ix, iii, iv, vi, vii, viii, ii\rangle \tag{4}$$

indicating a prioritization of which constraints should be attended to.

In the following Section, we discuss how this culpability ranking can be exploited for inconsistency resolution and show our algorithm, which includes the computation of minimal inconsistent subsets, culpability assessment and ranking.

3 Inconsistency Resolution Algorithm

3.1 Approach

To resolve inconsistency in a declarative constraint set, there are generally two possibilities [6]: One, a *new* constraint set is constructed, by iteratively moving elements of the old set to the new set, if their introduction does not cause an inconsistency. This technique can be compared to an optimisation problem. A potential disadvantage here is an information loss due to local optima [6]. A different possibility to resolve inconsistency is to use the original constraint set, and iteratively *delete* elements until the constraint set is consistent again. In this context, Grant and Hunter (2011) denote this approach as stepwise inconsistency resolution, and discuss its advantages related to less information loss. In order to resolve inconsistencies with the goal of mitigating information loss, we therefore base our approach on the latter approach of stepwise resolution. Let a constraint set $\boldsymbol{D}$, the deletion of a constraint γ from $\boldsymbol{D}$ is defined via $deletion(\gamma) = \boldsymbol{D} \setminus \{\gamma\}$. Stepwise inconsistency resolution by *deletion* is thus a sequence of deletions $S = <d_1,\ldots,d_n>$. We denote $d_\gamma(\mathbf{D})$ as the constraint set obtained from deleting the element γ from $\boldsymbol{D}$. We denote $\mathbf{\Gamma}_S = < \gamma_1,\ldots, \gamma_n>$ as the individual constraints deleted in the Sequence S via the deletions $d_1,\ldots,d_n$.

The challenge is to find suitable elements which to delete, such that the sequence S results in a low amount of information loss. The authors in [11] do not provide means to determine which elements should be deleted. Here, our algorithm extends the approach by [11] and utilizes the introduced culpability measure $C_{\#}$ to automatedly determine which elements to delete. Let a constraint γ with a $C_{\#}$ value of n_{γ}, then, deleting γ results in the resolution of n_{γ} minimal inconsistent subsets [9]. Thus, we exploit the culpability ranking to find the constraint with the highest culpability, which maximises the number of resolved minimal inconsistent subsets with loosing only one constraint. For example, as can be seen from Figure 4, deleting the constraint *ChainSuccession(a,b)* with the highest culpability value of 4 would result in the deletion of 4 minimal inconsistent subsets.

We iteratively perform the steps of *analysis*, *ranking* and *deletion* until the constraint set is consistent. In the following, we discuss the these steps of our algorithm in detail.

3.2 Algorithm

Our algorithm is shown in Figure 6.

Algorithm 1 Inconsistency Resolution

```
1: procedure RESOLVEINCONSISTENCIES(constraintSet)
2:     mis ← computeMIS(constraintSet)
3:     tempMaxConstraint ← ∅
4:     tempValue ← 0
5:     while mis.size > 0 do
6:         for each c : constraintSet do
7:             culpability ← | m ∈ mis | c ∈ m |
8:             if culpability > tempValue then
9:                 tempMaxConstraint ← c
10:                tempValue ← culpability
11:        constraintSet.delete(tempMaxConstraint)
12:        mis ← computeMIS(ConstraintSet)
```

Figure 6. Approach Algorithm

The algorithm takes as input parameter a set of constraints. A first step is the computation of minimal inconsistent subsets in line 2. (cf. the below discussion). The algorithm then performs the steps of a) analyzing the constraint with the highest culpability (lines 6-10), and b) deleting the constraint with the highest culpability (line 11), in an iterative

```
Algorithm 2 Computation of Minimal Inconsistent Subsets
1: function COMPUTEMIS(constraintSet)
2:     mis ← {∅}
3:     negativeTemplates ← {NotCoExistence, NotSuccession, NotChainSuccession}
4:     negativeConstraints ← getConstraintsInType(negativeTemplates)
5:
6:     for each n : negativeConstraints do
7:         contradictions ← getRulesByTypeAndParams(n.type.complement, n.params)
8:         for each c : contradictions do
9:             mis ← mis ∪ {n, c}
10:
11:    for each n : negativeConstraints do
12:        for each compType : n.type.complementSet do
13:            contradictions ← getRulesByTypeAndParams(compType, n.params)
14:            for each c : contradictions do
15:                mis ← mis ∪ {n, c}
16:
17:    graph = new ConstraintGraph(constraintSet)
18:    for each ns : getConstraintsByType(NotSuccession) do
19:        pathSet ← computeAllPaths(graph, ns.params)
20:        for each p : pathSet do
21:            mis ← mis ∪ {ns, p.getConstraints()}
       return mis
```

Figure 7. Computation of Minimal Inconsistent Subsets in Declare

manner, while there are still inconsistencies (line 5). To clarify, the deletion of constraints intuitively bears the danger of information loss. Yet, deleting constraints might be necessary to restore consistency, i.e. if there exist inherently contradictory constraints. In this context, our approach offers a recommendation as to which element should be deleted, with the goal of maximizing consistency while deleting the lowest amount of constraints possible. We also store the deleted elements and present them to the user for further inspection after the automated resolution process.

A substantial part of our algorithm is the computation of minimal inconsistent subsets, shown in Figure 7. The function depicted in Figure 7 takes as input parameter the declarative constraint set, and returns the set of minimal inconsistent subsets. We initialize an empty set *mis* for storing minimal inconsistent subsets (line 2). Then, the negative template *types*, as well as the individual *constraints* in the *constraintSet* are defined (lines 3-4). In the following, we denote constraints of the types defined in line 3 as *negative constraints*. We then proceed to compute inconsistencies.

Trivial Inconsistencies (lines 6-9). We iterate over all negative constraints to verify if there is a corresponding complement template with the identical parameter signature. This is performed with the method *findRulesByTypeAndParams(type, params)*, which returns a set of sets. This function takes as input a specific template type and parameters (i.e. an ordered pair of tasks, e.g. *a,b*) and returns a set of sets, where the inner sets contain all corresponding constraints. As depicted in line 7, we pass the complement of the respective negative constraints as a parameter. Consequently, the function used in line 7 returns all trivial inconsistencies to the respective constraint *c*. A new minimal inconsistent subset containing a pair with the found constraint and constraint *c* is added to the set of minimal inconsistent subsets.

Generalization-Based Inconsistencies (lines 11-15). Section 2 defines the complements to the negative template types *NotCoExistence*, *NotSuccession* and *NotChainSuccession*. We denote these complements as the *complementSet* of the respective negative template. For all negative constraints γ, we iterate over all constraints of a template type contained within the *complementSet* of γ, with identical parameter signature (line 12). To compute inconsistencies, we again use the function *findRulesByTypeAndParams*. Here, we pass as parameters the current complement type to the current negative constraint, and the parameters of the negative constraint (line 13). This yields all generalization-based inconsistencies to the current negative constraint. We add a set containing the negative constraint and the computed contradicting constraint to the set of minimal inconsistent subsets (line 15).

Path-Based Inconsistencies (lines 17-21). After the previous two steps, all constraints in contradiction to *NotCoExistence*- and *NotChainSuccession* constraints have been identified. The detection of all contradictions to templates of type *NotSuccession* requires a path-based perspective, due to inconsistencies arising through transitivity. To find path-based inconsistencies, we construct a graph-like structure consisting of the relations between individual Declare constraints (line 17). We denote this as a task entailment graph.

Definition 2 (Task Entailment Graph). Let the declarative process model $\boldsymbol{M}$, the task entailment graph of $\boldsymbol{M}$ is a tuple $\boldsymbol{G} = (\boldsymbol{A}, \boldsymbol{E}, \boldsymbol{t})$, where $\boldsymbol{A}$ is the set of tasks in $\boldsymbol{M}$, $\boldsymbol{E} \subseteq \boldsymbol{A} \times \boldsymbol{A}$ is the set of directed edges between activities, and $\boldsymbol{t}$ is a function $\boldsymbol{t}: \boldsymbol{E} \rightarrow \boldsymbol{T}$, which maps an individual edge to a template type from $\boldsymbol{T}$ in $\boldsymbol{M}$.

An edge $\boldsymbol{e} \in \boldsymbol{E} = (a,b)$ indicates that the task *a* entails the task *b* via the constraint $\boldsymbol{t(e)}$. To compute path-based inconsistencies, we iterate over all negative constraints of type *NotSuccession* (line 18). Let the parameters of the respective negative constraint be *a* and *b*, then, we compute all paths from *a* to *b* in the task entailment graph (line 19). Each path from *a* to *b* constitutes a contradiction to *NotSuccesion(a,b)*, thus the path is added to the set of minimal inconsistent subsets (line 21).

We revisit the example constraint set from the example in Figure 3. All non-negative constraints are used to construct the task entailment graph, shown in Figure 8. The graph can be understood, such that task *b* is entailed by task *a* via the template type *ChainSuccession*. The rest of the graph is constructed accordingly.

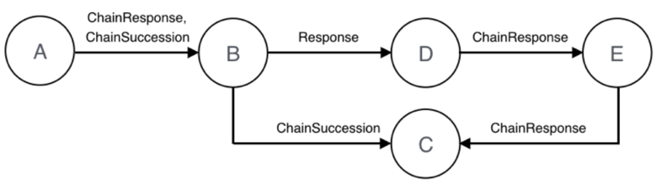

Figure 8. Task Entailment Graph for Example D_1 from Figure 3

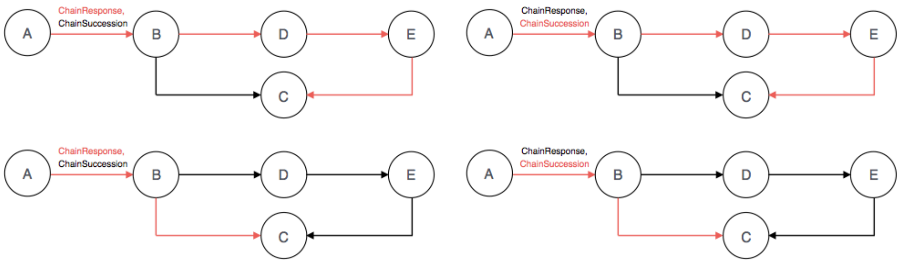
The constraint set in this example also contained *NotSuccession(a,c)*. To search for a contradiction to this negative constraint, we verify if there are paths from *a* to *c*. In total, there are four possible paths from *a* to *c*, shown in Figure 9 (Note that the edge from task a to b in the graph has two types, due to the constraints *ChainResponse(a,b)* and *ChainSuccession(a,b)*). Via these four paths, *c* can transitively be entailed from *a.* Hence, all these paths contradict *NotSuccession(a,c)*. Accordingly, the constraint *NotSuccession(a,c)* and all constraints on the identified paths in the task entailment graph
respectively constitute minimal inconsistent subset.



1. **Figure 9.** Paths found from task *a* to task *c*, for Example D_1 from Figure 3

In our algorithm, following the computed minimal inconsistent subset, the constraint with the highest $C_\#$ culpability is deleted. In the example, this is *ChainSuccession(a,b)* with a $C_\#$ value of 4. The proposed algorithm would therefore delete this constraint to generate $d_{ChainSuccession(a,b)}(D_1)$. Continuing the example, the element with the subsequent highest culpability would be *ChainResponse(a,b)* = 3. A deletion would consequently eliminate all remaining ***MIS***, with a total information loss of two constraints. The sequence $\mathbf{\Gamma}_S$ traces the constraints which were deleted for further inspection, i.e. here $\mathbf{\Gamma}_S$ = <*ChainSuccession(a,b)* , *ChainResponse(a,b)*>.

To conclude, our approach computes all minimal inconsistent subsets with the above algorithm. Then, we delete the constraint with the highest culpability value w.r.t. the $C_\#$ measure. This process is iteratively repeated until the set of constraint is consistent.

4 Evaluation

We implemented our approach to resolve inconsistencies in Declare models in Java. Our evaluation is based on data from the Business Processing Intelligence Challenge 2017 (BPI). In the scope of the BPI, real life event logs are provided.

The analyzed log[1] of the 2017 challenge is an event log of a Dutch financial institute and comprises 262.200 events in 13.087 cases. From this log, we mined a declarative process model in the Declare language using Minerful, which is a state-of-the-art tool for declarative process discovery [6]. We mined three different process

[1] https://www.win.tue.nl/bpi/doku.php?id=2017:challenge

models, with the respective support factors of 75%, 85% and 95%. We then applied our algorithm to all three models. Table 1 summarizes our evaluation results.

Table 1. Results from the application of our algorithm to the BPI challenge log

Support Factor	75%	85%	95%
Discovered Constraints	305	232	207
Initial number of MIS	28954	731	639
Deleted Elements needed	5	1	1
Information Loss	1,63 %	0,43%	0,48%
Runtime	101099ms	9148ms	4695ms

The declarative model mined with a support factor of 75% (*M1*) consisted of 305 constraints. We computed over 28000 inconsistencies in this constraint set, which shows that the lowering the support factor can result in inconsistent models, even for state-of-the-art discovery algorithms. Our algorithm was able to resolve all these subsets in *M1* by deleting a total of only 5 constraints, which equals a total information loss of 1.6% of all initial constraints. This was possible by iteratively determining the constraint with the highest culpability, as deleting this constraint warrants the highest number of resolved ***MIS*** for each iteration. Figure 10 shows an overview of the number of ***MIS*** remaining after each iteration of our algorithm for *M1*. As can be seen, in each of the first three iterations, the number of MIS is reduced roughly by half. Then, a significant reduction from roughly 4000 to 700 MIS can be achieved in iteration 4. Figure 10 also shows the $C_{\#}$ culpability value of the respective constraint with highest culpability in each iteration. As can be seen, the first iteration resolves around 16000 of all 28954 MIS.

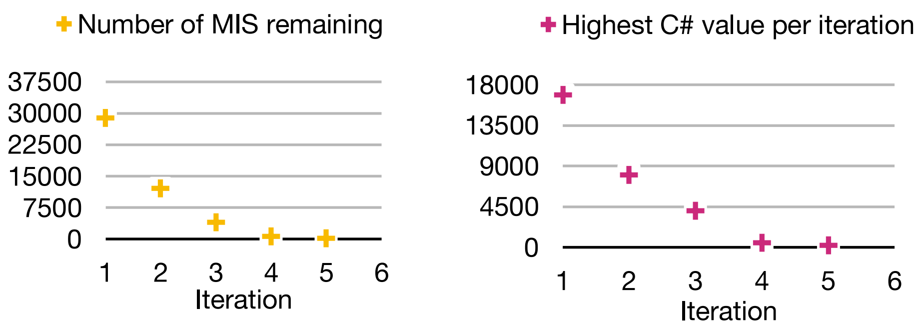


Figure 10. Number of MIS remaining (left) and highest C# culpability for a constraint (right) during the 5 algorithm iterations of resolving *M1*.

Specifically, for *M1*, the five constraints which needed to be deleted to completely resolve inconsistency are shown in Figure 11. The deletions as in Figure 11 can be presented to users. Should they deem this constraint must not be deleted under any circumstances, our approach can be extended with a „whitelist“.

Response(A_Incomplete, O_Accepted), $C_{\#}$ = 16890
Precedence(W_Validateapplication, W_PersonalLoancollection), $C_{\#}$ = 8020
Response(A_Incomplete, A_Pending), $C_{\#}$ = 3348
Precedence(O_CreateOffer, W_PersonalLoancollection), $C_{\#}$ = 496
Precedence(O_Created, W_PersonalLoancollection), $C_{\#}$ = 200

Figure 11. Constraints deleted corresponding to Figure 10.

For the other two process models, mined with 85%, resp. 95%, support factor, we observed an interesting case. The algorithm was able to make the set of constraints consistent by deleting only one element. In both cases, this was the constraint *NotCoExistence(W_PersonalLoancollection, O_Sent)*. Thus, this constraint was part of all ***MIS*** in both models. Apparently, the support factor configuration yielded exactly this one constraint which makes the entire model unusable. This is a good case for our approach idea of determining the constraint that has the highest blame in the overall inconsistency. Based on culpability measurement, our algorithm could effectively resolve all inconsistencies in a low runtime, deleting only one constraint.

Our results show, that even for a low number of constraints, the number of inconsistencies can be rather large. This underlines the need for post-processing techniques in process discovery such as our approach. Our algorithm was able to resolve these inconsistencies.

5 Related Work

This work is related to consistency checking in Business Process Management (BPM) and declarative process discovery.

Consistency checking in BPM is widely recognized as a challenging task [2-6, 13, 15]. A core task here is to ensure the consistency and correctness of BPM related artifacts. We have focused on the area of verifying the consistency of declarative process model artifacts, respectively a resolution of inconsistency. There have been many proposals for the *qualitative* analysis of the reasons of inconsistencies [1, 7, 14]. However, works such as [13, 15, 19] point out the benefits of a *quantitative* analysis. The intuition here is that individual problems can have a different severity. Hence, using such a quantitative assessment as proposed offers a more sophisticated insight on how to resolve inconsistencies in declarative constraint sets [5, 13].

As a directly related work, we identify the report by Di Ciccio et al (2017). Those authors also proposed an approach to resolve inconsistencies in Declare constraint sets. Those authors however do not consider all ***MIS***, but rather build a maximal consistent *new* constraint set. As discussed, we adapt the approach by [9] of resolution by *deletion*. The authors in [6] point out, that the computation of inconsistencies by comparing all possible subsets of constraints is intractable. We agree, that this would be indeed unfeasible. To solve this problem, we therefore defined different inconsistency types in Declare, based on the set of pre-defined template types, which allows for informed comparisons and feasible computation. Our evaluation shows, that the computation of ***MIS*** can be performed in a feasible run-time.

Our algorithm promotes declarative process discovery. Due to the introduced notion of a support factor, existing process discovery techniques can yield inconsistent declarative process models [6, 17]. Our work contributes with an approach for automated resolution, allowing for effective post-processing techniques in process discovery.

6 Conclusion

In this work, we presented an approach for resolving inconsistencies in declarative process models. Our approach was implemented for process models in the Declare language. Our evaluation based on a real-life event log showed that it was possible to compute and resolve around 28.000 minimal inconsistent subsets in a feasible runtime. In the process model mined with 75% support factor in our evaluation, there were 305 constraints. However, only 87 constraints were part of any ***MIS*** (i.e. all other constraints had a $C_{\#}$ value of 0). We therefore argue it makes sense to only consider those constraints that contribute towards inconsistency, as in our approach. Deleting constraints with a $C_{\#}$ value of 0 cannot decrease inconsistency in Declare [9]. Deleting the element with the highest value resolves the most ***MIS***. To the best of our knowledge, this work is the first to incorporate culpability measurement.

In our evaluation, all models could be resolved with a deletion of max. 5 constraints, which equaled an information loss of under 2% in all models. This shows that our algorithm is aligned with our goal of ensuring a low amount of information loss. As a direct limitation, elements to delete are automatedly selected. Hence, it would be possible that knowledge which domain experts would not delete is automatedly deleted. To solve this problem, we store the sequence of deleted constraints for further inspection by domain experts. The aim of this paper was to present an approach for fully automated resolution approach. In future work, we will include the possibility to define constraints which must not be deleted. In case such „marked“ constraint would have the highest culpability value in an iteration run, it would simply be possible to delete the constraint with the next highest $C_{\#}$ value based on the computed culpability ranking.

A limitation of this work is, that our algorithm considers only the predefined set of Declare templates. While the majority of declarative discovery tools only focus on these templates, future work should be directed to find ***MIS*** in arbitrary constraints.

As a key learning, we observed that the support factor used during declarative process mining strongly impacts the resulting model. This should be considered by companies seeking to implement declarative process discovery. Automated approaches as presented in this work should be utilized to verify the consistency of the resulting models to allow for correct and compliant process execution.

Abstract. This paper continues our previous work on modeling support for strategic analysis, by (1) extending a proposed modeling language for strategic analysis (called SAML), among others, with features proposed by business scholars to increase the expressiveness of the analysis, and (2) relating the extended SAML to a language for IT infrastructure analysis (called ITML). Thus, we explicitly contextualize strategic analyses by accounting for the role and impact of IT infrastructure. A scenario in the electricity industry is used to illustrate the analysis proposed.

Keywords: strategic analysis, conceptual modeling, NRGcoin.

1 Introduction

Strategic management, to which strategic analysis belong, can be considered as "a collection of decisions and actions taken by the business management in consultation with all levels within the company to determine the long-term activities of the company" [1, p. 125]. The aim of the actions to be undertaken may be manifold, among others, improvement of the competitive position, or the realization of profit growth. In the era of digital transformation those improvements are often achieved through the application of IT artifacts [2].

In this paper, we focus on a specific area of strategic management, namely strategic formulation [3, 4] and investigate strategic analysis tools and approaches, which can be used to support assessment of, among others, planned (digital) initiatives. In this context, a SWOT analysis (Strength, Weakness, Opportunity and Threat Analysis) is an instrument that is traditionally used [5]. However, although well-established and often used, SWOT is also considered to be vague and oversimplified [5]. As a response, approaches that extend SWOT have been proposed, which, among others, (1) suggest additional organizational aspects on which a SWOT analysis can be conducted [6], such as organizational culture and technologies, or (2) propose to combine a SWOT analysis

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

with the resource-based view [7]. The conceptual modeling community have also acknowledged the need for better instruments supporting strategic analysis [8], and proposed different approaches, cf. [9, 10]. However, they either do not provide semantically rich concepts, are still in their development phase, and/or fall short when it comes to integration with other perspectives (particularly the IT perspective).

Motivated, on the one hand, by this gap, and on the other hand, by the increasing number of digitalization initiatives, in this paper we introduce an instrument for a model-based strategic analysis that explicitly accounts for IT infrastructures. We follow the design school of strategy, cf. [4], thus, we focus on establishing the fit between the internal capabilities and external possibilities [11]. Since the goal of the proposed modeling method is to allow to rationalize the decision made, we treat IT as a white box and consider the large range of both its internal and external factors. To show the applicability of the proposed approach, we focus on the smart grid domain, being one of the domains heavily affected by digital transformations [12]. Particularly, we focus on the blockchain-based NRGcoin initiative in the energy sector [13].

In this paper, we continue and extend our earlier work in the area of multi-perspective valuation supported by modeling, cf. [14], and deliver a three-fold contribution: (1) we extend a Strategic Analysis Modeling Language (SAML) with additional features as found through a literature analysis. Prominently, the proposed extensions include accounting for additional features as proposed by business scholars, and comparing alternative strategic elements, partly on the basis of a root-cause analysis, partly on the basis of relations to other modeling languages; related to the latter, (2) we introduce a mapping between SAML and a language for expressing IT infrastructures called ITML [44]. Thus, we deepen the relation between two particular modeling languages, compared to the brief description of the different relations within the landscape of six languages in [14]; and (3) benefiting from the performed extensions, we deepen a strategic analysis of the NRGcoin initiative. To extend the relationships between SAML and ITML, and to extend SAML, we follow the method proposed by [15] (see Section 3).

The paper is structured as follows. First a short introduction to the strategic analysis with the main focus assigned to a SWOT analysis, as well as the role of conceptual modeling is provided. Then, we describe the extended SAML and its connections to ITML. Next, the case study is discussed showing the applicability of the proposed approach. The paper concludes with final remarks.

2 Background

Strategic Analysis: A strategic perspective emphasizes the long-term outlook on an organization or a network of organizations. This long-term outlook informs analysis of an initiative to be undertaken, e.g., in terms of the long-term organizational goals being pursued and the influence these have on the value-exchanges taking place [16]. Here, strategic orientation refers to analyzing, for a particular organization, the fit between its external situation and internal characteristics [17]. Such analyses are typically done with traditional business school instruments, prominent ones being the 5 Forces approach or Value Chain [18], balanced scorecard [19], and SWOT analysis [5]. For the remainder of this paper we focus on SWOT, since (1) SWOT, in part due to its simplicity, is still an often-used approach to support the strategy formulation [5], and (2) its shortcomings – being conceptually vague, a missing relation to organizational aspects other than strategy – make extensions to SWOT necessary.

SWOT [20] can be used to assess qualities internal to an organization in terms of Strengths (S) and Weaknesses (W), and situations external to the organization in terms Opportunities (O) and Threats (T). Furthermore, SWOT allows one to compare internal qualities to external situation, thus allowing for a so-called strategic fit analysis [5]. A typical SWOT analysis lists favorable and unfavorable internal and external issues in the four quadrants of an analysis table, thus providing a better understanding "how strengths can be leveraged to realize new opportunities and understand how weaknesses can slow progress or magnify organizational threats" [5, p. 1]. Although SWOT is a popular tool, it is considered to be **vague** and **oversimplified** [5], as it constitutes merely a list that does not "provide sufficient context for adequate strategy optimization" [5]. In line with these criticisms, authors of [8] state that (1) concepts of strategic analysis approaches are often ill-defined, with "strength" having a colloquial understanding at best, which is especially lamentable given the contingency of this concept [8, p. 47], and that (2) a relation of the strategic approaches to a detailed understanding of other aspects of an organization is often missing, with, e.g., IT infrastructure being treated as a black box [8, p. 48].

To address this oversimplification, business scholar literature combines SWOT analyses with other approaches. For one, [6] adopts the resource-based view (RBV) of the firm to provide a further assessment of the strengths and weaknesses internal to an organization, as identified per SWOT, so as to make a comparison with competitors. For instance, for a given "strength" one can use the RBV to assess its rarity, substitutability, and how easily the strength can be replicated (or imitated) by others. Yet another example is a telescopic observations strategic framework [7], which maps strengths, weaknesses, opportunities, and threats against suggested categories, such as technological advancements, economic considerations, legal, and regulatory requirements. Furthermore, to prioritize SWOT items, SWOT has been extended with (quantitative) methods, among others, Analytic Hierarchy Process (AHP)-SWOT [21], Analytic Network Process (ANP)-SWOT [22] and Importance-Performance Analysis [23].

Conceptual modeling in support of strategic analysis: To address ill-defined concepts, and a lacking relation to other aspects of an organization, conceptual modeling in general, and enterprise modeling in particular, can play an important role. Indeed, modeling techniques exist that support strategic analysis, in terms of, among others, goal-oriented requirements engineering (GORE), and modeling techniques that explicitly incorporate concepts from business scholar literature on strategic analysis. Regarding GORE, there exist a variety of conceptual modeling techniques, such as i* [24], the Goal-oriented Requirements Language (GRL) [25], or GoalML [26], for a recent overview cf. [27]. With their focus on modeling (short/medium/long)-term goals, these techniques form a useful point of departure for strategic analysis and have also been used to that extent, cf. [28]. However, the focus on goals means that these general

GORE techniques – with a few exceptions – are equally applicable to other types of analyses. Thus, in their key concepts they often do not address ideas pertaining to strategic analysis as we find them in the discussed business scholar literature.

Besides these generic techniques, however, there exist also GORE approaches that do explicitly take on board strategic analysis concerns from business literature. In line with the idea of analyzing the strategic fit, i* explicitly recommends to make both an analysis of the goals internal to actors, and an analysis of the interactions between actors [24]. Likewise, in [29] the authors provide an approach to analyze strategic fit by combining a domain-specific modeling language (which includes concepts such as goals, value proposition, activity, process, competence, etc.) with AHP and heat mapping techniques. The Business Intelligence Model (BIM) [9] offers concepts (e.g., goals, situations, influences, and indicators) to support strategic business analysis in terms of, both (1) continuous monitoring of organizational goal fulfillment based on KPIs, and (2) analyzing the strategic fit, particularly in terms of a model-based SWOT analysis [9]. The defined relations allow to reason on relationships between situations, influences, and indicators. Although the BIM approach seems to be a powerful tool, to the best of our knowledge, it is not integrated with other perspectives, i.e., with elements from the action system and the information system of an enterprise. As a consequence, BIM does not allow for more sophisticated analyses and strategy definition. Finally, some interesting initiatives may be observed to model strategic plans or strategic control in the realm of enterprise modeling, e.g., [10, 30], which aim at capturing, e.g., influence or impact of an initiative on an enterprise and its resources. However, those initiatives either are still in the development phase, or do not consider IT as a first-class citizen.

Existing enterprise modeling (EM) approaches, while providing the possibility to express various views on an organization, do not explicitly account for strategic analysis as defined by business scholars, cf. [14]. Yet, approaches exist that focus on the (strategic) analysis of IT infrastructure. For instance, ArchiMate [31] allows for relating IT infrastructure and strategy, in the sense that: (1) its motivation extension [31, p. 80] allows for expressing strategy concepts, as also reflected in the explicit mappings between ArchiMate's general motivational concepts (e.g., "Goal") and concepts from the business scholar discourse on strategy (e.g., "Mission"), cf. [32]; (2) ArchiMate provides a rudimentary expression of IT infrastructure elements; and (3) ArchiMate provides the ability to express various relationships between layers [31, p. 107]. However, being a language to express enterprise architecture concepts in general, ArchiMate's focus is not a strategic analysis of IT infrastructure per se. Therefore, various extensions have been proposed, e.g., [33, 34]. For instance, ArchiMate has been extended to relate business goals to IT projects and their underlying infrastructure [34]. The aim of this was to enable valuation of IT portfolios using ArchiMate together with Bedell's method, in order to measure the strategic importance of IT infrastructure to organizations' goals. Nonetheless, the overall method only focuses on analyzing IT portfolios of a single organization. Moreover, while concepts from both IT infrastructure and strategy play a notable role here, the focus is actually placed on quantitative valuations. As such, the particular characteristics of IT infrastructure, and the implication these have for the organizational strategy, are less of a focus. Similar to ArchiMate, ARIS [35] offers concepts to analyze an organization from both a strategic perspective and an IT infrastructure perspective, which provides the possibility to relate these perspectives. However, while ARIS offers more expressiveness than ArchiMate, as especially visible on the strategic end which combines ARIS's concepts with a balanced scorecard analysis [35, p. 187], the specific relation between IT and strategic analysis remains under-explored. Finally, in proposing a method for model-driven business-ICT alignment, [16] relates organizations' strategic perspectives (described in e3forces) to their corresponding IT/IS perspectives. However, the model-driven strategic analysis pertains mostly to the external market level only, whereas we require a focus also on the strategic analysis of *internal* (IT) resources. Also, the IT infrastructure is mostly depicted in an informal (arrow-and-boxes like) manner, which inhibits its differentiated analysis.

Strategic analysis of smart grid (SG) initiatives: The emergence of smart grids is driven by the convergence of information and power delivery technologies [12]. The cornerstone of a smart grid is the ability for intelligent devices (e.g., smart meters), dedicated software, processes, etc., to interact and cooperate via an ICT infrastructure. SG initiatives, as any digitalization initiative, are analyzed using the already mentioned instruments, e.g., by means of a SWOT analysis [36]. There are, nonetheless, domain-specific initiatives that aim to evaluate digitalization initiatives in the SG sector, too. For instance, the Smart Grid Maturity Model (SGMM) assesses smart grid initiatives by focusing on (1) six maturity levels (Level 0 Default to Level 5 Pioneering), and (2) eight domains (logical groupings of SG related characteristics). In a similar vein, [37] provides a method to assess the strategic value of IT in SG initiatives by combining the Smart Grid Architecture Model (SGAM), an enterprise-wide and service-oriented framework to describe SG architectures [38], and the Bedell method, which computes the effectiveness and importance of IT elements [39, 37].

3 Modeling Support for Strategic Analysis of IT

Based on the conducted study of business scholar literature and existing work in conceptual modeling, a set of requirements has been identified. Due to space restrictions, we present them clustered into three main postulates.

Postulate 1: Integrating strategic analysis concepts with other elements of an enterprise action system and an information system (IS). *Rationale*: [40] suggests that one of the primary misuse of the SWOT tool is not to link it with the other perspectives on an organization. Indeed, to make a rational decision and decide on the strategy to follow, considering aspects of an enterprise action system (business processes, goals, resources etc.) and IS, is important [4, 40]. In the era of digital transformation, especially the latter, i.e., accounting for the IT perspective, becomes crucial [2]. Indeed, if a modeling language is explicitly related to concepts expressing the IT perspective, one may conduct a strategic analysis that is grounded in the actual IT capabilities of an organization.

Postulate 2: Provision of well-specified, semantically rich concepts which account for proposed extensions to SWOT-based analysis. *Rationale*: Considering two mostly criticized aspects, namely vagueness and oversimplification of concepts used during the analysis process (cf. Section 2), a modeling method supporting a strategic analysis should provide a rich set of domain-specific concepts with a rich set of attributes that one could use during the analysis process. Here, the proposed extensions to SWOT, such as, e.g., the telescopic observations strategic framework [7] could be accounted for. It should be also possible to assign different weights and different probabilities to different situations in order to mark their importance, cf. [23], as well as to input a justification for the assigned classification (e.g., why we consider something as a strength). When it comes to the classification of a given situation, the modeling approach should enable the classification of some situation in some context differently to account for the fact that "external (or internal) factors of an organization are not always opportunity (strength) or threat (weakness); in other words, in different conditions, they have different meanings" [41].

Postulate 3: Accounting for a rich set of relationships, as proposed in the literature. *Rationale*: a SWOT analysis leads to the creation of a table of SWOT items, cf. [5]. As such, it does not account for the complexity of the phenomena and resulting consequences. Indeed, if instead of a table we use a diagram, we are able to represent a network of concepts connected using different relationships. This allows to conduct a more sophisticated analysis. Among others, SWOT is often criticized for providing "no indication of causality among the strengths and weaknesses, nor are they ranked into any hierarchy" [42, p. 5677]. As a response, the said set of relationships should allow to account for causality relations among all SWOT concepts (e.g., cause, effect) as well as to account for hierarchies of different states.

Language design: As we are interested in the integrated view on an enterprise, making a strategic analysis modeling language part of one of the existing enterprise modeling approaches seems to be reasonable. Based on the postulates, we need a language architecture that would, among others, (1) support the definition of semantically rich concepts, i.e., it should allow for expressing attributes and constraints; and (2) account for various aspects of organizational action system and information system. The MEMO family of languages [43], which we already extended in our previous work, cf. [14], has a language architecture fulfilling the stated postulates[1], and accounts for various perspectives on an organization. Therefore, we continue our previous work with MEMO and use the MEMO Meta Modeling Language (MML) [15] to make necessary extensions.

Fig. 1 (the upper part) shows the key concepts of the extended Strategic Analysis Modeling Language (SAML) [14] and their connections to concepts from other MEMO languages such as GoalML (goal modeling) or OrgML (organization structure modeling) [43]. The initial version of SAML has been extended with additional concepts, properties, relationships and constraints, as indicated in Fig. 1. In terms of the employed language design method [15], it is notable that (1) we consider the purposes and use scenarios as first-class citizens that drive the design of the language landscape, (2) we employ the guidelines for concept inclusion from [15]. For example, the concept *involvementContext* (see Fig. 1) and its various attributes and relations conform to both

[1] For an elaborate discussion on the selection of the approach to be extended, see [14].

the guideline "relevance", in terms of relevance to various analysis scenarios, and "invariant semantics", in the sense of its semantics being invariant over different analysis scenarios, as well as the concept having its own essential characteristics. Note that, due to space constraints, we unfortunately cannot further elaborate on the used language design method.

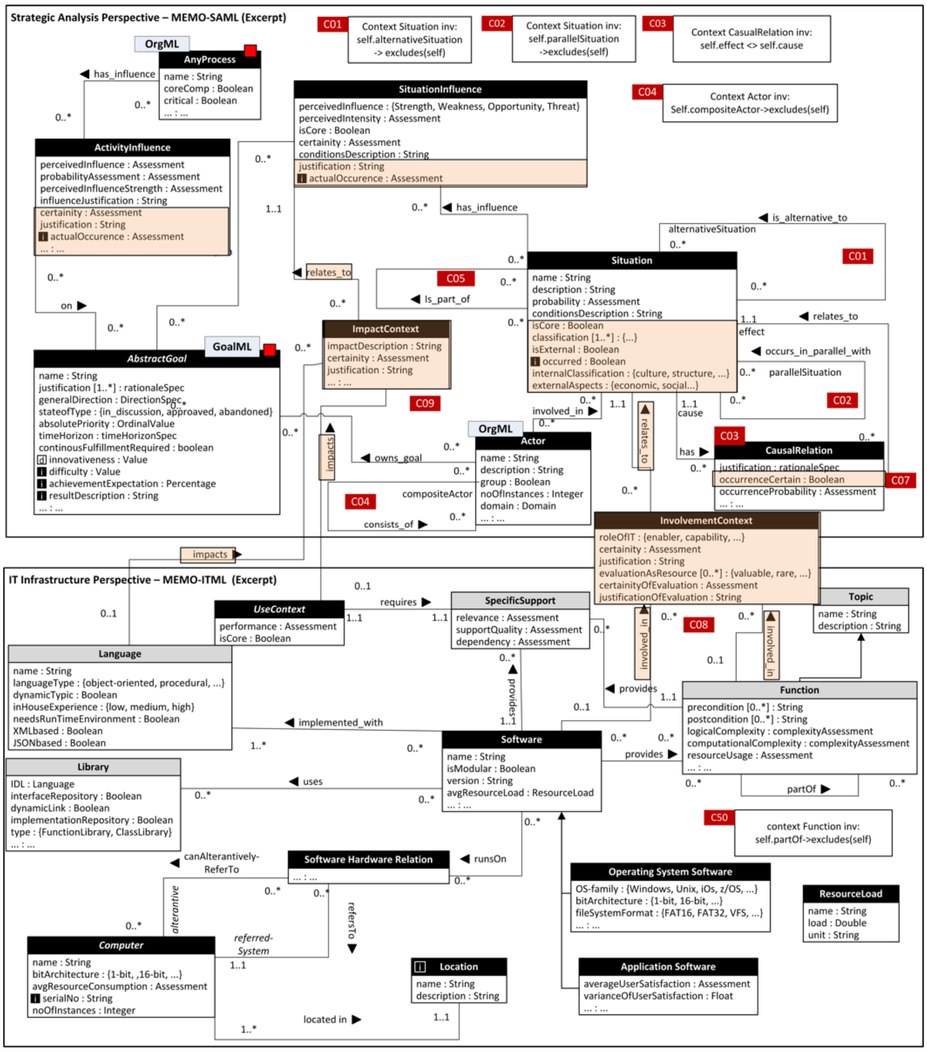

Figure 1. SAML and exemplary relations to the extended ITML

The main concept for analysis is a *Situation*, which, in line with BIM, is defined as a partial state of the world that has a structure consisting of relations and elements. In line with the presented postulates, a *Situation* has a rich set of attributes allowing to describe which state we mean, what is its probability, as well as, e.g., its classification (e.g., whether it is internal or external [4, 1]). For all concepts, in line with Postulate 2, the level of justification, scope, or importance can be defined. *Situations* may be linked to other *Situations* by relationships: (1) *is_alternative_to*, which allows us to model SWOTs arising from different alternatives in the same diagram. This is opposed to a typical SWOT analysis, whereby one has to draw a separate table for each alternative, which also makes it difficult to compare individual SWOT elements to each other; and (2) *occurs_in_parallel_with*, which allows us to cluster situations according to a logical grouping; and (3) *CausalRelation*, which allows to account for the fact that situations are not independent, cf. [42]. Here, to streamline the analysis, we differentiate in the concrete syntax between two types of relationships considering the probability of occurrence (cf. attribute *occurrenceCertain*): *results_in* and *may_lead_to*. Next, to aggregate situations into a more abstract situation, situations can be modeled as a hierarchy using the relation *is_part_of*. Finally, to account for the fact that depending on the context the same situation can be differently classified, we introduce *SituationInfluence* as an Association Class with a set of relevant attributes.

Furthermore, we include explicit relationships to elements of an IT infrastructure (i.e., to ITML [44]), such as *impacts*, *involved_in*, which allow us to identify the role and the type of influence of the IT infrastructure on possible situations. To increase the semantics of those relationships, we benefit from the already mentioned resource-based-view and characterize those relationships with an additional set of attributes such as: (1) evaluation of the IT as resource as valuable, rare, imperfectly imitable, or non-substitutable; as well as (2) assessing the certainty of an evaluation and its justification. In addition, it is possible to assign a role to an IT artifact in a given situation. Here, we differentiate the role by referring to classifications that point out the role of information systems in innovation processes (e.g., as an enabler or capability, cf. [2]).

To ensure that the created models are consistent with the underlying language specification, we extend the corresponding tool for modeling with MEMO, called MEMO4ADO [45]. Finally, MEMO4ADO is used to model the NRGcoin scenario.

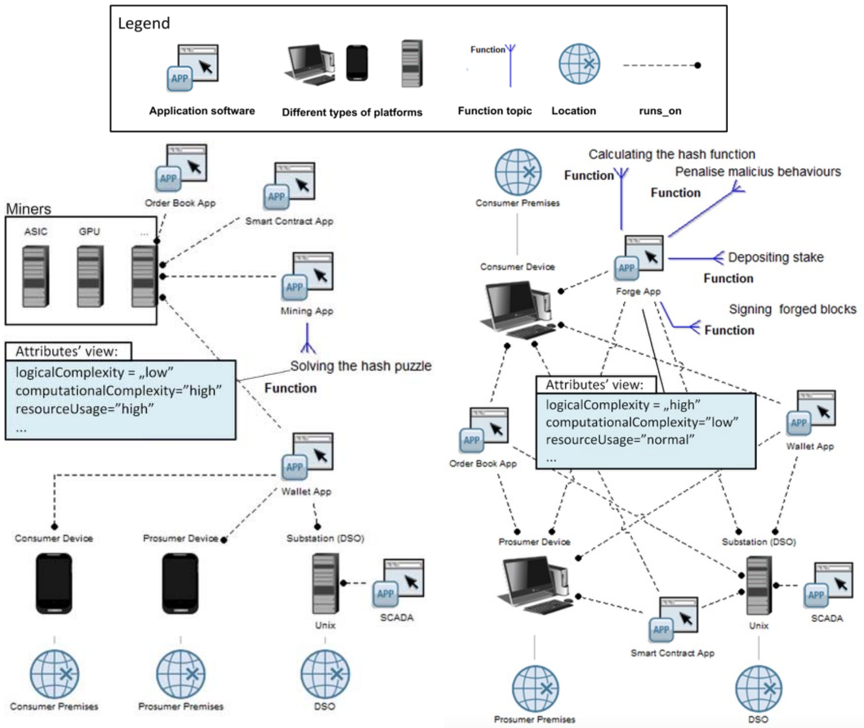
4 Illustration: Strategic Analysis of the NRGcoin Initiative

NRGcoin defines a blockchain-based support policy for renewable energy sources that aims to reward production and consumption of renewable energy [13]. The locally produced electricity is directly fed into the grid and withdrawn by consumers and prosumers. The electricity injected by prosumers is rewarded with NRGcoins, based on the amount of demand within a district the injection helps match. If the injected electricity does not match any demand, it is not rewarded, which encourages prosumers to consume their own electricity [13]. NRGcoins are rewarded to prosumers every 15 minutes, once smart meters inform the distribution system operator (DSO) about the amount of electricity being injected and withdrawn [13]. Thus, during the execution of the NRGcoin initiative, three types of transactions take place: (1) electricity consumption and injection transactions that record the amount of electricity being withdrawn/injected; (2) NRGcoin payment transactions that record: the number of NRGcoins being paid to the DSO for using the electricity grid infrastructure, the number of NRGcoins rewarded to prosumers for their injections, and the number of NRGcoins charged to consumers for their consumption; (3) NRGcoins trading transactions that record how NRGcoins are exchanged in the coin market against fiat currencies.

A tamper-proof ledger, as the one offered by a blockchain, serves as a promising mechanism to record these three types of transactions. Blockchain ledgers are distributed among the nodes that participate in the network. Transactions are organized in blocks that are chained up into blockchains. Every node in the network has access to the whole history of the transactions, and can check the validity of the blocks and transactions. Lacking a central authority to keep track of, validate, and write new records in such a distributed ledger, blockchain-based solutions make use of "consensus mechanisms" to reach agreement among nodes on who will (1) validate the transactions, (2) create the next block, and (3) broadcast it to the rest of the network [46].

In our previous work [14], we have demonstrated the advantages of NRGcoin initiative in achieving the following goals of stakeholders: (1) the share of green energy consumption is increased as consumers can purchase green energy at a fixed rate of NRGcoin; (2) self-consumption is promoted for prosumers because injection that does not match local demand will not be rewarded; (3) stress on DSO grids is relieved because local demand is met by local supply, and extra supply is self-consumed by prosumers, hence, there is less energy that needs to be transferred further up to the grid; (4) utilities' operational costs are reduced as most of the daily operations are automated with the help of smart contracts; and last but not least, (5) no dedicated budget from the government is needed because incentives to both green energy consumption and green energy production come from NRGcoin itself. In this paper, we address the problem of deciding which consensus protocol should be used to create the blocks in the NRGcoin ledger: Proof of Work (PoW) or Proof of Stake (PoS), cf. Fig. 2.

PoW is a pure cryptography consensus mechanism whereby so-called miners interested in becoming the creator of the next block compete to solve a cryptographic puzzle [46]. The first miner that finds the correct solution to the puzzle will become the creator of the next block. This miner will be rewarded with new coins (referred to as mined coins) and earns also fees associated with the validated transactions. In turn in PoS, blocks are said to be "forged" or "minted" instead of "mined". Candidates for the creator of the next block are referred to as validators. The probability for a validator to become actually the creator of the next block is in proportion to the amount of coins the validator owns. The selected validator earns fees associated with the validated transactions. Since the PoS technique is prone to security issues due to its simplicity [47, 48], various socio-economic counter-measures have been introduced. E.g., validators can be requested to lock a certain amount of coins as a stake in a security deposit in order to become a candidate for the next block. If the selected validator conducts malicious behavior while validating the next block, this validator will be punished by losing the stake (economical measure). A similar punishment measure can also be put in place from the social point of view, whereby the selected validator is required to sign the block she/he creates. If a peer node detects faults in the block and reports it to the network, the validator will be punished with bad reputation and will be forbidden to participate in future validations. In an extreme case, the node can even be expelled from the network.



(a) PoW IT infrastructure overview (b) PoS IT infrastructure overview

Figure 2. Overview on IT Infrastructure of Alternative Consensus Mechanisms

The decision on the used consensus protocol (PoS versus PoW) is important, as the protocols exhibit differing characteristics, which directly or indirectly impact the defined goals. We elicit and compare these characteristics by means of a SAML diagram for strategic analysis in combination with an ITML diagram for IT infrastructure analysis. Note that we focus only on those parts of the analysis that illustrate the added value of our approach, i.e.: (1) comparing alternative situations; (2) allowing to analyze how situations form a SWOT for achieving goals; and (3) enabling analysis on how situations relate to each other in terms of a root-cause analysis.

First of all, being a renewable energy initiative itself, NRGcoin's main goal is to promote energy efficient solutions (G1) as well as to promote production and consumption of renewable energy (G2). NRGcoin users are consumers and prosumers at the lower end of the electricity grid with the aim to set up a local energy community among them (G3) that calls for social responsibilities (G4). Achievement of the aforementioned goals can be examined from various perspectives. In the following, we show how the respective IT infrastructures underlying the PoW and PoS protocols (depicted in Fig. 2a and Fig. 2b respectively) contribute to the fulfillment of the goals of the NRGcoin initiative.

Looking at Fig. 3, we notice that the distinct features of PoW and PoS lead to two alternative *Situations* being the roots for two chains of Situations connected via causal relations differentiated into “results in” or “may lead to”, as explained in the previous section. Looking at the left side, among others, the mining application of PoW is simple, but very heavyweight, as the simple logic of PoW needs to be repeated several times until a hash code satisfying the condition can be found. As a consequence, mining takes on average long to finish, hence it likely causes delay to the validation of transactions (G5). In contrast, concerning time consumption, we find that PoS provides timely validation. In the diagram this is indicated by the situation “timely validation, little to no delays”, which subsequently, among others, traces back to a function topic “sign forged blocks” (an IT infrastructure element). Importantly, this tracing is done via an annotated SAML-ITML relation that (in line with the resource-based view of the firm, cf. the meta model in Section 3) is, both (1) “valuable”, with the justification that for PoS the signing of forged blocks happens in a short time compared to mining in PoW, and (2) “rare”, with PoS being novel and thus, not yet widely adopted. Moreover, due to its heavy weight, mining consumes a significant amount of electricity, which makes PoW a less energy efficient solution (G1). In our models, we first trace this significant electricity consumption to the situation “increased consumption of energy”, which has a relation “Weakness: very high” with goal G1. Subsequently, we trace this situation to the function topic “Solve the hash puzzle”, whose specific properties and underlying IT infrastructure we can further examine with the help of the corresponding IT infrastructure diagram (Fig. 2). More specifically, in the IT infrastructure diagram we find that the function topic “Solving the hash puzzle” is provided as a functionality of a “Mining App”, and that this functionTopic has the attribute “resourceUsage=high”. Furthermore, the resource use is also reflected in the underlying hardware required to run the mining application which often runs on dedicated, resource-intensive hardware (cf. Fig. 2a).

Considering that the validation is a time-consuming task, the management of the NRGcoin ledger may be outsourced to a set of miners, as indicated by the relation “may lead to”. This situation has two implications. Firstly, miners, being outside of the local energy community, have no access to the green energy produced within the community, hence would rather sell all earned NRGcoins than use them to purchase green energy for consumption. Therefore, this situation (being external from the point of view of our initiative) is a threat of PoW with respect to “G2: Promote Production and Consumption of Renewable Energy”. Secondly, miners have no sense of belonging to the community, hence their participation in validating transactions and mining is purely profit-driven. This is a threat towards “G4: Increasing Social Responsibility”.

In contrast to PoW, the PoS algorithm is complex (as it needs to integrate additional functions that implement social and financial counter-measures, Fig. 2b), but lightweight. As PoS is lightweight, validators consume modest amount of electricity to fulfill their tasks, hence PoS is an energy efficient solution (G1). Therefore, common

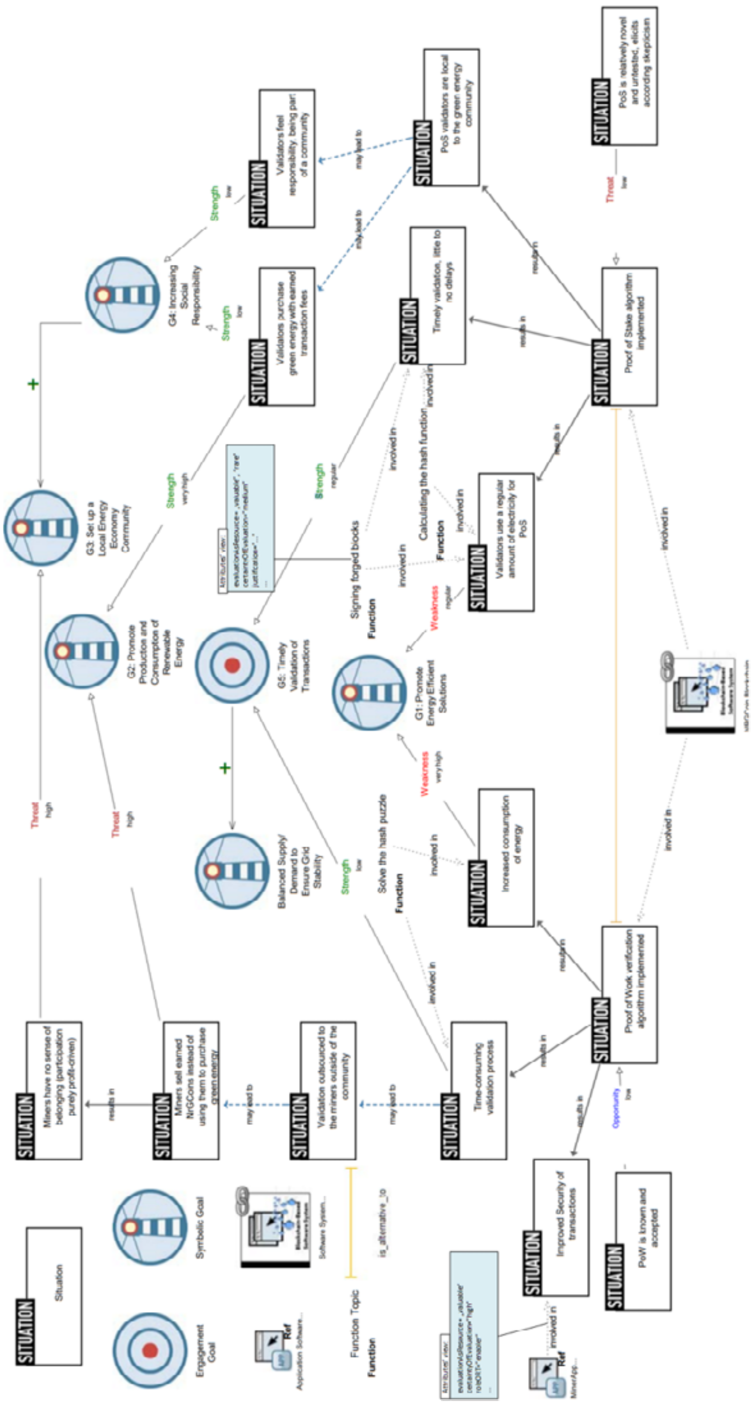


Figure 3. An excerpt of the Strategic Analysis Diagram of NRGcoin: PoW vs. PoS

PCs, which almost every family is in possession of, suffice to run the light PoS algorithm efficiently. This situation is a strength of PoS, because it allows any member of the NRGcoin community to become a validator. Unlike PoW, PoS validators are the same local participants (prosumers, consumers or DSO) in the green energy community, which can be interconnected by a local-area network (LAN). This has two implications. On the one hand, validators can purchase green energy with the earned NRGcoins. This is a strength of PoS contributing positively to G2. On the other hand, in addition to earn transaction fees, another reason for members of the local community to perform the role of validators is because they feel responsible to maintain the operation of the NRGcoin. This is a strength of PoS with respect to G4.

5 Conclusions

In this paper, we have shown how enterprise modeling can support the strategic analysis of digitalization initiatives by using a combination of two modeling languages: SAML, for expressing strategic analyses, and ITML, for expressing IT infrastructure. Specifically, we showed how (1) SAML allows for explicitly relating strategic elements to each other, allowing for root cause analyses, and how (2) the explicit relation of SAML to ITML can be used to contextualize elements of a strategic analysis.

In terms of limitations, firstly, we notice that the produced SAML models become complex quickly. While this complexity is not a novel phenomenon (goal models tend to have a similar issue), it should be addressed since it makes the models hard to interpret, thus potentially inhibiting the added analysis capabilities started with. Secondly, in this paper we focused on modeling languages to support mainly strategic analysis of IT infrastructures. Therefore, additional extensions are required to support the strategic formulation phase in its entirety. A method to support such a model-driven analysis is also part of our future work.

Zwischenbetriebliche Integration in der Möbelbranche: Konfigurationen und Einflussfaktoren

Norbert Frick[1]

[1] University of Koblenz-Landau, Institute for IS Research, Koblenz, Germany
{norbert.frick}@uni-koblenz.de

Abstract. In der Möbelbranche in Deutschland existieren seit mehreren Jahren Bemühungen, zwischenbetriebliche Kooperationen zu unterstützen. In einigen Branchensegmenten (vor allem Küche und Polster) konnten sich Infrastrukturen zur Integration etablieren, die von vielen Branchenteilnehmern akzeptiert und genutzt werden. Trotz dieser Entwicklung sind überraschende Unterschiede zu beobachten: Mängel in der Prozessintegration, Unterschiede im Standardisierungsfortschritt zwischen den Branchensegmenten und die Entstehung unterschiedlicher Infrastrukturen zur zwischenbetrieblichen Integration. Die Konfigurationsanalyse nach Lyytinen und Damsgaard betrachtet Unternehmensnetzwerke als Konfigurationen zwischenbetrieblicher Integration, die einem stabilen Muster von Kooperationsformen entsprechen. Sie ist insbesondere dafür geeignet, Unternehmensnetzwerke auf Branchenebene zu untersuchen. In 21 Interviews mit 19 Organisationen wurden Daten zu Konfigurationen zwischenbetrieblicher Integration in zwei Branchensegmenten der Möbelbranche (Küche und Polster) in Deutschland erhoben und analysiert. Insgesamt wurden vier Konfigurationstypen (Mittler, Branche, Dyade und Triade) identifiziert, die in 17 konkreten Konfigurationen zum Einsatz kommen (Mittler (4-mal), Branche (5-mal), Dyade (6-mal) und Triade (2-mal)) und von 39 Einflussfaktoren geprägt sind.

Keywords: Konfigurationen, Einflussfaktoren, Interorganisationssysteme, Möbelbranche

1 Einleitung

Die Arbeitsteilung auf nationaler und internationaler Ebene nimmt in der vernetzten Welt beständig zu. Die Konzentration auf bestimmte Teile der Wertschöpfungskette führt zu einem verstärkten Einsatz von Interorganisationssystemen [1]. Zugrunde liegende Geschäftsmodelle ändern sich ebenso wie die sie unterstützenden Organisationsformen [26]. Die Dynamik der wirtschaftlichen Entwicklungen reflektiert sich insbesondere in der weiter zunehmenden Bedeutung von interorganisatorischen Informationssystemen (IOIS), die zur elektronischen Unterstützung der arbeitsteiligen Prozesse unabdingbar geworden sind.

Mit zunehmender Arbeitsteilung wächst die Heterogenität von organisatorischen und technologischen Eigenschaften, die miteinander in Einklang zu bringen sind.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Potenzielle Kooperationspartner stehen vor der Herausforderung, die für sie passende Form einer zwischenbetrieblichen Integration zu identifizieren. Mehrere Autoren suchen die Heterogenität über modellhafte Beschreibungen nachzuvollziehen (u.a. [11], [21], [7]), betrachten dabei aber meist nur Teilausschnitte der Realität (z.B. die reine Einführung, die technische Umsetzung oder die Auswirkungen eines IOIS). Die Berücksichtigung der Komplexität zwischenbetrieblicher Kooperation und der damit verbundenen zwischenbetrieblichen Integration gelingt nur selten in einem zufriedenstellenden Maß [8].

In vielen Branchen sind Phänomene zu beobachten, für die nur mit einem vertieften Verständnis der Komplexität zwischenbetrieblicher Kooperationen Erklärungsansätze zu ermitteln sind. Eine dieser Branchen ist die Möbelbranche in Deutschland. Trotz der Nutzung etablierter IOIS zur Planung und Auslieferung von hoch konfigurierbaren Produkten zeigen sich konstant hohe Reklamationsquoten von bis zu 40%[1]. Selbst auf Branchensegmentebene sind Unterschiede zu beobachten. Im Branchensegment Polster und Branchensegment Küche werden hoch konfigurierbare Produkte produziert und verkauft, trotzdem unterscheiden sie sich u.a. in der Verbandsstruktur sowie der Infrastruktur zum zwischenbetrieblichen Datenaustausch.

Es bleibt unklar, welche Formen der zwischenbetrieblichen Integration in der Möbelbranche etabliert sind und welche Eigenschaften diese Formen maßgeblich beeinflussen. Entsprechend wurden folgende Forschungsfragen formuliert: (a) *Welche Formen der zwischenbetrieblichen Integration existieren in der Möbelbranche?* und (b) *Welche Faktoren besitzen Einfluss auf die identifizierten Formen der zwischenbetrieblichen Integration?* Da es bis zum Zeitpunkt der Untersuchung keine branchenweiten Arbeiten in der Möbelbranche zu IOIS gab, bot sich die Branche als Untersuchungsraum an, um eine erste Aufnahme und Analyse von Konfigurationen zwischenbetrieblicher Integration durchzuführen.

Im weiteren Verlauf dieses Beitrags wird zunächst der Stand der Forschung zu Formen der zwischenbetrieblichen Integration und der darauf einwirkenden Einflussfaktoren beleuchtet (Kapitel 2). Im Anschluss wird das mehrstufige Forschungsvorgehen erläutert (Kapitel 3). Kapitel 4 diskutiert die Ergebnisse, während Kapitel 6 eine Zusammenfassung und kritische Würdigung enthält.

2 Formen zwischenbetrieblicher Integration

Es finden sich zahlreiche Formen zwischenbetrieblicher Integration in der Literatur, die unterschiedliche Aspekte fokussieren. Viele Gestaltdefinitionen beziehen sich auf eine oder mehrere Ebenen, in denen eine Klassifikation der von den jeweiligen Forschern wahrgenommenen Formen zwischenbetrieblicher Integration formuliert wird. Exemplarisch seien die Arbeiten von Bakos [2], Choudhury [9], Klein [13], Benasou und Venkatraman [4] und Schubert [25] erwähnt.

---

[1] Küche: https://www.moebelfertigung.com/issues/17?topic_id=103 („Fehler in der Produktion vermeiden"), LA 10.09.2018; Polster: http://www.vhk-herford.de/presse/item/moebelhandel-will-in-die-ueberholspur-wechseln/, LA 10.09.2018

Die reine Formenbestimmung zwischenbetrieblicher Integration markiert jedoch nur den Anfang einer systematischen Auseinandersetzung mit den interorganisatorischen Strukturen und den sie unterstützenden IOIS. Als typische Beschreibungsmodelle beinhalten Klassifikationsmodelle in der zwischenbetrieblichen Integration eine möglichst umfassende Kollektion aller möglichen Ausprägungen eines IOIS. Bekannte Ansätze wurden unter anderem von Barrett und Konsynski [3], Klein [13] oder Hong [12] entwickelt. Sie konzentrieren sich vor allem auf die Klassifikation eines IOIS unter Berücksichtigung verschiedener Kriterien, die sich üblicherweise auf technologische, organisatorische und/ oder institutionelle Eigenschaften beziehen. Allerdings fehlt diesen Modellansätzen in der Regel jegliche Entwicklungsperspektive, da sich aus den Charakteristika eines IOIS nicht zwangsläufig die zu deren Entstehung führenden Einflussfaktoren und Veränderungsmechanismen ableiten lassen.

2.1 Einflussfaktoren auf Formen zwischenbetrieblicher Integration

Typische Formen zwischenbetrieblicher Integration, die in den zuvor genannten Arbeiten aber auch in vielen anderen Beiträgen thematisiert werden, sind von Faktoren auf institutioneller, organisatorischer und technischer Ebene abhängig. Wenngleich manche Arbeiten solche Faktoren nicht explizit erwähnen, so lassen sie sich aus dem jeweiligen Kontext heraus ableiten. Rodon und Sese [22] charakterisieren z.B. vier IOIS-Typen mit Hilfe der beiden Einflussfaktoren Macht und Regeln. Die Autoren beziehen sich hauptsächlich auf die beiden vorgenannten Differenzierungsmerkmale, indem sie anhand der Machtverhältnisse und Regelwerke die vier Typen beschreiben. Trotzdem fließt z.B. im Typ „Market" das Charakteristikum „Wettbewerb" mit ein, während im Typ „Hub" die zwischenbetrieblichen Beziehungen und die darauf basierenden Vertragsgestaltungen zusätzlich eine Rolle spielen.

Implizite Untersuchungen bzw. Analysen von Einflussfaktoren sind in vielen Beiträgen zu finden. Eine gemeinsame konzeptionelle Betrachtung von Formen zwischenbetrieblicher Integration und ihrer jeweiligen Einflussfaktoren gibt es hingegen nur selten. Meist findet man aus Einzelperspektiven heraus motivierte Untersuchungen (z.B. Information Sharing [3], IOIS Implementation [6], oder Transaction Costs [10]), die punktuell einzelne Einflussfaktoren herausgreifen und im Rahmen ihrer Perspektive untersuchen. Lyytinen und Damsgaard [16] schlagen in ihrem Positionspapier die Konfigurationsperspektive als adäquate analytische Linse vor, um einen ersten umfassenderen analytischen Blick auf Integrationsformen und ihre Einflussfaktoren zu gewinnen.

2.2 Konfigurationen zwischenbetrieblicher Integration

Lyytinen und Damsgaard [16] verstehen unter IOIS-Konfigurationen organisierte Cluster von IOIS-Nutzern, die durch ausgewählte Einflussfaktoren, sogenannte Schlüssel-Elemente, beeinflusst werden. Dabei berufen sie sich auf ähnliche Einsätze des Konfigurationsbegriffs in der Physik, in der Organisationsforschung oder in Service Science, die aus ihrer Sicht auf die IOIS-Domäne übertragbar sind. Eine bekannte Definition entstammt dem Buch von Miller und Friesen [18], die Konfigurationen auf den Organisationskontext beziehen: „These can be defined as commonly occurring clusters of attributes or relationships […] that are internally cohesive, such that the presence of some attributes suggest the reliable occurrence of others.” Die Grundlage einer Konfiguration bilden dementsprechend nicht nur die einzelnen Faktoren (attributes or relationships), sondern auch die zwischen ihnen existierenden Abhängigkeiten (internally cohesive). Meyer et al. [17] betonen dabei „coherent patterns“, schlüssige Muster, die sich aus den Interdependenzen der einzelnen Attribute ergeben. Konfigurationen basieren also nicht auf einem zufälligen Zusammenkommen einzelner Faktoren, sondern reflektieren eine begrenzte Anzahl stabiler Zustände [16].

Die von den Autoren beschriebenen Konfigurationstypen (Dyade, Hub and Spoke, Industry und Community) und die sie beschreibenden Schlüssel-Elemente (organizing vision, key functionality, mode of interaction, structure und mode of appropriation) stellen eine Auswahl der von ihnen im Laufe ihrer Forschungsarbeiten vorgefundenen Konfigurationen und Einflussfaktoren dar. Diese Auswahl ist vor dem Hintergrund bereits existierender Arbeiten nicht vollständig, bietet aber als eine der ersten Arbeiten einen konzeptionellen Rahmen für eine ganzheitliche Untersuchung zwischenbetrieblicher Integrationsformen und der auf sie einwirkenden Einflussfaktoren. Daher wurde die von Lyytinen und Damsgaard vorgeschlagene Konfigurationsperspektive als analytische Linse zur Beantwortung der in Kapitel 1 gestellten Forschungsfragen angewendet.

3 Forschungsansatz

Die Diskussion der Konfigurationsperspektive im vorangegangenen Kapitel zeichnet ein multiperspektivisches Bild der gegenwärtigen Betrachtungsweisen von Unternehmensnetzwerken und die sie unterstützenden IOIS. Es reicht nicht mehr aus, sich auf ein IOIS selbst als Untersuchungsgegenstand zu fokussieren. Die Forschungsfragen (siehe Kapitel 1) zielen auf ein möglichst ganzheitliches Verständnis der technischen, organisatorischen und institutionellen Eigenschaften von IOIS-unterstützten Unternehmensnetzwerken ab.

In der Konsequenz sind als Untersuchungsgegenstand die Konfigurationen zwischenbetrieblicher Integration selbst zu wählen. Die Konfigurationsperspektive erlaubt die Verwendung einer in sich geschlossenen Logik und Sprache zur Beschreibung/ Modellierung und ganzheitlichen Untersuchung von IOIS-gestützten Unternehmensnetzwerken. Als Untersuchungsbereich werden gemäß der in Kapitel 1 beschriebenen Motivation die beiden Branchensegmente Küche und Polster gewählt. In beiden Branchensegmenten gibt es gegenwärtig kaum öffentlich zugängliche Informationen über Form und Eigenschaften der darin aktiven IOIS-gestützten Unternehmensnetzwerke.

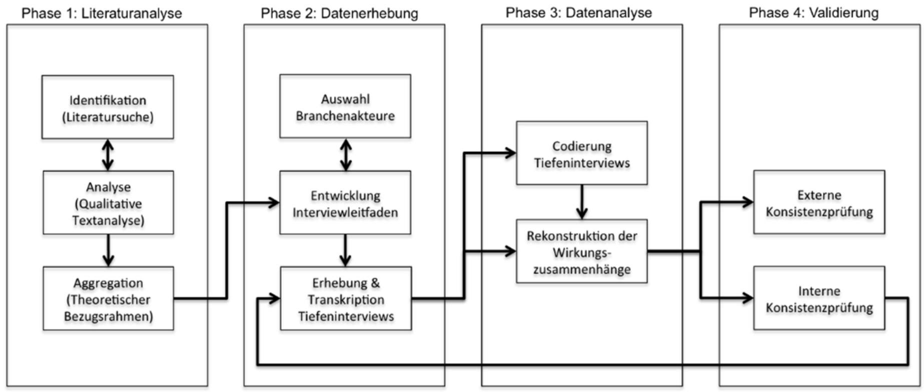

Abbildung 1: Forschungsvorgehen zur Konfigurationsanalyse

Die Konfigurationsanalyse nach Lyytinen und Damsgaard [16] bietet keine vordefinierten Verfahrensweisen für ein Forschungsvorhaben, sondern nur eine auf Basis eines gewählten Forschungsinteresses begrenzte Anzahl an Vorschlägen. Der explorative Charakter des Forschungsprojekts legt nahe, dass die genutzten Forschungsmethoden flexibel genug sein müssen, um dem Forscher genügend Freiraum zur Kreativität in der Informationsbeschaffung zu lassen [5]. Gemäß der Problemstellung (vgl. Kapitel 1) fehlt es an methodischen und inhaltlichen Informationen, um die gestellten Forschungsfragen zur Möbelbranche sinnhaft beantworten zu können. Folglich ist eine Datenerhebung in der einschlägigen wissenschaftlichen Literatur zur Abgrenzung des Konfigurationsbegriffs sowie der Operationalisierung der Konfigurationsanalyse ebenso notwendig, wie die empirisch belegte Bestimmung von Konfigurationen in den beiden zu untersuchenden Branchensegmenten. Dementsprechend wurde ein mehrphasiges Forschungsvorgehen auf Basis der Konfigurationsanalyse entwickelt, das vier Hauptphasen umfasst (vgl. Abbildung 1):

- Phase 1: Literaturanalyse ((1) Identifikation und Beschaffung von relevanten Literaturbeiträgen zu Konfigurationen zwischenbetrieblicher Integration, (2) Analyse der gefundenen Literaturbeiträge hinsichtlich Konfigurationstypen und Einflussfaktoren, (3) Ableitung eines Bezugsrahmens zur Weiterverwendung in der Phase der Datenerhebung, (4) Deskriptive Codierung der vorgefundenen Beiträge)
- Phase 2: Datenerhebung ((1) Entwicklung eines semi-strukturierten Interviewleitfadens, (2) Auswahl von relevanten Akteuren mittels „Snowball or chain sampling" [20], (3) Durchführung von 21 Tiefeninterviews mit 19 Unternehmen/ Organisationen [19].
- Phase 3: Datenanalyse ((1) Deskriptive und Strukturierte Codierung der Interviewtransskripte [23], (2) Durchführung von der Codierungszyklen, (3) Auswertung von mehr als 550 identifizierten Codes)
- Phase 4: Validierung ((1) Validierung von Aussagen mittels inhaltlicher Triangulation ([19], [20]), (2) Validierung mit begleitenden Dokumenten)

4 Konfigurationen zwischenbetrieblicher Integration in den Branchensegmenten Küche und Polster

Insgesamt können 39 Einflussfaktoren aus der Analyse der Codierung der 21 Interviews identifiziert werden, wobei 7 Faktoren (Marktdominanz der Filialisten, Wettbewerb Eigenmarken (Händler), Wettbewerb Eigenmarken (Verbände), Barriere zur Vertikalisierung der Hersteller, Verbandsdienstleistungen Verbände, Stammdatenverwaltung Verbände und Organisation Intermediäre) in beiden Branchensegmenten eine Rolle spielen. Im Küchensegment können 18 Einflussfaktoren den Konfigurationen zugeordnet werden, während es im Branchensegment Polster 28 Faktoren sind. Die in beiden Branchensegmenten vorgefundenen Einflussfaktoren und Konfigurationen zwischenbetrieblicher Integration lassen sich zusätzlich auf unterschiedlichen Analyseebenen identifizieren und diskutieren: Ebene der *Handelsbeziehungen*, Ebene der *Technischen Realisierung* und Ebene der *Standardisierung*.

4.1 Ebene der Handelsbeziehungen

Es lassen sich zwei Typen von Daten identifizieren, die zwischen den Akteuren auf Ebene der Handelsbeziehungen in beiden Branchensegmenten ausgetauscht werden müssen: Stammdaten zum Austausch von Informationen über das zwischen den Handelspartnern vereinbarte Sortiment (vor allem Katalogdaten), sowie Bewegungsdaten zum Austausch von Geschäftsbelegen, wie z.B. einem Auftrags- oder Rechnungsdokument. Ein Händler verhandelt mit einem Hersteller das von diesem zu liefernde Sortiment inklusive der dazugehörigen Konditionen und bezieht nach Vertragsschluss die entsprechenden Katalogdaten vom Hersteller. Auf deren Basis wird eine Küche bzw. ein Polstermöbel für den Endkunden beim Hersteller bestellt, dort produziert, zum Händler geschickt und vom Händler beim Endkunden aufgebaut. Die Händler in beiden Branchensegmenten sind in sogenannten Einkaufsverbänden organisiert, die v.a. Preisvorteile gegenüber den Herstellern realisieren sollen. Über die Jahrzehnte hinweg haben sich die Einkaufsverbände zu Organisationsverbänden weiterentwickelt, die nicht nur günstige Einkaufskonditionen erzielen, sondern ihren Mitgliedern weitere Dienstleistungen, wie z.B. ein Produktkatalogmanagement, anbieten. Sie dienen in vielen Fällen als Mittler zwischen Herstellern und ihren angeschlossenen Händlern.

Tabelle 1: Topologie der Konfigurationen auf Ebene der Handelsbeziehungen

		Branchensegment Küche		Branchensegment Polster	
H	S		**D**		**D**
		Einflussfaktoren Küche: W: Marktdominanz Küchenmöbelindustrie			

		Einflussfaktoren Polster: W: Eigenmarken (Händler), W: Eigenmarken (Verbände), W: Wettbewerb PKS, S: Fachkräftemangel (Filialisten), K: Multi-Channel (Kunden), K: Informationstransparenz (Kunden), K: Beratung (Kunden), K: Informationstransparenz (Kunden)			**D**
		Einflussfaktoren für beide Branchensegmente: W: Marktdominanz Filialisten; W: Barriere Vertikalisierung Hersteller, F: Produktplanung; P: Produktkomplexität; P: Preiskomplexität			
			**M**		**M**
		Einflussfaktoren Küche: *keine speziellen*			**M**

		Einflussfaktoren für beide Branchensegmente: W: Barriere Vertikalisierung Hersteller, W: Marktdominanz Filialisten, W: Stammdatenverwaltung Verbände, W: Eigenmarken (Verbände)			
	Bewegungsdaten		**D**		**D**
		Einflussfaktoren Küche: W: Marktdominanz Küchenmöbelindustrie			**D**
		Einflussfaktoren Polster: W: Eigenmarken (Händler) W: Wettbewerb PKS, S: Fachkräftemangel (Filialisten), K: Multi-Channel (Kunden), K: Informationstransparenz (Kunden), K: Beratung (Kunden), K: Informationstransparenz (Kunden)			
		Einflussfaktoren für beide Branchensegmente: W: Marktdominanz Filialisten; W: Barriere Vertikalisierung Hersteller, F: Produktplanung; P: Produktkomplexität; P: Preiskomplexität			

(1) Kategorien von Einflussfaktoren: W=Wettbewerb, M=Macht, P=Produkteigenschaften, B=Beziehungen, S=Struktur, F=Funktionen, K=Kundenanforderungen
(2) Konfigurationstypen: D=Dyade, M=Mittler

Auf Ebene der Handelsbeziehungen finden sich in beiden Branchensegmenten die gleichen Konfigurationstypen: Die *Dyade* als Repräsentant von bilateralen Austauschbeziehungen von Stamm- und Bewegungsdaten zwischen Herstellern und Händlern (D) und die *Mittler*-Konfiguration als Repräsentant von Hub-and-Spoke ähnlichen Strukturen (M), in denen ein zentraler Akteur die Koordination des Datenaustauschs übernimmt (vgl. Tabelle 1). Der Grund dafür liegt in den ähnlichen Geschäftsmodellen und Akteurskonstellationen in beiden Branchensegmenten, die sich in den genannten stabilen Austauschbeziehungen manifestieren.

Betrachtet man die Einflussfaktoren auf die jeweiligen Konfigurationen, so zeigten sich ebenfalls kaum Unterschiede. Der Wettbewerb zwischen den Branchenakteuren im Küchensegment ist weitestgehend stabil, während für dyadische Konfigurationen die strukturellen Voraussetzungen vor allem bei großen Unternehmen gegeben sind, die deren Weiterentwicklung im Polstersegment aus Eigeninteressen massiv vorantreiben. Dieser Umstand reflektiert sich auf Ebene der Handelsbeziehungen im Einflussfaktor „Wettbewerb zwischen Herstellern von Polsterkonfigurationssystemen (PKS)“, da die elektronisch gestützte Produktplanung im Gegensatz zum Küchensegment noch nicht dauerhaft im Polstersegment etabliert ist. Zusätzliche Faktoren aus dem Bereich Kundenanforderungen spielen ebenfalls eine Rolle, wenngleich deren Bedeutung für die Entstehung und Stabilisierung von zwischenbetrieblichen Kooperationsmustern untergeordnet ist.

4.2 Ebene der Technischen Realisierung

Branchensegment Küche. Auf der Ebene der Technischen Realisierung kommen im Küchensegment drei weitere Akteure hinzu, die im zwischenbetrieblichen Datenaustausch eine Rolle spielen: (1) Die KPS (Küchenplanungssoftware)-Anbieter nehmen im Branchensegment Küche eine zentrale Rolle in der technischen Realisierung ein. Sie unterstützen bei der elektronischen Planung von Küchen, die aufgrund der vielen unterschiedlichen zu beachtenden Rahmenparameter hochkomplex ist. Die KPS-Anbieter lassen sich direkt beim Handel verorten, da die von ihnen entwickelten Planungslösungen in erster Linie an Handelshäuser vertrieben werden und die KPS die von den Herstellern zugelieferten Katalogdaten verarbeiten. In der Beziehung zwischen Herstellern, Verbänden und Händlern zeigt sich ein ähnliches Bild. So werden KPS bei jedem einzelnen Händler direkt betrieben und verwalten die bei ihm eingespielten Herstellerkataloge zur Küchenplanung. Ein Verband hat i.d.R. keine KPS-Lösung im Einsatz. (2) Der Intermediär IM1 bietet Dienstleistungen zum Katalog- und Bewegungsdatenaustausch zwischen Herstellern und Händlern in beiden Branchensegmenten an, wobei im Branchensegment Küche nur Bewegungsdaten und im Branchensegment Polster sowohl Katalog- als auch Bewegungsdaten über die intermediale Plattform ausgetauscht werden. Das Angebot wird sowohl von Filialisten als auch von kleineren Händlern genutzt. (3) IT-Dienstleister mit dem Schwerpunkt Zentralregulierung bieten gerade kleineren Händlern einen signifikanten Effizienzgewinn dank der organisatorischen Abwicklung der Zahlungen zwischen ihnen und den angebundenen Herstellern als unverzichtbare Dienstleistung. Sie nehmen keinen besonderen Einfluss auf andere Konfigurationen.

Branchensegment Polster. Im Gegensatz zum Küchensegment spielen auf Ebene der Technischen Realisierung andere Akteure eine Rolle. (1) Softwareanbieter von Polsterkonfigurationssystemen (PKS) versuchen bereits seit etwa 10 Jahren, grafische Konfigurationslösungen im Handel zu platzieren. Es ist aber erst in den letzten zwei bis drei Jahren gelungen, ernsthafte Fortschritte in der Datenverfügbarkeit für die Lösungen zu erzielen. Dafür werden vor allem Anforderungen aus dem Handel verantwortlich gemacht (z.B. Informationstransparenz für Endkunden, steigender Fachkräftemandel), die eine entsprechende Nachfrage nach PKS beflügeln. (2) Im Branchensegment Polster sind gegenwärtig zwei Intermediäre aktiv, die ihre Dienstleistungen anbieten: IM1 und IM2. IM1 bietet den Austausch von Bewegungsdaten zwischen Herstellern und Händlern an, verteilt über seine Plattform im Gegensatz zum Branchensegment Küche aber auch Katalogdaten von einigen Herstellern an den Handel. Damit besitzt IM1 als neutraler Datenmittler im Branchensegment Polster eine größere Bedeutung als im Branchensegment Küche. IM2 hingegen bietet keine Plattform zum Datenaustausch an, sondern realisiert zwischen je zwei Geschäftspartnern (Hersteller und Händler) eine bidirektionale Integration, die tief in die jeweiligen Produktionssysteme (Hersteller) bzw. Warenwirtschaftssysteme (Händler) integriert ist. Dadurch ist eine nahezu vollständige

Daten- und Anwendungsintegration möglich, über die sowohl Katalog- als auch Bewegungsdaten ausgetauscht werden können. Die Integration wird über ein proprietäres Datenformat realisiert, das den Mitbewerbern nicht zur Verfügung steht.

Tabelle 2: Topologie der Konfigurationen auf Ebene der Technischen Realisierung

		Branchensegment Küche		Branchensegment Polster	
Technische Realisierung	Stammdaten		**M**		**M**

		Einflussfaktoren für beide Branchensegmente: *keine*			
(1) Kategorien von Einflussfaktoren: W=Wettbewerb, M=Macht, P=Produkteigenschaften, B=Beziehungen, S=Struktur, F=Funktionen, K=Kundenanforderungen (2) Konfigurationstypen: B=Branche, D=Dyade, M=Mittler, T=Triade					

Im Rahmen des Stammdatenaustausches liefern die für die Realisierung der zwischenbetrieblichen Integration zuständigen KPS-Dienstleister nicht nur Lösungen zur Umsetzung der Konfigurationen auf Ebene der Handelsbeziehungen, sondern nehmen aufgrund unterschiedlicher Faktor-Ausprägungen im Branchensegment Küche eine gestaltende Rolle ein. Diese Besonderheit reflektieren 21 Codes in der Kategorie „Wettbewerb“, die unterschiedliche Einflussfaktoren mit Bezug zu Softwareanbietern interpretieren. Besonders ist eine KPS-Konfiguration zu nennen (31 Erwähnungen in 16 Interviews), die als Mittler-Konfigurationstyp (M) die Bereitstellung von Katalogdaten für den Handel organisiert. Bei dieser Konfiguration liegt keine Hub-and-Spoke-Konfiguration im Sinne von Lyytinen und Damsgaard [16] vor. Die KPS-Anbieter werten die Daten massiv auf, indem sie dreidimensionale Produktmodelle und fotorealistisches Aussehen der Küchenplanung hinzufügen. Die Weiterleitung an die Händler ist hier nicht von einer Verbandszugehörigkeit abhängig, sondern davon, ob der jeweilige Händler Kunde des KPS-Herstellers ist. Insofern ist „KPS-Sortiment“ ein geschlossenes System.

Im Branchensegment Polster (Fokus Stammdaten) sind deutlich mehr Konfigurationen zwischenbetrieblicher Integration zu beobachten als im Branchensegment Küche. Die erste Konfiguration entspricht der KPS-Konfiguration und wird insgesamt 20-mal in den Interviews beschrieben. Dieser Mittler-Konfigurationstyp (M) wird von den PKS-Anbietern dazu genutzt, Katalogdaten aus der Industrie dem Handel zur Verfügung zu stellen, wobei die Katalogdaten entsprechend mit Grafiken aufgewertet werden. Der Konfigurationstyp hat eine deutlich geringere Verbreitung, da sich die PKS-Anbieter noch nicht in gleicher Weise im Branchensegment Polster als Datenmittler etabliert haben, wie die KPS-Anbieter im Branchensegment Küche. Die Branchen-Konfiguration (B), die durch IM1 realisiert wird, spielt kaum eine Rolle, da nur vereinzelt Kataloge übertragen werden. IM1 wird hauptsächlich für die Datenübertragung von Fachsortimentsdaten genutzt.

Besonders hervorzuheben sind die beiden dyadischen Konfigurationen (D) des Intermediärs IM2 (Stamm- und Bewegungsdaten), die aufgrund des proprietären Datenformats geschlossene Konfigurationen darstellen. Die Funktion der proprietären Schnittstellentechnik von IM2 entspricht der eines Konverters. Die IM2-Konfigurationen sind bei vielen Filialisten sowie den großen Polsterherstellern in Deutschland gegenwärtig im Einsatz.

Die Konfigurationen auf Basis von Bewegungsdaten unterscheiden sich kaum voneinander, da der Bedarf z.B. für den Rechnungsaustausch in beiden Segmenten gegeben ist. Ein Beispiel dafür ist die Triade-Konfiguration (T), die ein verbandstypisches Phänomen der Delkredere-Übernahme zur Absicherung der Zahlungsunfähigkeit von Verbandsmitgliedern beschreibt. Obwohl diese Konfiguration nur innerhalb von Organisationsverbänden eine Rolle spielt, komplettiert sie die Übersicht aller Konfigurationen, da sie für viele kleinere Handelsunternehmen ein integraler Bestandteil für deren Geschäftstätigkeiten darstellt.

4.3 Ebene der Standardisierung

Als zusätzlicher Akteur auf Ebene der Standardisierung im Branchensegment Küche ist das SG1 zu nennen. Das SG1 fungiert als Standardisierungsgremium u.a. für die beiden Branchensegmente Küche und Polster. Seine Aufgabe besteht darin, neue Versionen der ihm zugeordneten Datenstandards zu definieren und zu verabschieden. Mit der Standardisierung der einzelnen Formate versprechen sich die Hersteller vor allem Effizienzvorteile in der Bearbeitung von Handelsbestellungen. Die Reklamationsquoten in den beiden Branchensegmenten sind im Schnitt mit etwa 40% immer noch sehr hoch. Fehler sind durchaus auf der Herstellerseite in Produktionsmängeln zu finden bzw. in der Logistik. Einen großen Anteil der Reklamationen machen jedoch auch Fehler in den Handelsbestellungen aus.

Die Initiative zur Gründung des SG1 ist von der Möbelindustrie ausgegangen, die sich als Datenlieferant für den Möbelhandel versteht. Dieses Selbstverständnis hat dazu geführt, dass das SG1 sich nicht nur in der Datenstandardisierung engagiert, sondern auch Dienstleistungen als Datenmittler zur Verfügung stellt. Dazu existiert eine Kooperation mit einem IT-Dienstleister der Industrie, der für das SG1 einen Stammdatenserver betreibt. Auf diesen Server laden gegenwärtig fast alle Hersteller, die in Deutschland über Händler Küchen vertreiben, ihre Katalogdaten hoch und stellen sie dem Handel bzw. KPS-Anbietern kostenfrei zur Verfügung. Dabei können sowohl die KPS-Anbieter als auch große Händler (Filialisten) Katalogdaten direkt vom Stammdatenserver beziehen. Handelstransaktionen werden nicht über das zentrale SG1-Angebot abgewickelt. Dazu kommen weiterhin die bereits diskutierten bilateralen Schnittstellen oder IM1 als Intermediär zum Einsatz. Der Stammdatenserver wird finanziell vom SG1 getragen. Der Verband spielt im Zusammenhang mit dem SG1 kaum eine Rolle. In dieser Konstellation werden von den einzelnen Verbandshändlern i.d.R. keine Daten vom Stammdatenserver des SG1 heruntergeladen, sondern von den KPS-Anbietern den einzelnen Mitgliedern direkt zur Verfügung gestellt. Insbesondere die kleineren Händler sind in diesem Fall auf die Datenversorgung durch die KPS-

Anbieter angewiesen, da sie i.d.R. keine eigene oder nur eine begrenzte Stammdatenpflege betreiben.

Tabelle 3: Topologie der Konfigurationen auf Ebene der Standardisierung

		Branchensegment Küche		Branchensegment Polster	
Standardisierung	Stammdaten		**B**	-	
		Einflussfaktoren Küche: W: Marktdominanz Filialisten, W: Eigenmarken (Händler), W: Eigenmarken (Verbände), W: Informationsintransparenz (Händler), W: Informationsintransparenz (Verbände), F: Funktion Reklamation (Händler), W: Wettbewerb KPS, M: Blockadehaltung (Technologie)			**B**
		Einflussfaktoren Polster: *keine*			
		Einflussfaktoren für beide Branchensegmente: *keine*			
			**B**	-	
		Einflussfaktoren Küche: W: Marktdominanz Filialisten, W: Eigenmarken (Händler), W: Eigenmarken (Verbände), W: Informationsintransparenz (Händler), W: Informationsintransparenz (Verbände), F: Funktion Reklamation (Händler)			**B**
		Einflussfaktoren Polster: *keine*			
		Einflussfaktoren für beide Branchensegmente: *keine*			

(1) Kategorien von Einflussfaktoren: W=Wettbewerb, M=Macht, P=Produkteigenschaften, B=Beziehungen, S=Struktur, F=Funktionen, K=Kundenanforderungen
(2) Konfigurationstypen: B=Branche, D=Dyade, M=Mittler, T=Triade

In der ersten Branchen-Konfiguration (B) im Branchensegment Küche versorgen sich die aktiven KPS-Anbieter regelmäßig mit den aktuellen Herstellerkatalogen im IDM-Küche Format, die sie in ihren Küchenplanungssystemen einpflegen. Diese Konfiguration entspricht einer Branchenkonfiguration nach Lyytinen und Damsgaard [16], da sie für alle registrierten Branchenteilnehmer einen offenen Zugang zu den Katalogen der Hersteller darstellt. Die Idee eines öffentlichen Guts [24] für alle Akteure in der Branche wird durch den registrierungspflichtigen, kostenfreien Zugang und die Informationstransparenz in der Standarddokumentation unterstrichen.

Die zweite vom SG1 gestützte Branchen-Konfiguration (B) sieht nicht die KPS-Anbieter, sondern die Händler in der Rolle des Datenbeziehers. Diese Konfiguration spielt jedoch gegenwärtig kaum eine Rolle, da die Verarbeitung und Bereitstellung der Daten hauptsächlich über die KPS-Anbieter stattfindet. Es gibt bislang (Stand: September 2018) nur drei gelistete Händler, die am Stammdatenserver registriert sind und Katalogdaten beziehen.

Im Branchensegment Polster gibt es im Gegensatz zum Küchensegment gegenwärtig keine Konfiguration zwischenbetrieblicher Integration auf der Ebene der Standardisierung. Das SG1 bietet die Leistungen des Stammdatenservers nur für den

IDM-Küche-Standard an. Die Verbreitung von Katalogdaten im IDM-Polster-Format wird aktuell den jeweiligen Branchenakteuren selbst überlassen.

5 Diskussion der Ergebnisse

Akteursrollen: Die vorliegende Untersuchung liefert nicht nur ein detaillierteres Bild einzelner Konfigurationen, sondern hebt die Bedeutung einzelner Akteursrollen innerhalb und zwischen den Konfigurationen hervor Dies zeigt sich sehr deutlich am Beispiel der IT-Dienstleister in der Branche, die für sieben der 12 Konfigurationen verantwortlich zeichnen. Die zwischen ihnen herrschenden wettbewerblichen Bedingungen und die darauf resultierenden Systementwicklungen sind teilweise für branchendominante Konfigurationen verantwortlich. In den identifizierten Literaturbeiträgen der Konfigurationsforschung wird IT-Dienstleistern als branchenrelevante Akteure jedoch kaum Bedeutung beigemessen. Die von IT-Dienstleistern bereitgestellten Konfigurationen werden auf die jeweiligen Handelspartner in der Regel implizit übertragen: IOIS werden als infrastrukturelle Elemente betrachtet, die losgelöst von anderen Einflussfaktoren den Datenaustausch realisieren. In der vorliegenden Arbeit zeigt sich, dass der Wettbewerb zwischen IT-Dienstleistern und die daraus entstehenden unterschiedlichen Konfigurationen sehr wohl eine signifikante Rolle spielen können. Es ist also in künftigen Untersuchungen zu klären, anhand welcher Kriterien eine Konfiguration auf der Ebene der Technischen Realisierung anzusiedeln ist und damit ein Einfluss der Akteursrolle IT-Dienstleister auf die Branche bzw. auf die Konfigurationen in einer Branche anerkannt wird.

Analyseebenen: Die herausgearbeiteten inhaltlichen Schwerpunkte (Handelsbeziehungen, Technische Realisierung und Standardisierung (Analyseebenen), sowie Stamm- und Bewegungsdaten (Datentypen)) sind auf andere Branchen entsprechend der dort herrschenden Akteurskonstellationen und der Art der Datenintegration anzupassen bzw. zu ersetzen. So kann z.B. die Ebene der Standardisierung entfallen, wenn es keine Bestrebungen zu einer branchenübergreifenden Formatentwicklung gibt. Auf der anderen Seite können u.U. nicht Stammdaten, sondern strategische Informationen (z.B. Echtzeitdaten zur Kundennachfrage) für den Datenaustausch relevant sein [15]. Der Fokus der beiden Analyseperspektiven ist somit abhängig vom Untersuchungsgegenstand und -ziel zu wählen.

Generalisierbarkeit der Ergebnisse: Im direkten Vergleich der beiden Branchensegmente auf den drei Ebenen Handelsbeziehungen, Technische Realisierung und Standardisierung zeigt sich, dass die Rolle und das Selbstverständnis der Branchenakteure maßgeblich das Zustandekommen von Konfigurationen zwischenbetrieblicher Integration beeinflussen. Die Konfigurationen stammen aus unterschiedlichen Motiven der Akteure heraus, die teilweise wirtschaftliche, teilweise aber auch normative Hintergründe besitzen. Die Einflussfaktoren für das Zustandekommen sind somit als branchenspezifisch zu bewerten. Eine Generalisierung der Konfigurationen auf andere Branchen(segmente) ist insofern möglich, als dass sich die Konfigurationen selbst als modellhafte Repräsentation der zwischenbetrieblichen

Zusammenarbeit in vielen unterschiedlichen Bereichen wiederfinden lassen. So haben Lyytinen und Damsgaard die Konfigurationstypen „Dyade“ und „Branche“ bereits in früheren Untersuchungen identifiziert. Konfigurationen können somit als gestaltende Elemente einer Modellierung von interorganisationalen Kooperationen genutzt werden.

6 Zusammenfassung, Kritische Würdigung und Ausblick

Die vorliegende Arbeit hat als eine der ersten Arbeiten die von Lyytinen und Damsgaard [16] konzeptionell vorgeschlagene Konfigurationsanalyse operationalisiert und in zwei Branchensegmenten (Küche und Polster in der Möbelbranche) die Forschungsfragen (a) *Welche Formen der zwischenbetrieblichen Integration existieren in der Möbelbranche?* und (b) *Welche Faktoren besitzen Einfluss auf die identifizierten Formen der zwischenbetrieblichen Integration?* beantwortet. Mittels eines explorativen Forschungsansatzes wurden 21 Tiefeninterviews mit 19 Organisationen geführt. Die vorgefundenen 17 Konfigurationen und die auf sie einwirkenden 39 Einflussfaktoren wurden systematisch untersucht. Es konnten vier Konfigurationstypen (Branche, Dyade, Mittler und Triade) sowie sieben Kategorien von Einflussfaktoren (Wettbewerb, Macht, Produkteigenschaften, Beziehungen, Struktur, Funktionen, Kundenanforderungen) identifiziert werden.

Die Untersuchung bietet trotz des tieferen Einblicks in die zwischenbetrieblichen Kooperations- und Integrationsbeziehungen keine vollumfängliche Branchenanalyse. Selbst mit einer sorgfältigen Auswahl der Interviewpartner (im Hinblick auf die einbezogenen Perspektiven und Rollen der Akteure) ist nur ein eingeschränkter Blick in die Branche möglich. Die Ergebnisse sind folglich in künftigen Untersuchungen in der Branche empirisch zu validieren.

Die Analyse der Konfigurationen in den Branchensegmenten Küche und Polster zeigt, dass ein in der zwischenbetrieblichen Integration engagierter Akteur in der Regel an mehreren Konfigurationen beteiligt ist, die darüber hinaus in Beziehung zueinanderstehen. Dieses Phänomen der geschachtelten Konfigurationen bietet sich als weiterer Untersuchungsgegenstand an, der in künftigen Forschungsprojekten untersucht werden sollte.

Novices' Quality Perceptions and the Acceptance of Process Modeling Grammars

A Trans-disciplinary Quality Approach

Andrea Fürst-Graßl[1]

andrea.fuerst@uni-passau.de

Abstract. As Process Modeling Grammars provide a means to visualize and communicate complex business processes, it is crucial to convince novices to adopt them for every-day business. As their drivers of acceptance are widely unknown, my study develops a trans-disciplinary quality approach to investigate how quality perceptions affect novices' adoption intentions. The survey data were analyzed using PLS-SEM. The main result of my study is that the identified quality dimensions are interrelated and differ in their impact on adoption intentions. This provides a 'new', coherent view on quality perceptions of modelling grammars and deeper insights into how they affect behavioral intentions.

Keywords: Business Process Management, Modeling Grammar, Quality Perception, Adoption Behavior, Technology Acceptance

1 Introduction

The increasing complexity and digitalization of business processes requires depicting relevant process information in a clear and transparent manner. Process modeling provides a proper means to visualize, communicate, and evaluate complex business processes [1, 2]. As modeling grammars provide the conceptual base for process modeling by defining a set of graphical constructs and rules for their combination, a standardized modeling grammar is an indispensable prerequisite to integrate process modeling in ever-day business [3, 4]. It enables the use of modeling software to generate process models and to develop a shared understanding of their informational content.

To gain this shared understanding among all employees, the modelers of process models as well as their recipients must have sufficient knowledge about the applied modeling grammar and the willingness to use it in their daily routines [5]. Especially process modeling novices must be encouraged to learn and voluntarily adopt a commonly used modeling grammar. Therefore, it is essential to gain knowledge about the key-drivers of their adoption intentions to foster their acceptance behavior.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Previous research, however, provides only minimal insights into the behavioral mechanisms underlying novices' initial adoption intentions in the context of modeling grammars. Therefore, these relevant key drivers are widely unknown. Prior publications, however, indicate, that quality perceptions are likely to influence the acceptance of a modeling grammar [e.g., 2, 3, 6]. Therefore, this study aims at empirically investigating if and how quality perceptions influence novices' adoption behavior.

The proposed research model develops a two-level quality approach. It builds on the observation, that process modeling novices usually experience a modeling grammar on two levels during a training period: They are taught (1) the language specification including the provided constructs and their rules of interaction and (2) its concrete usage in building process diagrams. Therefore, the quality approach in this study separates between quality perceptions on the *Language Level* and quality perceptions on the *Diagram Level* and poses two main research questions:

1. Do quality perceptions influence novice users' initial acceptance of a modeling grammar?
2. And do the different perceptional levels differ in their impact?

To answer these questions, this research applies a transdisciplinary approach. It aims at taking advantage of the fact that the influence of quality perceptions on adoption intentions is relatively well-investigated in the context of software systems – but poorly investigated in the context of modeling grammars. Therefore, this study identifies conceptual parallels between both research contexts and to transfer valuable insight from the one to the other to gain a well-founded research model as a base of the subsequent empirical investigation.

2 Theoretical Background

2.1 Previous Research on Technology Acceptance

The widespread Technology Acceptance Model (TAM) was originally developed by Davis [7] to explain a user's intention to initially accept a certain technology. Its core statement is, that users intend to accept a certain technology based on their perceptions of its Ease of Use (PEOU) and Usefulness (PU). In recent years, the TAM has been widely applied in the broader context of information systems [8 for an overview]. With regard to process modeling grammars, the publications of Recker [9, 10] showed a good applicability of the TAM in this specific context as well.

Numerous studies on information systems also indicated that quality perceptions may affect the TAM constructs PU and PEOU. Recker et al. [3] were the first who transferred this idea to the context of modeling grammars: They tested a research model combining a quality perspective (focusing on specific ontological deficiencies) with the TAM to investigate experienced users' continuance decisions. Based on their results, it can be presumed that a relationship between quality perceptions and the TAM also exists in the context of modeling grammars. Therefore, my study adopts this approach and builds on merging the TAM with a quality perspective specifically tailored to novice users' quality perceptions.

2.2 The Influence of 'Quality'

Quality-Related Research on Information Systems. In the context of information systems quality perceptions were identified as a key driver of usage intentions and success [11–13]. A clear definition of 'quality', however, is difficult. As quality perceptions are context dependent 'quality' can be interpreted from various perspectives [14–16]. Previous research on quality-driven adoption behavior mainly focused on 'quality' as meeting customer expectations. Particularly the conceptualization originally developed by DeLone & McLean [12] evolved into a de-facto standard.

The original DeLone & McLean model distinguishes between the two dimensions *System Quality* and *Information Quality* which were integrated, adapted, supplemented, and refined in a variety of subsequent investigations [e.g., 12, 14]. *System Quality* reflects the technical component of an information system (e.g., its features and functions) whereas *Information Quality* captures quality perceptions of its informational output like understandability and applicability. Both dimensions were found to have a significant influence on users' intentions to use an information system [12, 13].

Quality-Related Research on Modeling Grammars. In the context of process modeling grammars various researchers consider 'quality' a critical driver of acceptance, too, and continually called for more empirical research in this context [e.g., 2, 3, 6, 17]. However, a clear, commonly used and empirically proven conceptualization of quality in this context is still lacking. Existing quality approaches differ in their conceptualization of quality emphasizing different evaluation criteria, different contexts of usage, and different objectives. Well-regarded publications in this context are for example the SEQUAL-framework focusing on semiotic aspects [e.g., 18, 19], the subsequent publication of Krogstie [5] focusing on model based software development, the CD-framework [20] emphasizing cognitive aspects, Moody's 'Physics of Notations' [2] as a guideline for the design and improvement of modeling grammars, the Bunge-Wand-Weber (BWW) Model [4, 21, 22] focusing on ontological aspects, and the subsequent investigation of Recker et al. [3], focusing on user perceptions of ontological deficiencies.

All of these quality-approaches provide valuable insights into the meaning of 'quality' in the context of modeling grammars. However, due to their specific contexts or missing empirical foundations, none of these approaches provides a proper base for my research. Instead, it seems necessary to merge their core-findings to develop a perception-oriented quality conceptualization focusing on 'quality' as meeting novice users' expectations.

Conceptual Parallels between both Research Contexts. To gain such a conceptualization, it seems appropriate to consider the transferability of findings from the well-investigated field of information systems to the specific context of modeling grammars based on two major parallels:

First, both research fields basically agree that perception-oriented quality approaches are more appropriate to investigate users' acceptance behavior than detailed checklists of objective evaluation criteria [e.g., 3, 11, 23]. Whereas such perception-oriented approaches are already established in the field of information systems, existing quality approaches in the context of modeling grammars predominantly base on detailed and objective evaluation criteria. Moody's "Physics of Notations", for example, provides nine design principles including 25 single criteria [2]. Such detailed evaluation-checklists, however, are not appropriate to investigate novices' adoption behavior as particularly novices were found to develop rather general perceptions including less attributes than knowledgeable individuals [24].

Second, in both research fields, a quality approach including perceptions on different levels seems most appropriate. Quality-related publications in the context of modeling grammars can be divided into two major research streams: Some publications are concerned with quality aspects on the *Diagram Level* whereas others try to make improvements on the *Language Level* [6 for an overview]. Nevertheless, existing quality conceptualizations in the context of modeling grammars do not clearly distinguish between those two perception levels. In contrast, previous research on information systems applies such a two-level approach and clearly separates between S*ystem Quality* and *Information Quality* [12].

This two-dimensional conceptualization for information systems seems well transferable to the context of modeling grammars: As *System Quality* captures the ability of a software system to provide a sound technological base including relevant features and functions [12–14], quality-related publications on the *Language Level* focus on providing a sound constructional base, including ontological, syntactical and semantical aspects of the provided constructs [e.g., 2, 5]. As *Information Quality* is described "in terms of outputs that are useful for business users, relevant for decision making and easy to understand" [14], quality-related publications on the *Diagram Level* emphasize essentially identical issues like applicability, cognitive effectiveness and a clear understandability of the derived process models [e.g., 2, 6, 23, 25, 26]. In both contexts, the quality of the informational output is, to some extent, restricted by the quality of technical or conceptual base.

3 Research Model and Hypotheses Development

3.1 Effects of Quality Perceptions on the Language Level

Quality perceptions on the *Language Level* reflect the evaluation of a modeling grammars specification. As the *Language Level* aims at providing a proper constructional base to generate process models, it corresponds to *System Quality* which aims at providing a proper technical base to generate an informational output.

Gorla et al. [14] suggests to further group the relevant attributes for *System Quality* into the relevant subcategories *System Flexibility* and *System Sophistication*. Previous quality-related research on modeling grammars indicates a similar dichotomy: On the one hand, a wide range and proper definition of the provided constructs – often referred to as *Expressive Power* – is considered fundamentally important [e.g., 2, 3, 28]. On the other hand, previous research claims for a certain level of *Grammar Flexibility* to reduce complexity and use it on different levels of experience [28–30]. Consequently, my study distinguishes between the two constructs *Expressive Power* and *Grammar Flexibility* at the *Language Level*.

Expressive Power refers to the question if a modeling grammar is able to provide constructs to express relevant information completely and concisely [2, 3, 31]. For that aim, especially construct overload and construct deficit must be prevented. Construct overload occurs in situations in which the provided language elements "appear to have multiple real-world meanings and, thus, can be used to describe various real-world phenomena" [31]. This may cause confusion and involves the threat of ambiguity and misinterpretation. Construct deficit occurs when there is no notational element corresponding to a particular real world issue [21]. This causes the problem that relevant facts cannot be expressed by the provided constructional elements. As the Expressive Power of a modeling grammar, therefore, determines its fundamental applicability, I hypothesize

H1a) Expressive Power is positively associated with Perceived Usefulness.

On the other hand a high level of Expressive Power accompanied with a wide range of modeling vocabulary reduces the intuitiveness of a modeling grammar, increases complexity and makes it difficult to learn and handle [28]. Therefore, Expressive Power is supposed to negatively affect its ease of use [28]. I hypothesize

H1b) Expressive Power is negatively associated with Perceived Ease of Use.

Grammar Flexibility addresses the question, if a modeling grammar's specification includes possibilities to reduce it to subsets of core-constructs. This question is of high practical relevance: A study by Sedick & Seymour [28], for example, showed that all surveyed organizations tried to simplify process modeling grammars depending on their individually required level of detail. Zur Muehlen & Recker [29] found out that in every-day business usually a core set of constructs is used and additional constructs are included where necessary. Consequently, a modeling grammar's specification should include a clear distinction between core-sets and expansion sets of constructs (as e.g., BPMN2.0). This may reduce the aforementioned negative effects of increasing complexity to foster an easy usage. Thus, I hypothesize

H2) Grammar Flexibility is positively associated with Perceived Ease of Use.

3.2 Effects of Quality Perceptions on the Diagram Level

Each novice user has a certain set of process models in mind, after finishing a process modeling training. The *Diagram Level* reflects his quality perceptions of these diagrams – as the informational output of a modeling grammar – and, therefore, corresponds to *Information Quality*.

Previous research on information systems suggests breaking *Information Quality* down into content-related and formal evaluation criteria [14]. Content-related quality criteria capture the usefulness and applicability of the provided information whereas the formal criteria correspond to its appearance and understandability [14, 32, 33]. Previous research on process modeling analogously emphasizes a distinction between ‘content’ and ‘format’ with regard to diagrammatic representations [2, 26, 34]. Therefore, my research adopts this dichotomy and distinguishes between *Formal Capability* and *Content Capability* on the *Diagram Level*.

Formal Capability emphasizes the striven goal of the ‘cognitive effectiveness’ of the formal representation of process information in process diagrams [2, 26, 35]. “Cognitive effectiveness is defined as the speed, ease and accuracy with which a representation can be processed by the human mind” [2]. The formal capability of the resulting process diagrams, therefore, reflects a modeling grammar’s ability to visualize processes in a clearly structured and understandable way. BPMN, for example, provides structuring elements like pools and lanes to display interaction, whereas EPC diagrams lack a similar structuring. Following Johansson et al. [36], this leads to a good evaluation of BPMN-models with regard to structure and a rather bad evaluation of EPCs in this context. Consequently, a novice user will probably perceive the underlying modeling grammar as useful and easy to use, if the resulting diagrams appear to foster his efficient information processing. I hypothesize

H3a) Formal Capability is positively associated with Perceived Usefulness.

H3b) Formal Capability is positively associated with Perceived Ease of Use

Content Capability captures the functional perspective of the informational output of a modeling grammar. A process modeling grammar can only be perceived as useful if it provides the ability to build process models for various purposes [2, 3, 18, 23, 27]. If the resulting diagrams seem to be useful in every-day business, to facilitate decision making, and to provide a proper base for communication, the underlying modeling grammar will probably be perceived as useful. Thus, I hypothesize

H4) Content Capability is positively associated with Perceived Usefulness

3.3 Dependencies between the Language Level and the Diagram Level

As a process modeling grammar is not an end in itself but serves the sole purpose of building process models, there may be interdependencies between the quality-constructs on the two levels:

Expressive Power. Though a well-designed modeling grammar does not automatically lead to well-designed process models, a poorly designed modeling grammar makes it impossible to design high-quality diagrams [5]. Therefore, a wide range and proper definition of modeling constructs is a necessary prerequisite for deriving organizational benefits from process modeling [3]. This is especially important to meet the various purposes of process modelling [28]. A lack of well-defined constructional elements, consequently, restricts the applicability of the resulting process diagrams. Therefore, I hypothesize

H5a) Expressive Power is positively associated with Content Capability.

A proper supply of constructional elements affects the *Formal Capability* of the resulting process models as well. Construct overload on the *Language Level* may result in ambiguous process models which include constructs with multiple real-world meanings. This requires users to bring in external knowledge to understand the proper meaning of a construct in a certain context [3, 31] and, therefore, diminishes the understandability of a diagram. Additionally, a modeling grammar may provide – on the *Language Level* – constructs that help to structure the derived diagrams to foster a clear structure and to prevent cognitive overload [2]. Thus, I hypothesize

H5b) Expressive Power is positively associated with Formal Capability.

Grammar Flexibility. A flexible specification with defined subset of constructs may also foster the applicability of the resulting process diagrams. As process models are intended to provide a base for effective communication it "is desirable that a Business Process Model can be understood by the various stakeholders involved in an as straightforward manner as possible" [37]. These process stakeholders may differ with regard to their educational level and modeling experience. Therefore, a subset of core-constructs is helpful for an effective communication between stakeholders on different levels of experience.

H6a) Grammar Flexibility is positively associated with Content Capability.

The reduction to a core-set of constructs may foster the cognitive effectiveness of the resulting diagrams as well. Following Moody [35] the most common mistake in modeling practice is the request to show too much information on a single diagram. The resulting complexity rather impedes than enables effective communication [35]. Therefore, company-wide agreements to only apply a defined subset of constructs may foster the appearance and understandability of the resulting diagrams. Thus, I hypothesize

H6b) Grammar Flexibility is positively associated with Formal Capability.

3.4 The Basic TAM-Hypotheses

The well-established TAM hypotheses have already been tested and verified in numerous TAM-studies [8 for an overview]. Following Recker [9, 10], they turned out to hold in the context of process modeling grammars as well. Thus, I hypothesize:

H7a) Perceived Ease of use is positively associated with Perceived Usefulness

H7b) Perceived Usefulness is positively associated with Intention to Use

4 Research Methodology

4.1 Study Design and Data Collection

This study applies an experimental survey approach, which is a common method to investigate behavioral intentions. Data were collected using a survey of students from a German University of Applied Sciences in January 2017.

In preparation of the survey, all participants were trained in the use of two process modeling grammars (BPMN2.0 and EPCs) during winter term 2016/2017. The students were taught the specification of both modeling grammars (including their notational elements) as well as the concrete use of each grammar for the creation of process models. All of the students were provided the same training documents and the same exercises. Both modeling grammars were taught to a similar extent.

To train each student in two different modeling grammars seemed especially important, as perception development processes are comparative by nature [24].

BPMN2.0 and EPCs were chosen – analogously to the studies by Recker [9, 10] – for two main reasons: on the one hand, both are well-known modeling grammars of high practical relevance focusing on the visualization of information. On the other hand, the two grammars show enough differences with regard to their expressive power and diagram appearance to capture different effects on adoption intentions.

Each participant was asked to answer the questions in the questionnaire for each of the two modeling grammars. As all of the participants were students of a German-speaking class, the questions were provided in German language as well. To ensure content-equivalence between the German and English version of the measurement items, the translation procedure recommended in Brislin [38] was applied.

I received 44 completed and usable questionnaires, each including assessments of the two different process modeling grammars. This resulted in 44*2=88 total observations for further analysis. Among the 44 participants, 20.5% were female, 79,5% were male. The average age was 22.7 years. The participants were all students of an Information Systems Bachelor Degree Program (100%).

4.2 Construct Measurement

Due to a lack of appropriate measures in Process Modelling Research, the measurement items for *Expressive Power, Grammar Flexibility, Formal Capability* and *Content Capability* were derived from the *System Quality* and *Information Quality* measures in the study of Gorla [14]. These measures represent a well-founded synthesis of quality-related measures from various Information Systems studies (see [14] for an overview). As these measures were designed for the evaluation of Information Systems, they had to be reformulated and adapted to the specific context of process modelling. These adaptions were discussed with several experienced researchers to ensure content validity and understandability of the resulting measures.

The measures for the TAM constructs are based on the publications of Recker [3, 9, 10, 39], Moore and Benbasat [40], and Venkatesh and Davis [41]. All constructs were measured reflectively on a 7-point Likert Scale (1=”fully disagree” to 7=”fully agree”).

Table 1. Measurement Items of the Applied Constructs

Expressive Power (EXP)
The process modeling grammar provides notational elements to…
…capture information accurately
…capture information completely
…capture information concisely
Grammar Flexibility (FLEX)
The process modeling grammar…
…can be reduced to a set of individually useful features and functions
…can be handled by all levels of users
Formal Capability (FORM)
The resulting process depiction…

…has a good appearance …has a clear structure …is clearly understandable
Content Capability (CC)
The created process models … …are useful for the professional work …facilitate decision-making …provide a proper foundation for communication
Perceived Ease of Use (PEOU)
Overall, I believe, that using this process modeling grammar is easy. Modeling processes in the intended way is easy with this modeling grammar I find creating process models using this modeling grammar is easy.
Perceived Usefulness (PU)
Overall, I find this modeling grammar useful for process modeling. I consider this modeling grammar appropriate for process modeling. I find this modeling grammar useful for meeting my process modeling objectives
Intention to Use (INTU)
If I have access to this modeling grammar, I intend to use it for process modeling. My intention is to use this modeling grammar for process modeling. I prefer to use this modeling grammar instead of using another process modeling grammar.

5 Measurement Validation and Hypotheses Testing

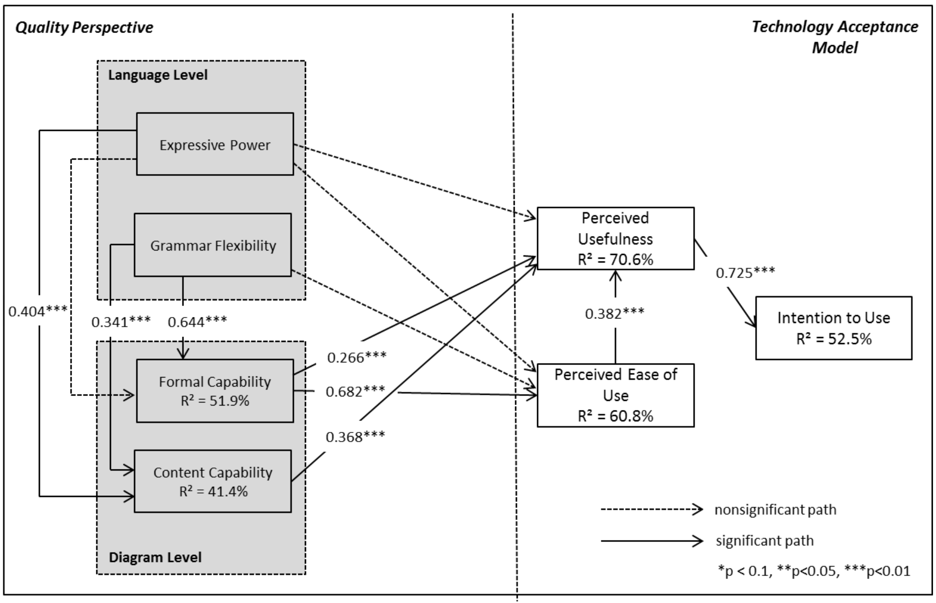

Figure 1. Results of the PLS-estimation of the research model

As the quality-driven adoption of modeling grammars is poorly investigated so far, applying the PLS-SEM method seems appropriate to meet the exploratory character of this study. This method is particularly suitable to test theories in early stages, as it makes fewer demands on data distributions and sample sizes compared to covariance-based approaches [42, 43]. Based on the research of Cohen [44], Hair et al. [43] recommend a minimum of 58 observations for a respective research model with maximally four arrows pointing at a construct. As 88 observations easily exceed this recommendation, the sample size should be sufficient for a sound data analysis.

Table 2. Cronbach's Alpha, CR, AVE and HTMT

Constr.	*Cr. α*	*CR*	*AVE*	*EXP*	*INTU*	*PEOU*	*PU*	*FORM*	*CC*
EXP	0.880	0.925	0.805						
INTU	0.928	0.954	0.874	**0.355**					
PEOU	0.923	0.951	0.866	**0.468**	**0.701**				
PU	0.927	0.954	0.873	**0.473**	**0.776**	**0.802**			
FORM	0.884	0.929	0.813	**0.507**	**0.677**	**0.854**	**0.823**		
CC	0.829	0.897	0.745	**0.652**	**0.640**	**0.551**	**0.762**	**0.669**	
FLEX	0.744	0.886	0.796	**0.602**	**0.504**	**0.726**	**0.646**	**0.874**	**0.669**

The **evaluation of the measurement model** followed the established evaluation criteria recommended in Hair et al. [43]. With regard to **Internal Consistency Reliability** all constructs meet the established quality criteria recommended in Bagozzi & Yi [45] and Hair et al. [43] (Cronbach's $\alpha > 0.7$ and $CR > 0.7$). With all outer loadings exceeding the recommended threshold of 0.7 [43], **Indicator Reliability** is also given. As all AVE values are higher than the recommended threshold of 0.5 [43], **Convergent Validity** is also fulfilled. The **Constructs' Discriminant Validity** was evaluated by applying the recommended HTMT approach [43, 46]. Henseler et al. [46] propose two types of limits for HTMT-values: a strict limit of 0.85 and a more permissive limit of 0.9. 19 of 21 HTMT-values in this study meet the strict threshold of 0.85; only two exceed this limit minimally (0.874 and 0.854) but are below the limit of 0.9 (see Tabel 2, bolded values).

Hair et al. [47] propose to **validate the structural model** as follows: To avoid critical levels of **collinearity** among the predictor constructs, computing the VIF values for all predictor variables is recommended. All VIF values turned out to be far below the established limit of 5 [47]. The amount of **variance explained** (R^2) was considerable high exceeding the level of 50% for all of the endogenous TAM constructs and exceeding 40% for all of the endogenous constructs on the Diagram Level (see figure 1). The **cross-validated redundancy value Q^2** [48, 49] was >0 for each of the endogenous constructs (0.428 for INTU, 0.481 for PEOU and 0.543 for PU, 0.383 for FORM, and 0.278 for CC), which indicates predictive relevance [50].

The **path coefficients** of the proposed hypotheses were computed using the PLS-SEM algorithm implemented in SmartPLS [51] (see Figure 1). To test the significance of each path, the corresponding **t-values** were computed applying the PLS SEM Bootstrapping Routine in Smart PLS with 5000 subsamples and a two-tailed test. All hypothesized relationships between the quality constructs on the *Diagram Level* and the TAM constructs were supported and turned out to be significant at a 1% level. Significant paths between the *Language and the Diagram Level* could be identified as well: The hypothesized relationships between *FLEX* and FORM, between *FLEX* and *CC*, and between *EXP* and *CC* were found to be significant at a 1% level. The assumed relationship between *EXP* and *CC* was not supported. Interestingly, none of the hypothesized direct relationships between the constructs on the *Language Level* and the TAM constructs was significant. This surprising result will be discussed in detail in the subsequent section.

6 Results, Conclusions and Future Research

This study posed two research questions in the introduction. With regard to the first question, a clear link between quality-perceptions and novices' usage intentions could be found and the identified quality dimensions could explain a considerable portion of the variance of the TAM-constructs. With regard to the second question, the identified quality dimensions turned out to influence the TAM-Constructs in different ways. Whereas the perceptions on the *Diagram Level* directly affected the students' intention to use a modeling grammar, the perceptions on the *Language Level* affected their usage intentions only indirectly via the *Diagram Level*. Consequently, the *Diagram Level* can be interpreted as a kind of perceptional mediator between the *Language Level* and the resulting acceptance intentions. This somewhat surprising result can be explained by the fact that information in diagram form can be processes and remembered better than ordinary language [2 for an overview]. Information about a modeling grammar in diagram form, consequently, is likely to have a stronger and instant influence on the subsequent acceptance behavior than the rather abstract grammar specification. Quality perceptions about the specification, however, are not irrelevant, as they do influence the users' perceptions on the Diagram Level.

In summary, the main results of my investigation are that (1) considerable parallels between the 'quality' of information systems and modeling grammars can be found, (2) that a coherent, perception-oriented approach is appropriate to capture novice users' quality perceptions, (3) that these quality perceptions do influence the initial acceptance of a modeling grammar, and (4) that the identified perceptional levels differ in their cause-effect relationships. They contribute to theory and practice:

From a **theoretical perspective**, my study introduces a 'new' view on quality perceptions in the context of modeling grammars. It clearly indicates that perceptions on the Language Level cannot be investigated separately from perceptions on the Diagram Level, as one depends on the other. By combining the Language and the Diagram Perspective, it merges the core-subjects of two wide research streams into a single quality model. This may provide a base to better understand and further investigate open questions from prior research. Recker et al. [3], for example, received mixed and inconsistent results whether certain perceptions of ontological deficiencies directly affect PEOU and PU. Building on my results, it seems possible that perceptions of some ontological weaknesses influence subsequent perceptions of PEOU and PU only indirectly via perceptions on a Diagram Level.

From a **managerial perspective** my results may help (1) to choose a modeling grammar that will probably be voluntarily accepted among all employees and (2) to design proper training strategies:

With regard to selection decisions, my study showed that *Expressive Power* and *Grammar Flexibility* both positively affect users' quality perceptions of the resulting diagrams and subsequently their adoption intentions. This indicates that it is crucial to select a modeling grammar that provides – on the one hand – a wide and well-defined supply of constructs and – on the other hand – is kept flexible enough to work on individually required subsets.

Knowing about the drivers of novices' acceptance intentions (including their cause-effect relationships) may help to develop appropriate training strategies as well: It seems reasonable to first introduce a modeling grammar on the Language Level and to teach the concrete usage for building process diagrams in a second step. If modeling novices were first shown the provided constructs as well as recommended subsets, this knowledge is likely to influence their subsequent perception of the resulting diagrams – which was found to directly influence their adoption intentions.

As this study has a few **limitations** as well it encourages further research in the following areas: First, the study is an exploratory approach to provide a first insight into the relevance of quality perceptions for novice users' adoption behavior. It was based on novices' perceptions of only two modeling grammars. Future research should extend this study on bigger sample sizes and additional modeling grammars.

Secondly, the focus of this study was on novice users. The level of individual experience may, however, influence individual quality perception development processes. Therefore, the study needs to be repeated with a respective sample of more experienced users.

Entwicklung einer Definition für Social Business Objects (SBO) zur Modellierung von Unternehmensinformationen

Berit Gebel-Sauer[1], Petra Schubert[1]

[1] Universität Koblenz-Landau, FG Betriebliche Anwendungssysteme, Koblenz, Deutschland
{gebelsauer,schubert}@uni-koblenz.de

Abstract. Der folgende Beitrag enthält Ergebnisse aus dem Langzeitforschungsprojekt SoNBO *(Social Network of Business Objects)*, dessen Ziel es ist, ein generisches Konzept für die Integration von Geschäftsinformationen aus verschiedenen Anwendungssystemen zu entwickeln. Nachdem zwei prototypische SoNBO-Anwendungen in einem strukturierten *Design-Science-Research-(DSR)-Prozess* erstellt wurden, wurde in der Folge die Definition des für SoNBO zentralen Begriffs des *„Social Business Objects"* entwickelt und nachvollziehbar dokumentiert. Quelle für die Entwicklung der Definition waren eine strukturierte Literaturanalyse, die Auswertung von Interviews mit Unternehmensvertretern und eine Analyse der zwei bereits existierenden Anwendungen. Den drei Quellen war gemein, dass unter *Business Objects* eine Klassifizierung bzw. Kategorisierung von Unternehmensinformationen für die Speicherung in Informationssystemen verstanden wird. Der SoNBO-Ansatz greift dieses Verständnis auf und macht die Struktur von *Social Business Objects* explizit für den User in Enterprise Social Software sichtbar (im Frontend). Die vorgenommene Schärfung der Terminologie ist ein wichtiger Meilenstein im SoNBO-Langzeitforschungsprojekt und dient als Input für den nächsten DSR-Zyklus.

Keywords: Social Business Object, Geschäftsobjekt, Integration, Information, SoNBO

1 Motivation und wissenschaftliche Einordnung

Betriebliche Anwendungssysteme werden in Unternehmen zur Beschaffung, Verarbeitung, Übertragung, Speicherung und/oder Bereitstellung von Informationen genutzt und sind das Rückgrat der elektronischen Informationsverarbeitung [1]. Sie lassen sich grob in vier Softwaretypen unterteilen: (Typ 1) Betriebliche Kernsysteme, häufig in der Form von *Enterprise-Resource-Planning-Systemen (ERP-Systeme)* (z. B. SAP ERP) und *Customer-Relationship-Management-Systemen (CRM-Systeme)* (z. B. Salesforce), unterstützen die funktionalen Bereiche eines Unternehmens und bestehen aus unterschiedlichen Modulen, wie z. B. Finanzmanagement, Materialmanagement, Personalmanagement, Verkauf/Marketing oder Einkauf [2]. Diese Systeme speichern

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

und verarbeiten unternehmenskritische Informationen in der Form von *Business Objects (BO)* (z. B. Personen oder Produkte), die für die Tätigkeit der Wertschöpfung notwendig sind. (Typ 2) *Enterprise Collaboration Systems (ECS)* (Kollaborationssysteme, z. B. IBM Connections) unterstützen Mitarbeitende in ihrer gemeinsamen Arbeit (z. B. an Dokumenten oder in der Kommunikation) und sind damit komplementär zu den prozessorientierten ERP-Systemen. ECS umfassen Module für die Kommunikation, Kooperation, Koordination und die gemeinsame Arbeit an Content [3]. Sie kombinieren traditionelle Groupware-Komponenten (z. B. E-Mail oder Gruppenkalender) mit Social-Software-Komponenten (z. B. soziale Profile, Wiki, Blog) [4, 5]. (Typ 3) *Enterprise-Content-Management-Systeme (ECMS)* (z. B. Alfresco) stellen Software bereit, um Content wie z. B. Grafiken oder Dokumente zu verwalten oder zu archivieren. Sie bilden das Bindeglied zwischen ERP-Systemen und ECS. (Typ 4) Ein *Business-Process-Management-System (BPMS)* (z. B. Camunda) ist ein Softwaresystem, das Arbeitsabläufe mit Hilfe der zugrundeliegenden Prozessdefinitionen steuert und die Umsetzung von Geschäftsprozessen koordiniert [6]. Im Rahmen der darin durchgeführten Prozessorchestrierung werden Funktionen der drei zuvor genannten Softwaretypen bedarfsweise im Prozessablauf aufgerufen. Neben diesen Haupttypen betrieblicher Informationssysteme, die alle als Standardsoftware am Markt verfügbar sind, findet sich in Unternehmen eine Vielzahl an geschäftsspezifischen Spezialapplikationen (meist in der Form von Individualsoftware), die speziell für dieses Unternehmen entwickelt wurden.

Historisch bedingt sind geschäftsrelevante Informationen auf verschiedene Informationssysteme verteilt, was eine umfassende und konsistente Sicht auf Business Objects erschwert [7]. Daher ist es notwendig geworden, die benötigten Informationen mit der Hilfe von Integrationslösungen aus verschiedenen betriebswirtschaftlichen Anwendungssystemen zu aggregieren, um sie den Mitarbeitenden (idealerweise unter einer einheitlichen Oberfläche) zur Verfügung zu stellen. Für diese Herausforderung gibt es bereits technische Ansätze zur Integration, die in der akademischen Literatur z. B. unter den Stichworten [8] *Enterprise Application Integration* (EAI) [9, 10] oder *Service Oriented Architecture* (SOA) [11, 12] diskutiert werden. Bei diesen existierenden Ansätzen wird in der Konzeptionsphase zunächst der Informationsbedarf der Anwender ermittelt, woraufhin eine Integrationslösung (Softwarekomponente) entwickelt und eingeführt wird [9, 13]. Allerdings ist der mit diesen Lösungen (z. B. SOA) verbundene Aufwand oftmals zu hoch, um eine flexible und effektive Datenintegration in der heutigen dynamischen Unternehmenswelt zu realisieren [14].

Vor diesem Hintergrund wurde **SoNBO** *(Social Network of Business Objects)* entwickelt, ein *graphenbasiertes Konzept* für eine Informationsintegration. In einem SoNBO [15, 16] werden die Geschäftsinformationen der betrieblichen Anwendungssysteme in Klassen kategorisiert (z. B. Mitarbeitender oder Angebot) sowie deren Attribute und die Beziehungen zwischen den Klassen identifiziert. Zu den Klassen gibt es jeweils Instanzen (vgl. Abbildung 1, links). Das auf diese Weise entstehende Netzwerk (auf Klassenebene) wird in einer SoNBO-Anwendung (vgl. Abbildung 1, rechts) konfiguriert und das Frontend wird als Webanwendung in einem ECS integriert.

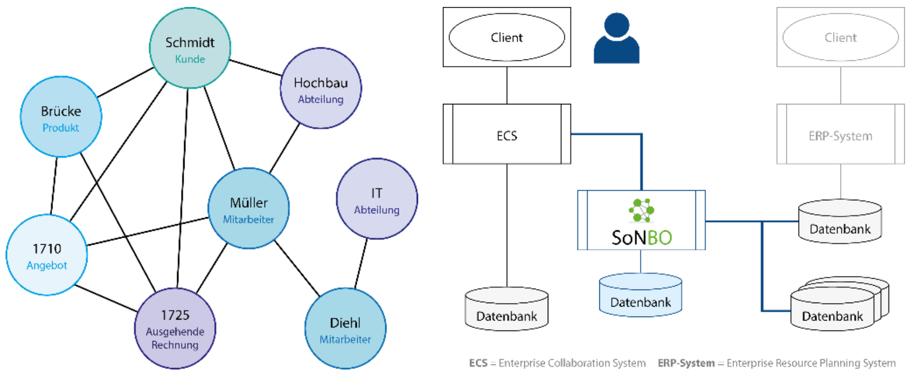

Abbildung 1. SoNBO-Ansatz (verändert nach [15])

Dadurch werden die Informationen der transaktionalen Systeme (ERP-/CRM-System) in das Kollaborationssystem (ECS) integriert. Wenn ein User eine Information zu einer konkreten Instanz (= BO) einer Klasse benötigt, wird dieses BO zur Laufzeit mit Hilfe von Konfigurationseinstellungen aufgerufen (z. B. Angebot *1710* oder Kunde *Schmidt*), die vorher für die zugehörige Klasse festgelegt wurden. Beispielsweise werden im Frontend (vgl. Abbildung 2, Mitte unten) die umliegenden Business Objects angezeigt, sodass der User auf das nächste BO bzw. Knoten navigieren („surfen“) kann.

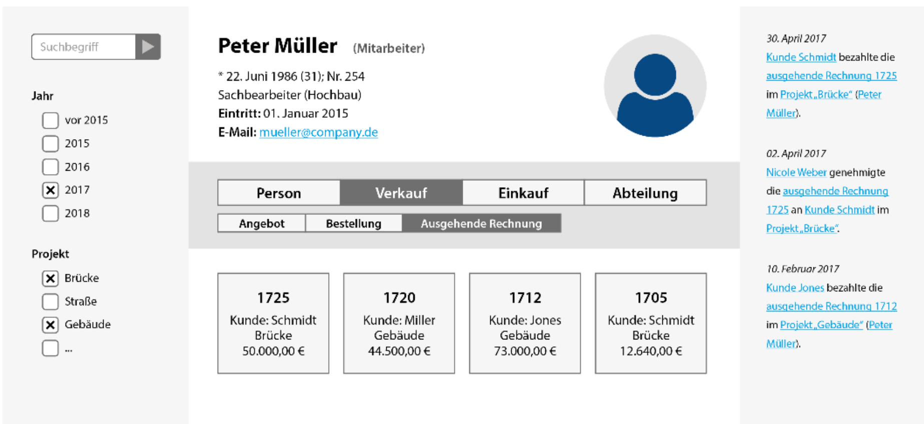

Abbildung 2. Mock-up einer SoNBO-Anwendung

Gewehr et al. [15] beschreiben das Konzept als innovativ für die Informationsintegration, da durch diese Art der Integration die Informationen in den Systemen zur Laufzeit abgerufen werden und somit keine redundante Datenspeicherung erforderlich ist. Außerdem kann dieses Konzept flexibel auf Änderungen im Unternehmen reagieren, indem das Netzwerk durch Konfiguration angepasst werden kann. Im Forschungsbereich Semantic Web gibt es zwei vergleichbare graphenbasierte Integrationsansätze, die das abstrakte Konzept auf die konkrete Anwendung in Unternehmen übertragen: *Linked Enterprise Data* [14] und *Enterprise Knowledge Graph* [17].

Wie der Name *Social Network of Business Objects* (SoNBO) bereits andeutet, spielen die *Business Objects* und daraus abgeleitet die *Social Business Objects (SBO)* in diesem Konzept eine zentrale Rolle. Die Entwickler des Konzepts benutzen bei SoNBO den Begriff Business Object (deutsch: Geschäftsobjekt) bzw. *Social Business Object* für die konkreten Instanzen (Schmidt) einer Klasse (Kunde).

Der SoNBO-Ansatz wurde bereits mit Hilfe von zwei konkreten Anwendungen in der Praxis evaluiert. Die erste SoNBO-Anwendung wurde in einem Unternehmen entwickelt, implementiert und wird seitdem von den Mitarbeitenden aktiv genutzt. Die Evaluationsergebnisse wurden in Form einer Fallstudie dokumentiert [15]. Die (positiven) Ergebnisse aus diesem Projekt gaben den Anstoß zu einer Vertiefung der Forschung im Bereich SoNBO. Das erste Projekt war erfolgreich in einer spezifischen Branche mit einer spezifischen Problemstellung. Die weitere SoNBO-Forschung verfolgt das Ziel der Entwicklung eines generischen Konzepts, das die Übertragbarkeit auf beliebige weitere Unternehmen ermöglicht. Die Herausforderung bei der Implementation einer SoNBO-Applikation besteht u. a. darin, das *unternehmensspezifische Netzwerk* zu identifizieren und dieses dann zu konfigurieren. Für die Evaluation der Übertragbarkeit benötigten die Autoren dieses Papers daher zunächst eine eigene SoNBO-Anwendung, um mit deren Hilfe die notwendigen Schritte zur Konfiguration zu identifizieren und anschließend ggf. zu generalisieren. Während der Entwicklung der Anwendung stellte sich heraus, dass eine eindeutige Definition eines Social Business Objects für das Konzept von zentraler Bedeutung ist, dass aber eine allgemein anerkannte Definition in der Literatur zum jetzigen Zeitpunkt nicht existiert. Fachgebiete wie das Informationsmanagement werden von dieser Schärfung der Begrifflichkeiten profitieren, da durch SoNBO Unternehmensinformationen mittels einer Ontologie in ein Unternehmensnetzwerk (= Graphenstruktur) kategorisiert und somit organisiert werden.

Ziel des Papers ist daher die Entwicklung einer Definition für Social Business Objects. Da diese eng mit Business Objects verbunden sind, ergeben sich die folgenden zwei Forschungsfragen:

1. Status Quo: Welches Verständnis über ein Business Object existiert aktuell in Wissenschaft und Praxis?
2. Definition: Wie kann auf dieser Basis eine Definition für ein *Social* Business Object abgeleitet werden?

2 Forschungsdesign

Wie bereits zuvor erläutert, ist die Entwicklung einer Definition für den Begriff des Social Business Objects Teil eines Langzeitforschungsprojekts. Nachdem eine selbst entwickelte Individualsoftware (im Folgenden referenziert als: „erste“ SoNBO-Anwendung) in einem mittelständischen Unternehmen als innovatives Konzept für eine Informationsintegration von den Forschern identifiziert wurde, wurde diese durch eine Tiefenfallstudie [18, 19] erhoben und veröffentlicht [15]. Um das übergeordnete

Forschungsziel zu erreichen (aus diesem Fallbeispiel eine Übertragbarkeit zu generieren) wurde nach der Methodik *Design Science Research (DSR)* [20] der SoNBO-Explorer (die „zweite" SoNBO-Anwendung) entwickelt, konfiguriert und die Ergebnisse dazu ebenfalls veröffentlicht [16]. Der SoNBO-Explorer integriert Informationen aus einem produktiv genutzten CRM-System einer universitären Forschungsgruppe (GEDYS IntraWare) in deren Kollaborationssystem (IBM Connections). Im Zuge der Entwicklung und Konfiguration stellte sich heraus, dass die verwendete Terminologie (Social Business Object) in der Literatur unterschiedlich genutzt wird und für den SoNBO-Ansatz präzisiert werden muss. Die Entwicklung der Begriffsdefinition folgte der Empfehlung des DSR-Zyklus nach Kuechler & Vaishnavi [20]. Der entstandene Erkenntnisgewinn dient als Input für den nächsten Durchlauf des DSR-Zyklus (hier: Fortsetzung der SoNBO-Forschung mit dem oben angesprochenen Ziel).

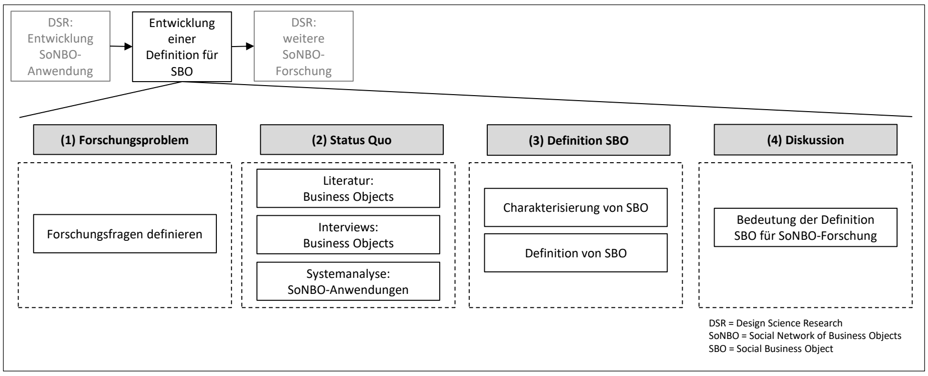

Abbildung 3. Forschungsschritte

Die Forschungsschritte, die zu der Definition über Social Business Objects führen, lassen sich folgendermaßen strukturieren (vgl. Abbildung 3): Nachdem die zweite SoNBO-Anwendung entwickelt und konfiguriert wurde, ergaben sich (1) die Forschungsfragen, die bereits in Kapitel 1 vorgestellt wurden.

Die Etablierung des Status Quo begann mit (2) einer Literaturanalyse [21, 22] zur Verwendung des Begriffs in der *akademischen Literatur*. Dazu wurden die Schlagworte *„Business Object"*, *„Business Objekt"* und *„Geschäftsobjekt"* in google scholar und in den Literaturdatenbanken verwendet, die den Autoren über die Universität zur Verfügung stehen. Für die Auswahl der Literaturquellen wurde keine zeitliche Einschränkung bezüglich des Publikationsdatums vorgenommen. Anhand des Abstracts erfolgte eine Vorauswahl von relevanten Beiträge. Anhand der Literaturverzeichnisse wurden weitere Beiträge identifiziert. Relevante Beiträge wurden systematisch ausgewertet und die Ergebnisse wurden kategorisiert. Die Kategorisierung diente als Ausgangspunkt für die Entwicklung einer Definition in diesem Paper. Da der Fokus des vorliegenden Papers auf der Entwicklung einer Definition zu Social Business Objects liegt, wird die Literaturanalyse in der Form der wesentlichen Ergebnissen vorgestellt, um das grundsätzliche Verständnis aus der Literatur zu vermitteln.

Für die Etablierung eines groben Verständnisses zur Verwendung des Begriffs „Business Object“ *in der Praxis*, wurden sechs ausgewählte Unternehmensvertreter an einem Fachkongress interviewt [23]. Die qualitativen Interviews waren offen und geleitet durch die konkrete Frage „Was verstehen Sie unter einem Business Object?“. Den Befragten war gemeinsam, dass sie alle einen technischen Hintergrund (IT-Abteilung) hatten. Außerdem benutzten die Befragten betriebliche Anwendungssysteme (auch ERP-Systeme) intensiv im Berufsalltag. Allerdings waren diese nicht an der Entwicklung von ERP-Systemen beteiligt. Die Antworten wurden im Anschluss ebenfalls analysiert und kategorisiert. Im nächsten Schritt fand eine Analyse der Software der beiden existierenden SoNBO-Anwendungen statt, um das darin enthaltene Verständnis zu Business Objects zu identifizieren.

Die folgenden Abschnitte beschreiben die Entwicklung der Definition (3). Den Einstieg bildet eine Charakterisierung eines Social Business Objects mit Beispielen. Anschließend wird eine Definition für ein Social Business Object mit Hilfe der drei Ergebnisse des Status Quo (Literatur, Praxis, Systemanalyse) präsentiert. Abschließend wird (4) die Bedeutung der Definition für die weitere SoNBO-Forschung erläutert.

3 Business Objects

Der Begriff *Business Object* wird sowohl in der wissenschaftlichen Literatur als auch in der Praxis verwendet. Im Folgenden werden die Ergebnisse der Literaturanalyse, die Auswertung der Interviews mit den Praxisvertretern und anschließend das Ergebnis der Systemanalyse der beiden existierenden SoNBO-Anwendungen und das darin implizit enthaltene Verständnis zu einem Business Object präsentiert.

3.1 Ergebnis der Literaturanalyse

Die identifizierten Beiträge in der wissenschaftlichen Literatur zu Business Objects lassen sich in *drei Bereiche* kategorisieren, die in Tabelle 1 dargestellt sind: (1) Softwareentwicklung, (2) Softwareeinführung und (3) Softwareorchestrierung. Zu jedem Bereich ist ein Zitat zu dem Begriff Business Object gelistet, das charakterisierend für das Verständnis in dem jeweiligen Fachgebiet ist.

Business Objects sind für die *Informati*k und insbesondere für die *Softwareentwicklung* von Bedeutung. Mitte der 1990er Jahre führte die Business Object Management Special Interest Group (BOMSIG) (später: BODTF = Business Object Domain Task Force) als Einheit der Object Management Group (OMG) das Business Object-Konzept ein. Das Ziel bestand darin, softwaretechnische und betriebswirtschaftliche Modelle stärker miteinander zu verbinden sowie auf der Basis von CORBA (= Common Object Request Broker Architecture) ein Framework zu spezifizieren, das Softwareentwickler unterstützen sollte, komplexe Anwendungssysteme unter der Verwendung von Business Objects zu entwickeln [24]. SAP definierte beispielsweise ein Business Framework für eine komponentenbasierte Architektur, mit dessen Hilfe die Softwarekomponenten von verschiedenen Herstellern interoperieren können [24]. Das SAP-Datenmodell beschreibt die zugrundeliegende betriebswirtschaftliche Struktur in über 4000 Entitätstypen [25].

Es gibt zwei weitere Frameworks, die beschreiben, wie Business Objects strukturiert sein müssen, damit sie zu komplexen betrieblichen Anwendungssystemen zusammengefügt werden können: *OMG Business Object Facility* und *San Francisco Framework*. Unter Business Objects werden hier ausführbare Softwarekomponenten verstanden, die die Struktur und das Verhalten von betriebswirtschaftlich relevanten Einheiten kapseln [26]. Es handelt sich dabei um die Repräsentation eines Gegenstandes aus dem realen Geschäftsleben und es enthält neben der Artbezeichnung sowie der Beschreibung auch die Angaben über Attribute, Verhalten, Beziehungen und Regeln [27]. Ameling [28] unterscheidet zwischen Business-Object-Typen und Business-Object-Instanzen. Ersteres kann mit einer Klasse verglichen werden und beschreibt, welche Elemente sich in dem Business Object befinden können und wie die Struktur aufgebaut ist. Business-Object-Instanzen sind analog zu den Instanzen einer Klasse.

Tabelle 1. Verwendung von Business Objects für betriebliche Anwendungssysteme

Fachgebiet	Teilgebiet	Business Object	Beispiele	Literatur
Informatik	(1) Software-entwicklung	"A business object is a representation of a thing active in the business domain, including at least its business name and definition, attributes, behavior, relationships, rules, policies and constraints." [29]	Mitarbeiter, Produkt, Rechnung, Auftrag, Adresse, Konto, LKW	[24–27, 29–31]
Wirtschafts-informatik	(2) Software-einführung (z. B. ARIS)	„Eine Anwendung besteht aus mehreren Business Objects, die von einem für die Anwendung definierten Geschäftsprozess gesteuert wird." [32]	Auftrag, Artikel, Lieferant, Kunde	[32–34]
Wirtschafts-informatik	(3) Software-orchestrierung	„Ein Geschäftsvorfall (Gesamtprozess) benötigt für seine Abwicklung immer Informationen aus mehreren BO." [35]	Kunde, Produkt, Mitarbeiter, DR-Antrag, Genehmigung, Ablehnung	[35–37]

Ein weiterer Bereich, in dem Business Objects verwendet werden, ist die *Wirtschaftsinformatik*. Das ARIS-Konzept (Architektur integrierter Informations-systeme) wurde zu Beginn der 1990er Jahre entwickelt, um Informationssysteme möglichst vollständig beschreiben zu können. ARIS dient beispielsweise dazu, Unternehmen bei der *Softwareeinführung* und beim Customzing zu unterstützen. Nach Scheer [32] gibt es dazu fünf verschiedene Sichten: Funktionssicht, Organisationssicht, Datensicht und Leistungssicht. Zwischen diesen Sichten werden die Beziehungen modelliert, was die Steuerungssicht darstellt. Das ARIS-Konzept sieht Business

Objects als komplexe Datenobjekte, die Beziehungen zu weiteren Business Objects haben und die charakterisiert sind durch Attribute und zugeordneten Methoden [32]. Die Reihenfolge des Aufrufs der Objekte wird mit Hilfe eines Prozessmodells visualisiert.

Das Business-Object-Konzept wird auch bei der *Softwareorchestrierung* genutzt. Für die Abwicklung eines Geschäftsvorfalls (Gesamtprozess) sind Informationen aus mehreren Business Objects notwendig. Der Geschäftsvorfall *Vertragserstellung* benötigt beispielsweise Attribute der Business Objects *Produkt* (z. B. Bezeichnung, Material), *Kunde* (z. B. Kundennr., Name, Adresse) und *Mitarbeiter* (z. B. Name, Personalnr.) [35]. Bei einer Service-orientierten Architektur stellt dann ein Service dem Anwender eine einheitliche Repräsentation von Business Objects zur Verfügung, wodurch eine homogene Sicht auf die Daten und Operationen eines Business Objects ermöglicht wird [36].

3.2 Ergebnis der Interviews

Alle Interviewpartner (N=6) arbeiten in der IT-Abteilung und sind Administratoren oder Endanwender von betriebswirtschaftlichen Anwendungssystemen. Drei der Befragten hatten *keine* Vorstellung, was sich hinter dem Begriff verbirgt. Drei weitere der Befragten verorteten das Business Object in den Bereich der ERP-Systeme. Bei einem dieser drei Befragten wird SAP im Unternehmen eingesetzt und dieser ordnete den Begriff in das Umfeld von SAP ein. Ein weiterer Interviewpartner (kein Einsatz von SAP in diesem Unternehmen) gab eine beispielhafte Erklärung: „Ein Geschäftsobjekt kann (…) sowohl ein Formular-Inhalt sein (zum Beispiel von einem Urlaubsantrag) wie auch ein Dokument – zum Beispiel ein Kundenauftrag oder eine Rechnung.“ Für diesen Befragten ist ein Business Object „(…) eine Instanz, und Objekte gehören zu Objektklassen und das ist dann ein Mitarbeiter.“

Anhand der Antworten wird deutlich, dass Administratoren oder Endanwender entweder keine oder nur eine vage Vorstellung von einem Business Object haben. Die drei Befragten, die überhaupt eine Vorstellung hatten, stellen allerdings keinen Bezug zum Bereich der Software*entwicklung* her, aus dem das Konzept ursprünglich stammt. Lediglich ein Befragter spricht die Kategorisierung von Unternehmensinformationen an und differenziert zwischen Klassen und Instanzen. Zusammenfassend kann festgestellt werden, dass der Begriff des Business Objects in der Praxis von IT-Abteilungen anscheinend keine wahrnehmbare Bedeutung hat. Aufgrund der sehr geringen Aussagekraft der Interviews wurden nach sechs Durchläufen keine weiteren Daten aus dieser Quelle erhoben.

3.3 Ergebnisse der Systemanalyse der SoNBO-Anwendungen

Wie zuvor erwähnt, gibt es bereits zwei SoNBO-Anwendungen, die die Informationen aus verschiedenen betrieblichen Anwendungssystemen integrieren. In beiden Anwendungen werden die Unternehmensinformationen als *Business-Object-Typen* (z. B. Kunde, Lieferant, Angebot, Auftrag, Rechnung) klassifiziert. Dies dient dazu, dass für jeden Typ die Attribute (z. B. Name) und die Beziehungen in der

Administrationsoberfläche konfiguriert werden. Dabei wählt der Administrator das Feld in dem betriebswirtschaftlichen Anwendungssystem aus, das den Wert (z. B. Name) enthält. Wird vom Endanwender ein konkretes Business Object aufgerufen, wird anhand der Konfigurationen von der Anwendung geprüft, welche Attribute (falls vorhanden) angezeigt werden und welche Beziehungen (falls vorhanden) geladen werden. Diese Informationen werden dem User im Frontend angezeigt. Somit wird die Klassifizierung der Unternehmensinformationen in den Business-Object-Typen sowie in den konkreten *Business-Object-Instanzen* transparent gemacht. Die Klassifizierung der unternehmensinternen Informationen in die Typen ist zum einen durch die technischen Gegebenheiten in den betriebswirtschaftlichen Anwendungssystemen entstanden und zum anderen durch die Anforderungen der User.

3.4 Zusammenfassung Status Quo

Zusammenfassend lässt sich festhalten, dass das Business-Object-Konzept für die objektorientierte betriebswirtschaftliche Anwendungsentwicklung entwickelt wurde. Die OMG leitete die Entwicklung dieses Konzeptes in die Wege. Ein Business Object ist ein logisches Abbild eines betriebswirtschaftlichen Sachverhaltes [38]. Dies wurde von ARIS für die Beschreibung von Softwaresystemen aufgegriffen, um z. B. Software in Unternehmen einzuführen. Für die Softwareorchestrierung wird ebenfalls auf das Business-Object-Konzept zurückgegriffen. Gemeinsam ist allen drei Bereichen, dass Business Objects zur Strukturierung und Kategorisierung von Unternehmensinformationen verwendet werden und dadurch Aufbau und Definition ähnlich sind, sie sich allerdings im jeweiligen Zweck unterscheiden. Außerdem geben Beiträge aus dem Bereich der Softwareentwicklung auch als Beispiel für ein Business Object eine Adresse an, was in den anderen beiden Bereichen (Softwareeinführung und Softwareorchestrierung) als Attribut betrachtet wird. Dies verdeutlicht, dass die Softwareentwicklung einen funktionalen Zweck in den Business Objects sieht, während die anderen beiden Bereiche stärker auf die Bedürfnisse des Unternehmens fokussiert sind. Weiterhin ist den drei Bereichen gemeinsam, dass sich die Kategorisierung auf das Backend bezieht (Zielgruppe: Entwickler, Administratoren), diese Strukturierung allerdings dem Endanwender nicht transparent gemacht wird. Der SoNBO-Ansatz für die Integration von Unternehmensinformationen greift die Strukturierungsmöglichkeit auf, benutzt diese für die Entwicklung und Administration der SoNBO-Anwendung und macht diese auch für den Endanwender transparent.

Offen bleibt in der Literatur, ob es sich bei einem Business Object um eine *Klasse* oder eine *Instanz* bzw. um einen Überbegriff der beiden handelt.

4 Social Business Objects

In diesem Abschnitt wird die Entwicklung einer Definition für Social Business Objects beschrieben. Dazu werden zunächst auf Basis von Abschnitt 3.3 Beispiele eines Social Business Objects sowie deren Charakterisierung aufgeführt, um anschließend auf Basis von Abschnitt 3 eine Definition abzuleiten.

Wie eingangs erwähnt, gibt es graphenbasierte Ansätze zur Integration im Bereich Semantic Web, die auf Unternehmen übertragen werden können: Linked Enterprise Data und Enterprise Knowledge Graph [14, 17]. Ein wichtiges Element ist dabei die Ontologie, die die Zusammenhänge der Informationen abstrakt in „Concepts" (Klassen) beschreibt [39], und der „Knowledge Graph", der die Informationen als Instanzen darstellt. Ein Knowledge Graph ist demnach eine Ontologie verbunden mit einer Faktenbasis (z. B. Datenbank). Eine Ontologie [39] beinhaltet eine Taxonomie sowie eine Konzeptualisierung, die den Bereich definiert, den eine Ontologie beschreiben soll.

4.1 Beispiele und Charakterisierung

Im SoNBO-Ansatz ist das Social Business Object die Instanz einer Klasse, die in Anlehnung an ein Concept in einer Ontologie [39] auch Social Concept genannt wird. Die Unternehmensinformationen (Instanzen, Social Business Objects) werden so strukturiert, dass sie in Kategorien (Klassen, Typen, Social Concepts) zusammengefasst werden können. Ein Social Concept (Mitarbeiter) kann auch Social Subconcepts (Sachbearbeiter, Geschäftsführer, Ingenieur) beinhalten.

Tabelle 2. Beispiel und Charakterisierung eines Social Business Objects (SBO)

	Name	Social Concept	Attribut	Beziehung zu	Methode
Beispiel 1	*Peter Müller*	*Mitarbeiter*	*Alter: 31 Position: Sachbearbeiter*	*1725*	*Position ändern; Nachricht über geränderte Position senden*
Beispiel 2	*1725*	*Ausgehende Rechnung*	*Datum: 02.04.17 Betrag: 50.000,00*	*Peter Müller*	*Rechnungs-datum ändern; Folgen*
Eigenschaft	Ein SBO hat einen Namen.	Ein SBO gehört zu einem Social Concept	Ein SBO hat Attribute. Verschie-dene SBO können nach Attributen gefiltert und sortiert werden.	Ein SBO steht in einer Beziehung zu beliebig vielen weiteren SBO.	Ein SBO bietet CRUD und soziale Funktiona-litäten/ Methoden.

CRUD = create, read, update, delete

Ein Social Business Object ist beispielsweise ein Eintrag in einer (relationalen) Datenbank, während das Social (Sub)Concept die Kategorie des zugehörigen Datenbankeintrages ist. Ein Social Business Object kann sich aus mehreren Datenbankeinträgen zusammensetzen. Ein Social Business Object hat einen Namen und gehört zu einem Social Concept (vgl. Tabelle 2). Für das Social Concept wird identifiziert, welche Attribute (z. B. Alter) es gibt. Die Attributwerte (z. B. 31) werden beim Aufrufen eines Social Business Objects durch den User geladen. Der User kann verschiedene Business Objects nach den Attributen filtern. Weiterhin stehen Social Business Objects in einer Beziehung zu weiteren Social Business Objects. Diese Information befindet sich in dem Datensatz des Social Business Objects. Außerdem hat ein Business Object verschiedene Methoden. Zum einen gibt es CRUD-Funktionalitäten. Ein User kann ein Business Object in einer SoNBO-Anwendung erstellen (create). Weiterhin kann er die Informationen lesen (read). Außerdem ist es möglich, ein Social Business Object zu aktualisieren (update) und auch zu löschen (delete). In den beiden existierenden SoNBO-Anwendungen ist *read* von größter Bedeutung. Auch *update* und *create* (Urlaubsantrag erstellen) wurden implementiert. *Delete* wurde noch nicht realisiert, ist aber prinzipiell auch umsetzbar.

Weiterhin werden für die Gestaltung des Frontends soziale Funktionalitäten benutzt, wie sie aus Kollaborationssoftware bekannt sind [40]. Jedes Social Business Object wird mittels eines *Profils* dargestellt. In Kollaborationssoftware ist ein Profil immer eine Person, während in einer SoNBO-Anwendung ein Profil auch eine Rechnung oder ein Angebot sein kann. Auch das *Folgen* ist vorhanden, wobei sich die Social Business Objects nicht selbstständig miteinander verknüpfen müssen, sondern diese Verknüpfung in den Informationen der betrieblichen Anwendungssysteme bereits vorhanden ist und für SoNBO identifiziert und genutzt wird. Außerdem werden Nachrichten von jedem Social Business Object generiert, wenn sich Änderungen ergeben (z. B. Rechnung wurde vom Kunden bezahlt). Diese Nachrichten werden den umliegenden Social Business Objects in deren Neuigkeiten (Activity Stream) angezeigt.

Die Identifikation der Social Concepts und des Netzwerkes erfolgen durch eine initiale Analyse der betrieblichen Anwendungssysteme und den Anforderungen der User. Dabei gibt es keine richtige oder falsche Kategorisierung der Unternehmensinformationen in Social Concepts. Das Ziel besteht darin, dem User eine sinnvolle Strukturierung transparent zu machen und nicht eine für das Backend logische Struktur zu erstellen.

4.2 Definition

Anhand der Beispiele und der Charakterisierung von Social Business Objects ist zu erkennen, dass diese Business Objects sind. Dadurch besitzen sie die Natur und Struktur von Business Objects und werden um soziale Funktionalitäten erweitert. Allerdings unterscheiden sie sich im Zweck. Während das Business-Object-Konzept vor allem zur Kategorisierung der Unternehmensinformationen im Backend verwendet wird, wird das Social-Business Object-Konzept als Erweiterung verwendet, um die Kategorisierung dem Endanwender transparent zu machen und diesem so eine Informationsexploration zu ermöglichen. Grundlegend dafür ist die Graphenstruktur (= Unternehmensnetzwerk), in der die Beziehungen zwischen den (Social) Business Objects beschrieben werden.

Definition. Social Business Objects sind konkrete Instanzen von Social Concepts. Ein Social Concept kann Social Subconcepts beinhalten.
Social Concepts kategorisieren die in den betrieblichen Anwendungssystemen enthaltenen Organisationsinformationen unter Berücksichtigung der technisch vorhandenen Business Objects in den betrieblichen Anwendungssystemen und den Anforderungen einer Organisation. Die Daten eines Social Business Objects sind (zusammengesetzte) Einträge aus Datenbanken.

Alternative Bezeichnungen.
Social Concept ≙ Klasse, Typ, Kategorie
Social Business Object ≙ Instanz
Hinweis: Der Begriff Business Object wird in der Literatur (abweichend von der hier vorgestellten Definition) auch für das abstrakte Konzept der Klasse verwendet. Dies ist nach Ansicht der Autoren nicht zweckdienlich für die Schaffung von Klarheit.

Aufbau. Ein Social Business Object hat einen Namen, Attribute, Beziehungen zu weiteren Social Business Objects und Methoden. Die Methoden beinhalten CRUD und besitzen soziale Funktionalitäten.

Zweck. Die Strukturierung der Unternehmensinformationen durch Social Concepts und Social Business Objects hat das Ziel, diese dem Endanwender transparent zu machen. Die darin enthaltene Information wird für die Gestaltung der Administrationsoberfläche und für die Entwicklung einer SoNBO-Anwendung verwendet.

Da der graphenbasierte SoNBO-Ansatz sich an betriebswirtschaftlichen Herausforderungen orientiert (Schaffung einer umfassenden Sicht auf Unternehmensinformationen), soll im Folgenden der Zusammenhang zu existierenden graphenbasierten Integrationsansätzen hergestellt werden (vgl. Tabelle 3).

Tabelle 3. Vergleich der Terminologie des Semantic Web und SoNBO

Semantic Web	**SoNBO**		
Bezeichnung des Graphen	**Bezeichnung des Graphen**	**Bezeichnung der Knoten**	**Beispiel**
Ontologie	Social Network of Concepts	Social Concept	Ausgehende Rechnung
Knowledge Graph = Ontologie & Faktenbasis	Social Network of Business Objects	Social Business Object	1725

Im SoNBO-Ansatz wird der abstrakte Graph, der den Aufbau der Unternehmensinformationen beinhaltet und was im Semantic Web als Ontologie bezeichnet wird, *Social Network of Concepts* genannt. Ein Knoten wird dabei als *Social Concept* bezeichnet. Das Netzwerk mit den konkreten Instanzen wird Social Network of Business Objects genannt, wobei ein konkreter Knoten als Social Business Object bezeichnet wird.

An dieser Stelle sei erwähnt, dass der Graph im SoNBO-Ansatz streng genommen „Social Network of *Social* Business Objects“ heißen müsste. Aus Gründen der

Einfachheit wird auf das „Social“ vor „Business“ verzichtet, wobei es aber bei der Knotenbezeichnung verwendet wird, um sich von den Business Objects abzugrenzen.

5 Zusammenfassung und weitere Forschung

Der vorliegende Beitrag beschreibt den Status Quo des Verständnisses zum Begriff „Business Object“. Das Konzept kommt aus der Informatik (Softwareentwicklung von betriebswirtschaftlichen Anwendungssystemen) und wurde von der Firma SAP für ihre ERP-Software aufgegriffen und damit bekannt gemacht. Die Wirtschaftsinformatik verwendet das Konzept zudem für Softwareeinführung und Softwareorchestrierung. Der SoNBO-Ansatz zur Integration von Informationen benutzt ebenfalls das Business-Object-Konzept. Gemeinsam ist diesen vier Ansätzen das grundlegende Verständnis eines Business Objects als Mittel zur Strukturierung von Unternehmensinformationen. Allerdings verstehen die ersten drei Ansätze diese Kategorisierung für den *Softwareentwickler* und der SoNBO-Ansatz benutzt das Konzept, um dem *Endanwender* diese Kategorisierung transparent zu machen und somit eine Informationsintegration umzusetzen. Dazu werden die Social Business Objects miteinander zu einem Netzwerk verknüpft. Das Business Object erhält zusätzlich soziale Funktionalitäten, wodurch der Begriff des Social Business Objects entstand. Außerdem differenziert der SoNBO-Ansatz zwischen einem Social Business Object als konkrete Instanz und einem Social Concept als beschreibende Klasse.

Durch die nun erfolgte Begriffsbildung auf der Grundlage einer Literaturrecherche, Interviews und einer Systemanalyse kann die SoNBO-Forschung in der Folge fortgesetzt werden, indem auf der Basis einer trennscharfen Terminologie an einem Framework gearbeitet wird, das eine Übertragbarkeit von SoNBO auf beliebige Unternehmen ermöglicht. Die Herausforderung besteht darin, das Social Network of Concepts eines konkreten Unternehmens zu identifizieren, um die bestehende SoNBO-Anwendung anhand der Anforderungen dieses Unternehmens zu „konfigurieren“.

Somit stellt der Beitrag einen Erkenntnisgewinn in zweierlei Hinsicht dar. Zum einen wurde herausgearbeitet, welches Verständnis in der wissenschaftlichen Literatur zu einem Business Object vorhanden ist (Status Quo). Weiterhin wurde ein Vorschlag für eine fundierte Definition des Begriffs „Social Business Objects“ entwickelt, der eine notwendige Voraussetzung für die weitere Forschung im Bereich SoNBO darstellt.

Abstract. Since the manufacturing industry is nowadays facing increasingly heterogeneous customer requirements, digital product configurators (DPC) have become a popular means for integrating customers into organizational value creation. DPC are information systems, which serve as a frontend to the customer and enable the individualization of products. The design of such a DPC is time consuming, expensive and lacks appropriate models offering guidance for its development. The paper at hand addresses these issues by providing a reference model (RM) for DPC development. The model has been constructed by means of an extensive literature review and was subsequently demonstrated and evaluated in a real world scenario. In order to ensure a flexible and individual development of company specific DPC the RM includes adaptation mechanisms. Therefore, our research provides a first building block to the endeavor of facilitating or even automating DPC development.

Keywords: Reference Model, Product Configurator, Information System Modeling, Software Engineering.

1 Introduction

Nowadays organizations experience a business environment, where the focus has shifted from mass produced goods to individual products tailored to customer needs [1]. This trend towards personalization was mainly driven by the development of information and production technology [2]. The customer's active involvement in the product design serves as an example, whereby so-called digital product configurators (DPC) enable user-friendly and fast communication and the collection of customer preferences regarding the product customization [3]. Well-known examples are car configurators enabling customers to personalize their car by choosing e.g. interior, engine types, or color. Although DPC promise many advantages, such as reducing process cycle times through automation, decreasing faulty orders, or increasing sales [4], they exhibit downsides, too. High development efforts and costs as well as the difficult maintainability of DPC have to be emphasized [5, 6]. Especially for small organizations, developing and deploying a DPC is challenging and time-consuming. At the same time the DPC has a huge impact on their business and becomes a key system that centralizes the exchange of product, tender, and customer data [7]. This effect

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

occurs because the DPC supports one of the company's core processes (selling the product in combination with customer contact) and thereby requires access to adjacent systems such as customer relationship management, enterprise resource planning, or product data management systems [8]. In small companies without such information systems (IS), parts of these IS must be integrated into the DPC, e.g. to store the product specification necessary for the configuration task. This leads to very complex DPC and highly individual company requirements towards it. Missing guidelines for a sound development of DPC constitute a major challenge often resulting in an ad hoc development of these complex IS without conceptual planning and in problems such as the entanglement of software layers, e.g. the graphical user interface (GUI) in the frontend and the business logic in the backend [6].

While researchers have addressed many different aspects of DPC development in an isolated way such as product knowledge modeling, principles for designing GUI, or reasoning algorithms [9] and studies have been conducted examining several hundred DPC [10], a consolidation of the results from a variety of research fields such as economics, innovation or production research is missing. Therefore, a transformation of the acquired knowledge from the different research fields to the IS research as a holistic conceptual view for the development of DPC is absent. On the one hand, the motivation to build a guidance supporting the DPC software developers lies in the importance of DPC in the modern business environment and on the other hand in the challenges of their development. To guarantee that this guidance is suitable for as many organizations as possible, an artifact representing the best practices for DPC is needed. This artifact should be reusable and universally applicable for many cases. Reference models (RM) are particularly suitable for such purposes. They support system design and development since they streamline the design process and facilitate the implementation by providing best practices, recommendations and represent the knowledge in a particular field [11].

Taking the mature research field of DPC into account, the paper at hand aims to consolidate prior research findings from the last decades to this novel, overarching artifact. The authors develop a RM for DPC as an IS on a conceptual level, based on a secondary literature study including prior literature reviews and studies. This approach leads to the following research question (RQ): *How does a DPC RM need to be built in terms of design decisions and scope to make existing knowledge accessible to IS scholars and practitioners?* To answer this RQ, the remainder of the paper is organized as follows: The (1) introduction with the problem definition is followed by the (2) DPC foundations, and then the (3) research approach is described. Afterwards, the (4.1) DPC characteristics are derived from literature. Using this foundation the RM is (4.2) built, (5) applied, and evaluated. The paper ends with the (6) discussion of the findings and an (7) concluding section.

2 Foundations

Product configuration as a sub-class of configuration in general, constitutes a particular type of design activity. The product to be designed is composed of a set of predefined components that can only be combined in a certain set of combinations, which are called solution space [12]. In order to address and facilitate this often complex task, IS are used, which contain the knowledge about the components and the rules how these can be combined [13]. DPC can support quotation, marketing, and rapid manufacturing of customized products in various industries from car manufacturers to software vendors [9, 13]. The application of DPC in this context has already been discussed in academia and practice since the late 1970s [14]. In DPC research, topics ranging from system design to the impact of configuration have been discussed [9]. Research on this topic, however, often revolved around user or customer interaction. Aspects such as complexity perception, customer satisfaction, and user interaction patterns were addressed [5] in order to optimize the experience with DPC. Not only the experience or fun of configuring products was discussed, but also how DPC as an advisory systems can help customers find the right product to meet their needs [8]. In contrast, a study in which 500 online business-to-customer DPC were evaluated and categorized by features, indicates that they are often still parameter-based, decision-focused, and technology-oriented [10]. This leads to the conclusion that the customer experience is widely discussed in theory, however not properly addressed in the real world. In addition, good and bad practices of development were presented, e.g. a study of 111 web sales DPC raised questions about the presentation of configuration options, the handling of restrictions, and the support of configuration processes [6].

A more comprehensive view of DPC is provided in Subsection 4.1, where a systematic literature review is carried out to analyze the domain as an integral part of reference modeling. The reference modeling itself is described in Section 3 below.

3 Research Approach

To design the RM for DPC, the development process according to [15] has been used in conjunction with an evaluation framework for RM [16] and the design science research approach [17]. In contrast to a (project or enterprise) specific model that would describe a specific DPC, a RM for DPC describes this class of IS in an idealized way [15]. The method of reference modeling can be divided into two phases: (A) construction of the RM and (B) usage of the resulting RM [15]. Both phases are each divided into four individual steps. Common construction steps are (A.1) problem definition, (A.2) conceptualization, (A.3) evaluation, and (A.4) maintenance of a RM. Typical usage steps include (B.1) selection, (B.2) customization, (B.3) integration, and (B.4) application of the RM to solve a problem [15]. The paper at hand addresses the steps (A.1) to (A.3) and (B.2). For (A.1) a systematic literature review was conducted [18, 19] (cf. Subsection 4.1). We have focused on existing research results and DPC studies to consolidate the previous extensive research into a secondary study [20]. After the DPC characteristics have been derived, the (A.2) conceptualization follows, in which adequate views, such as a functional view and the corresponding modeling language, are defined (cf. Subsection 4.2). The multiperspectivity constitutes an important modeling concept, meaning that the same IS is described from multiple viewpoints. In addition to the views, the adaptation mechanisms are developed in the conceptualization step. In general, adaptive RM are models that can be adjusted to a particular application and/or condition. Adaptation mechanisms are needed to guarantee that the RM is suitable for different situations and to provide a solution to the reference modeling dilemma, which states: the more specific a RM addresses an organizational problem the more likely the company will choose it, but the more specific a RM is the fewer companies are addressed by it [21]. The focus on adaptive reference modeling in the paper at hand is justified by the wide range of DPC that need to be accommodated (cf. Subsection 4.1). There are two kinds of adaptive RM: the configurative and the generic adaptive RM [21]. Configurative models contain rules on how the model is to be adjusted to a specific situation via configuration parameters, hereby they are mostly easier to use but harder to construct. Generic adaptable models provide a framework but can only be adjusted manually and thereby are easier to construct, however require more effort in use [21]. Since the goal of the RM for DPC is to reduce development efforts and to imprint obtained knowledge into the RM, we have opted for a configurative RM. To guarantee the best possible fit of the generated specific model we have additionally included generic adaptation mechanisms and thereby keep the possibility of altering the specific model after the model configuration.

After the construction, the RM has been demonstrated by (B.2) customizing it for a real world scenario (cf. Subsection 5.1). The final step of reference modeling presented in this paper encompasses the (A.3) evaluation (cf. Subsection 5.2). On the one hand, for the analytical part we have used the Guidelines of Modeling (GoM) [22] and on the other hand, for the empirical part, we have conducted expert interviews. In the second round of the empirical evaluation, the RM has been used in an organizational setting in the ongoing research project PROFUND to build and deploy a cross-organizational DPC for companies without pre-existing DPC.

4 Construction of the RM

In this section, the paper at hand addresses the first two steps of the construction phase of reference modeling. The following literature review defines the problem and analyzes the domain of the RM. By deriving the DPC characteristics, it builds the foundation for the conceptualization in Subsection 4.2. During the conceptualization, the views and adaptation mechanisms are built.

4.1 Deriving the DPC Characteristics from Literature

Although some reviews and studies partly focus on DPC as an IS from a design and development perspective, to our best knowledge the holistic conceptual view for the development of DPC is neglected. Our secondary literature study based on [18, 19] aims to fill this gap. It includes prior literature reviews and studies describing an extensive amount of DPC in order to gain a comprehensive overview (cf. Table 1 for a fact sheet) and addresses the questions of how the DPC is described as an IS, which perspectives exist, and which overall picture emerges. Through the analysis of the papers we have developed ten different concepts in several rounds by axial coding, in order to summarize and aggregate the DPC characteristics. The morphological box is used in accordance with the general morphological analysis [23] to break down the complex properties of DPC into individual concepts and aspects. This creates a clear structure and a solution space that is easy to interpret. The disadvantage of the morphological box for this review - that common or valid combinations of aspects are not recognizable - is disregarded in favor of concept centricity and easy readability of the results. The percentages for each aspect in the morphological box indicate in how many documents of the literature corpus the specific aspect has been described as shown in Table 1.

Table 1. Morphological Box with DPC Characteristics

Concepts	Aspects					
(1) Purpose of configurator	Product development (25,93%)	Product configuration & sales (92,59%)	Customer preference formation (25,93)	Data collection & data analysis (33,33%)		
(2) Product type	Tangible (74,07%)	Intangible (40,74%)				
(3) Addressee of configurator	External (81,48%)	Internal (33,33%)				
(4) Production concept	Development- / Engineer-to-Order (29,63%)	Make-to-Order & Assemble-to-Order (55,56%)	Match-to-Order / Locate-to-Order (7,41%)			
(5) Type of configuration	Parameter-based & component-based (96,30%)	Requirement-based (55,56%)	CAD (25,93%)			
(6) Standard functions (GUI)	Active input (92,59%)	Product information (77,78%)	Visualization (70,37%)	Videos & animations (33,33%)	Sound (3,70%)	
	Price calculation & display (51,85%)	Guided process & navigation (51,85%)	Save & share (29,63%)	Feedback (62,96%)		
(7) Support functions	Validation (70,37%)	Recommendation (59,26%)	Basic configuration (51,85%)	Comparison (22,22%)		
	Automated solution generation (44,44%)	Simulation (11,11%)	Prototype & 3D print (11,11%)	Community & expert feedback (40,74%)		
(8) Knowledge repres. / logic	Rule-based-reasoning (33,33%)	Case-based-reasoning (25,93%)	Model-based-reasoning (37,04%)			
(9) Data models / management	Customer / session data (44,44%)	Configuration rules (62,96%)	Product model (74,07%)	Configuration (81,48%)	User interface data (22,22%)	Administration data (14,81%)
(10) System design	Structure (51,85%)	Function (59,26%)	Data / function integration (59,26%)			

Fact sheet - Search Terms: Produktkonfigurator, Konfigurator, Produktkonfiguration, Sales Configurator, Configurator AND Product, Configurator AND Mass Customization, Toolkit AND Mass Customization, Frontend AND Mass Customization, Customer-Company Interaction System. Databases and Search Engines: IEEE Xplore, AIS eLibrary, Wirtschaftsinformatik-Genealogie-Datenbank (wige.net), Web of Science and Google Scholar; searched in titels only. Number of Articles found: 101 initially, 76 relevant after titel-check; 136 additional paper after forward-backward search; total 214, 68 relevant after abstract-check; 27 relevant after full paper check. Definition of relevanc: the DPC is discussed as a IS from a software engeneering / design perspective.

Existing literature addresses various (1) purposes of DPC ranging from product development over sales and customer preference formation to data collection and analysis [8, 24]. The most discussed purpose is product configuration with the intention of selling the product afterwards. The (2) product type a DPC is used for can be tangible, like cars or intangible, like software [8]. The (3) addressee of a DPC ranges from engineer or salesman to customer, including companies as a customer or end customers. To simplify the fact of user group variation, the different users were divided into two groups: external, which means customers or the public, and internal representing employees. DPC for tangible products and those which are used externally are examined most frequently, respectively. The focus of customer integration by DPC lies on Made-to-Order (MTO) and Assemble-to-Order (ATO), but the entire spectrum from Engineer-to-Order (ETO) to Match-to-Order (MCHTO) or Locate-to-Order

(LTO) [25] is represented [26–28], as shown in the (4) production concept. The different production concepts relate to the grade of the customizability of the product ranging from pure customization (ETO) to mass production (MCHTO/LTO). The (5) type of configuration describes, how the product can be altered, e.g. by changing parameters or components or by stating a requirement which presets the parameters and components needed to satisfy this requirement [29]. As our literature corpus indicates, the configuration via parameters and components is by far the most common way to realize product customization with DPC. Many (6) standard and (7) support functions of a DPC, e.g. updating the product visualization or automatic validation [30] could be identified. Some functions such as active input, which means the act of entering, e.g. a configuration parameter, are almost always mentioned but others such as (listening to product) sounds are rarely mentioned. To realize the different customization approaches and to guide the user through the configuration task, DPC need to include the configuration rules and algorithms, which can be multi-tiered and complex [29, 31]. This is addressed by (8) knowledge representation and reasoning for DPC, which typically distinguishes the three categories: rule-based, case-based, and model based. Each approach represents the knowledge in different ways, either by if-then-rules or by case similarity or by using constraints [8]. In addition, various (9) data models and (10) system designs have been discussed in literature, e.g. the distinction of user frontends and technician frontends with their respective corresponding logic [32]. It is notable that researchers discuss the system design concepts less distinctively, which forms a strong contrast in regards to the intensively discussed distinct functions of DPC.

All in all, DPC is an umbrella term encompassing wildly different IS, which only have in common that they are used for product configuration tasks in a broad variety of domains. Due to this, the (cost-) efficient development of DPC remains a challenge, as there is no standard procedure to guide such development. No single perfect DPC design is available because of the variety concerning: the industries they are used in, the products they can be used for, the customer integration point they can be used at, the customization approach they can realize, and even the user they can address. This leads to the conclusion that the RM needs to be specific enough for software developers to guide the development of a specific DPC but at the same time generic enough to be applicable for ETO, MTO, or MCHTO settings in different industries. Therefore, a preferable solution for the aforementioned problem is a configurative RM addressing the variety in this class of IS [cf. 21].

4.2 Building the Views

The Approach. Based on the findings from the literature review the requirements for the RM for DPC were derived and led to some major design decisions. The views of the RM could be determined, since from a development perspective on the results, there is a clear emphasis on DPC functions, architecture, and data models with a strong focus on functionality. Accordingly, the RM needs at least two different views to represent the different DPC aspects: a functional view describing user interaction with the DPC and an architectural view describing the system architecture including the data models in the backend. The literature review indicates that the RM must be adaptable in order to cover the broad field of DPC applications. Figure 1 illustrates how the morphological box was used to build the foundation of the RM. There are three different sections the concepts can be divided into. The first five concepts build the setting options for the modeler represented by a choice board. The standard and support functions can be converted to a functional view and the last three concepts can be converted to an architectural view. The resulting three artifact types are interconnected via RM configuration rules. The components of the artifact are described in detail below.

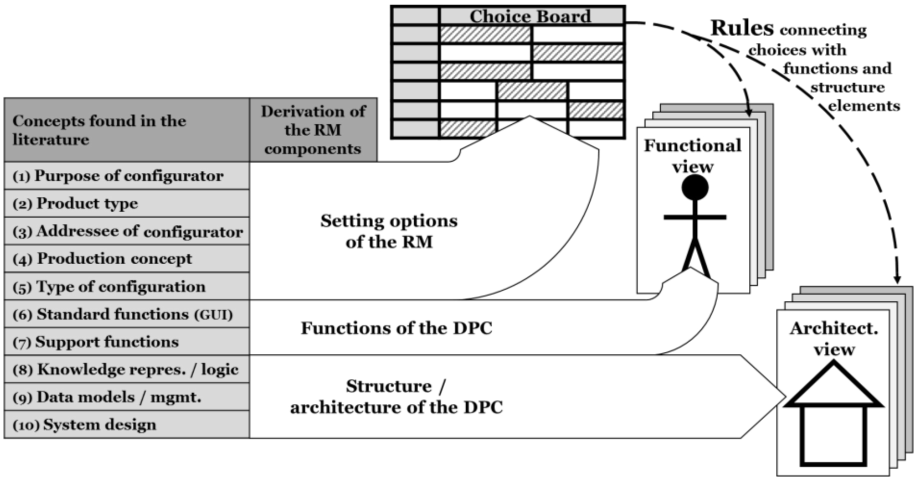

Figure 1. Derivation of the RM Components

Choice Board. What is here called a choice board, is again a morphological box. It is well suited to show configuration dimensions (concepts) of the RM as well as selection options (aspects) in the dimensions. This is a common representation of the multidimensional solution space that illustrates the multitude of variations of RM [33]. There are six questions asked representing the dimensions on the left side of the choice board such as: “Which purpose will the configurator have?”. On the other side, there are predefined answers as selection options like: “Product development” or “Product configuration & sales” (cf. Table 2 in Subsection 5.1). Two kinds of rules were defined in the RM construction. The first one describes the effects of the choice board selections on the two views (cf. rules below) and the second one describes valid combinations in the choice board. It is possible to configure over 270 different versions of the model. An example of a rule is: IF product development THEN NOT Match-to-Order AS production concept. It is suggested to use the choice board by answering the questions in a top-down order, which makes it easier to use.

Functional View and Architectural View. Once the views were identified, we chose adequate modeling languages. In our context, we apply the unified modeling language (UML) Use Case diagram to build the functional view due to two reasons:

First, UML is commonly used in this specific context (describing DPC) and therefore already used in this domain and second, UML is widely accepted and a well-known standard in the field of software engineering [31, 34]. The application of an established modeling standard leads to RM, which are easier to use and avoids starting barriers. Applying a use case diagram has multiple advantages. First, it is possible to build hierarchies of DPC functions like "View product information" as a generalization of "View pictures", "Read description", and so on. Second, the actors included in this diagram type are representing the different DPC users showing the typical interaction with the DPC. During the design process the frequency of mentioning the function in the literature review was taken into account, resulting in mandatory DPC functions in the RM. The full version of the diagram is shown in Figure 2 in Section 5.

For the architectural view an architecture diagram also based on UML was chosen, taking the principle of systematic design into account. This modeling principle demands the inter-model consistency between different views [22]. The condition is fulfilled by using a specified modeling standard such as UML for both views. The architectural view is based on the common three-layer architecture with GUI, application layer, and persistence layer. The view contains components, data elements, and their relations corresponding to the functional view. Both views are linked by a set of rules, so that a selection in the choice board results in changes in both views.

Adaptation Mechanisms and Rules. After determining the representation (modeling language) and the model elements for the views (functions and architectural components), the adaptation mechanisms for the RM were defined. By analyzing the literature, it became clear that dependencies between the DPC functions as well as the architecture and the application field of DPC exist. The RM constitutes a logical representation of these dependencies and therefore becomes a configurator for the DPC as an IS on a conceptual level. The rules for the RM were fully elaborated, resulting in over 100 rules for the configuration and about 40 rules for the generic adaptation. The software developer configures the model by using the choice board. In the first step (the configuration) both views are generated and in the second step (the generic adaptation) individual components are modified if necessary. The result is the recommended functional and architectural scope for a specific DPC. An example of two configuration rules combined is as follows: IF product configuration & sales AS purpose of DPC THEN calculate price information AS function AND price calculation service AS architectural component. Several rules have been defined for each selection option in the choice board. That is, when a selection is made in the choice board, a corresponding set of functions and components is added to the diagrams. In the case that the software developer does not agree with these recommendations, he/she can use the configured model as a starting point and delete or add elements in the model using the generic adaptation rules. Removing, e.g. the price function triggers the generic adaptation rule: IF REMOVE calculate price information AS function THEN REMOVE price calculation service AS architectural component, vice versa. Adding functions and components is limited to the maximum scope of the RM, which is shown in the following section. The demonstration will point out how this RM can be used for a real world scenario.

5 Usage and Evaluation of the RM

In this section, we address the second step of the usage phase and the third step of the construction phase of reference modeling. To perform the customization step of reference modeling, both adaptation variants including the configuration and generic adaptation mechanisms were demonstrated in Subsection 5.1. After this demonstration of the usage, the analytical evaluation to assess the quality and expressiveness of the RM diagrams and the empirical evaluation to assess the suitability and applicability of the RM in real world cases follows in Subsection 5.2.

5.1 Using the RM for DPC

The procedure to use this DPC RM is as follows: First, the DPC developer gathers the initial requirements, second, the DPC developer fills in the choice board with these requirements, third, the RM generates a recommended solution diagram, fourth, the DPC developer uses the generic adaptation to get a better fit of the solution, and finally fifth, the DPC developer uses the specific model to develop a DPC.

For the demonstration and the subsequent evaluation a software development company specialized in DPC development was involved. They described a real case of a prior DPC they had developed for an Austrian manufacturer of customizable front doors. The manufacturer wanted to be able to support its own sales and trading partners in the preparation of quotations. The DPC development company used our choice board to specify the requirements of the manufacturer. To avoid any bias, the developers did not know the rules and logic behind the RM. In Table 2, the selected configuration is shown in the choice board.

Table 2. Choice Board

Dimension / Question	Answer		
Which purpose will the configurator have?	Product development		**Product configuration & sales**
Who will use the configurator?	**External (customer)**		Internal (employee)
Which are additional pursued objectives?	**Customer preference formation**		Data collection & data analysis
Which production concept is pursued?	ETO	**MTO / ATO**	MCHTO / LTO
What type of configuration is needed?	**Parameter / component**	Requirement	CAD
How will the system be integrated?	**Stand-alone**	Data exchange	System integration

The use case diagram shown in Figure 2 includes the maximum scope of functions in the RM, even though not all functions are included in the solution for the manufacturer. This is done for illustration purposes, the legend explains which functions are included and why.

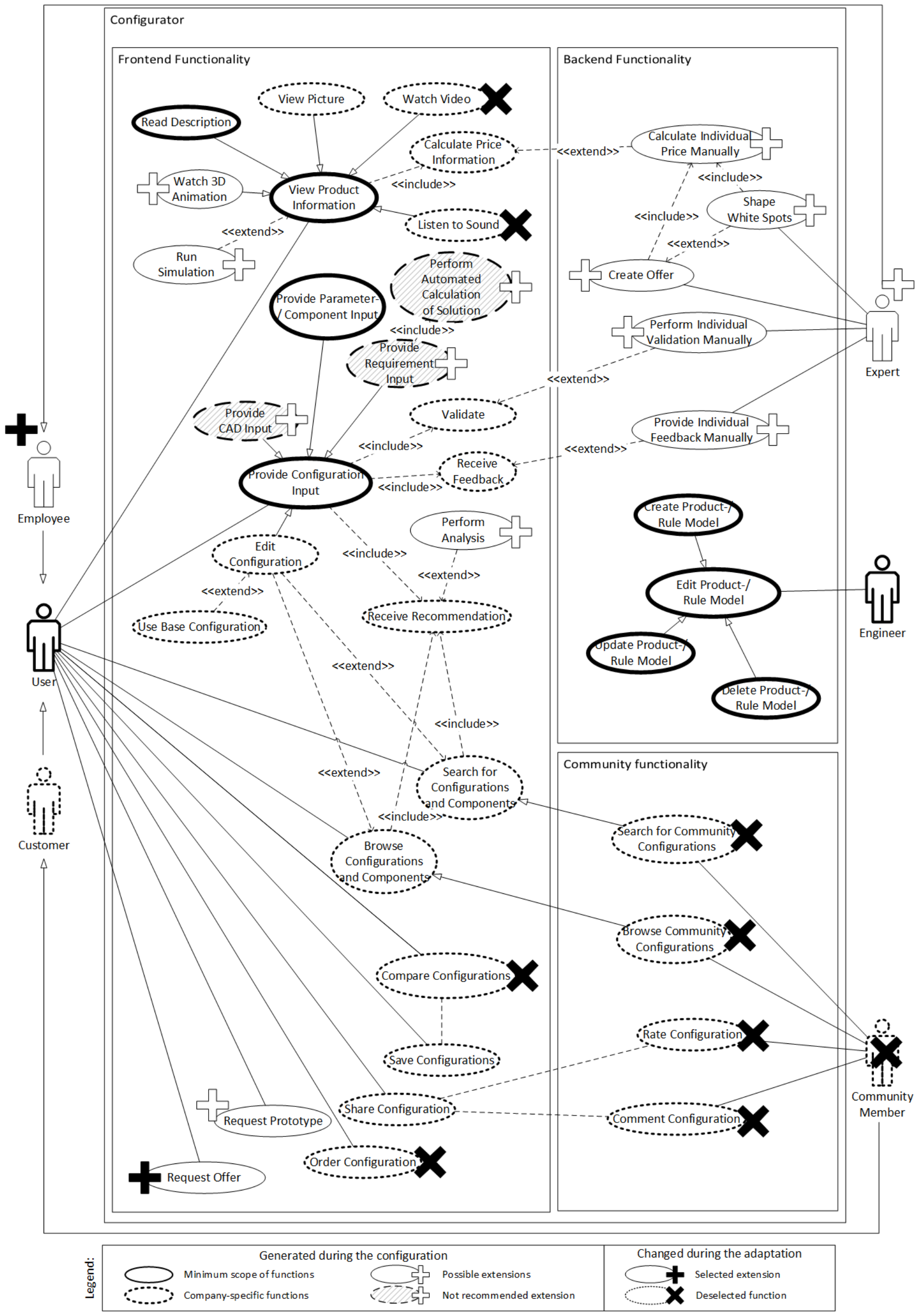

Figure 2. Demonstration of the Functional View

The four symbols on the left side of the legend describe the highlighting of the function explaining the recommendations of the RM after the configuration. The two symbols on the right illustrate the highlighting of the functions, which are added or removed during the general adaptation.

After the model configuration we presented the result to the DPC development company. The developer then had the chance to perform the generic adaptation step to have a closer match to the real DPC of the manufacturer. It is recognizable in Figure 2 that, besides a few other functions, those concerning community integration have been removed whereas the function “request offer” and the employee-actor have been added by the DPC development company. As mentioned before, the architectural view is interconnected with the functional view. Its components correspond with the functions. However, this diagram is not included in this section. Nevertheless, the whole demonstration including both views was performed with the DPC development company and was used for the evaluation afterwards.

5.2 Evaluating the RM for DPC

Analytical Evaluation. For the analytical evaluation, the GoM were used to assess the quality and expressiveness of the RM diagrams. The GoM consist of six principles: (1) construction adequacy, (2) language adequacy, (3) economic efficiency, (4) clarity, (5) systematic design, and (6) comparability [22]. The conclusions of the assessment were the following. (1) and (3) are completely fulfilled, since: first, the problem definition has proven that a RM is a suitable way to address the situation, second, the two views (functional and architectural) are a well-accepted way to describe IS, third, the RM does not include unnecessary content, and fourth, it is considered as economically efficient to build a RM to address a cross-industry problem. The assessment of the latter is based on the fact that in the empirical evaluation the development company estimated an acceleration of DPC development using the RM, which could also be confirmed in the research project PROFUND. Also (4) and (6) were classified as fully satisfied, since UML and UML-related modeling languages were used. However (2) and (5) were rated as partially satisfied, due to the semiformal language and the slightly altered diagram types, although a meta model integration for both views was carried out (though not included in this paper) to guarantee a systematic design.

Empirical Evaluation. At first, the usage perspective was evaluated with the question how suitable the choice board is and whether it is sufficient for the elicitation of requirements in the first stage of DPC development. This was realized by conducting an expert interview with a developer and a requirements engineer in the DPC development company mentioned above. The experts have considered the approach as promising and suitable, but a refinement of the questions and answers is desirable in order to obtain a higher degree of detail in the initial requirements engineering phase. They also identified three major shortcomings of the choice board: First, the external use of the DPC is not divided into the categories of business-to-business and business-to-customer, which can have implications for the frontend design or user handling. Second, the dimension / question for the addressed customization approaches is missing (fit, style, etc.), and third, the rules in the choice board were too strict. While the ruleloosening was realized during development process iterations, the other issues need to be addressed by a broader approach in the RM including, e.g. design suggestions for the frontend or the user handling, e.g. a user login in case of a business-to-business DPC.

At second, the result after using the RM in a real world scenario was assessed. Since the RM was applied to configure a specific model for an already implemented DPC, the resulting model could be compared with the functionality and the architecture of the real system backend of the Austrian front door manufacturer. The comparison was carried out by one of the developers and not by us. The feedback exhibited that a function in the functional view and respectively a component in the architectural view concerning "requesting offers" were missing. As it can be seen in Figure 2, the missing parts were added in the prior RM refinements and are already included in the paper at hand.

At third, the RM was used in the research project PROFUND. The RM was used to accelerate the requirements engineering and the conceptual design of the information technology landscape in the project including a DPC. This led to a prompt conceptual model of the DPC, which was generated by the RM and was used as a foundation for discussion. However, the usage has also shown that it is not facilitating the solution space development and knowledge representation of DPC so far. The usage of the RM in this context will lead to a broader evaluation concentrating on distributed configuration in value chains in an ETO environment and including the whole process of software development. Feedback rounds with to the suggested functionality of the DPC showed that searching for parts, configuring as well as saving the configuration related to the customer data were seen as the most important functionalities, whereby generating offers or sending messages to the customer were deemed irrelevant by the textile companies. The first prototype of the DPC based on the RM has been developed and first feedback indicates that the prototype constitutes a promising approach.

6 Discussion

This paper presents a RM for DPC, which consolidates prior research findings and integrates them into the views, the choice board, as well as the rules and thus forms a novel overarching artifact. The recommendations included in the RM are derived from a comprehensive sample of individual cases and therefore offer general validity. We addressed the missing holistic approach by consolidating prior research viewpoints on DPC such as functionality, architecture, usage, and point of customer integration. While studies like [10] examine a specific type of DPC in a comprehensive way, this paper specifically targets the wide range of DPC to identify the underlying structure and mechanisms of this IS type. Thereby, the presented approach of reference modeling is an example on how to deduce specific features of a RM via a systematic literature review in a mature research field, instead of abstracting from specific models in an inductive way [35].

The evaluation results indicate that the RM is able to accommodate real world requirements successfully and that the RM is applicable across different industries, such as the discrete manufacturing industry (e.g. front doors) as well as the process industry (e.g. technical textiles). The application of the RM in a software development project for small and medium sized enterprises in the textile industry has confirmed the potential benefits of the RM, but has also revealed its limitations. The current RM only allows manual deriving of a specific model. Instead, the model could be automatically generated by a software tool with the option to analyze the usage of the RM for subsequent optimization. In addition, the current RM provides abstract recommendations and no specific support for the actual design and implementation.

Further development could break the RM down to more specific models in order to support the development efforts not only in the initial stages, but also in the subsequent development stages. This purpose could be achieved by, e.g. refining the modules with class diagrams.

7 Conclusion

The paper at hand aims to support organizations in the development of DPC. In a first step we have deduced the characteristics and functions of DPC by conducting a systematic literature review. Considering the wide variety of DPC applications, we have made the design decision that the RM must be adaptive to ensure universality but also specificity. As shown in the demonstration, the adaptive RM constitutes a tool, which can support the development of DPC starting with the requirements engineering stage. The RQ on how to build a DPC RM in terms of design decisions and scope to encompass existing knowledge was answered successfully. The resulting RM is designed to address the problem of high expenses related to the development of DPC, since recommendations for the functional scope and the architecture of the DPC are provided at a very early stage in the development process.

In summary, our research contributes to the knowledge base by applying reference modeling to the field of DPC by making knowledge from research and practice available and thereby usable for developers. Thus, it provides a first building block to the endeavor of facilitating DPC development.

Terminology for Evolving Design Artifacts

Hannes Schlieter, Jeannette Stark, Martin Burwitz, and Richard Braun

Technische Universität Dresden, Chair of Wirtschaftsinformatik, esp. Systems Development, Dresden, Germany
{hannes.schlieter,jeannette.stark,martin.burwitz,richard.braun}@tu-dresden.de

Abstract. Many design researchers evolve artifacts in succeeding projects. Yet, these researchers lack a terminology to describe how their artifacts evolve. We provide such a terminology by paralleling concepts from evolution with design artifacts using examples from conceptual modeling. We found seven concepts from evolution that we think are useful to describe evolving design artifacts. Evaluating whether these concepts have been addressed, we identified six conceptual modeling design studies, whose authors have addressed some of the concepts with their own words. Using two of these studies, we explain how terminology from evolution can be used to describe evolving design artifacts. We hope that our results are useful to be integrated in design science procedure models to help researchers increasing rigor and relevance of their research, e.g. by allowing to clarify how the artifact at hand has evolved or to describe the evolutionary distance to preceding artifacts.

Keywords: Design artifacts, Evolution, Coevolution, Design Science, Conceptual Modeling.

1 Introduction

Researchers often evolve their modeling artifacts in succeeding design projects. Thereby, artifacts sometimes evolve differently. For example, the Unified Modeling Language (UML) specifications were revised to fix shortcomings and support concept integration (cf. [1]) leading to a successive UML versions. In this type of evolution, successive UML versions evolve within the context of general-purpose modeling and consider e.g. changed user needs. An example for another type of evolution comprises parts of the UML being transferred to the field of systems engineering, leading to SysML [2]. In this case evolution happens within a specific domain so that design researchers need to address the specific requirements of the new domain. Yet another type of evolution may be distinguished for versions of UML (e.g. UML 2.0 and 2.5) and corresponding revisions of standards-compliant UML modeling tools (e.g. [3]) that were evolved based on revisions of the UML. In this type of evolution, evolving the modeling tool depends on how the corresponding modeling language evolves and is thus, dependent on the evolution of another artifact.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Prior design research has discussed evolution in the context of mutability [4–6]. Mutability is a core component of design research and researchers are asked to address mutability when publishing their results [7]. For mutability, two paradigmatic perspectives are distinguished: in-design and in-use [4, 5]. In-design mutability refers to the degree of artifact change encompassed by the design theory [7] and allows for designing mutable artifacts that are adaptable to varying organizational contexts [4] and situations [5]. In-use mutability refers to artifacts that evolve over time with users adapting the artifact to new situations, e.g. through configuration [5] or tailoring [8]. Gregor and Jones state that mutability goes even further by "allowing for a certain amount of adaptation or evolution", [7], p. 326. However, how artifacts evolve and adapt is so far not specified in in-use and in-design mutability, so that design researchers lack a specification to describe artifact evolution and hence, cannot address mutability of their design artifacts for this particular aspect.

Specifying how artifacts evolve may help design researchers to increase rigor and relevance for their design projects. Rigor in design science depends on how researchers ground their project with existing artifacts [9]. Being able to specify how artifacts evolve instead of just claiming that it evolves may help identifying important requirements for the evolution at hand. Relevance in design science depends on how researchers address opportunities and problems with their artifacts in the application domain [9, 10]. Specifying how their artifact evolves from preceding artifacts may help to address relevance more precisely. For example, differentiating between different types of evolution allows for discussing the evolutionary distance more precisely e.g. by explaining what features have been added or removed, whether new domain has been entered or an artifact has now coevolved with another artifact. Beyond helping researchers to enhance rigor and relevance, specifying how artifacts evolve contribute to discuss evolutionary lineages on different levels such as single artifacts or artifacts of a domain such as conceptual modeling design artifacts. Investigating evolutionary lineages for single artifacts can also help to discuss and compare maturity of different artifacts and to reveal future potential for evolution. Investigating evolutionary lineages of different domains contribute also to the discussion of how mature domains, such as conceptual modeling, are in contrast to other IS domains. Furthermore, discussing evolution in the context of mutability may help to further advance mutability research.

In this paper we aim to investigate concepts to specify evolving design artifacts. Although we believe that specifying design artifacts is important for all IS domains that develop design artifacts we focus on conceptual modeling design research in this paper. Conceptual modeling is a major topic of the Wirtschaftsinformatik domain, which is primarily design-oriented [11]. Furthermore, this domain was chosen as the authors are familiar with it so that concepts can be transferred to this domain more easily and better examples can be given than for other domains. Finally, to allow for comparing evolutionary lineages between domains, other domains will follow in future research. This paper represents an interim struggle in theorizing [12] that needs to be built on to provide for more rigor and relevance in design science projects, to develop and compare evolutionary lineages and to enhance mutability research.

Hence, these research goals still need to be addressed in succeeding research. Yet, this paper also contributes a specific outcome and concepts discussed in this paper can already be used as a terminology to describe evolution more specific than it was possible before so that evolution as one aspect of mutability can already be specified more precisely as demanded by [7]. For investigating concepts to describe evolution and deriving the terminology of evolving design artifacts, we use argumentative reasoning between evolution of design artifacts and evolution in biology. For a first proof of relevance, we employ a content analysis according to Krippendorff [13]. Using this method, we investigate whether concepts identified to describe evolution have already been applied in recent conceptual modeling design science research.

2 Theoretical Background

2.1 Mechanisms that Drive Evolution

Evolution is described as a change in the heritable characteristics of populations over successive generations [14] and is pushed forward through diverse mechanisms, including mutation, migration, natural selection and gene drift [15]. **Mutations** alter the genome of organisms and result from random errors during DNA replication [16]. For example, a mutation can cause a change in a beetle's genotype from genes for grey to white coloration (Fig. 1a). Those beetles that gain genes for white coloration can have offspring with a gene for white coloration, too. Accordingly, genes for white coloration can be more frequent in future populations. Mutations may result in a gain of a new feature or a loss of an ancestral feature. For example, the bacterium Sphingobium has evolved a metabolic pathway as a new feature to degrade toxins [17] whereas birds have lost their wing function when there was no need to fly. In analogy to evolution in biology, we refer to mutation of design artifacts as a gain of a new function or withdrawal of an ancestral function. Yet, there are also differences within these two contexts. While in biology mutations occur randomly and might have a positive, neutral or negative impact on survival and reproduction capabilities [16], mutations in design science can typically be planned and can hence, rather be classified as non-random. As design researchers plan mutations also the impact is more likely to be positive than in biology. Nonetheless, using the analogy in conceptual modeling design science may help to specify a gain or a loss of an ancestral feature. Yet, the implication of impacting randomly versus non-randomly needs further investigation for design artifacts and should therefore not be made. As an example, for conceptual modeling design artifacts, we refer to the Business Process Modeling and Notation (BPMN) that has experienced major and minor revisions that have continuously produced a variety of BPMN features. For example, the major revision that lead to version 2.0, not least introduced the choreography diagram as a mean to model interactions of multiple communication partners. An additional feature of this mutation comprises the extension mechanism that enables modelers to systematically extend the BPMN core by custom elements.

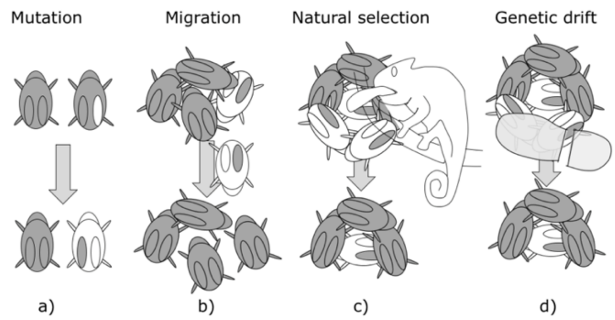

Figure 1. Evolutionary mechanisms: mutation and migration to induce variation as well as natural selection (non-random) and genetic drift (random) for transferring variation

While mutations lead to genetic variation within a population, **migration** allows transferring this variation to further populations of a specie (Fig. 1b). Imagine, beetles with genes for white coloration migrate into another population and thus, allow for variety in a second population. Please note that a specie usually includes several populations. A population is defined as a group of organisms, in which reproduction takes place [18]. In contrast, organisms of a specie only potentially interbreed as they live in distinct areas and thus, may form separate populations whose organisms do usually not interbreed. Migration allows referring to transferring design artifacts to another context and thus, give way for an own evolutionary lineage. For example, BPMN has initially addressed the management of business processes, but has already been used in a variety of other domains, that even sometimes lead to new BPMN species by using the extension mechanism (e.g. [19–22]).

Mutation and migration allow for variation within populations and create the basis for two further mechanisms: natural selection and gene drift. **Natural selection** acts on variation by non-random sorting [23]. Imagine, white beetles live in a habitat with green plants so that predators can easily spot them. In this case, they are not likely to survive and reproduce, which lead genes for white coloration being reduced non-randomly for future populations (Fig. 1c). Also, **gene drift** acts on variation. Yet, while natural selection acts non-randomly, gene drift acts randomly [24]. For example, a beetle population with white and grey coloration is threatened by a storm, in which most of the white beetle die resulting in a random drift towards grey beetles (Fig. 1d). Genetic drift may cause two populations starting with the same genotype drifting apart into divergent populations or even species [25].

2.2 Outcome of Evolution

Evolutionary mechanisms lead to diverse evolutionary outcomes such as speciation [26], adaptation [27, 28], coevolution [29], and extinction [30]. **Speciation** refers to populations of one specie diverging into two or more species and is made responsible for diversity of life [31]. After having diverged, organisms of the two species might still produce common offspring that are in most cases infertile such as mules resulting from horses reproducing with donkeys [32]. A specie is used as a concept to differentiate organisms that cannot reproduce even if manipulated (e.g. moved to another area) while population is used to differentiate organisms of a specie that actually do not mate, e.g. as they live in different areas or times. In design science, **species** may be used in analogy to **artifact types** as this concept helps indicating that design artifacts can potentially be used to produce offspring that address similar requirements or allow to solve similar tasks. In this sense, succeeding artifacts do not represent distinct artifact types but rather succeeding artifact instances of the same type. Furthermore, **populations** may be used in analogy to **artifact variants** to indicate that instances of artifact types can be migrated into another context. For example, the core BPMN 2.0 can be considered a BPMN artifact type, which meets requirements for modeling business processes. Using the core BPMN 2.0 for software process modeling [20] led to a new artifact variant that was able to meet the same requirements in a new context. Based on this artifact variant, the revision and extension of the core BPMN 2.0 regarding new context-related requirements evolved a new BPMNt artifact type. While **speciation** leads to a new specie, **extinction** means that an entire specie disappears. In biology, speciation and distinction happen regularly [30]. When using speciation and extinction to describe design artifacts, we might rather refer to **entry** and **exit** in analogy to the product life cycle [33].

Adaptation refers to organisms evolving adaptive traits by mutation and natural selection and characterizes a population's movement towards a fit to the environment [34]. Adaptations mostly occur through mutations, which impact positively, negatively or neutrally on the organism's survival and reproduction capabilities. Based on how mutations impact, they may prevail or be sorted out. Adapting artifact instances by introducing a new function usually occurs in succeeding **artifact versions**. For example, the introduction of the choreography diagram as a new feature in version BPMN 2.0 can be considered an adaptation to the rising demand for modeling and managing communication between business partners (cf. [35]).

Coevolution occurs across pairs of species that interact with each other [36]. These interactions can lead to adaptations of one specie to cause adaptations in another specie and vice versa. Accordingly, a cycle of adaptations emerges that is referred to as coevolution [29]. Based on how species interact, coevolution is distinguished into conflict and cooperation. Conflict usually emerges between predators and prey. Predators can coevolve to catch their prey more effectively. As a result, selective pressure increases for their prey and leads to coevolving the prey, e.g. to escape more effectively. Adaptive traits developed in conflict comprise speed of movement, ability to detect and habitat choice [37]. Cooperation e.g. occurs between insects and flowers that reward insects with nectar but rely on them for reproduction. Insects and flowers have evolved interactions such as communication via scent or attraction via color [38]. Coevolution has already been applied to organizational adaptation [39], strategic management [40], and strategic alliances [41]. It has also been used for IS by discussing mutual adaptations of business and IS strategies and for coevolutionary choices of platform-based ecosystem owners [42] and the ecosystem's environment [43]. Using coevolution as analogy for evolving design artifacts, we consider the BPMN an artifact type in coevolution with process execution languages (e.g. XPDL or BPEL) that represent business processes in context of machine-based workflow execution. These artifact types and the BPMN artifact type complement one another in terms of language concepts, semantics and interchange formats [63].

Coevolution in biology may lead to **endosymbiosis** that references to cases where one partner is integrated into the other partner's body [44]. This concept has been shaped by Mereschkowsky [45] and has been used as example that evolution may lead to more complexity. Endosymbiosis can be used as analogy to describe evolving design artifacts that incorporate versions of other artifact types. Referring the example of BPMN, the *Lane* concept may be classified as endosymbiotic integration of swim lanes from other modeling approaches (cf. [46, 47]). Please note a distinction between endosymbiosis and coevolution: In coevolution an artifact type adapts with another artifact type. In case of endosymbiosis only certain versions of an artifact type may be incorporated while other versions of that artifact type may remain independent.

3 Concepts and Relationships for Evolving Design Artifacts

We summarize concepts and relationships that connect these concepts in Table 1. Furthermore, we show how these concepts and relationships interrelate in Fig. 2. Examples are taken from conceptual modeling languages. This provides a larger scope of consideration in comparison to the specific BPMN examples in Section 2. As depicted in Fig. 2, we parallel species with artifact types, in analogy to an instance-type relationship, to reflect the idea behind its instances. The artifact instances, which in biology reflect organisms, can further be paralleled with artifact versions indicating that versions evolve, e.g. during iterations [48], [9]. Furthermore, populations are paralleled with artifact variants as this concept allows for summarizing versions that are designed for different application domains and that can develop their own evolutionary lineage. Among relationships, adaptation refers to gaining new or loosing ancestral functions that lead to a better fit to the application domain. Accordingly, adaptations reflect iteration cycles in design science.

Migration relates artifact versions to variants indicating that a particular version is used for another application domain. A further relationship, that we found useful to describe evolving design artifacts is coevolution. Coevolution can happen between versions of one artifact type and those versions of another artifact type and is therefore used as relationship between artifact types. In contrast, endosymbiosis may be used with the term incorporation for design artifacts, meaning that artifact versions of one artifact type may be incorporated for artifact versions of another artifact type.

Table 1. Notions to describe evolving design artifacts and examples from conceptual modeling

Concepts from biology	***Use for IS design artifacts***	***Example***
Specie: Potentially interbreeding organisms	Artifact type: Summarizing artifacts with similar goals and user requirements	Enterprise Modeling Languages
Population: Organisms of a specie that actually mate, e.g. as they live in the same habitat	Artifact variant: Summarizing artifact versions that are used for the same application domains	Enterprise Architecture Languages, Business Process Modeling Languages, Software Modeling Languages
Organism: Instance of a specie	Artifact version: Instance of an artifact type	BPMN 1.0/1.1/1.2/2.0 [49], UML 1.0-1.5/2.0/2.5 [1]
Relationship from biology		
Adaptation: Developing or losing traits as well as non-random sorting towards a fit to the habitat	Adaptation: developing or losing functions and sorting these functions, e.g. towards user acceptance	Revisions of UML specifications in order to fix shortcomings and support concept integration, for instance (cf. [1])
Migration: Transferring variation (e.g. mutations) in between populations	Migration: e.g. using an artifact version within another context	Parts of UML are transferred to the field of systems engineering, leading to SysML [2]. Some parts are completely reused (e.g., Use Case Diagrams), while other parts are adapted domain-specifically (e.g. Block Definition Diagrams [50])
Coevolution: Evolution of a species causes adaptations in a second specie and vice versa. Is distinguished in conflict and cooperation.	Coevolving in cooperation: Artifact types that evolve together (modeling grammar and its tool)	Versions of the UML (e.g. UML 2.0 and 2.5) and corresponding revisions of standards-compliant UML modeling tools (e.g. [3])
Endosymbiosis: Incorporation of an organism within another species' organisms	Incorporation: Artifact versions of an artifact type being incorporated in versions of another artifact type	Use Case Diagrams were integrated in UML (cf. [51]). Parts of the UML were refined in SysML (e.g. Ports [2])

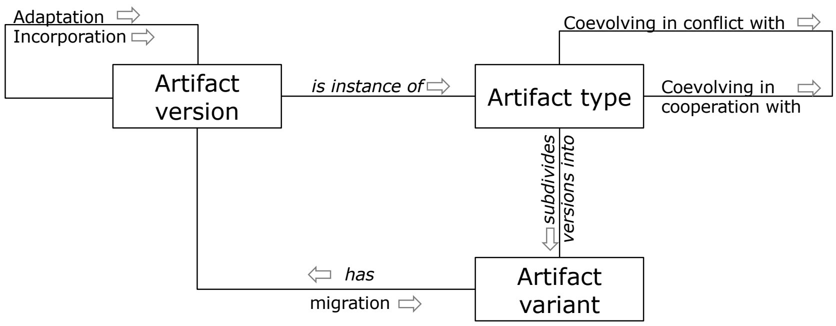

Figure 2. Relating concepts and relationships derived from evolutionary biology (cursive relationships are only integrated for a better readability)

4 Evaluation

Although this works focusses on discussing concepts and relationships that might be used for further theorizing in future work, we include a pilot content analysis following Krippendorff [13] to investigate whether these concepts and relationships are relevant to describe evolving design artifacts. We believe that “when theories are particularly interesting or important, there should be greater leeway in terms of empirical support” [52], p. 383, allowing for just a small demonstration to show that concepts and relationships of this study may be of relevance. Of course, subsequent research is required to assess whether concepts and relationship will hold up [52]. In this pilot study we focus on recent conceptual modeling design science research and limit the analysis to articles published in the Business & Information Systems Engineering (BISE)-journal during the last five years. This journal represents the flagship of the Wirtschaftsinformatik domain, which is primarily design-oriented [11].

We found six conceptual modeling design studies that we have summarized in Table 2. In these studies, we could detect all relationships identified in Section 2 and 3, including adaptation, migration, incorporation and coevolution. Hence, we could provide a first proof that identified concepts and relationships are relevant to describe evolving conceptual modeling design artifacts. Furthermore, we identified the words the authors used to refer to these concepts. We found that adaptation is primarily referred to with “extend” while migration is rather referred to “extent” plus a specification such as “extends by combining” [53], p. 65 or “extends with the required aspects” [54], p. 318. In contrast, incorporation was referred to in different ways using words such as “building on” [55], p. 252, and “the techniques were sequentially arranged to form” [55], p. 258. Likewise, coevolution was referred to in different ways such as with “corresponding software prototype” [55], p. 251. Although we found words how authors describe the different types of evolution that we have presented in Table 1, we refrain from suggesting words to address these types of evolution. For discussing how authors may refer to these concepts we expect that more empirical research is required.

Providing an example how to use the terminology, we use the study from Johannsen and Fill [55] in Fig. 3a and Gailly et al. [59] in Fig. 3b. Johannsen and Fill have developed an artifact type that represents a roadmap for Business Process Improvement (BPI) with conceptual modeling support. Whereas in their first version they describe the method [61], they add conceptual modeling support in succeeding studies [55], [62]. The authors describe these artifact versions as first contribution (BPI-roadmap) and second contribution (modeling support) [55], p.252 and develop these contributions in separate papers. Johannsen and Fill further incorporate versions of artifact types such as SIPOC and Ishikawa, which they further describe as foundations of their artifact type [55], p.253f. Furthermore, we found their artifact type in coevolution with the ADOxx platform [63]. This platform has been developed by members of the current research group so that implications of the evolution of one artifact may be implemented for the other artifact.

Table 2. Studies that evolve conceptual modeling design artifacts

Ref.	*Artifact type*	*Types of evolution*	*Coding examples*
[56]	Business Activities for modelling Processes and process-rel. RBAC models	**Adaptation** of Business Activities UML 2.0 extension [57] for process-related delegation models as a new artifact version	"[…] implemented our approach as a delegation extension […]", p. 235
[53]	Business model repr. lang. for business model analysis	**Migration** of VDML [58] by adaptation for specialized VDML business model constructs and views	"This paper extends the previous work by combining […]", p. 65
[59]	Recommendation-based conceptual modeling and ontology evolution framework (CMOE+)	**Incorporation:** The variant incorporates e.g. versions of the of the Unified Foundational Ontology [60] **Migration**: Conceptualization of a generic framework (CMOE+) and extending this framework for a BPMN instantiation as a new variant **Coevolution**: The variant exists in coevolution with the eclipse plugin extension for BPMN2 Modeler	"[UFO] was selected as a core ontology", p. 242 "CMOE+ […] may be instantiated and further specialized to support different concrete modeling languages.", p. 236
[55]	Business process improvement (BPI) roadmap with conceptual modeling support	**Incorporation**: the BPI roadmap (first version) incorporates versions of artifact types such as SIPOC and KPI **Adaptation**: Conceptualizing a BPI roadmap [61] and adapting it for further conceptual modeling support [62], [55] as a new artifact version. **Coevolution** with ADOxx [63]	"The roadmap […] is […] building on BPI techniques", p. 252; "the techniques were sequentially arranged to form a roadmap", p. 258 "Based on this BPI roadmap, a domain-specific conceptual modeling method (DSMM) has been developed.", p. 251 "a corresponding software prototype has been implemented using a meta modeling platform ", p. 251
[54]	Extended ITML for IT platforms and multilevel model of IT platforms	**Migration** of Memo ITML [64] for IT platform constructs as a new variant of MML [65] **Coevolution**: Memo ITML for IT platforms exists in coevolution with the Flexible Meta modeling language implemented in Xmodeler [66]	"we undertake an attempt to extend ITML […] with the required aspects", p. 318 "we apply FFML to model different aspects of IT platforms.", p. 234
[67]	Business-oriented Service Description Language	**Migration**: Developing a UML-profile for the graphical Notation of BoSDL as a variant of UML	"[…] develop such a format based on the UML, which we adapted by creating a profile", p. 12

Gailly et al. [59] developed a recommendation-based conceptual modeling and ontology evolution framework (CMOE+) that they present as a generic framework in its first version. In its second version a specific instantiation for CMOE+BPMN was developed. Because of the different versions being either generic (CMOE+) or specific (CMOE+BPMN) we present these versions as variants. The authors describe that this artifact type "might further be instantiated and further specialized to support different concrete modeling languages" [59], p.236 indicating that there may be further variants. Gailly et al. incorporate versions of artifact types such as the Unified Foundational Ontology (UFO) [60] into their artifact. Furthermore, they describe that they implemented an eclipse plugin in their BPMN2 modeling tool, which may indicate that CMOE+BPMN is in coevolution with BPMN2 modeler. Please note that these two examples represent our interpretations of the authors' publications. Although two authors of this paper coded independently and discussed and merged their results, our view may include misinterpretations and is limited to aspects we found relevant. We suggest the terminology for evolving design artifacts to be more powerful in case the authors use it themselves to describe their artifact evolution rather than other researchers trying to interpret their results.

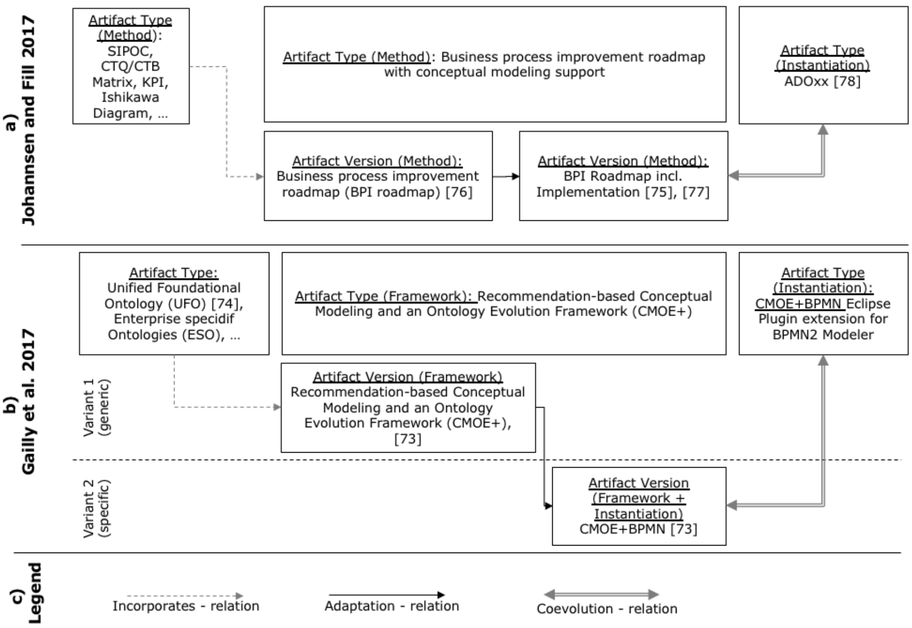

Figure 3. Describing an artifact evolution using a) the example from [55], b) the example from [59] and c) providing a legend for the different relations that occur in evolving design artifacts

5 Discussion

The terminology to describe evolving design artifacts, summarized in Table 1 and Fig. 2, can be used to help researchers to increase rigor by grounding their projects with existing artifacts. Accordingly, design researchers may clarify how present and prior artifacts relate to one another or can describe artifacts that they coevolve with. Thereby, design researchers address mutability of their design artifacts such as Gregor and Jones asked for [7]. Furthermore, we suggest that the terminology for evolving design artifacts helps to decide where to focus on when evaluating design artifacts as suggested by Gregor and Hevner [68]. For example, when adapting an artifact version that has been evaluated profoundly and that has positive impact, evaluations of the new version may focus on those features that have been added or abandoned instead of again evaluating the whole version. In contrast, when evaluating an artifact variant, evaluation can focus on distinct characteristics of the application domain the variant is used in.

To improve relevance, design researchers can use the terminology for evolving design artifacts to clarify their contribution. In analogy to the design science contribution types presented in [68], design researchers can distinguish different contribution types for their artifacts. As one contribution type, their artifact instance may base on well-developed and evaluated artifact instances and thus, include mature knowledge. In this case, design researchers could discuss the distance between their current and preceding artifact instances, e.g. by devising the number of new functions or abandoned functions, as well as the effort required to implement or abandon these functions. As another contribution type, researchers might describe their design artifacts to only have a limited evolutionary lineage. In this case, design researchers justify their contribution by discussing the novelty and originality of their ideas as well as the problems their artifacts help to solve. Furthermore, as mutations in design projects are subject to human activity, relevance for future design projects might be increased by facilitating mutations. For example, allowing for more creativity in design projects or for appropriate time slots for evolving the design artifact might impact on the number and quality of mutations. For instance, the act of creativity has been discussed as bisociation, that can be achieved by relating issues that at first seem unrelated to produce new insights [69]. Bisociation has been discussed in psychology but to our knowledge not been reflected for design science.

So far, the terminology for evolving design artifacts does not fully relate to recent mutability approaches. In-design mutability refers to the degree of change encompassed within one artifact version [7] and does not reflect relationships between artifacts. In-use mutability describes artifacts to evolve over time by allowing users to adapt the artifact. However, also designers evolve their artifacts (e.g. [53–55, 59]), which is not reflected in in-use mutability. We suggest that the terminology for evolving design artifacts may enhance in-use or may be treated as a unique aspect.

6 Limitations

As this work represents an interim struggle in theorizing we include a discussion of potential boundaries that need further investigation. We have limited our analysis to conceptual modeling design research but presume that these concepts can be applied to other IS domains that deal with design science. We suspect that coevolution is possibly not a relevant type to describe artifact evolution in any IS domain. In conceptual modeling, coevolution was reconstructed for artifact types and their corresponding modeling tool. Accordingly, for this domain we found coevolution to be tool-dependent and might hence not apply to any domain. Yet, more research is needed to specify whether coevolution is indeed dependent on tools.

Furthermore, one might question whether concepts of the terminology for evolving design artifacts may apply to any conceptual modeling project. In the evaluation we have only focused on types of artifact evolutions that were published in the BISE-journal from 2014-2018. We found that artifact evolutions had a low to mid-range complexity including one to three different evolutionary relationships. For example, Fill and Johannsen described an artifact evolution that includes an incorporation, adaptation as well as coevolution [55]. In contrast, other artifact evolutions only included one type of artifact evolution and might in this sense be described as less complex in terms of evolutionary steps. Yet, we suspect that concepts of the terminology for evolving design artifacts may be also used for more complex evolutions such as the evolution of the UML or BPMN. We have already pinpointed to how these different types of evolution may correspond to the development of UML in the introduction but agree that more research is needed to proof whether concepts can also be applied to large artifact design projects.

7 Conclusion and Future Research

As design artifacts evolve over time, design researchers need a terminology to describe this evolution. We have developed such a terminology based on evolution in biology and evaluated whether its concepts and relationships are already used, although in other words. We found that authors describe evolution in their own words but lack a consistent terminology. For further evaluation we suggest to use a larger sample size and to check the coders' interpretations against the designers' experience by conducting interviews. Thereby, usefulness of the terminology and the need for further notions may be assessed. So far, we only provide examples of evolving artifacts [55, 59]. A systematic approach to describe evolving design artifacts might help to compare evolutions of different design artifacts and thus, to render evolution of design artifacts more transparent. The terminology derived in this paper bridges the gap between the need to address mutability [7] and the guidance required to do so [70]. So far, this guidance is available as a terminology and not as a mid-range theory [71] between evolution in biology and evolution in design artifacts. To further approach theory, e.g. boundaries need to be investigated, concepts need to be refined for other domains, propositions about e.g. typical sequences in which types of evolutions occur should be developed and translated into hypotheses.

Abstract. Representing and reusing the business objects of a domain model for various use cases can be difficult. Especially, if the domain model is acting as a template or a guideline, it is necessary to map the enterprise's individual structure and processes on the shared domain model. Structural modeling languages often do not meet this requirement of reusing structures and complying to established processes. We propose a modeling language called BROS (Business Role-Object Specification) for describing the business objects' structure and behavior for structural models, based on a given domain model and process models. It utilizes roles for a use case related specification of business objects as well as events as interfaces for the business processes affecting these roles. Thus, we are able to represent and adapt the business object in different contexts with individual requirements, without changing the underlying domain model. We demonstrate our approach by modeling a simple case.

Keywords: Structural Model, Role, Behavior, Business Logic

1 Introduction

Software modeling enables the design, construction, configuration, and checking of static and dynamic parts of a software system, that is the structure and behavior, before implementation. Especially for enterprise information systems, we are in need of modeling new or changed model parts, as enterprises frequently use individual, enterprise-specific business processes. Therefore, during modeling of information systems, one often encounters conflicting goals and has to choose between either following a unified and possibly standardized domain model or adhering to the individual and unique business logic of the targeted system context. On the one hand, software engineers want to stick to the principle of standardization and rely on the unified domain model. On the other hand, stakeholders want their individual requirements to be implemented.

When modeling a software system, the model should have four characteristics: clarity, commitment, communication, and control [1]. Especially the last two aspects are important: "The model truly and sufficiently represents the key properties of the real world to be mapped into IT solutions", and "The model is used for the assessment

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

of specifications, design, implementation, reviews and evolution." [1] Both aspects need to be fulfilled if the model is to be effectively used in software construction. However, current models for such software construction are strong in modeling either the static part (like UML class diagrams [2]), or the dynamic part of a system (like BPMN models [3]). To address the "communication" aspect of the model, both parts need to be taken into account to represent the properties of the real world and their mapping into the IT world. However, the new or changed model should avoid divergences from an available or given domain model that is supposed to serve as a basis for many application models. This is important for the "control" property of a model, to be able to assess the specification, design, and implementation of the future software system. Therefore, compliance with the domain model and realization of specific business logic needs to be harmonized.

In this paper, we propose a new modeling language as part of a method to solve this issue. Our modeling language named BROS (Business Role-Object Specification) can be used to describe and extend a software system that is based on an underlying domain model, and explicitly includes process-driven business logic with respect to its effects on the structural model. In general, BROS is a structural modeling language for design time specification of business objects concerning a (maybe given) domain model as well as specific business logic. Roles fulfilling objects cover the static specification part regarding the separation of concerns, whereas the dynamic specification part of the business logic is expressed via events. The final BROS model serves as a blueprint for development and can be implemented in role-based modeling languages. Although the structural part dominates, we strive for a behavior-aware modeling approach.

The remainder of this paper is structured as follows. Section 2 discusses the related work and current approaches of behavior-aware structural modeling. Section 3 gives an overview of the BROS method, whereas in section 4 we describe the BROS language. Section 5 demonstrates the language with a use case of ordering a pizza, followed by the summary and conclusion in section 6.

2 Related Work

As mentioned before, we strive for a behavior-aware structural modeling method with roles and events. We want to address the issues of using single domain models for various use cases as well as model towards the individual business logic of an enterprise. Especially the tailoring of conceptual business objects of the domain model for different process models is an important feature of modeling software systems.

The role-based paradigm has increased its visibility in the last decades [4, 5]. The static "class" as the main object is not sufficient for modeling business concepts because of its limitation on fixated identity, type, and context. Therefore, various authors propose the role as an appropriate modeling construct in business domains [6–8]. Thus, role-based enterprise modeling is not unknown in modeling.

There are various approaches that model enterprise-specific use cases with roles. In the field of ontologies, many authors state the conceptual foundation of role-based modeling (e.g., [9, 10]). However, conceptual foundations lack implementation details and are only a preliminary stage. In contrast, several works contribute to the methodological aspect of role-based enterprise modeling (e.g., [7, 11]). Kühn et al. present a role meta-model approach of modeling roles for different contexts. However, they do not elaborate in detail on methods of using roles for given business logic.

Colman [12] defines two different ways of representing a role: "player-centric" and "organization-centric", where the latter is focused on the organizational boundary of business logic. Regarding the modeling of information systems, the understanding of "processual roles" is proposed (e.g., in [13]), determining that a role of an object is used as a participant of a certain process. In general, the inclusion of temporal information of business processes is handled in many different ways. Thus, modeling behavior in structural models receives attention in software and system construction. One may use model transformation to solve this issue by transforming process models into structure. However, such approaches do not relate to an underlying domain model as the target structure in general, which is not preferable for template-based system design. A reversed approach includes temporal information into structural models where the modeling of elements like events, situations, and states are in focus. Various papers examine the more abstract, semantic, and conceptual views on events and scenes (e.g., [14, 15]), to increase the foundational understanding of events. However, the details of the method are missing, how one may model an event within a structural model, although that was not the author's intention. Edelweiss et al. [16] propose a method that introduces temporal aspects and object changes to object-oriented models. However, the structural modeling method remains unconsidered. As a relevant related work for BROS, Olivé and Raventós [17] present an approach for defining the concept of an event entity within structural object-oriented models. The authors define the event as a UML stereotype and utilize OCL to formalize post-conditions for events. Nevertheless, by including events into the core model, the reuse of an underlying domain model, as well as modeling towards different business processes, would be difficult. In addition, events as UML stereotypes are still classes, which can be difficult when modeling towards business process models such as BPMN.

3 The BROS Method

Our method was designed to construct and extend software systems by (re)use of domain models. The initial domain model with its business objects may already have been discovered by a domain analysis or given by a domain standard (like in-house templates or reference models). Also, the enterprise-specific business logic should be known. As motivated in the introduction, the BROS method has, in fact, two major core concepts: *(a)* the (re)use of a single domain model to fit different enterprise's business logic, and *(b)* to specify the behavior of objects with respect to the specific business logic. As a result, the final BROS model serves as a blueprint for the construction of an enterprise's software system according to the unique business logic.

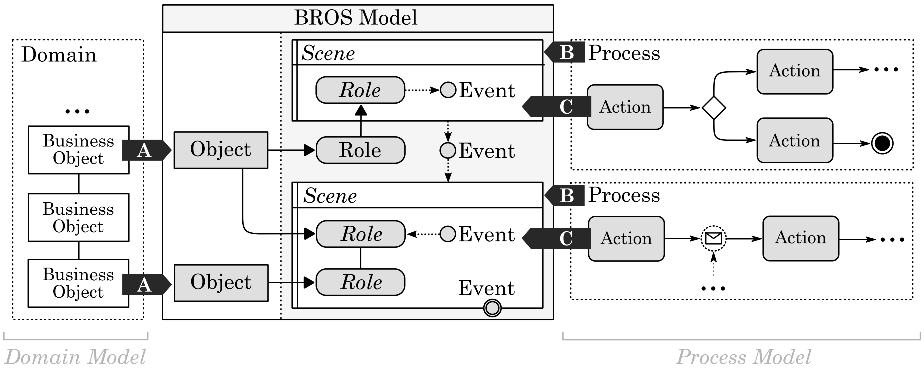

Figure 1. The composition of a BROS model by use of structural and behavioral models

Figure 1 illustrates the BROS method and exemplifies the relationships between the modeling constructs. The objects carry the identity of business objects within the domain ("A" arrows). The (for the enterprise's business logic needed and chosen) objects can be determined by the modeler. Often, the initial domain model is standardized or used by other modelers as well, in which case the modeler must adhere to the domain model as a template, which limits the possibility of introducing new or modifying existent business objects. However, new and changing business logic has to be implemented during the construction and lifetime of the software system. Thus, to express the purpose of (rather static) objects for different (enterprise-specific) business logic in single applications and to support future extensibility, we utilize *roles* as the adaptation construct at design time. A role represents the object and specifies a particular purpose for it. As the objects may be limited to the given domain model, the modeler is free to design roles to fit the objects into the enterprise-specific business logic (e.g., "Meeting Room" as a role of a "Room" object). Even without a limitation to a domain model, roles are useful as a specialization mechanism, since they do not introduce new types and identities for every use case related to the object (e.g., the roles "Meeting Room" and "Dining Room" may use the identity and type of the object "Room" for different use cases). Further, future extensions and evolutions of new functionality are possible by introducing new roles for existent objects.

So far, the specification of objects and roles are the minimum requirements for being a valid BROS model, specifying the static business logic, but not the dynamic behavior. However, for more expressive modeling regarding the enterprise-specific business logic, one can use *scenes* and *events* to describe the behavior and dynamics of roles. A scene is a temporal context for business logic and can often be derived from available process models ("B" arrows). Roles within a scene are acting as participating entities in that process. For example, a "Person in Charge" could be a role within the scene "Room Booking". To specify the lifetime and the participation of roles, we use events as a temporal construct. Events describe a point in time when something has happened (which in turn is based on the enterprise's process model), e.g., "Room Booked". Events are selected by the modeler in such a way as to model the effects of the process on the roles ("C" arrows). The process model that is responsible for the occurrence and impact of events is called the *background process*. In contrast to the domain model, the final BROS model always uses the background process only as guidance, not as a template. That is also why the processes do not need to be BPMN models but may also be of any other behavior model type, e.g., petri nets or sequence diagrams. An extraction of suitable events out of these model types may, however, be different. In conclusion, the BROS model fills a gap between a generic domain model and the specific business logic by providing a possibility to model towards specific requirements of an enterprise's information system.

4 BROS Modeling Language

In this section, we describe the BROS modeling elements in detail. For a formal representation, the complete BROS modeling language is shown in figure 2. We based our meta-model on [18] and modified it towards our requirements.

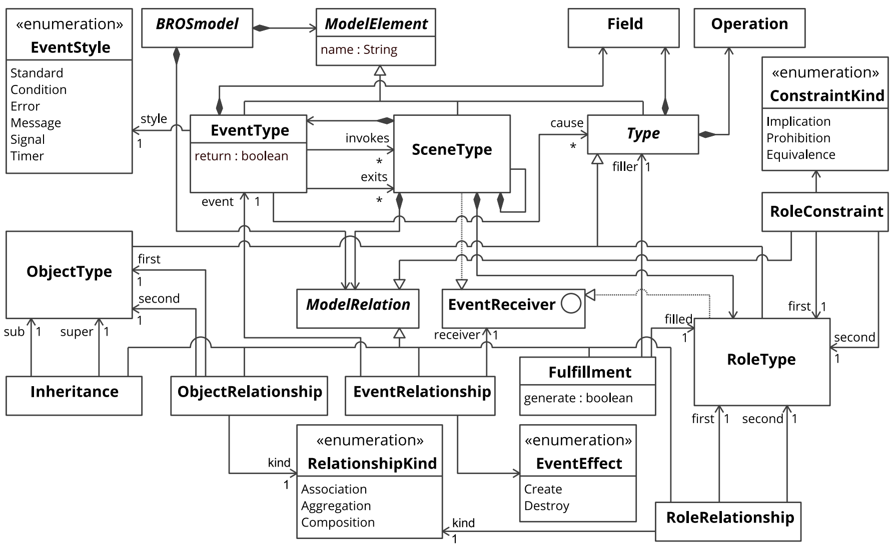

Figure 2. The BROS language meta-model

4.1 Objects

The BROS objects represent the business objects of the model, such as a customer, a rocket, an order, a receipt, or an appointment. The objects are the basic concept for the structural BROS model and are specified using roles, events, and scenes. In theory, we do not need any domain model to start a BROS model. However, if we have such a domain model, we can use its (possibly standardized) business objects as a template for the BROS objects. We define an object as follows:

> *The object is the central modeling construct for representing business objects within a given business domain. The object has an own identity and is uniquely*

identifiable among all other objects. It contains all necessary information to represent the business object with its universally valid properties, behavior, and relationships within the system.

BROS objects are shaped and act similar to the classes from UML. They can be associated with or inherited from other objects and may contain attributes and operations. The reason why we do not call them class but object is simply due to stress that objects always represent a real business object and not any technical class concept. Should the domain model already be in an implementable format (e.g., UML classes with attributes and methods), then we are able to use its classes as BROS objects. However, if this is not the case, one has to create the necessary objects and their relationships in an implementable format.

Please note that the *object* only concerns the object itself. A *compound object* [19], instead, comprises the object as well as all its roles and related events. With the model element of objects, we provide a suitable base for starting the construction of the software system, regardless of whether the object is newly created or already available via an implementable domain model.

4.2 Roles

The definition and understanding of a role in a conceptual model are already well elaborated, e.g., in [20]. In BROS, roles are the static adaptation and configuration parts of business objects. The context may be dynamic (within a scene) or static (the basic BROS model). For both, we use the context definition from Dey [21]:

"Context is any information that can be used to characterise the situation of an entity. An entity is a person, place, or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves." [21]

We interpret this definition in such a way, that a scene (and the model itself) is a particular "information" (the "context") that characterizes the situation of objects (the "entities") whereas the objects then are relevant for the general interaction within the scene, expressed as roles as context participants. Our definition of a BROS role is based on the context definition:

A role is a contextual modeling construct with state and behavior that is fulfilled by an object or its roles to represent it in the user's context and extend or change its corresponding specifications and interactions.

A role can be fulfilled either directly by the object or indirectly by a role that is already fulfilled by the object. In our definition, at the type level, the role is "fulfilled by" an object as a *player*. However, at the instance level, the object instance "plays" the role instance (respectively the role is "played by" its player). A fulfilled role shares the related player's identity at runtime. Graphically, a role is represented by a rectangle with curved edges. Figure 3 shows a role fulfillment.

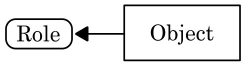

Figure 3. A player object fulfills a role

Role Relationships. In order to successfully represent business logic and unique structure, different relationship kinds are needed to represent the interaction between two elements. Roles can be related to each other to represent their related business logic and interactions, based on the UML language. This includes the kinds shown in table 1.

Further, BROS also supports the usage of role constraints, introduced by [5]. We may use the constraints *Implication*, *Prohibition*, and *Equivalence* to specify constraints between two roles.

Table 1. Role relationship kinds

Name	*Icon*	*Description*
Association		interaction-based connection
Composition		"contains" connection
Aggregation		"owns" connection (special case of composition)
Implication		role A implies playing role B
Prohibition		role A and B cannot be played at the same time
Equivalence		role A and B can only be played together

Role-based Adaptation. To redefine several aspects of an object in a specific context, roles can be fulfilled to alter its structure or behavior. For that, we use the delta concept, based on the ideas of delta programming [22]. We only use the *add* (+) and *delete* (–) actions, as those two are logically sufficient to represent all other modifications. For convenience, we also allow *modify* (~) as a combination of both. A role, therefore, may use add, delete or modify as *adaptation actions* to alter properties of its player object. The things we may redefine with roles are manifold: attributes, visibility, methods, parameter, types, or other type-atomic elements. However, we never alter the actual object, but only its roles hold the delta information. In fact, with roles, it is possible to represent (and modify) the original object aligned to the specific requirements of the business logic. Nevertheless, it is not mandatory to specify any delta for using roles. A role may be empty in its delta, but can still be used to express certain business logic, e.g., a state of an object. Note that a given delta implies knowledge about the (future) player and its properties to which the delta refers. If new players are added, the delta may require changes. Figure 4 shows an example of an adaptation.

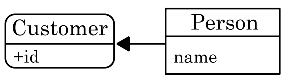

Figure 4. A role changes the player's properties (adds "id" as delta)

4.3 Events

We use events as an essential mechanism for the dynamic aspect of roles. In the UML, events are introduced as “something that may occur at a specific instant in time. One event may have many occurrences, which may happen at different times.” [2] We share this definition and extend it further:

> *An event is a modeling construct for specifying the temporal behavior of roles. It occurs at a specific instant of time, with possible reoccurrences. An event may have causes to define the objects that may trigger the event and determines the object fulfillment of roles.*

Event modeling is a frequent topic in conceptual modeling, mainly in process models [23]. However, in BROS, we explicitly focus on the impact of process events on the objects (and their roles) of structural role-based models. Such events are, as described in section 3, interfaces to business process models and represent the impact of process models in the structural model. Events are context-dependent, which means that they only apply in the context and can be triggered by objects or roles in the same scene in which they are located.

When modeling an event, it appears as a simple circle within the diagram. At design time, an event in the model means that it can occur in the course of business logic and certain effects regarding roles result from it. However, at runtime, an event is something that must be triggered, for example, by a method call. As a result of events, roles are created and dropped by the *event effect*. Each role created and orchestrated by an event is called a *dynamic role*, whereas roles that occur independently of events in the system are called *static roles*.

Event Styles. Events are also known from BPMN and described as “something that happens during the course of a process”. [3] The BPMN specification differentiates several types of events like message, error, or cancel. As such a classification of events is useful for business modeling, BROS uses some of them within its specification, too: standard, message, timer, error, condition, and signal. Those *event styles* are shortly represented in table 2. However, BROS uses slightly different semantics. Whereas the BPMN event types are focused on the different participant actions, in BROS an event only types the origin of something that happens (e.g., in BPMN, the timer event is involved in an actual workflow, and in BROS it is triggered by an “invisible clock”).

Table 2. General event styles

Name	*Icon*	*Description*	*Example (Pizza Ordering)*
Standard		- standard event	customer added
Message		get message event	order received
Timer		get timer event	pizza 20 minutes baked
Condition		get condition event	pizza less than 40°C

Error		get unexpected event	no more salami available
Signal		get signal event	successful credit card check

Event Effects. An event defines a specific instant in time at which a role instance is created or destroyed. This enables orchestration of the roles at runtime. If an event is triggered, it handles the roles as a consequence (the event's effect). The event's effect options are shown in table 3. Although events can only be triggered within their context, event effects can in principle have roles outside of their own context as a target.

Table 3. Event effects

Name	*Icon*	*Description*
Create		bind a new role to an object
Destroy		unbind a role from an object

4.4 Scenes

The grouping of roles that belong to a specific (temporal) task is called a scene, adapted from [15, 24]. A scene is the main element for describing the execution of any business logic that affects the roles. We define a BROS scene as follows:

> *A scene is an instantiable temporal collaboration context of roles and events, related to the same business logic part.*

Good indications of such scenes are activities or operations, e.g., "student enrollment" or "order pizza". The scene does not model the business process of such tasks but only the role composition and lifetimes. When defining roles for a scene, it is important to always focus on the scene and its required roles as participants, not the existing business objects and the roles they might be able to use. Thus, the background process acts as a hint but does not give a complete answer on the needed roles for scenes. Further, a scene may vary in its granularity. A rather coarse-grained scene would be "book flight" while a fine-grained scene would be "pay with credit card," possibly also as a sub-scene of the former one. However, events are not limited to scenes. Due to readability, the fulfillment arrows do not cross the edge of a scene, but note the target role name, as shown in figure 5. If an object instance is newly created as soon as it takes part in a certain scene, it is marked with a double arrowhead, also shown in figure 5. That arrow is called a *generate fulfillment* and only possible for fulfillments targeting dynamic roles.

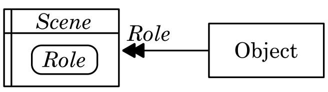

Figure 5. A new object instance is created as soon as the role is created in the scene

Special Event Functions. Scenes also define some other special functions for events and roles to better integrate the business logic flow, which is summarized in table 4.

Table 4. Scene event functions

Event Function	*Description*	*Notation*
Invoker Event	specifies the start of a scene (invokes the scene); all *init roles* of the scene are created	Exit Event	specifies the termination of a scene from the outside; the scene terminates, and its roles are destroyed; invoked scenes are interrupted (exit)	Return Event	specifies the end of the scene from the inside; all roles in the scene are destroyed	
A scene may start by any possible *invoker event*. At runtime, multiple instances of a scene, started by possibly different invoker events, may exist. *Init roles*, which occur with the invoker event, are particular roles within a scene that get played (like a parameter) as soon as the scene is invoked. There is always a multiplicity given with a role to determine the number of possible instances for that role at runtime. An init role has a lower bound of at least one instance (e.g., “1..*”).

Exit events are events, which are triggered outside of the scene. A triggered exit event is like an external interrupt. All roles within the scene are destroyed, and the scene is over. However, the actual exit event may have some further effects on other roles as well as causes.

The standard way of exiting a scene is using the scene’s *return events*, a double lined circle on the scene’s edge. They are for the intended outputs of the business logic, even errors or unexpected behavior. The difference between return and exit events is that return events are always triggered within the scene and from the business logic itself, not from the outside. A return event’s effect will always take place, regardless of the invoking context. The background process may indicate one or more return events, but it could also be determined by the modeler due to technical reasons.

5 Modeling Case Study

In order to demonstrate our approach, we present a business use case regarding different mechanisms of BROS. As a foundational background process, we use a very simplified “order pizza” BPMN example, as shown in figure 6. It describes a simple pizza ordering within a restaurant plus a routine for customer feedback.

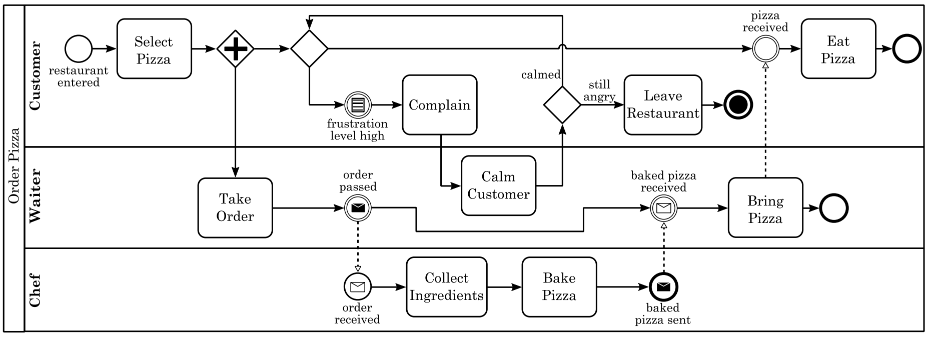

Figure 6. The background process for this case study

It is not possible to translate a BPMN directly into a BROS model. Instead, the construction of BROS models uses BPMN as the background process. We rather assume that a basic structural domain model already exists and is adapted to fit a specific use case or process. Figure 7 shows the final BROS model. We omit attributes and operations due to better readability.

<BROS Example Restaurant>

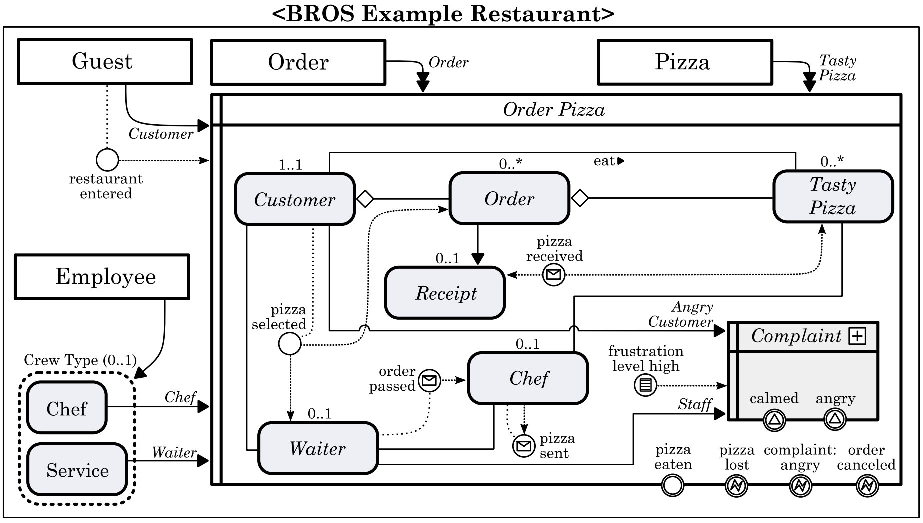

Figure 7. The “Order Pizza” modeled with BROS

Context and Objects. For this example, we use static contexts (the named BROS model), dynamic contexts (scenes), and the corresponding objects out of the business object set given within the domain model. This is either done by the modeler’s requirements or by using objects provided by a standardization, e.g., a reference model for the specific domain. We identified the context of the *Order Pizza* model first:

- The background process example describes the pizza ordering process. Thus, our domain is the restaurant, modeled as the *Example Restaurant* BROS model.

- We used four objects: *Employee*, *Guest*, *Order*, and *Pizza*. They serve as the most founded elements and carriers of identities. We assume them to be given within our domain model.
- Our background process implies a scene called *Order Pizza* (probably only one of many scenes within a restaurant). We decided to implement another sub-scene *Complaint* (instead of a single event) due to any existing complexity in the background process related to this.

The additional scene is *folded*, as we are not interested in its inner role behavior but only the players and the outcome. However, other models still might use the full representation of these scenes.

Roles. The roles adapt the objects, tailored for our own (enterprise-specific) business logic of ordering a pizza. Often, the roles can be derived from the given participants of the related background process (e.g., a swim lane in BPMN), which interact with each other in that specific scene. However, one should not forget to also define roles for things and not only for persons.

- We refined the *Employee* object with two static roles: *Service* and *Chef*. Both roles are not part of our scene (means independent of ordering a pizza). We grouped them as *Crew Type*. Every *Employee* has to play at most one role of the *Crew Type*, marked by the multiplicity.
- The *Order Pizza* scene has the following dynamic roles to fulfill its desired business logic: *Customer*, *Waiter*, *Order*, *Chef,* and *Tasty Pizza*. The *Customer* is an init role.
- One needs to define players for the scene's roles. Thus, we use given objects as players. Further, *Order* and *Pizza* use the generate fulfillment so that it is clear that these generate a new instance when taking on the role within the scene.
- Since *Complaint* is folded, we imply knowledge about the inside roles. Thus, a *Waiter* fulfills the role of *Staff* and *Customer* fulfills the *Angry Customer*.
- There is a dynamic role called *Receipt* to respond to the finished order in the form of "pizza received". This role will be played indirectly by the *Order* object.

Please note how the role *Chef* is fulfilling the role of *Chef* again. This is due to the different context. The outside *Chef* has, logically, nothing to do with the *Chef* within the scene. The former role states a crew member, the latter states a person who bakes the pizza. This may be different in other scenes involving the crew's *Chef*. At runtime, both *Chef* roles use the same identity as the related *Employee* instance.

Events. The adding of events depends on the modeler's intention and the background process and can differ widely. We chose one possibility for our use case.

- We stated *restaurant entered* as the invoker event for the *Order Pizza* scene.
- The start and end of a participant on a swim lane in BPMN could provide information about BROS events that start and end a role. For example, we used *order passed* as the start event for the *Chef* role, which ends with *pizza sent*.

- We modeled several return events that end the *Order Pizza* scene. Further, also the returns of the folded scene *Complaint* were defined.
- We used the *Receipt* role as the event effect of *pizza received* to generate the receipt for the customer.
- Finally, optional event causes are added. For example, we modeled that any *pizza sent* event may only be triggered by *Chef*.

Remarks. In general, we used the process, described with BPMN, as a reference for the final structural model, described with BROS. Our BROS implementation is only one possible option. The extent of modeling (and thus the richness of detail and readability) depends on the modeler's requirements and needed scope and granularity. Although the final model may be more complex and larger, it is a detailed adaptation of a (possibly already existing) structural model for a specific business logic use case. Additionally, for example, we could add an "order pizza online" or "payment" scene within the same domain without changing the underlying domain model. Please note that in order to make the model implementable, the (delta) attributes and operations would now have to be added.

6 Conclusion

In the context of role-based modeling, event modeling, and temporal behavior, we have proposed BROS, a new modeling language for behavior-aware structural modeling. It utilizes objects, roles, events, and scenes to describe business objects as role objects, orchestrated by events to represent business logic.

The BROS model reconciles the disparity between a conceptual domain model and individual business logic of the target context. Thus, the BROS method comprises three steps: *(a)* refining of the conceptual model for implementation-ready objects, *(b)* using roles as the variable part of objects for tailoring them towards individual business logic, and *(c)* defining a temporal context regarding business logic in the form of process models, guiding the occurrence of roles and their interaction. We defined a language meta-model and used a fictional case study to show the application of our BROS method in principle and in order to demonstrate feasibility. We consider that the best application of BROS occurs at an early stage of software development when the domain model's expressiveness turns out to be a limitation and software engineers are in need of further details regarding the targeted business logic that has to be fulfilled. On the basis of this, we argue that the possibility of detailed and expressive modeling is helpful for defining new and changing functionality of a software system. Nevertheless, this is also a limitation of BROS, since a BROS model of a comprehensive software system would be too complex. Thus, BROS is possibly better suited for modeling only an excerpt of the complete system, as BROS roles and scenes allow the separation of concerns. However, it is not appropriate to provide a complete system overview. Therefore, a combination of BROS (for detailed views) with a previous model instance (e.g., the overall domain model) works best.

However, some future work is still needed. BROS is currently in its first version. Some modeling scenarios might not yet have been considered, or there might exist some inconsistent features. Further, BROS is formalized by a meta-model, but a concrete syntax (e.g., notation) is also needed. We want to enhance the event element so that more functionality of process models can be covered. The integration of pre- and post-conditions of events also has its benefits [17]. Eventually, our approach needs to be tested in contexts closer to real applications. We also intend to do a broader evaluation and study of the resulting BROS models regarding their applicability and usability (e.g., with [25]) in practice. Additionally, we want to develop tool support and concrete guidelines on how to create BROS models concerning existing background processes.

Generating Smart Glasses-based Information Systems with BPMN4SGA: A BPMN Extension for Smart Glasses Applications

Jannis Vogel[1] and Oliver Thomas[1]

[1] University of Osnabrueck, Chair of Information Management and Information Systems, Katharinenstr. 3, 49074 Osnabrueck, Germany
{jannis.vogel,oliver.thomas}@uni-osnabrueck.de

Abstract. Although smart glasses allow hands-free interaction with information systems and can enhance business processes, they face problems with the adoption in businesses. Implementation challenges arise due to specific hardware conditions e.g. computational power, limited battery, small screen size and privacy issues caused by the camera. In addition, not many programmers are specialized for the development of smart glasses-based applications to conquer the mentioned challenges. We address this issue with a generation tool for smart glasses-based information systems. A BPMN extension for smart glasses applications allows the abstract specification. Specified processes are then integrated into a model-driven software development approach that transforms processes directly into smart glasses applications. This paper covers the design and development phase of the abstract and concrete syntax of the BPMN extension and the representation of the architecture to generate smart glasses-based information systems with the new developed BPMN extension.

Keywords: Smart Glasses, BPMN Extension, Model-driven Software Development, Domain-specific Modelling Language.

1 Introduction and Motivation

Due to the mobility, hands-free interaction with information systems and a range of different functionalities, smart glasses are suitable for various application areas [1]. Widespread applications are pick-by-vision [2], remote assistance [3] and step-by-step guidance [4]. In particular smart glasses are suitable as a service support system to guide users through a complex working process such as in the technical customer service domain [4]. In general, smart glasses are applied in businesses to enhance business processes due to information provided in the user's field of view.

However, different obstacles arise during the implementation of smart glasses in businesses. Hobert and Schumann identified 25 challenges with the integration of wearables (i.e. smart glasses and smart watches) into businesses through 21 semi-structured interviews. They recognized that organizations have an urgent demand for software developers that know the implementation of wearables into businesses.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Furthermore, interviewed experts in the study mentioned that only a few wearable third-party experts exist [5]. This circumstance hinders the adoption of smart glasses and hampers an adequate dealing with smart glasses specific implementation barriers such as the small screen size [6], limited battery capacity and privacy issues [5].

A promising approach to overcome the mentioned obstacles is the usage of domain-specific modelling languages (DSML) to design software [7], in this case smart glasses applications, and to steer the implementation process with a model-driven software development (MDSD) approach [8], i.e. models have a direct effect on the desired software. During the research project Glasshouse [9] we followed that approach by using the modelling language BPMN to describe smart glasses-based use cases in the logistics domain. Thereby, we identified that existing process modelling languages such as EPC or BPMN are not suitable for the technological representation of smart glasses functionalities [10]. Consequently, a proper model-based design of smart glasses applications and their utilization in a MDSD approach was not feasible.

Hence, we address implementation obstacles and the non-technical expressiveness of process modelling languages in terms of smart glasses with the development of an abstract and concrete syntax of a BPMN extension for smart glasses-based information systems. Thereby, adequately represented smart glasses-based process models lead to smart glasses-based information systems by a MDSD concept. The BPMN extension supports a precise technological representation of smart glasses functionalities into business processes and the MDSD approach allows non-technical experts the design and readjustment of smart glasses-based information systems. Thus, the superordinate research question is: *How can smart glasses-based functionalities be integrated within a BPMN extension, whose models allowing the generation of smart glasses applications with a model-driven software development approach?*

The paper is structured as follows: In the first section, we declare the relevance, motivate for a BPMN extension and explain the connection with a generating system for smart glasses-based information systems. In the second section, related work regarding smart glasses applications in the domain of process modelling is explained. Further, the objectives of the solution are outlined. Afterwards we describe the applied research method in section three. Excerpts from the results of the applied research method are presented in section four. In the next section, the implemented architecture for the MDSD approach is explained. Section six mentions discussions and limitations points that appeared during the research project and sums up the article.

2 Smart Glasses Applications related to Process Modelling and Objectives of BPMN4SGA

In the range of smart glasses applications, some have a close connection with process modelling in various forms. For instance, Metzger et al. [11] developed a smart glasses-based modelling system to model service processes during process execution. The worker uses specific speech commands and can take pictures with the smart glasses camera to create a process model. In addition, modelled processes can be used as step-by-step process guidance. Furthermore, Fellmann et al. [12] propose a process modelling recommender system to accelerate process modelling activities with smart glasses. A different approach presents Petersen et al. [13], their application allows the real-time elicitation of work processes with videos from the smart glasses user's view. The videos being used to generate an augmented reality manual that presents correct performed tasks with a green coloring of the worker's hands.

In comparison with the mentioned smart glasses applications, BPMN4SGA with an additional generating system provides step-by-step guidance based on process models like in [11], too. Though a distinction is the abstraction level, the smart glasses-based modelling system by Metzger et al. [11] uses simple workflow patterns like sequences or exclusive choices with the dedicated activities, whereas BPMN4SGA's objective is to support smart glasses functionalities within smart glasses information systems, e.g. to use the smart glasses camera or specific voice commands. Generally, BPMN4SGA allows a more detailed description of smart glasses applications. Besides a more precise description, other advantages come with the generation system and the applied MDSD approach.

This leads to several use cases that result in specific objectives of the solution. One use case is in the area where companies with no IT departments facing difficulties to adopt smart glasses from a technical point of view due to dependencies from third-party developers [5]. This circumstance ensures a rejection of new technologies such as smart glasses, although the advantages of the technology are well-known. A generating system for smart glasses-based systems can encounter technological rejection that is based on difficulties in software development. Therefore, especially small and medium-sized companies should benefit from the solution. Furthermore, smart glasses in a digitalized and mobile environment needing a fast readjustment of their information systems that can be accomplished with the proposed solution. Another tackled aspect is the reduction of investment costs and -risks into smart glasses-based systems. Assuming that one company provides the solution, economies of scale could be achieved that lead to lower and predictable costs. Particularly intangible benefits of smart glasses systems are hard to collect that makes a clear investment decision challenging [14]. BPMN4SGA and the associated generating system allow testable and fast running smart glasses systems that help to identify intangible benefits beforehand.

3 Research Method

The overall research project applies the Design Science Research Method (DSRM) by Peffers et al. [15]. This paper partly covers the design and development phase. For the actual phase, we use the method for the domain-oriented development of BPMN extensions by Braun and Schlieter [16] that extends the method for the technical development of BPMN extensions by Stroppi et al. [17] that is shown in figure 1. The domain-oriented analysis is covered in [10]. The outcome was the identification of 19 extension requirements for a BPMN extension that allows the representation of smart glasses-based processes, which can be transformed into smart glasses-based information systems with a MDSD approach.

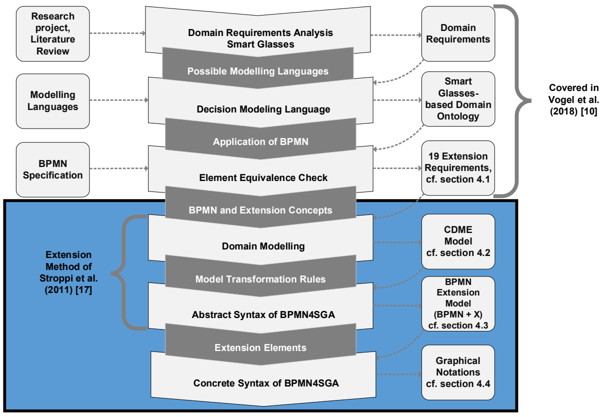

Figure 1. Applied method for the domain-oriented development of BPMN4SGA in accordance with Braun and Schlieter [16]

This paper focuses on the following steps highlighted in blue, which are overall three steps. The first step covers a domain model which is represented by a Conceptual Domain Model of the Extension (CDME) that is depicted by a UML class diagram. The CDME is the groundwork for the abstract syntax definition of the BPMN extension that is represented by a BPMN extension model (BPMN+X) and is also depicted by a UML class diagram. For the conversion of the CDME into the BPMN+X special model transformation rules are applied. Both steps are covered by the extension method of Stroppi et al. and are explained in detail in [17]. After that, the concrete graphical syntax is developed based on the BPMN+X diagram. Further design recommendations have to be covered. For instance, the shape of standard BPMN notation elements should not be altered [16].

4 Design and Development of BPMN4SGA

4.1 Extension Requirements for the BPMN Extension

Based upon insights from a one-year project phase for the identification of potential use cases in the logistic domain [9] and design guidelines from literature regarding smart glasses-based systems, we listed in an in-depth analysis technical- and software-based requirements for a dedicated BPMN extension that allows representing smart glasses-based information systems [10]. Thereby, we identified six technical-based (TB-DR) and six software-based (SB-DR) domain requirements (DR) (cf. table 1). In order to link the derived requirements with BPMN concepts, a further developed smart glasses-based domain ontology represents BPMN concepts and their linking with the developed DR. Apart from its use as a representation of knowledge, the ontology was used to steer the element equivalence check. In doing so, DR were compared with directly linked BPMN concepts. Thereby, the element equivalence check revealed 19 extension requirements where 14 requirements were not equal (NE) and 5 were conditional equail

(CE) regarding compared BPMN concepts. For all requirements occurs a specific extension, a graphical representation as an extension format is designated for smart glasses activities and their event types. Further, additional domain concepts that are not covered by standard BPMN are extended through new attributes. The design decisions were made based on the level of equality of domain to BPMN concepts and their novelty. This led only to new graphical notation elements for events and activities that will simplify learning BPMN4SGA.

Table 1. Element Equivalence Check and Extension Format for BPMN4SGA [10]

DR	Domain Concept	BPMN Concept	Equal?	Extension Format
TB-DR1	Activity and event support by the tracking concept	Activity Event	NE NE	Graphical Graphical
TB-DR2	Interactions steer the process flow, can trigger events and confirm activities.	Process flow Event Activity	NE NE NE	Attribute Graphical Graphical
TB-DR2	Manual decision through interaction inputs	XOR Gateway	CE	Attribute
TB-DR3	Visualisation of the process, brightness, and display size	Process flow Notation elements	CE	Attribute
TB-DR4	Camera to take pictures or videos	Activity	NE	Graphical
TB-DR5	Context via sensors	Event	NE	Graphical
TB-DR6	Communication	Activity Event	CE CE	Graphical Graphical
SB-DR1	Distractive visualisations	Process Flow	NE	Attribute
SB-DR2	Information provision Content type	Activity Activity	NE NE	Graphical Attribute
SB-DR3	Process improvements	Process	NE	Attribute
SB-DR4	Additional information	Data Object	CE	Attribute
SB-DR5	Object identification	Activity Event	NE NE	Graphical Graphical
SB-DR6	Communication system	Activity	NE	Attribute

4.2 Conceptual Domain Model of the Extension (CDME)

The Conceptual Domain Model of the Extension (CDME) represents the domain and BPMN concepts and their relationships (cf. figure 2). The CDME includes BPMN concepts and extension concepts that are derived from the identification of extension requirements (cf. section 4.1). Thereby, BPMN concepts are also covered in the BPMN metamodel and extension concepts, filled in grey, include concepts from the smart glasses domain [17]. The connection between standard BPMN concepts and extension concepts occurs through generalization relationships. The new graphical extension concepts have a generalization relationship to existing BPMN concepts e.g. TrackingTask has a generalization relationship to the BPMN concept task and are the new introduced notation elements (cf. section 4.4). The generalization relationships between BPMN concepts to extension concepts like GraphicalRepresentation, ProcessImprovement, SteeringProcessSetting, VisualisationSetting, ManualDecision and AdditionalInformation should add additional attributes to existing BPMN concepts. For instance, GraphicalRepresentation class attributes should be included in any task.

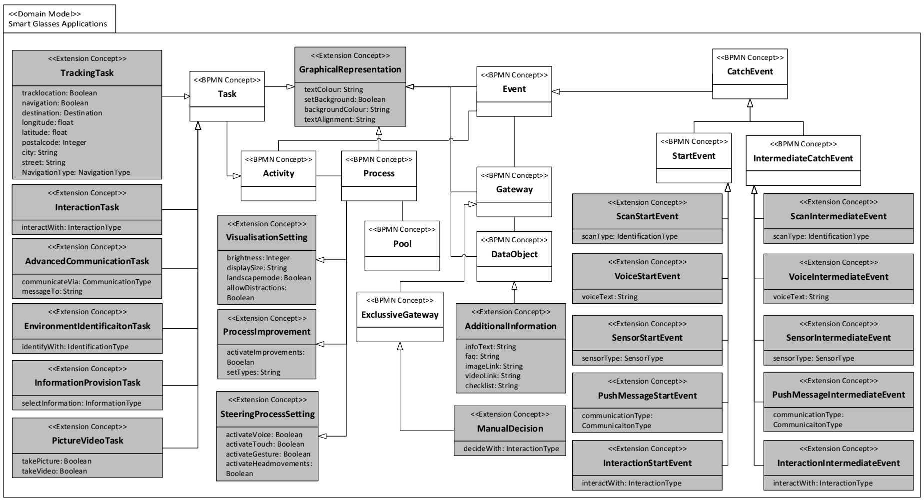

Figure 2. Conceptual Domain Model of BPMN4SGA

In summary, the CDME consists of six new tasks that have further unique attributes. They are getting complemented with distinctive graphical attributes such as text colour, background colour or alignment of the text content. Furthermore, additional information can be attached at tasks through data objects to provide the user with additional information if they request it. Events can be either catch or throw events. Thereby, catch events catching a trigger, whereas throw events throwing a result that can be caught [18]. We only covered catch events for several reasons. Firstly, the user throws events indirectly through the smart glasses functionalities that have to be caught by start or intermediate events. When the worker uses smart glasses in the work environment – he triggers different kinds of events that are also indirectly covered in the smart glasses specific tasks. Encountering this problem, we decided to avoid a doubling and we do not cover throw events in the BPMN extension. Further, with this division, a clearer understanding of the process flow is realized. Start events of the extension model can catch a trigger and starting a smart glasses-based process. This allows a technical selection of processes through e.g. identification of objects through scans, voice-based commands, sensors, interaction inputs or push messages.

Intermediate events can interrupt the process until a specific event is thrown. Additionally, intermediate events can steer the process flow when an event-based gateway is used. On the one hand, we are aware that the decision not to include throw events is debatable and have to be observed during the evaluation phase. On the other hand, it allows no confusion regarding the differences between smart glasses-based tasks and thrown events. Further comparable BPMN extensions, like uBPMN that represents ubiquitous computing processes, do only cover catch events too [19]. The manual decision class represents an exclusive decision that can be handled by the smart glasses user by interactions such as voice, touch or gestures. Further, the different kinds of process steering settings can be enabled in the process settings. Finally, process improvements can be activated to enable the functionality to retrieve feedback from the smart glasses user regarding the work process, and visual and graphical settings set the general design of the information system. Thereby, the CDME includes all listed requirements (cf. table 1) and brings the concepts in a sufficient order.

4.3 BPMN Extension Model (BPMN+X)

The evolved CDME is transformed into the BPMN extension model (BPMN+X) (cf. figure 3). BPMN+X is a specific language developed by Stroppi et al. [17] that is based on the BPMN extension mechanism [18]. Classes covered by the BPMN metamodel are in white and classes representing the extension domain are in grey. To evolve the BPMN+X model, we applied the transformation rules defined by Stroppi et al. [17]. Especially rules five and seven are used to represent a CDME generalization relationship in the BPMN+X model. Rule 5 implied that the BPMN generalization relationship remains by two BPMN concepts. In contrast, if a generalization relationship exists in the CDME with an extension concept, then the relationship is presented in the BPMN+X model through an ExtensionRelationship. According to Stroppi et al. [17], an ExtensionRelationship represents the conceptualization of extensions and their connected extensions are understood as customization of existing elements from the BPMN metamodel [17]. Further extension enumerations (Extension Enum) are represented for new attribute types e.g. SensorType.

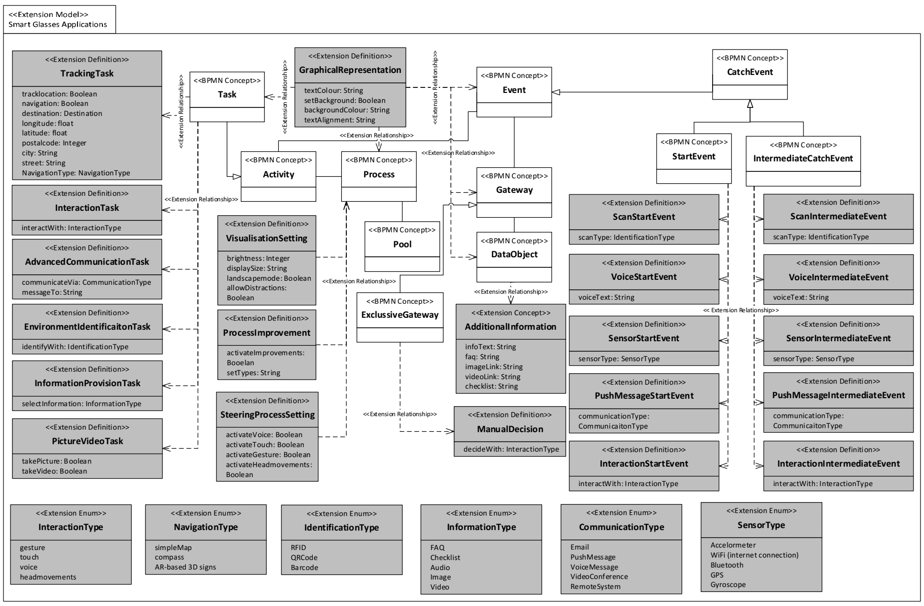

Figure 3. BPMN Extension Model (BPMN+X) of BPMN4SGA

In a next step, Stroppi et al. [17] suggest two further transformation steps. The created BPMN+X can be used to create an XML schema extension definition model that can be transferred into an XML schema document. Similar to the development in [20], we do not execute these steps, because the research project focuses primarily on the development of a DSML. To cover the extension model into a new visual BPMN extension, we propose a graphical representation of the new tasks and events (cf. section 4.4).

4.4 Graphical Representation of BPMN4SGA

The graphical representation of BPMN4SGA is represented through additional events (cf. figure 4) and activities (cf. figure 5). Further extension elements are represented through additional attributes. We include the design guidelines for DSML by Frank [21] to design the specific graphical notation elements. Because of the usage of standard BPMN shapes and just the alteration of symbols, we indirectly fulfilled all design guidelines, except design recommendations in regard to symbols. Therefore, we checked popular icon databases such as NounProject [22] to identify common icon designs for specific word phrases. Assuming that many persons use these icons to represent specific domains an approximation will increase the understandability of the graphical notation of BPMN4SGA. Based upon a selection, we adapted the icons for smart glasses applications and created scalable vector graphics (SVG).

In summary, ten start and intermediate events are added as graphical elements. Figure 4 shows the new events of the BPMN extension for smart glasses applications. The sensor (1), voice (2) and scan (3) start and intermediate events are in accordance with the uBPMN [19]. Sensor-based events (1) react to build in smart glasses sensors. For instance, the Vuzix M300 is equipped with the sensors: acceleration, Bluetooth, internet connection, GPS or gyroscope [23]. Voice-based events (2) capture voice commands and can start new smart glasses processes and can have an impact on the process flow. The same applies to scan-based events (3) regarding the identification of objects e.g. through QR- or barcodes. Start and intermediate events catch specific user-generated interaction-based events (4). These could be gestures, voices, touches on buttons or head movements. Voices are also covered by this extension element to depict combinations with other user-generated interactions. Push message-related events (5) trigger new smart glasses processes for a user or can have an impact on the process flow by using communication systems. They allow in combination with the advanced communication task the collaboration between other smart glasses users.

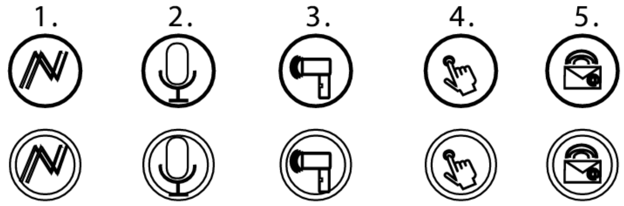

Figure 4. Events of the BPMN Extension for Smart Glasses Applications (BPMN4SGA)

The smart glasses specific tasks are depicted in figure 5. The tracking task represents the identification of the user's position. The user should be navigated to a specific location. The location can be declared as longitude and latitude attributes or as an address. The concrete navigation type can be a simple map, a compass or augmented reality-based 3D sign in the user's field of view. The interaction task is especially suitable to gain user-aware interactions. They are suitable to retrieve interactions to create checks e.g. retrieve a special interaction command to confirm the receiving of goods in the logistics domain. The environment identification task provides the declaration of the task in combination with an object identification e.g. for a package with a specific barcode some value-added-services have to be carried out. The information provision task allows the representation of information for the smart glasses user that is for instance necessary to execute complex tasks. The different kinds of information types could be an image, video, audio, checklist or FAQ. A picture or video-based task enables the recording of the environment e.g. pictures can be taken to collect defections in the process receipt of goods. As mentioned before the advanced communication task represents the communication possibilities of smart glasses for instance via e-mail, audio messages, video conferences or remote systems.

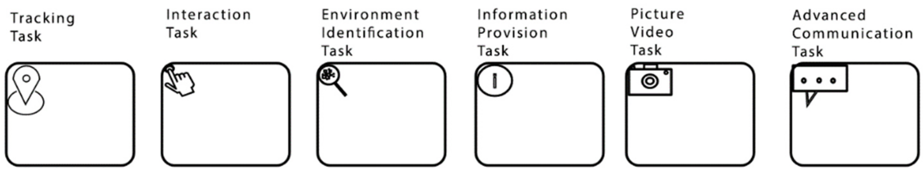

Figure 5. Activities of the BPMN Extension for Smart Glasses Applications (BPMN4SGA)

4.5 Implementation into a suitable Modelling Tool

To realize an application of the BPMN extension for smart glasses applications, we implemented the extension model into a modelling tool and extended the BPMN metamodel [24]. Business users should document smart glasses-based processes effortlessly without the need to install a new program. Therefore we favour web-based modelling tools over desktop-based modelling tools that need additional software modules e.g. language packets such as Java. To identify a suitable BPMN modelling tool that fulfills our requirements, we conducted a market analysis. Hence we do not use established desktop-based meta modelling platforms such as ADOxx [25] or MetaEdit+ [26]. Instead, we build upon BPMN-js a rendering toolkit for BPMN 2.0 that is based on JavaScript [24]. It allows a comfortable integration into web applications and is further extendable. The project is supported by the company Camunda and an active community. Further example projects simplify the customization and extension of the web-based modelling tool [27].

In figure 6 a screenshot from the adjusted modelling tool is presented. The left side shows a palette with the standard BPMN notation elements. The right side provides options to edit the element specific attributes. In the middle is the drawing surface. The domain-specific notation elements can be reached through a click on a standard BPMN element e.g. task or event. After that, a context menu opens and through a further click on the screw-wrench icon the BPMN element can be changed into a more specific form e.g. a start event into a voice start event. We represented BPMN4SGA elements in blue for precise identification. We do not include the concrete syntax in the palette (left side) to keep the clarity of the task/event notation elements and to retain the same user interface as for standard BPMN elements.

The icons are implemented into JavaScript code as SVG graphics. For a correct representation of the BPMN extension, the BPMN metamodel was enhanced with the domain-specific elements. This step ensured a correct transformation of the formal model into an XML document. Therefore, we edit the JSON sources that are representing the BPMN 2.0 metamodel. This is realized in bpmn.io through the bpmn-moddle library [28].

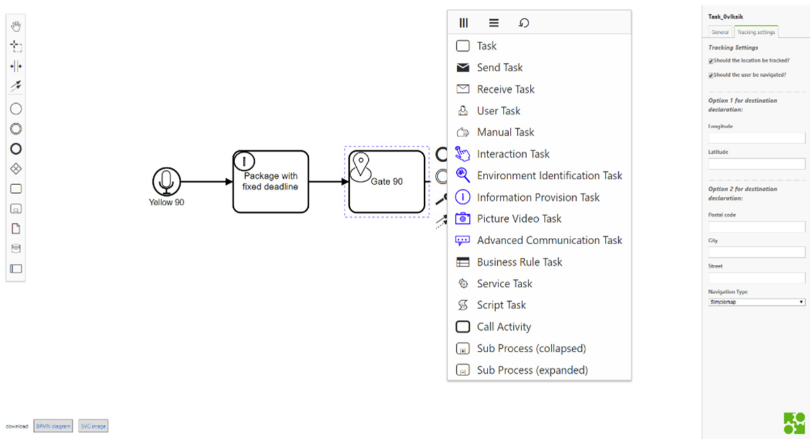

Figure 6. Demonstration of the BPMN4SGA in bpmn.io (screenshot)

5 Architectural Integration of the Model-driven Software Development Concept

MDSD aims to "automatically transforming formal models into executable code" [29]. This can be realized through the generation of code or interpretation. The generation of code is widely-used regarding structural parts, in contrast interpreters are used for behavior characteristics of a system [29]. Behavioral-oriented information system models are representing process and functional characteristics [30]. Because of, BPMN4SGA models focus on the representation of behavioral-oriented information systems, i.e. smart glasses applications, we favour the interpretation approach. Further reasons are the two differences between generators and interpreters that makes interpreters more suitable for our research project. The first reason is the time of analysis. The analysis of generators occurs during build time, whereas interpreter can parse models at runtime. Therefore, changes in BPMN4SGA models have a direct effect on smart glasses applications through direct interpretation. Second, the mode of execution differs. Interpreters execute directly different kind of code based on the read model. In contrast, generators link code fragments that are compiled in a next step [29]. Because the solution tries to contribute non-technical experts with a tool to readjust smart glasses applications directly (cf. section 2), we decided to implement an interpreter that binds code during runtime and does not need a further compilation step.

The architecture of our system is in accordance with Metzger et al. [11] and is shown in figure 7. The domain expert can model smart glasses-based processes through the web-modelling tool that includes the BPMN4SGA notation elements and attributes. The generated XML file can be uploaded through a web interface that saves metadata e.g. process id, process name and creation date from the process in the database. The web and REST interfaces for the platform are implemented with the PHP framework Symfony [31]. Further, an authentication system was implemented with Symfony that enables user-specific storing and client-side loading of BPMN4SGA models. Additionally, an Android PacKage (APK) was programmed and installed on the smart glasses. We implemented the generation system for the Vuzix M100. Thereby, the installed mobile app represents the generation system. The app includes the interpreter, which consists of an individual programmed parser that is implemented into the application. In doing so, the parser is written in Java and it is adjusted to our needs to read BPMN4SGA XML files. Based on the interpretations specific Android activities are called. We decided to download the XML files completely and execute the parsing steps locally on the smart glasses device to enable offline functionality and to minimize the number of requests. During the process execution, the generation system loads activity specific content through REST request e.g. pictures. Also, the system sends data to the server e.g. messages or log files and has further connections to additional systems e.g. to handle speech recognition.

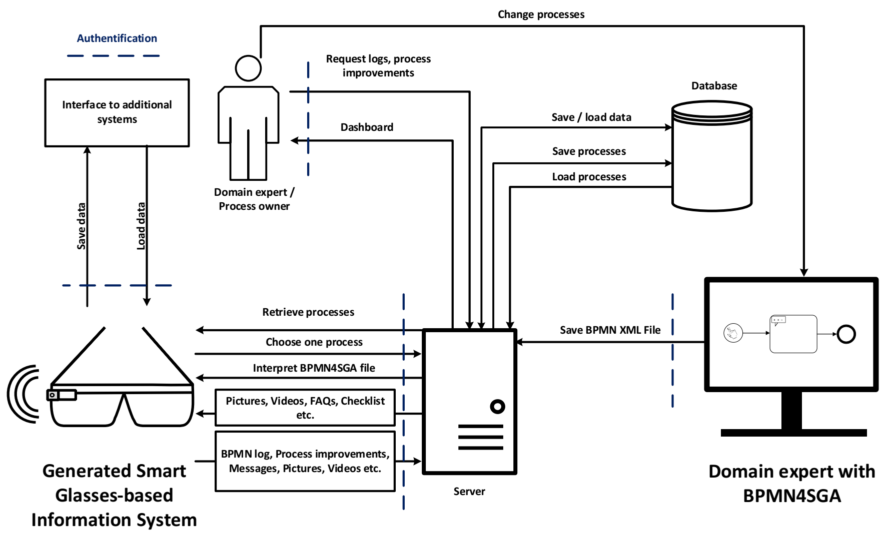

Figure 7. Architecture to generate Smart Glasses-based Information Systems with BPMN4SGA in accordance with Metzger et al. [11]

In close relation to figure 7 shows figure 8 the concrete MDSD approach: Thereby, a modelled process based on BPMN4SGA (1) will be interpreted by a parser (2) and calls specific views and methods. The triggered functions will be reflected in the user's field of view (3). The smart glasses use case "receipt of goods" is a common use case in the logistics domain [9] and is used to demonstrate the solution. The logistician starts the process with a specific speech command that can be specified in further attributes. Next, the worker has to scan the qrcode of the product to identify it. After that, he should give feedback regarding the condition of the goods. For instance, if the product is damaged, he creates a picture and does a damage classification. Finally, after the completion of the process tasks, the data is accessible and new processes can be triggered or selected by the smart glasses user [32].

The presented approach ensures high flexible information systems that can be changed by business experts without programming skills due to a direct transformation of the BPMN4SGA model into the desired information system. Thereby smart glasses-based information systems can in particular facilitate service processes [4].

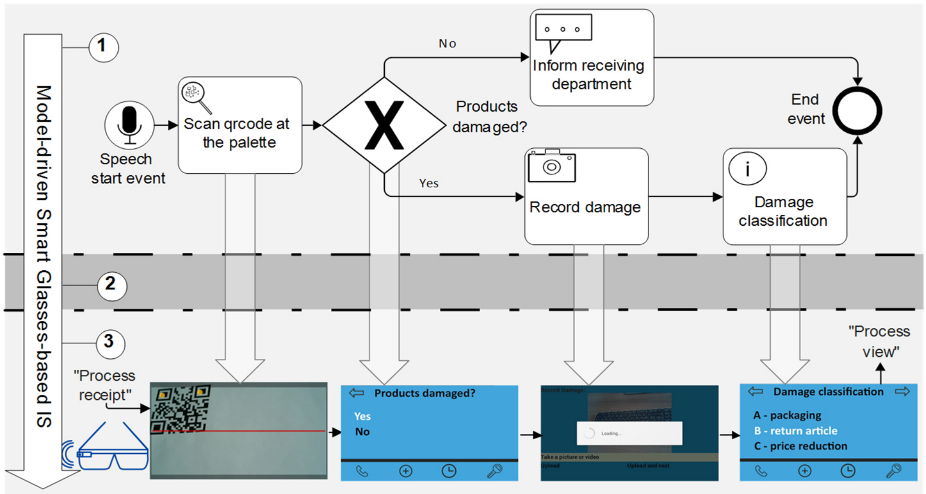

Figure 8. Demonstrating Smart Glasses-based Information System based on BPMN4SGA [32]

6 Discussion and Conclusion

Discussion. During the research project, some points for discussion arose. Additionally, we noticed limitations that are mentioned here. We are aware that the development and design of the BPMN4SGA are mostly based on the insights from the research project and our understanding of smart glasses applications. While we included requirements based on additional smart glasses literature, an overall requirement elicitation was not fully covered. In our point of view, the developed BPMN extension offers the possibilities to discuss with external experts and evaluate the implemented notation elements and attributes. Additional adjustments can be implemented in a further step. Moreover, we do not claim a full applicability of the developed generation system for every smart glasses-based use case – to cover most of them will be a further challenge in the future. Furthermore, the developed BPMN4SGA is mainly based on smart glasses functionalities and it is questionable if a broader software-based focus has to be included. For instance, the communication system was yet not implemented due to the complexity and further relationships with additional interfaces. We developed a closed ecosystem that is mainly focused on visualization purposes and does not reflect business boundaries e.g. to enterprise resource planning systems. So far the representation of businesses interfaces is underrepresented. Additionally, an evaluation with practice experts and field test can deliver valuable insights and are the next research steps.

Conclusion. This research project presents BPMN4SGA, the BPMN extension for smart glasses applications. The paper describes the technical development and implementation of the abstract and concrete syntax, and the implementation steps into a web-based modelling tool. The modelling tool is added into an architecture to realize smart glasses applications based on formal models through a MDSD approach. The implemented artifact enables the direct transformation of BPMN4SGA models into smart glasses applications. As technical DSML are still underrepresented in the range of various DSML, the research project contributes to the development and usage of these. Further, the research addresses a relevant topic to enhance the adoption of new technologies in businesses and delivers a solution to implement business specific smart glasses applications. The implemented solution enables non-technical domain experts to create and modify smart glasses applications for business use cases without the need to write one single code line.

Using Blockchain in Peer-to-Peer Carsharing to Build Trust in the Sharing Economy

Paul Bossauer[1], Thomas Neifer[1], Christina Pakusch[1], and Paul Staskiewicz[1]

Abstract. Trust is the lubricant of the sharing economy, especially in peer-to-peer carsharing where you leave a valuable good to a stranger in the hope of getting it back unscathed. Central mechanisms for handling this information gap nowadays are ratings and reviews of other users. The rising of connected car technology opens new possibilities to increase trust by collecting and providing e.g. driving behavior data. At the same time, this means an intrusion into the privacy of the user. Therefore, in this work we explore technological approaches that allow building trust without violating the privacy of individuals. We evaluate to what extent blockchain technology and smart contracts are suitable technologies to meet these challenges by setting up a prototype implementation of a blockchain-based carsharing approach. In this context, we present our research approach and evaluate the prototype in terms of trust and privacy.

Keywords: Blockchain, Carsharing, Trust, Peer-to-Peer, Privacy

1 Introduction

The sharing economy market has grown strongly in recent years [1, 2]. Peer-to-peer platforms (short: P2P-platforms) such as AirBnB, UBER, Drivy or BlaBlaCar enable private individuals to make a good or a service (e.g. a room, a trip or a car) available to someone else for a certain period of time or to use this good for a fee. Looking at P2P-carsharing, there is – in addition to the fee – a difference between the sharing of a car e.g. within the family or with a complete stranger. Therefore, trust plays a central role here [3–6]. Trust is also sometimes referred to as the *currency* or *lubricant* of the sharing economy, as it is an efficient way of reducing search and informational effort in social exchanges [7].

The lending of cars is a particularly emotional topic for many people. Traditional sharing concepts are often based on reputation systems where users evaluate each other. The rating and review processes aim at establishing trust towards unknown persons. The evaluation in such reputation systems is usually characterized by subjective ratings and reviews in respect of the experiences made during the rental process. The traditional reputation system in P2P-carsharing often reaches its limits, so that tenants often have a lack of confidence in a neutral damage event regulation [8]. Due to these challenges,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

P2P-carsharing is still a niche market in the everyday mobility. In this paper we want to examine, how blockchain can help to reduce these barriers and build trust by creating a blockchain-based P2P-carsharing prototype and evaluating it in existing living lab environments.

2 Related Work

A relatively new development in carsharing is the growth of P2P-carsharing platforms such as Turo, Snappcar, Getaway or Drivy, which allow users to rent or lend cars to each other. In contrast to the local context of traditional carsharing, the peers usually do not know each other personally. This gives rise to a similar challenge as in the case of e-commerce and online auctions to build trust among strangers via the Internet [9]. Over the last decades, reputation systems have been adopted as a prevailed mechanism, where users leave comments and rate others. This source of information was accomplished by information provided by oneself like name, images, and personal preferences. Both types of information serve as surrogates to build trust in an online world [10].

Nowadays, computational gathered information using connected car technology could be used as an additional source for building trust, e.g. monitoring the driving behavior and calculate trust scores based on these data. This, however, raises new questions with regard how these sources of information are valued by the users to gain knowledge about the other in order to increase the willingness to offer her or his good or service. In addition, it also raises new privacy issues as users must balance the costs to disclose the privacy opposite to the benefits of a better reputation.

There is no consistent definition of trust in the literature, but it is generally understood as a multidimensional, socio-psychological construct [3, 7]. Hawlitschek et al. [3] see trust as the expectation and obligation that an exchange will take place in the future. In this paper we follow the definition of Huurne et al. [7]:

"[Trust is] the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party"

This type of trust is particularly important in potentially risky and insecure situations where parties are interdependent [11]. Such situations are typical for the sharing economy since Internet-based mediation removes the usual mechanisms for developing social and economic bonds that promote the emergence of trust. In addition to the trust in the peer, trust in the platform and the product made available must also be built [3].

To solve this trust problem, an often-discussed technology is the blockchain [12–18]. Miraz describes Blockchain as the "Trust Machine", as it preserves a permanent record of all transactions while making sure that any identity-related information of users can be kept incognito [17]. Weber et al. [18] used the Blockchain to monitor and execute untrusted business processes with smart contracts. They explored the fundamental problem of trust in collaborative processes by using smart contracts in three use cases: supply chain choreography, incident management choreography, and insurance claim handling. There are various studies exploring the impact of blockchain on trust, but none in the context of P2P-carsharing. Sarantini et al. give an insight how blockchain-based mobility concepts may look like in the future, but without discussing the trust issue in the sharing economy [19]. Therefore, we want to address this gap and take a closer look at how capable Blockchain is in solving trust issues in P2P-carsharing.

3 Research approach

In the first step, we carried out three focus group interviews and eight problem-centered individual interviews *to understand how car-lenders and car-tenants deal with connected car data and derive implications for blockchain-based carsharing*. We explored how these new possibilities of computational trust mechanisms are perceived by the users and discussed, what sensors might be relevant and what information they would be personally interested if they were a lender as well as where they see privacy concerns from the perspective of a tenant. In the focus group interviews the participants evaluated the data and information discussed from the perspectives of lenders and tenants, whereas in the individual interviews only one perspective was asked. The decision to analyze only one perspective in the individual interviews was made deliberately to prevent distortion of the results due to a perspective transfer. The focus groups were divided into mobility professionals (3 women, 3 men, 20-48 years), those interested in innovative sharing concepts (1 woman, 5 men, 20-32 years) and those highly interested in private car sharing (3 men, 28-47 years). The problem-centred individual interviews were divided between potential tenants and lenders (1 woman and 3 men per group, 20-65 years).

In the second step, we are programming a prototype in the sense of a minimum viable product (MVP) [20] for a blockchain-based carsharing platform. By iteratively testing, evaluating and improving the prototype in close cooperation with the users, we consider the Action Design Research principles [21]. The goal of the first prototype is *to achieve that users can execute the basic functions to get a fast feedback*. These include the initial rent, the return, and the payment. Each car creates a deployed contract on the Ethereum blockchain. Regarding to the MVP principle, we decided to use the Ethereum Blockchain, due to the high distribution as well as many existing projects and tutorials. When the prototype reaches an advanced stage of development, we must evaluate existing technologies in detail and decide whether a purpose-built or derived blockchain is more advantageous. Once the basic functionalities have been integrated, we want to add new functionalities to the smart contracts to simulate the scenario of the allocation of data to specific events.

The third step of our research will be the evaluation of the prototype in a living lab. In this step, *the hypothesis shall be tested whether the blockchain technology and the associated transparency of data access can increase the trust on the part of lenders and tenants*. The carsharing process will be carried out and validated via interviews and app feedback in a real environment with test households. Together with the participants, the prototype is to be further developed and evaluated according to their requirements.

4 Discussion and Conclusion

The current state of our research shows that many people do not use P2P-carsharing, because they are not ready to share their car with strangers due to a lack of trust. The lack of trust is particularly evident in the interviews with potential car lenders. From the tenant's perspective, privacy is often the reason for not disclosing their data. However, our findings show that the privacy concerns depend on the appropriateness and proportionality of the purposes. The willingness to respect the principle of reciprocity increases user acceptance and confidence that the data will not be misused. In this regard, respondents frequently argued that they accept the disclosure of data under certain conditions, such as e.g. accidents or the crossing of a spatial boundary. With smart contracts, such conditions can be technically implemented and thus allow a higher security for car lenders in cases of emergency, as well as the protection of privacy for car tenants if the emergency does not occur.

Currently, we are analyzing the findings from the focus groups and the problem-centered individual interviews more deeply to derive requirements for the prototype of the blockchain-based carsharing platform. Especially the data disclosure in certain situations or after certain events will be a challenge in the programming of smart contracts. Since these requirements differ from user to user, there must be a possibility that car lenders and car tenants can negotiate about the disclosure of certain types of data. After the requirements have been implemented in the prototype, it is to be researched and further developed in a real environment with a vehicle. In the literature, blockchain is often described as a substitute for intermediation [22]. An essential role of intermediaries in the internet economy is the regulation of supply and demand and in the sharing economy especially the building of trust [23]. Only by evaluating our prototype in a real environment will it become clear, whether blockchain technology plays a key role in building trust in the sharing economy or not.

Testing in Big Data: An Architecture Pattern for a Development Environment for Innovative, Integrated and Robust Applications

Daniel Staegemann[1], Johannes Hintsch[1] and Klaus Turowski[1]

[1] Otto-von-Guericke University, Faculty of Computer Science, Magdeburg, Germany
{daniel.staegemann,johannes.hintsch,klaus.turowski}@ovgu.de

Abstract. Big Data is a crucial pillar for many of today's newly emerging business models. Areas of application range from consumer analysis over medicine to fraud detection. All of those domains require reliable software. Even though imperfect results are accepted in Big Data software, bugs and other defects can have drastic consequences. Therefore, in this paper, the software engineering sub discipline of testing is addressed. Big Data exhibits characteristics which differentiate its processing software from those that process traditional workloads. Consequently, an architecture pattern for testing that can be integrated into development environments for Big Data software is proposed. The paper features a detailed description of the artifact as well as a preliminary plan for evaluation.

Keywords: Big Data, Testing, Design Science, Software Engineering.

1 Introduction

Big data ranked the top-most important area of IT investments throughout the past five consecutive years [1]. Firms use data to get new insights (e.g., about customers' purchasing preferences) or to make decisions (e.g., in credit card fraud management). Even though the potential is high [2], companies are struggling to cope with the implicated challenges [3–5]. As an important part of the software development process "Software testing is a process, or a series of processes, designed to make sure computer code does what it was designed to do and, conversely, that it does not do anything unintended" [6]. Therefore, all activities that are supposed to determine the congruence of a program and its pre-defined requirements can be deemed software testing. The necessity to rigorously test software stems from the potential harm, that even seemingly little mistakes in the software can cause [7]. Architectures are the "fundamental concepts or properties of a system in its environment embodied in its elements, relationships, and in the principles of its design and evolution" [8]. Big Data, as a new paradigm, challenges the architecture of traditional software engineering environments, particularly in testing [9]. This is due to the properties of Big Data, often characterized as the four "V"s. Those are volume (amount of data), variety (different sources of data), velocity (rate of the dataflow) and variability

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

(change of data characteristics). These characteristics overstrain traditional data architectures and require new techniques, like the usage of horizontal scaling, to efficiently handle the respective datasets. Those challenges are also reflected in the related testing necessities [10].

To accommodate those necessities we follow the Design Science Research [11] paradigm to outline a testing architecture to support the development of big data applications. The focus is on domain specific applications that facilitate investigating the meaning of data and the relationships between different data. So far, social media analysis is deemed a promising domain for investigation.

2 Related Work

The diversity of different preliminary works in the existing literature reflects the complexity as well as the relevancy of the topic. It ranges from general descriptions of problem areas that also require testing [12], concepts on how to benchmark or test in the area of Big Data [13–16] and on the challenges of quality assurance [17] to more concrete approaches like an implementation for dataless testing [18]. There is however not a universally optimal solution yet, resulting in a need for further research.

3 Artifact

As mentioned beforehand, there are significant differences between software solutions for traditional data and those for Big Data. This results in additional challenges that need to be considered in the testing process as well as in the corresponding architecture of a software engineering environment. The three most notable challenges for testing in Big Data are the following. These were derived from literature [19–22] and from discussions with two experts.

- Difference 1: In contrast to traditional software in Big Data applications non-functional properties (like the ability to handle high volume and velocity) have a higher importance [10].
- Challenge 1: Huge amounts of varying data are required to test non-functional properties.
- Difference 2: Data are often heterogeneous (variety, variability) and the data quality is often poor [16].
- Challenge 2: Necessity to test the clearing and converting of source data.
- Difference 3: Due to the use-cases there is often a higher difficulty to determine if the tested system delivers optimal results [17].
- Challenge 3: The system is drafted to tackle situations that are complex in terms of data and could therefore not be handled with traditional technology, for this reason there is often no known set of inputs and matching outputs. (oracle problem) [23].

To provide maximum value, an architecture for testing Big Data systems should offer solutions for all of the mentioned challenges. Since the reviewed existing approaches were considered not sufficient in light of those challenges, the proposed one was created from scratch.

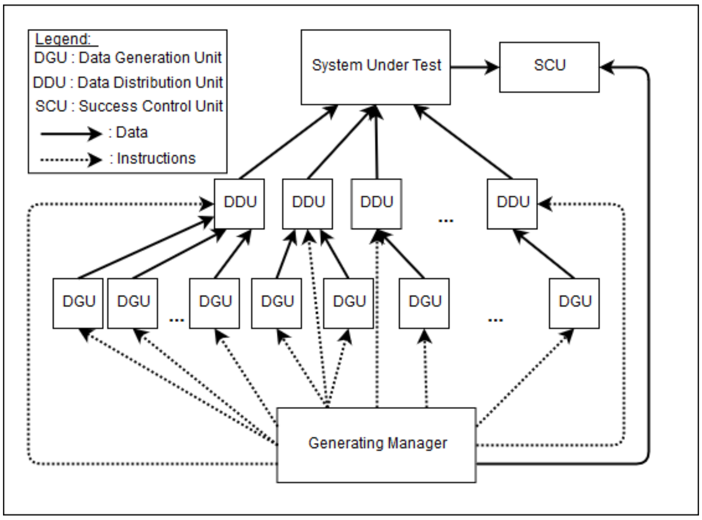

Figure 1. Architecture pattern for testing in Big Data development environments

The proposed architecture pattern, shown in Figure 1, consists of several elements, that aim to fulfill the identified requirements, when combined, to extensively stress the System under Test (SUT). A Generating Manager (GM) controls the whole process and steers the Data Generating Units (DGU) as well as the Data Distribution Units (DDU). If needed the GM can also create and terminate DGUs and DDUs. It is currently investigated, if an algorithm based on MapReduce [24] might be suitable for organizing the test procedure. The Success Control Unit (SCU) monitors the test, comparing the information sent by the GM with the results of the SUT. This allows for a real time monitoring of the performance of the SUT, regarding functional as well as non-functional aspects. The DGUs are each specialized on outputting one type of data (e.g. Twitter posts, reviews) and if needed specific characteristics (e.g. incompleteness, conflicting statements). This allows to choose the best possible solution for each creation sub-task instead of being bound to a solution that delivers acceptable but possibly suboptimal test data for all cases. This approach aims at testing the SUT's clearing, converting and processing of source data by feeding it data of varying type and quality, therefore tackling challenge 2.

Each DGU can generate data from scratch, by recreating existing data patterns, or outputs data that are provided by existing databases or data scientists. For this purpose it is given instructions by the GM. It is possible to have several DGUs with the same characteristics to achieve a higher rate of data generation. It is also feasible to create DGUs that are only providing data corresponding to the pattern the SUT is supposed to detect, while other DGUs are creating "decoy data" that does not comply. The chosen approach targets an easy assessment regarding the detection rate of the SUT. This is because the GM knows which DGU's data are supposed to be detected by the SUT, therefore enabling the SCU as a test-oracle, addressing challenge 3. The DDUs are each devoted to one type of data, therefore utilizing the possible benefits of specialization. They are forwarded the data directly by the DGUs assigned to them by the GM. In the DDUs a buffer of data can be created for further use. When ordered by the GM, the DDUs send their data to the SUT, using the requested pattern, volume and velocity, utilizing the buffered data if needed, taking on challenge 1.

4 Evaluation

The evaluation follows the pattern proposed by Sonnenberg and vom Brocke [25]. EVAL 1 explores if the research and the accompanying creation of an artifact are justified or unnecessary. This step is included in the publication at hand. The general need for research in the outlined topic was illustrated, experts and relevant literature were included in the derivation of significant challenges and those were subsequently the foundation of the taken design decisions. This results in the hypothesis that the proposed architecture constitutes an improvement compared to existing approaches. EVAL 1 can therefore be deemed as completed. EVAL 2 focuses the feasibility and practicability of the suggested approach. It will use logical reasoning, comparing the challenges and the solutions, provided by the artifact, as well as an analysis to verify if the chosen test organization algorithm terminates and expert interviews, e.g. concerning expectable performance, to judge the feasibility of the developed architecture and to remedy possible flaws in the architecture or the algorithm. The prototype of the artifact itself and its testing constitute EVAL 3. Once the concept is implemented in real-life scenarios, a case study and further expert interviews are planned (EVAL 4). An overview of these described steps is depicted in Table 1.

Table 1. Evaluation Plan

Evaluation Steps	*Description*	*Status*
EVAL 1	This publication	Completed
EVAL 2	Logical reasoning and expert interview	Planned
EVAL 3	SAP HANA and OpenStack based prototyping	Planned
EVAL 4	Case study and expert interview	Planned

5 Conclusion

Big Data poses new challenges compared to traditional software engineering. The same applies to the corresponding testing. As a consequence there is currently no universally applied approach for testing Big Data systems. Using the modular artifact introduced in this publication provides possible solutions for those challenges of testing Big Data applications, while still respecting the potential uniqueness of individual projects and the belonging test scenarios.

eGovernment Competences revisited – A Literature Review on necessary Competences in a Digitalized Public Sector

Bettina Distel[1], Nadine Ogonek[1] and Jörg Becker[1]

Abstract. With the growing proliferation of digital technologies, organizations at all levels are faced with a changing environment to which employees and leaders have to adapt. Digital competences can be considered a key factor for the successful implementation of digital technologies in organizations of all kinds. Public administrations are exemption from this trend and are the focus in this study as a special organizational form. Despite the importance of these competences, extensive research on this subject is yet missing. To better understand the shape of knowledge contributions made so far, a structured literature review is conducted to uncover the state of the art of research on these competences. Results of this study indicate that only very few scholars have so far researched public administration competences more closely. Besides functional competences, a focus on so-called soft skills and personality traits is unveiled. Based on the findings, directions for future research are derived.

Keywords: eGovernment, digitalization, competences, literature review

1 Introduction

"[P]olicy makers face a race between technology and education, and the winners will be those who encourage skill upgrading so that all can benefit from digital opportunities" [1]. This statement nowadays becomes a postulate amongst decision makers worldwide, given the growing realization that digitalization is not just a temporary phenomenon but rather a revolutionary game-changing intrusion: "The number of internet users has more than tripled in a decade—from 1 billion in 2005 to an estimated 3.2 billion at the end of 2015. This means that businesses, people, and governments are more connected than ever before" [1]. On the one side, this offers great potentials, but at the same time organizations' and peoples' competences are heavily challenged by digitalization, needing to constantly adapt to an ever changing environment [2]. This is equally true for all organizations that in large part have acknowledged the need for the right skills in a digital world, but when being asked if

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

their employees embody these competences “[…] 53% rather or strongly disagreed with the statement” [3]. The increased use of information systems has entered public administrations worldwide equally and governments also have started to recognize the potential benefits in terms of efficiency and effectiveness gains, if comprehensively leveraged. Yet, “[s]uccessful digital transformation comes not from implementing new technologies but from transforming an organisation to take advantage of the possibilities that new technologies provide” [4]. Thus, the transformation needs to be thoroughly prepared and implemented, since it greatly affects the way the work is done and organized, and requires organizational adjustments [5], [6]. [7] point to the fact that employees from all organizational layers need to refresh their digital skills as a prerequisite for digital transformation to be successful. [8] advocate for a better understanding of this changed environment in order to equip “[…] students with useful models, methods, and technical skills for customer-centric and service-centric information systems” [8].

The basic assumption underlying this study is that competences are a key resource for the successful implementation and use of digital technologies. If public administrations wish to exploit the full potential of digitalization, the development of competences to deal with a diverse set of technologies should therefore be of equal importance as the development of the technology itself. Yet, in spite of the topic’s importance, scientific contributions in this area, are only rarely to be found and do not seem to be among the domain’s research priorities [9], [10], [11]. There are few attempts that started the endeavor to structure the competence necessities for eGovernment education, e.g. [12], [13], [14]. In this context, it is especially [14], who are the only ones that offer a differentiated clustering of necessary competences. Their study, however, was already published in 2015. Therefore, we would like to find out, how this line of research has developed since then and put forward the research question: *Which competences do public administrations employees need from a research perspective?*

2 Research Background

Next to providing definitions of key concepts in order to establish a clear understanding, we also investigate existing research on competences. The term *competence* used throughout this study refers to the combination of an individual’s work-related knowledge, skills and abilities [15]. In accordance with prior research [16], we propose that competences are a key prerequisite for the skillful use of information systems. With the increased use of Information Systems (IS), the way public bodies act is and will keep changing considerably. In general, the organization’s technical infrastructure has the power to improve its performance significantly. "In particular, information systems are considered to be a major asset for leveraging organizational transformation owing to the disruptive nature of IT [Information Technology] innovations, the deep digitalization of business, and their cross-organization and systemic effects, notwithstanding the amounts of investments in enterprise systems." [17]

Even though there are huge efficiency and productivity gains ascribed to the use of IS in public administrations [18], employees have to be provided with digital competences to be able to work in the digital age [19]. The adequate preparation of public servants is therefore indispensable, because the success of implementing IT highly depends on the employees' skills and expertise [20], [21]. Despite its importance, as has been mentioned before, education in the area of eGovernment has not yet been a major topic of interest in research. However, there have been limited intents to identify the necessary competences. Early studies on required competences in the public sector mainly focused on IT competences, e.g. [2], [22]. It is rather later studies that acknowledge the need for more diversified skill sets [23], [24]. Yet, it seems that these competences are not very well covered. According to a report by the European Commission, almost one quarter (23%) of the total EU population has no digital competences at all. Although this ratio is better amongst the working population, where only 14% have no digital skills at all, 39% are considered to have an insufficient level of digital skills [25].

However, quite some practice frameworks have been set up to classify and cluster the necessary competences, notably in the context of the ongoing *digitalization*, which can be referred to as "[…] the manifold sociotechnical phenomena and processes of adopting and using these technologies in broader individual, organizational, and societal contexts." [8] The Skill Framework for the Information Age (SFIA), for instance, is a reference guide, describing 97 skills for employees in information systems-related roles of any type. It provides a reference model embracing two dimensions, namely skills and different levels of responsibility [26]. Another framework to cluster "e"-related competences is the European e-competence framework (e-CF) [27]. The framework, initially developed in 2005, is designed as a means for describing necessary IT professionals' skills and knowledge requirements. It is based on 40 predefined competences, split into five ICT (Information and Communication Technology) areas. It relates to the European Qualifications Framework with five different proficiency levels. Both frameworks offer guidance for practitioners working with IT, however they do not consider the peculiarities of the public sector, inhibiting their application to the domain of eGovernment.

Therefore, another study, developed by [14], seems to be more promising, since it offers a categorization of different competence categories and is especially designed for the public sector. It builds on the findings from earlier studies in the same domain. Consisting of five different competence categories, which are composed of technical, socio-technical, organizational, managerial and political-administrative competences, it offers a more differentiated view on this topic. Technical competences are IT-related skills like the fundamentals, strategy and design of Information Systems (IS). Socio-technical competences encompass all the skills that are located at the interface of technical systems and human beings and involve both of them. Examples for such competences are framework requirements on the impact of eGovernment/technology. Organizational competences refer to the organizational integration of IT/eGovernment, organizational structures, process management etc. The category of managerial competences deals with business-related and management skills in the context of IT/eGovernment, like project, change and financial management. Political-administrative competences consist of skills that deal with the environment that

IT/eGovernment is embedded in. Examples are legal conditions and policies. These competences seem to better grasp the competence diversity needed in the public sector. Although this framework is a valuable approach, it is one of the very few attempts to systematically cluster competences and derive explicit categories. Further systematic research on which competences public sector employees need for the digitalization, has not been put on the IS research agenda.

3 Methodology

In order to uncover the status quo of research on competences in the public sector, we conducted a structured literature review, following the guidelines by [70]. Following their approach, we did not focus on one specific discipline, but widened the scope of our research. Contrary to the propositions by [70], we did not focus exclusively on journals but intentionally decided to include different kinds of publications, because of the fact that research on competences just recently gained in academic interest in the public sector [11], [12]. We first defined a set of relevant search terms that included synonyms to *competence* and *public administration* as well as *eGovernment*. We included the term e-government and variations of it, because a lot of research around the digitalization of public administrations is summarized under this umbrella term. In addition, we ran a second search in the database, this time reducing the search to articles also including keywords on digitalization, innovation or technologies. We used the database *SCOPUS* as it allows for various settings and includes a wide range of scientific outlets. The results were limited to outlets from the year 2000 onwards, because of the rapid changes technologies have undergone since then and it can be assumed that the needed competences have changed as well. As the study does not only aim at describing the status quo of research on competences in public administration but also on deriving an agenda for further research, this limitation is valid. Combining both searches led to a total set of 1235 articles. We excluded all results of doubtable quality, such as students' theses and grey literature as well as all non-scientific articles. Also, we only considered English articles, assuming that important research is published in English to make it accessible to a broader audience. We did, however, consider full as well as research in progress-papers and journal articles as well as conference proceedings and book chapters. Based on the title and abstract, we assessed the remaining articles with regard to their fit for this study's aim. The inclusion criterion was whether the development of *competences* in or for *public administrations* was a key topic of the articles. Although we rather included than excluded articles, also in borderline or unclear cases, in the end we only considered 63 articles to be relevant. We read these articles to evaluate whether they dealt with competences as a core topic or not. After a thorough pre-evaluation, a final set of 21 articles remained. 42 articles were not considered in the end, because they either purely focused on IT skills or they had a very specific target group that would not allow for comparability. We eliminated the majority of articles, because they only mentioned competences and/or skills on a side note, without specifying their nature and making them an explicit unit of analysis or the studies mentioned skills and competences as one factor influencing adoption decisions without further distinguishing the needed competences. With the remaining papers, we conducted a *forward* and *backward* search, applying the same inclusion and exclusion criteria as set forth above. All articles referencing one of the 21 articles were assessed which led to the inclusion of another 7 articles. For this search, we used *Google Scholar* as it yielded considerably more citations than SCOPUS. In the same way, we also examined all articles cited in the first 21 papers and included another 14 articles as relevant in our final data set.

4 Results

The final sample contains 42 articles (see Table 1). Out of these, 26 were published in journals, 13 of them were conference proceedings and 3 articles were book chapters. All articles were published between 2000 and 2018. Table 2 contains all identified sources, their shortened title, and outlet form. We also evaluated the extent to which the analyzed articles referred to each other as indicated by the columns 'citing' and 'cited by'. This analysis shows that only few articles refer to others in the sample and are frequently referred to by others such as [14], [21], [28] and [29].
For the analysis, we intentionally decided against following the chosen categorization of competences by the authors, although most articles already included some kind of categorization. We decided for breaking them up to identify patterns or differences ourselves. We did this to first eliminate possible ambiguities that could exist due to the authors' different foci and chosen terms and second to not overlook any skills that we would not have expected in certain categories. The articles' categorizations were coined very differently, given the difference in focus of the respective article. [62], for example, deal with skill sets of a successful collaborator, which is why their article naturally concentrates primarily on personality traits and soft skills. We found that similar skills were categorized differently in different articles; therefore, we summarized them in a new category.

In total, we identified two overarching categories, i.e. competences and personality traits. Those were split again into 12 sub-categories, identifying the concrete skills. Table 2 exhibits all sub-categories with exemplary mentions and corresponding references. The first identified category contains competences, which can be subsumed as all the skills and abilities that are related to a certain professional area or field, i.e. functional competences. The analysis of those competences yielded eight sub-competence areas. *Business skills* are mentioned most often. 33 of the 40 articles relate to some kind of business expertise. Competences in this sub-category relate to the organization and management of a public agency but are not necessarily domain-specific. Exemplary competences are project, program, performance and strategic management, which are among the most often cited ones. HR, economic, finance and accounting and marketing skills also fall into this category. Besides those business-related skills, *IS/IT skills* are the second most often cited competences that appear in 28 of the 40 articles. Again, skills listed in this category are not necessarily domain-specific and could be applied to competence frameworks for private organizations as well. Whereas some authors describe this category very generic with “IT content” [34] or “Familiarity with ICT systems” [33], other authors elaborate more detailed on those skills, like [38], [39] or [14], who mention concrete competence areas such as architecture, cyber security and managing information systems.

The next category *organization* unites abilities that are centered in the organization itself and, thus, are domain-specific. Competences in this sub-category deal with the characteristics of an organization, thus including skills such as administrative processes, organizational design or the identification with one’s agency. This sub-category is mentioned in 23 articles and, thus, seems to be an important asset in the job profile of the public sector. *(Public) Policy* was mentioned in 21 articles and includes skills such as knowledge about an agency’s policy area, policy planning and politics.
The category *law* occurred in 14 articles and is concerned with all legal aspects that arise in the work of a public administration. Those two sub-competence categories seem to be very specific to the public servant’s profile. The next sub-category summarizes competences that were either rarely mentioned or could not be grouped in a meaningful way to any other competence category, but still we deemed them worth mentioning. They are grouped under the name *other* and include competences in research (2 sources), socio-technical skills (5 sources) and professional experience (6 sources). After having categorized all the “hard”-knowledge based competences (functional competences), the last competence category lists all the *soft skills*, i.e. abilities that can be trained but do not count as knowledge. These competences are unrelated to any specific domain and include, for example, communication skills, teamwork, leadership, customer and service orientation and alike. It is noteworthy that those skills appear in 37 of the 40 articles and can thus be considered as highly important. Only in the categorization by [14] they are not explicitly mentioned. Within this group, especially the soft skill “leadership” is prominently mentioned in 25 articles. The second identified category are personality traits. Those traits are inherent to a personality and are not related to a specific (job-related) task. Furthermore, they cannot be acquired through formal education. We identified four sub-categories here. The most frequently mentioned one are *analytical skills*, which appeared in 24 articles. Analytical skills are more geared towards how a person tackles tasks and challenges.

Table 2. Identified competences and personality traits in identified articles

Type	***Area***	***exemplary competences/personality traits***
competence	business	strategic planning [29], [34] project management [33], [65]; program management [41], [57]; contact management [31], [41]; finance [36]; economics [47]; accounting [36],[42]
	IS/IT	management (information) systems [42], IT skills [14]; information systems [43], [47]; cyber security [39]; enterprise architecture [38]; technology management & assessment [57]
	organi-zation	organizational design [12], [14]; administrative processes & workflows [21],[37]; coordination/implementation [32], [48]; identification with agency [42], organizational theory [34]
	(public) policy	public policy [28],[46]; knowledge of agency's policy area [42]; social policy [42]; policy planning [45]; politics & political processes [65]; policy processes [31]
	law	administrative law [21]; legal aspects for data management [36]; legal tools [36]; legal aspects [39]; legal framework [40]; regulatory theory [53]
	other	professional experience [36], [42], [50]; evaluation & research [42], [61]; socio-technical skills [14], [35], [40]
	soft skills	leadership [56]; conflict management/negotiation [55]; (cross-cultural/unit, oral & written) communication [62]; mediation [62]; assertiveness [44]; influencing [54]; relationship [63];
personality	character traits	tolerance [33]; continuous learning [39]; creativity [48], commitment [45], [52]; tenacity & perseverance [44], flexibility [50]
	analytical	critical thinking [58]; analytical thinking[55]; strategic & innovative thinking [51]; decision making [49]; problem-solving [48], abstraction [41]
	self-management	self-organization [64]; self-control [28], self-awareness [62]; self-confidence [63]; self-reflection [64]
	other	psycho-social stability [45]

This category subsumes employee qualities indicating a view behind one's own horizon, i.e. critically reflecting on past events but also planning and envisioning scenarios, which requires thinking out of the box. The next sub-category consists of *character traits*. In contrast to the analytical skills, the articles here mostly describe more than one character trait and mention certain types of personality that public agencies need or look for. Character traits named here are, for example, tact, respect, patience, tolerance, and alike. Those seem to be preferable character traits in public administrations. This personality trait appeared in 23 of the 40 articles. The third sub-category of personality traits, mentioned in 14 articles is some kind of *self-management*. Again, competences in this category are more related to an employee's professional behavior. Those characteristics include self-organization, self-control and self-reflection, amongst other similar traits. The last sub-category under personality is coined *other*, which includes psycho-social stability. This sub-category was deemed so special, although it only appeared in one sole article that we decided to add it.

5 Discussion

The purpose of this research was to identify which competences public sector employees need from a research perspective. The analysis of articles allows drawing several conclusions, which we present in the following.

First, the literature review shows that only very few articles deal with the development of competences in the public sector. Moreover, only seven articles were published after or at the same time as the study by [14], which was a review of prior research on competences in the public sector as well. Although organizations such as the EU have recognized the need for the development and education of administration specific competences [27], this area has so far received only little scientific interest. While eGovernment scholars often mention competences as an important driver of the digitalization of the public sector, the study of competences in the public sector is still in its infancy. Although only few articles deal with the training of competences in the public sector, these studies analyzed a variety of different competences that public administrations need. Moreover, the studies do not differentiate whether the competences are needed everywhere to the same degree or not and if one employee should be trained equally in every competence category. Although. on a higher level, they differentiate between leaders in the public administration, e.g. [62] and employees, e.g. [44] and between IT related jobs, e.g. [38] and non-IT related jobs, e.g. [58], finer grained differentiations are not applied. For example, it remains unclear, whether the identified competences are needed in the public administration in general or whether they are task-specific. For example, an accounting clerk may need different competences than does the caseworker. Furthermore, ambiguities exist with regard to the relevance of specific competences for the different administrative levels. While some studies focus on a specific administrative level, e.g. [58], most of the articles do not provide information on whether the need for particular competences varies between the administrative levels. Again, the competences required of a municipal employee may differ from those required of an employee at the national level.

Second, our results show that all analyzed articles are empirical studies, whereas conceptual and theoretical approaches are missing completely. It is noteworthy that only few articles refer explicitly to conceptual works, e.g. [62], [34]. Instead, most articles directly introduce their method, e.g. [14], [56], rather than reviewing theoretical approaches related to the development of competences for the public sector, e.g. [36]. The focus of current research on empirical studies leads to the production of practically relevant knowledge but contributes to a lesser degree to the scientific body of knowledge. [34] point out: “As a *pracademic* field, public administration is based on the integration of academic concepts with its practical applications, as its boundary and scope are increasingly expanded in an ever-complex world”. However, the exclusive emphasis on empirical studies revealed by means of the literature review raises doubts if scholars in the field of competence research actually “[…] strive to maintain this balance” [34] between practice and academia. Accordingly, we find that only very few of the articles include references to another paper of our sample, although all articles deal with the development of eGovernment competences. This finding highlights a need for a better linkage of existing research. This fact is all the more astonishing as most of the papers are published in related outlets such as the proceedings of the *Hawaii International Conference on System Sciences* [12], [14], [21], [29], [64], *Public Administration* [50], [65], *Public Administration Review* [62], *International Review of Administrative Sciences* [46], *International Journal of Public Sector Management* [37], [52] or the *International Journal of E-Government Research* [38]. Thus, we propose to better link existing research on eGovernment competences and to conduct more conceptual research to establish a common theoretical understanding.

Third, the review shows that number of specific competences is very high. The proposed framework of competences for the public sector should, thus, be refined and validated – theoretically and empirically. As outlined above, the analyzed articles do not provide any information on whether the identified competences are task-specific or should be trained in general. Thus, the question remains to what degree employees in different departments should be educated in every category. To the best of our knowledge, only one study exists, which was implemented for the German IT planning council, that takes into consideration that competences may be task-specific and that the distribution of competences may depend on the specific job profile of an employee [67]. The authors distinguish the development of competences with regard to two aspects: First, public administration staff may need different competences according to their task or role. Second, the employees needing the same competences may not need them to the same degree. The depth of the competence acquaintance ranges from designing (highest level) over usage to knowledge (lowest level) and is based on the well-known taxonomy of educational objectives by [68]. In accordance with this study, we propose to not only categorize competences that are needed in digital public administrations overall but to differentiate the competences on two levels. On the *horizontal level*, competences are distinguished in relation to tasks within the public administration. For example, leaders of public agencies may need more business skills than does a case worker who may need more personal skills. Not every task may require every competence listed in the framework (see Table 2). On the *vertical level*, competences are distinguished according to the degree to which they have to be appropriated by the employees, i.e. although employees may need the same competence, e.g. competences in enterprise architecture, one may only need to know what this term comprises, whereas another employee may need to design such systems.

Fourth, the literature review revealed that business skills are far more often required than technical or other competences. Although the ubiquitous digitalization is reality, research seemingly puts less emphasis on the training and recruitment of technical competences. Moreover, it is noticeable that public administration-specific competences are less often required as compared to business skills. The analyzed articles are less context-specific as one might expect. About half of the identified competences were not domain or task-specific but more related to the employee's personality (e.g. soft skills, character traits etc.). Thus, we conclude that competences independent from the tasks are equally important for the public administration as are task-related competences. In relation to the overall competence framework, this leads us to the assumption that instead of looking for specialists, public administrations rather seek all-round talents. Given that researchers have recognized the necessity of the interplay between ICT and institutional settings as success factors for eGovernment implementation, e.g. [69], further research is needed that sheds light onto the specific competences public administrations need to successfully implement eGovernment, i.e. the framework proposed here needs to be validated. It also offers an estimation with regard to whether weighting of the competences as revealed by the literature review adequately addresses the challenges public administrations have to face in the digital age. Regarding the development of research on competences over time, it seems that the topic was of special interest in the beginning of the eGovernment area. 7 articles were published between 2000 and 2014. From 2005 to 2009, research on competences declined to 6 articles. It was not before the year 2010 that eGovernment competences received more attention with 17 articles published until 2014, which seems to go on, because since 2015 until today we could identify 12 articles.

6 Conclusion and Outlook

This study set out to identify the competences public sector employees need from a research perspective. To answer the research question, we conducted a structured literature review on competences in the public sector literature. Our review shows that to date only few studies exist that are concerned with competences in the public sector. Within these studies, we identified two overarching categories, competences and personality traits that could be further split up into 8 and 4 sub-categories respectively. We set up a research agenda to list all future research directions that can be derived from this study. It shows that besides the need for functional or task-related competences like organizational or management skills, there is also an increased need for soft skills and personality traits. Task independent competences seem to be equally important for the public domain as are functional competences, thus requiring public servants to be all-rounders rather than specialists in one specific area. Having said this, future research should also consider examining the respective competence depth more critically, since not every employee is required to embody one specific competence in the same way. Given the limited amount of studies identified in total and the finding that those are primarily of empirical nature, more research on this topic is needed in general and especially with regard to theoretical contributions that provide a solid basis as a commonly agreeable set for further research in this area to build on. After all, a diversified look into interdisciplinary competences, required by public servants working in a digital environment today, only picked up real speed in terms of scientific contributions by the year 2010. Thus, this topic has gained considerably in importance and more contributions are to be expected. The main limitation of this study is the choice of database that naturally fails to provide a complete picture of competence research in eGovernment. Thus, further research should look into other databases to round out and verify these results. Due to the pace of changes, induced by technology, competences also might undergo much more frequent changes than it was the case before. This is why more and particularly constant research is required to monitor these developments to competently address possibly new challenges.

Say Hello to Your New Automated Tutor – A Structured Literature Review on Pedagogical Conversational Agents

Sebastian Hobert[1], Raphael Meyer von Wolff[1]

[1] University of Goettingen, Goettingen, Germany
{shobert, r.meyervonwolff}@uni-goettingen.de

Abstract. In this paper, we present the current state of the art of using conversational agents for educational purposes. These so-called pedagogical conversational agents are a specialized type of e-learning and intelligent tutoring systems. The main difference to traditional e-learning and intelligent tutoring systems is that they interact with learners using natural language dialogs, e.g. in the form of chatbots. For the sake of our research project, we analyzed current trends in the research stream as well as research gaps. Our results show for instance that (1) there is a trend towards using mobile conversational agents in education, (2) a proper generalization of existing research results (e.g. design knowledge) is missing, and (3) there is a need for comprehensive in-depth evaluation studies and corresponding process models. Based on our results, we outline a research agenda for future research studies.

Keywords: pedagogical conversational agent, intelligent tutoring system, technology-enhance learning, chatbot, natural language processing.

1 Introduction

Intelligent learning systems can be used in educational contexts to improve learning processes [1]. In traditional learning settings (like in university lectures or in seminars in vocational trainings) it is challenging to provide individualized learning support to learners or to respond to every personal demand of learners individually. This challenge is targeted by intelligent tutoring systems [2]. They promise to provide individualized and personalized learning support regardless of the number of learners.

Due to the increasing spread and media attention of artificial systems as well as machine learning applications, the demand of learners and teachers for intelligent learning systems rises. The availability of intelligent dialog-based systems like Facebook Messenger bots increases the demands further. This results in a growing research interest *in pedagogical conversational agents* as part of the research stream of intelligent tutoring systems [3]. Research projects targeting pedagogical conversational agents deal with the question of how to provide proper learning support to learners via natural language interfaces. Thus, these research interests combine the pedagogical view on individualization of learning processes with promising technologies like

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

artificial intelligence and natural language processing to provide easy to use learning systems.

The use of natural language user interfaces for learning systems seems especially promising as learners already use messenger-like systems in private life commonly. According to recent representative surveys in Germany, over 90 % of those questioned use messenger services – over 75 % of them on a daily bases [4]. Thus, using chat-based systems including chatbots (i.e. conversational agents for non-educational use cases like FAQ bots [5]) are common. So, it is to expect that learners need (almost) no time to get used to natural language-based learning systems.

Even though the use of pedagogical conversational agents seems to be promising, the success of such systems should not be pledged early. In fact, researchers should carefully analyze whether the demand of users towards using the technology is just because of the current rise of artificial intelligence in general or whether it really enables improvements in learning processes. As a first step to consolidate the existing research interest and to provide a structured guidance towards a research agenda for design-oriented research, we outline the results of a structured literature review targeting text-based pedagogical conversational agents in this research paper. Thus, we ask the following research questions to describe our research targets:

RQ1: What is the current state of the art of using pedagogical conversational agents in education?

RQ2: Which design-oriented research gaps exist in the current research on pedagogical conversational agents?

To answer these research questions, the remainder of this paper is structured as follows: First, we briefly describe the term *pedagogical conversational agent* and outline related concepts like *intelligent tutoring systems*. Based on these basic terms, we describe the research approach of our literature review process in section 3. Following, we present our results focusing on four main perspectives (time, technical, didactical and methodical perspectives) in section 4 and discuss them in section 5 to outline a future research agenda. Finally, we briefly summarize the findings in the conclusion.

2 Basic Terms

Pedagogical conversational agents can be defined as a special form of learning applications that interact with learners individually [6]. The conversation of those agents usually takes place using natural language [2]. From a technical perspective, there exist two common types of pedagogical conversational agents:

1. *Messenger-like agents* that use common chat interfaces (e.g. known from WhatsApp or similar chat interfaces),
2. *Embodied conversational agents* (like game characters or avatars) that consist of a (virtual) representation of a person in virtual environments and communicate either via text-based or voice-based language.

Whereas in the past embodied agents were common, nowadays especially messenger-like agents (a.k.a. chatbots) are widespread. The reason is that messenger apps are considered to be easy to use, because “interaction takes place through messaging applications to which students are already very keen on” [7].

To enable a language-based communication, pedagogical conversational agents usually combine technical methods from natural language processing and machine learning. Thus, pedagogical conversation agents have the possibility to act in different human roles like tutors, students or colleagues [2]. Because of this stream in research, pedagogical conversational agents have similarities and intersections with intelligent tutoring systems [3, 8]. Both software systems are learning applications that aim at providing (individualized) assistance to learners [6, 8]. The combination of both definitions is also known as “conversational intelligent tutoring system” [3].

3 Literature Review Process

To answer the research questions raised in section 1, we conducted a systematic literature review. We followed established methodical approaches in performing literature analyses including those of *Cooper* [9], *Webster/Watson* [10] and *Fettke* [11]. Furthermore, we especially took the work of *vom Brocke et al.* [12, 13] into account that outlines recommendations on how to deal with the existing “literature overload” [12]. By adopting the *Framework for literature reviewing* [13], we apply the proposed five consecutive research steps that we briefly describe in the following. During the whole literature review process, we documented all process steps in a search protocol as proposed by [12]. To ensure the traceability of our research process, we attached a condensed version of the search protocol including our list of reviewing criteria at https://publikationen.as.wiwi.uni-goettingen.de/getfile?DateiID=739.

3.1 Definition of Review Scope

As we intend to identify the current state of the art of using pedagogical conversational agents for supporting learners especially in higher education as well as in workplace learning, we primarily focus our literature review on the research outcomes as well as on applications of published research papers. In this literature review, our goal is to identify central aspects on a conceptual level. As we intend to share the results not only with specialized scholars but also with interested practitioners, we synthesize the outcomes to highlight important results. Table 1 summarized the characteristics of the review by adapting the taxonomy of [9].

Table 1. Definition of review scope (adapted from [9])

Focus	**Outcomes**	Methods	Theories	**Applications**
Organization	Historical	**Conceptual**	Methodological	
Perspective	Neutral representation	**Espousal of position**		
Coverage	**Exhaustive** (in analyzed sources)	Representative	Central or Pivotal	
Audience	**Specialized scholar**	**General scholars**	**Practitioners**	General public

3.2 Conceptualization of the Topic

As a basis for the conceptualization of the topic of pedagogical conversational agents in the context of this paper, we rely on the definitions outlined in section 2. Using those definitions as a starting point as well as the works of [14, 15], we derive the following systematization that we use to classify the corpus.

First, we conceptualize the relevant papers based on technical considerations (see Table 2). In particular, we focus on the *type* of pedagogical conversational agents that are examined in the paper corpus: (1) Messenger-like conversational agents that provide user-interfaces in forms of text-based chats. (2) Embodied conversational agents that include visualizations of the agent like an animated virtual avatar. We also take the target *platform* of the considered conversational agents into account: (1) Mobile-first agents that focus mainly on smartphones (and tablet computers). (2) Web-based agents that are usable on any platform but do not follow a mobile-first approach. (3) Others, like standalone applications, that are limited to specific desktop operating systems.

Table 2. Criteria for conceptualizing the literature review (1/2)

<table>
<tr><td>Type</td><td colspan="2">Messenger-like conversational agent</td><td colspan="2">Embodied conversational agent</td></tr>
<tr><td>Platform</td><td>Mobile-first</td><td colspan="2">Web-based</td><td>Standalone/Others</td></tr>
</table>

In addition to the classification based on technical aspects, we distinguish the analyzed papers by the targeted *learning settings*. In this category, we differ between formal learning settings (like using a pedagogical conversational agent at a university during seminar sessions) and non-formal learning settings (like using an agent at home for self-study). Even though there exist more sophisticated forms of distinguishing learning settings, this seems sufficient for the given view on the literature. Furthermore, we categorize the articles by *learning form* and distinguish the following types: isolated, collective, situated and collaborative learning (see [14, 15] for detailed explanations of the learning forms). Finally, we consider the *content* view of the papers in which we differ single-topic learning content or multi-topic learning content. We distinguish both because pedagogical conversational agents (1) can be built for just a single purpose (e.g. training a special situation in language learning; single-topic) or (2) can be used to assist learners during a series of lectures or seminars (multi-topic). Table 3 summarizes the conceptualization that is a basis for the conduction of the literature review.

Table 3. Criteria for conceptualizing the literature review (2/2) based on [14, 15]

3.3 Literature Search

To identify relevant publications according to the review scope (see Table 1 above), we conducted a keyword search in bibliographic databases in June 2018. As the focus of the literature review can be assigned to the field of technology-enhanced learning, we selected databases that have at least partly a technology-oriented view. We further broadened the search scope by including all eight journals of the AIS Senior Scholars' Basket of Journals [16]. In doing so, we included in the following sources:

Table 4. Selection of searched sources

Journals	Scientific databases
– European Journal of Information Systems – Information Systems Journal – Information Systems Research – Journal of AIS – Journal of Information Technology – Journal of MIS – Journal of Strategic Information Systems – MIS Quarterly	– AIS Electronic Library – ACM Digital Library – IEEE Xplore Digitial Library – ScienceDirect – EBSCOhost Business Source Complete

To perform the literature search, we used the search terms listed in Table 5 in all selected databases and journal sources. In doing so, we included articles that match our research target directly (search term #1) as well as articles that cover most likely closely related topics (search terms #2 and #3). In total, we obtained approx. 550 papers.

To evaluate the search results for relevance, we defined criteria for inclusion as well as exclusion in accordance with [12]. Using those criteria, we reviewed titles and abstracts of all search results in a first step. Based on the resulting corpus, we reviewed the full text to the best of our knowledge and came up with a total number of 41 papers that represent original findings as the final corpus.

Table 5. Overview over search terms

Search terms	
#1	"pedagogical conversational agent"
#2	"smart teaching assistant" OR "AI teaching assistant" OR "artificial intelligence teaching assistant" OR "virtual teaching assistant"
#3	(chatbot OR chatterbot OR talkbot OR "interactive agent" OR "dialog system" OR "conversational agent") AND (learning OR teaching)

3.4 Literature Analysis and Synthesis and Proposition of Research Agenda

In the next two phases of the literature review process, we first analyze and synthesize the final corpus of relevant articles. We first examine the corpus using a time perspective before we analyzed its content in full depth by focusing on technical, didactical and methodical aspects (see section 4). Second, we discuss trends and research gaps in the corpus in order to derive a research agenda that is shown in section 5.

4 Results

In the following, we outline the results of our literature review using four perspectives. First, we focus on the time perspective of the paper corpus. Afterward, we examine the technical foundation, before we take a didactical perspective. Finally, we switch to a methodical perspective and outline how the researchers of the identified relevant papers conducted their research.

4.1 Time Perspective

A first descriptive analysis of the corpus regarding the distribution of publications per year shows an increasing interest in recent years. In 2017, the number of relevant publications reached an all-time high in the considered timeframe. Furthermore, the number of papers published in the first month of 2018 already reached the second highest number of publications. After interpolating the publications for 2018 based on the first six months (see Figure 1), we expect that the number of relevant publications in 2018 will exceed the current high. Thus, we conclude that there is an increasing interest apparent.

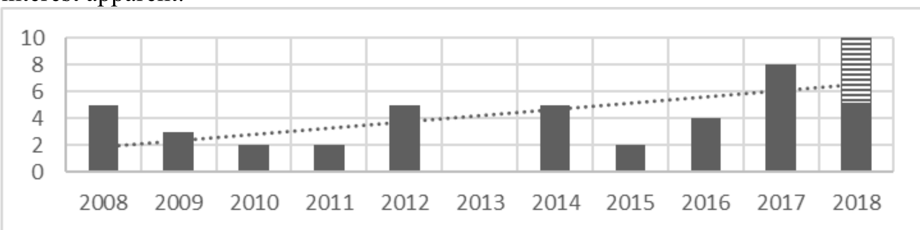

Figure 1. Distribution per year (grey shaded: 2018 interpolated based on June 2018)

4.2 Technical Perspective

As the first step of the content analysis, we categorized our final paper corpus by looking at the different technical types of agents as well as on their target platforms.

Agent Type. First, the distribution outlined in Figure 2 shows that the number of messenger-like conversational agents is more than twice the number of articles targeting at embodied conversational agents.

Figure 2. Distribution of articles per conversational agent type

Furthermore, the average publication date of all articles targeting messenger-like conversational agents (MCA: 2013.2) is approx. one year newer compared to the average of all embodied conversational agent papers (ECA: 2012.2). Thus, there is a trend present to use messenger-like conversational agents instead of embodied conversational agents. Even though the difference seems not to be huge, the trends become apparent when looking at the time lines and trend lines in Figure 3.

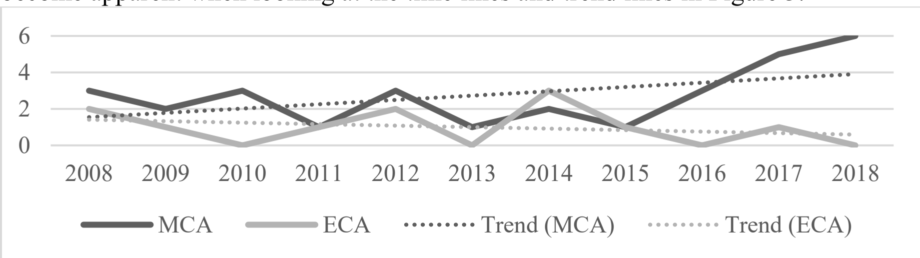

Figure 3. Trends per conversational agent type (year 2018 interpolated based on June 2018)

Target Platform. By analyzing the technical foundations of the identified conversational agents independently of the type, we could identify a trend towards implementing conversational agents for mobile platforms. Whereas mobile conversational agents are targeted in the paper corpus since 2016 with an increasing amount, the number of web-based or standalone conversational agents is decreasing. This is also reflected in the average publication date: Mobile agents have been published in average in 2017. In contrast to that, papers in both other categories have an average publication date of approx. 2012. However, it needs to be remarked that some web-based conversational agents are implemented responsively (e.g. [17]), i.e. they can be used on smartphones as well. However, if the primary focus of such prototypes is a desktop computer, we did not count them as mobile-first approaches.

Technical system architectures. Focusing on the technical system architectures of pedagogical conversational agents, we could identify that there is a large variety of system architectures present. Nevertheless, most implementations are based on a client-server architecture where natural language processing is done on the server side (e.g. [18]). However, the language processing steps vary in the different implementations from simple command-based matching approaches to the application of advanced machine learning based toolkits. Concerning the storage of data, some authors store, for instance, predefined question and answer tuples in relational databases, whereas others use AIML-files to store patterns and related answering templates (e.g. [19]). In some cases, answers are based on learning objects or learning paths (e.g. [20]). On the client side, user interfaces differ as well: Some agents are implemented as standalone clients (e.g. [21]) whereas others are integrated into third-party messaging platforms (e.g. [7]) or learning systems (e.g. [19]).

Summary. We conclude that the current research mainly focuses on messenger-like interfaces in mobile settings. On the one hand, the trend towards researching messenger-like agents seems like a reduction of complexity as the user interfaces get simpler. However, on the other hand, we could not identify a reduction in complexity in the system design as we could not identify a uniform architecture approach.

4.3 Didactical Perspective

Whereas the technical perspective focuses on the underlying software of conversational agents, we use the didactical perspective to analyze the educational application scenarios and the learning settings of pedagogical conversational agents.

Learning Setting. First, we categorized the papers of the corpus into formal or non-formal learning settings. As a result, we can conclude that only approx. 25 % of the papers that we could categorize[1] focus on formal learning settings. An exemplary paper is [22] in which the authors developed a virtual embodied avatar that can be used to simulate a virtual patient. Medical students can interview the embodied avatar to train diagnosing the avatar's diseases. The learning situation can be categorized as formal learning setting as the virtual embodied avatar is used by the students in a laboratory and not in a non-formal situation (e.g. at home). Another example of a mostly formal setting is presented by [23]. In this case, a pedagogical agent is used in an online tutoring task to guide the learners. As the learners need to communicate with the agents as a homework task, we categorized it as a formal learning setting.

Even though some papers cover formal learning settings, according to our analysis most pedagogical conversational agents target non-formal settings and provide communication possibilities to learners independently of a specific location, time or learning environment (e.g. course or lecture). However, in many cases the learning setting depends on the concrete use: In many cases, learners can interact with the agent location independent whenever they want using a smartphone or a desktop computer. But if the use of the pedagogical agent is integrated into the curriculum (like homework; see e.g. [23]), the transition to formal settings is smooth. Selected examples of non-formal learning settings are the prototypes *Oskar* [8] that can be used by learners for training the use of the database language SQL via an intelligent tutoring system and *Charlie* [19], which is a natural language user interface to the *INtelligent Educational System (INES)*.

Learning Form. The large number of papers covering non-formal learning settings is also reflected in the learning forms. As many conversational agents can be used by learners in any location independent of the user's environment, the learning often (approx. 66 %) takes place in an isolated way (i.e. learners interact with the conversational agent without any interaction with other learners, human tutors or lecturers). The remaining learning forms (collective, situated and collaborated learning) only take place in approx. 14 %, 3 %, and 17 % respectively.

Topic Focus. According to our statistics, the pedagogical conversational agents that have been researched in the paper corpus are almost equally distributed among single-topic agents or multi-topic agents. In many cases, the authors of the papers state that the agents are intended to support a specific learning scenario (e.g. the agent *Dr. Roland* [24] focuses on supporting learners to solve math problems; [25] is able to ask very specific questions and give hints about a special simulation). In other cases, the described agents can be used in almost any learning scenario, because teachers or lecturers are able to edit the learning content or add additional content via control

[1] In some cases, we could not categorize the papers, because too few information was available.

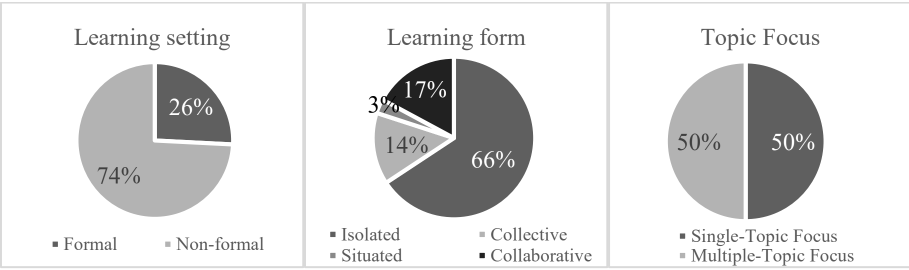

Figure 4. Summary of the didactical perspective on the paper corpus

panels. Exemplary systems that we identified are *MentorChat* (see e.g. [26]) or the agent by [27] that provides a so-called *Learning Objects Authoring Interfaces*.

Summary. Based on these results of taking an didactical perspective on pedagogical conversational agents (see Figure 4), we conclude that most available agents target non-formal learning situations in which learners interact with the agents alone (in an isolated way). However, it has not yet been conclusively investigated whether these use cases are beneficial over use cases in formal learning settings. Nevertheless, it needs to be remarked that this observation does not imply that such pedagogical conversational agents just support simple learning cases as known from simple mobile learning applications (like vocabulary training). On the contrary, pedagogical conversational agents are able to provide interactive, natural language-based opportunities to convey learning content in a way that was previously only possible in human-to-human training settings (like in classroom training or individual tutoring). Consequently, the isolated learning form as we used it in our classification only means that the learner uses the agent alone without any interaction with other learners. Nevertheless, the learners are not really isolated as they interact with an automated, virtual, but natural language-based chat partner.

We could not determine any trend regarding the topic focus of agents. On the one hand, agents that allow an administrator to configure and provide multiple topics seem useful. On the other hand, many researchers focus on single-topic agents that are specialized to fulfill a given learning task.

4.4 Methodical Perspective

In addition to the analysis of the content of the papers, we also examined the applied methods. Thus, we aim at identifying how researchers in the domain of pedagogical conversational agents are conducting their research.

First, we need to acknowledge that the methods that are described in the papers differ because the research field of pedagogical conversational agents is interdisciplinary: Researchers from the domains of computer science, information systems, pedagogy, and psychology are participating. This makes it difficult to classify the methods, as they differ depending on the discipline or the individual research background. For this reason, we have opted to an aggregated, qualitative view. Two aspects are particularly noteworthy: Prototype development and evaluations.

Prototype Development. In a majority of the papers, the authors based their research on implemented software prototypes (including *Charlie* [19], *Oskar* [8], *MentorChat (e.g. [26])*, *Dr. Roland* [24], *Ville* [28], *DEAL* [28], *AutoTutor* [29], *WrenchTalker* [30], *CiboPoli Bot* [31] and many unnamed more). From a methodical view, it is difficult to classify the methods as often there are not enough details available, but they seem to belong to the methods of design science research. However, to our knowledge, none of the research projects covers the whole design science research cycle starting with the problem identification phase and continuing with the definition of objectives, design, implementation, demonstration, evaluation and communication [32].

Evaluation. Focusing on the evaluation step, we identified two major directions: On the one hand multiple researchers chose Wizard-of-Oz experiments as an option to evaluate the potentials of pedagogical conversational agents in a simulated experiment. On the other hand, field studies were conducted to observe the operability, acceptance and beneficial value of the pedagogical conversational agents. However, there is no uniform evaluation method approach.

Summary. Based on the methodical view of the paper corpus, we conclude that the applied methods are quite heterogeneous. Only in the evaluation of pedagogical conversational agents, we can observe a trend towards using Wizard-of-Oz experiments as well as field studies. Considering the other steps of typical design science research cycles, we cannot identify a consolidation towards using specific methods. In many cases, only parts of the design science cycle are covered. Often the authors focus either on a technical view (covering conceptualization and implementation) or on a pedagogical view (covering learning scenario and evaluation). Comprehensive approaches are usually missing. In particular, it needs to be noted that neither generalizable requirements nor design theories are presented.

5 Discussion of Trends and Future Research Agenda

The first research goal (RQ1) of our study was to identify the current state of the art of using conversational agents for educational purposes. For this reason, we conducted a structured literature review and analyzed the resulting final paper corpus from four perspectives: From analyzing the time perspective, we determined that there is an increasing interest in research about pedagogical conversational agents. This becomes apparent as the total number of relevant papers reaches an all-time high in 2017 and we expect an even increasing number of publications by the end of 2018.

The technical perspective outlines that both, messenger-like conversational agents as well as embodied conversational agents, are objects of research. However, we can observe an upward trend in the number of publications focusing on messenger-like conversational agents whereas the number of embodied conversational agents seems to be decreasing. We explain this mainly with the increasing popularity of messenger apps in private life [4]. Additionally, an increasing number of messenger platforms and social networks started to provide APIs that can be used for developing chatbots (e.g. Slack, Facebook or Telegram). This resulted in a growing number of chatbot applications. In addition to that, an increasing interest of researchers and practitioners to adapt methods known from the machine learning or artificial intelligent domain can be observed (e.g., complex natural language understanding and generation algorithms). Due to this, intelligent chatbots receive more attention in research.

Our analysis of the didactical perspective shows that pedagogical conversational agents are most often designed for non-formal learning settings. Thus, learners can use the agents anywhere and anytime because of the common mobile or web-based implementation. For this reason, learning often takes place isolated from other learners but in interaction with a conversational agent. Regarding the topic focus, we could not identify a trend either towards single-topic or multiple-topic agents. However, we argue that the quite large number of single-topic agents is especially related to that fact that it is easier for researchers to limit the complexity of the software to a single topic, as this is often sufficient for conducting an evaluation. In some cases, we assume that the software artifacts are even capable of supporting multiple-topic scenarios, but the authors did not state this explicitly in the written papers. Thus, we argue that there is a trend towards multiple-topic agents when the focus is on actually using them in real settings and not only in laboratory experiments.

Finally, the methodical perspective shows the presence of a heterogeneous method mix. This represents the fact that the field of pedagogical conversational agents is quite interdisciplinary. As information system researchers, we must admit that complete design science research cycles and especially generalizable results in almost all design science research steps are missing.

Trending Characteristics. Based on our literature review and our interpretation of the results in the discussion above, we summarize the trends for pedagogical conversational agents in the following Table 6.

Table 6. Trending characteristics of pedagogical conversational agents

<table>
<tr><th>Type</th><td colspan="6">Messenger-like conversational agent</td><td colspan="6">Embodied conversational agent</td></tr>
<tr><th>Content</th><td colspan="4">Mobile-first</td><td colspan="4">Web-based</td><td colspan="4">Other</td></tr>
<tr><th>Learning setting</th><td colspan="6">Formal learning settings (e.g. at a university while attending a seminar)</td><td colspan="6">Non-formal learning settings (e.g. self-study)</td></tr>
<tr><th>Learning form</th><td colspan="3">Isolated learning</td><td colspan="3">Collective learning</td><td colspan="3">Situated learning</td><td colspan="3">Collaborative learning</td></tr>
<tr><th>Content</th><td colspan="6">Single-topic learning content</td><td colspan="6">Multiple-topic learning content</td></tr>
</table>

Future Research Agenda. With these results, we state the following research gaps and research opportunities:

(1) Need for generalized design knowledge. As most publications in the field focus on specific implementations of pedagogical conversational agents and miss to provide in-depth transferable insights, we propose that researchers should focus especially on the generalization of their design results. We are aware that it might be difficult to propose requirements that are generalized but also meaningful. Nevertheless, proposing generalizable system architectures for pedagogical conversational agents that can be transferred for different learning settings will be useful for researchers and

practitioners. As information system researchers, we propose to conduct multiple design science research cycles as a proper method to achieve this.

(2) Need for comprehensive in-depth evaluations. In the paper corpus, we identified many evaluations of pedagogical conversational agents. However, those papers often focus on very specific evaluation targets. Comprehensive evaluations covering multiple aspects (like learning success, technology acceptance, software quality, algorithmic quality, suitability of application scenarios) are missing. Even though an in-depth analysis of the evaluation methods was not in the focus of this article, we recognized that this needs to be addressed in the future. In particular, it would be meaningful to provide researchers with a detailed overview of suited evaluation methods. This is especially important for conducting comprehensive evaluations in research studies focusing on pedagogical conversational agents as the research field is interdisciplinary.

(3) Need for process models. Currently, the range of approaches on how to conduct research in the interdisciplinary field of pedagogical conversation agents is huge, because there is no uniform procedure. We assume that a common understanding of (a) how to develop and use pedagogical conversational agents in practice-oriented projects and (b) how to evaluate those agents comprehensively would advance the research field. For this reason, we propose that future research studies should focus on providing process models that cover both, design steps and evaluation methods. In particular, it would be helpful for design-oriented researchers as well as for practitioners to obtain a guideline that describes at which stage of the development process which evaluation methods are useful (e.g. conducting Wizard-of-Oz experiments seem especially useful in an early stage of the design process whereas field experiments are more useful after a functional prototype is available).

6 Conclusion

In this research study, we evaluated prior research papers in the interdisciplinary research stream of pedagogical conversational agents by taking time, technical, didactical and methodical perspectives on the literature base. Using this approach, we identified the state of the art and outlined trends that are present in research projects targeting at pedagogical conversational agents. Additionally, we proposed a research agenda. Possible limitations of this study lie in the selection and interpretation process of the analyzed papers. We are aware that these steps are dependent on the judgment of the individual researchers. Through a systematic literature analysis approach in which we defined inclusion and exclusion criteria, we tried to minimize the subjective influence as much as possible. Our results can contribute to both, research and practice: Researchers can base future projects on our research agenda to develop the field further. Additionally, our research might be helpful for practitioners. Especially developers of chatbot applications might use our results as a starting point to inform themselves about current trends in the field of pedagogical conversational agents.

Teaching the Digital Transformation of Business Processes: Design of a Simulation Game for Information Systems Education

Alexander Löffler[1], Borys Levkovskyi[1], Loina Prifti[1], Harald Kienegger[1], and Helmut Krcmar[1]

[1] Technical University of Munich, Chair for Information Systems, Munich, Germany
{alexander.loeffler,borys.levkovskyi,prifti,harald.kienegger, krcmar}@in.tum.de

Abstract. The ability to manage business processes in the context of the digital transformation is a key competency that should be addressed in Information Systems (IS) education. One possibility for teaching this competency is through simulation games, but the current ones lack a dynamic view on changing business processes induced by the digital transformation. In this paper, we present the design of a simulation game to teach the digital transformation of business processes within IS education. The game simulates the transformation of a bike manufacturing company to a bike-sharing provider, in which students have to manage changes in the production process in teams during different transformation phases. We argue how our game supports central learning objectives for teaching the aforementioned topic and show the benefit of our game design by running a pilot test with students from IS education using the Systems Usability Scale to evaluate the utility of our implementation.

Keywords: Simulation Games; Game-based Learning; Digital Transformation; Business Processes.

1 Introduction

Digital technologies are becoming a main driver for changes in today's companies. The combination of information, computing, communication, and connectivity technologies fundamentally transforms business strategies, products and services, or business processes of an organization [1]. This implementation of digital technologies goes beyond an increase in the efficiency or effectiveness of current processes and leads to changes in the way a company operates, which is defined as "digital transformation" [2]. A core part of this transformation is to manage the business processes and their changes induced by the current technological developments [3, 4]. To prepare students for their future working environment, these changes require adoption by academia, such as including current trends and technological developments of the digital transformation into the curricula. Based on the previous analysis by Prifti et al. [5], business processes and their change management can be seen as a core competency for

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

the future workforce to be competitive in this dynamic environment. Therefore, teaching the digital transformation of business processes is a highly relevant topic for Information Systems (IS) education.

However, in current IS education, specific concepts for teaching the digital transformation of business processes are still missing [6]. As previously stated by Jeyaraj [7], changes of business processes should not only be taught to students in a theoretical manner, but also be experienced by the students. Therefore, Jeyaraj [7] proposes to use a simulated environment for teaching the topic in a more experiential way. Despite the importance of providing enough practical insights into the effects of business process changes, a detailed solution to experience these changes is missing [8, 9]. A promising approach to achieve this are simulation games, which model parts of the reality and simulate dynamic situations based on the model [10]. A simulation game would provide the ability to imitate process change scenarios with students in a classroom environment [11]. However, current simulation games that focus on business processes, such as the simulation game called ERPsim [12], are geared towards static business processes instead and are not designed to simulate dynamic business processes [12, 13]. Hence, there is a need for a simulation game to teach the digital transformation of business processes from a practical perspective.

In order to address this, we present the design of a simulation game to teach the aforementioned topics. Building upon previous findings for teaching business processes in the context of the digital transformation, we provide practical scenarios for experiencing changing business processes. We use a bike manufacturing company as an example and provide a storyline in which the company transforms to a bike-sharing provider. In the course of the transformation, the production process changes, and students playing the game will have to take different actions to manage the process. We argue whether such a game supports the predefined learning objectives when teaching the digital transformation of business processes and evaluate the game by using it in a pilot test with a group of students from IS education. In summary, the main objectives of the study are to design the simulation game and to show its utility for teaching the aforementioned topics in IS education.

The rest of the paper is structured as follows: First, we present related work in the area of simulation games, business processes, and teaching in the context of the digital transformation. Afterwards, we present our research approach for the design and development of the simulation game. As the core of the paper, we present both the didactical and technical design of the implementation. Finally, we present the results of an evaluation with students from IS education using the Systems Usability Scale (SUS) to show the utility of the implementation.

2 Related Work

Simulation games have a long history in various disciplines. While the initial focus was on simulations in the military or economics, it changed to the usage of simulation games for education in business over the last decades [14]. In IS research, this “gamification” becomes more and more important [15] and various examples for simulation games to serve specific goals of IS education exist. For instance, Baume [10] presents a simulation game to teach information management based on the example of the tasks of a Chief Information Officer. The game is based on the structure for simulation games by Kern [16] and consists of a preparation, interaction, and evaluation phase. Thereby, it is shown that the game provides a useful method to teach information management to students. Another example is the work of Léger [12], who presents a simulation game called ERPsim, which teaches the execution of integrated business processes based on a real Enterprise Resource Planning (ERP) system from the software manufacturer SAP. Moreover, Grund & Meier [17] argue that there is a lack of simulation games to teach business information visualization in IS education and a respective game is developed in a following research project [18]. In summary, these games provide useful methods to teach IS content to students. However, they do not contain a dynamic aspect in which students have to adapt to a changing business environment.

In general, handling changing business processes is not a novel topic that arose in the context of the digital transformation, but has been a topic of IS research for a long time. Leading corporations have used the management concept of Business Process Change (BPC) to manage their processes and the resulting changes induced by current developments. Overall, BPC involves any type of process change, either revolutionary or evolutionary [19]. There has been previous research on the impact of BPC on the success of BPC projects [20] and their dynamic complexities [21], but this was geared toward researchers and practitioners. However, it was already mentioned that an integration of the findings into a simulation game could be a fruitful avenue for future research [22]. In the context of the digital transformation, BPC becomes an important concept, as the restructuring of business processes is a core task within the transformation [3, 4]. Therefore, it is also a topic of high interest for IS education [5].

When it comes to teaching BPC, Jeyaraj [7] proposes use of a simulated environment, as this allows students to experience the impact of changing business processes. In this environment, students can simulate the elicitation, modeling, and reengineering of business processes using role-playing activities. For the context of the digital transformation, where BPC becomes a core competency for the future workforce [5], a previous work [6] analyzes requirements for teaching BPC, which include making decisions on the design, execution, and redesign of business processes using a modern ERP system and user interface. In addition, another work compares two prototypes for simulation games that focus on the digitization of business processes [23] and therefore provide basic insights on the development of simulation games in this context.

3 Research Approach

For the development of our simulation game, our research applies the design science approach according to Peffers et al. [24], additionally considering the guidelines from Hevner et al. [25]. In general, we follow their methodological steps that involve the following activities [24]:

1. **Problem Identification and Motivation.** As previously stated, there is a need for more practical approaches such as simulation games for teaching the digital

transformation of business processes in IS education. This fact can be strengthened by considering the experience in IS classes with teaching the digital transformation of business processes. Focus group discussions with lecturers from the IS context, such as the ones conducted by Prifti et al. [5], showed that teaching in the context of the digital transformation requires different learning strategies and curricula, which are not yet covered in traditional IS courses. More specifically, further focus groups highlighted that simulation games offer the possibility to teach behavioral competencies such as teamwork, competition, and decision making [6], which is difficult to address with traditional teaching methods. Therefore, simulation games are highly suitable to teach the digital transformation of business processes to students in IS education and to provide them with a more practical perspective.

2. **Definition of Objectives for a Solution.** As our planned solution is a simulation game for education, the central objective is to reach learning outcomes with our game. In general, students can achieve learning outcomes at three different levels, which are the institutional, program, or course level [26]. In our case, we focus on the development of a simulation game for an IS course and therefore develop learning outcomes on course level. For this, Biggs developed the Structure of the Observed Learning Outcome (SOLO) taxonomy, which defines action verbs for learning outcomes based on five levels [26]. However, as the verbs in the taxonomy are limited, we also considered the revised Bloom's taxonomy as recommended by Anderson & Krathwohl [27] for the definition of learning objectives for the simulation game. In our case, this taxonomy is highly suitable, as it provides action verbs for a range of learning activities [26, 27], which is necessary to cover all tasks in the simulation game. Hence, we define the relevant learning objectives for our solution based on the action verbs from the revised Bloom's taxonomy [27].
3. **Design and Development.** Based on the learning objectives, we iteratively developed a prototype for our simulation game. This prototype serves as design research artifact whose desired functionality is to address the previously defined learning objectives, according to the approach from Peffers et al. [24]. Based on this, the technical architecture was derived and the artifact was created in iterative development rounds. As described by Hevner et al. [25], an iterative development of the artifact helps to get immediate feedback on the design in the construction phase and supports the creation of an artifact that satisfies the requirements that it is meant to solve. In our case, we built a project team that consisted of four people and met every two weeks. From the fourth week on, we had a running prototype of our simulation game that we discussed and extended iteratively. After four months, the final prototype of the simulation game was ready for the first user tests. At this stage, we were able to compare the artifact's functionality with the previously defined learning objectives it should address.
4. **Demonstration.** To demonstrate our artifact, we conducted a pilot user test with 13 students from IS education. During this test, the participants played the game in a 90-minutes session. Therein, we introduced the company and its digital transformation to the players, explained the process they have to manage, as well as the game rules and its user interface. Afterwards, the participants played the game, in which course they worked with the artifact in order to be able to evaluate it later.

5. **Evaluation.** In the previous design and development phase, we argue whether the game has potential to teach the digital transformation of business processes effectively. In order to evaluate this with a quantifiable measure, we used the questionnaire of the SUS by Brooke [28] for the technical aspects of the game. The SUS is an easy to use scale to measure the usability of a system or product, which covers the effectiveness, efficiency, and satisfaction of a user when working with a system. It consists of a ten-item questionnaire, can be used on small sample sizes and still provides reliable results [28]. In our case, with this measure, the students can give feedback on the usability of the simulation game and we can analyze the utility of our artifact for teaching the aforementioned topic.
6. **Communication.** The communication of the results is fulfilled within this article.

4 Game Design

4.1 Learning Objectives

The central goal of our simulation game is to prepare IS students for their future working environment by gaining a deeper understanding of the digital transformation and its effects on a company's business processes. To derive specific learning objectives for this overarching goal, we analyzed learning objectives in the literature for simulation games in IS education and related disciplines. The literature review has been structured according to the methodology proposed by Vom Brocke et al. [29]. We considered databases including IS and education outlets, such as the IEEE Xplore Digital Library, SpringerLink, the ACM Digital Library, and the AIS Electronic Library. In these databases, we searched for learning objectives in IS education that can be applied on simulation games for business processes. Furthermore, we considered previous analyses on competencies in the context of the digital transformation, such as change management, understanding and coordinating workflows, decision making, and teamwork [5]. Based on the results, we built ten learning objectives that define what the students should learn after playing the game. These objectives are defined based on the revised Bloom's taxonomy [27] and are listed below, clustered by the different activities in the simulation game. After playing the game, the students will be able to

1. … explain the described process and its sequence of process steps [30]
2. … illustrate the interdependencies between different process steps [31, 32]
3. … explain the impact of the digital transformation on the business processes [5, 6]
4. … explain the digital transformation in the production process [5, 6]
5. … explain the challenges of BPC in the context of the digital transformation [6, 33]
6. … develop a strategy for profit maximization based on the current market demands [34]
7. … adapt and change the described process according to the developed strategy [35]
8. … analyze and solve problems in a team [5, 6, 36]
9. … make decisions in a changing and competitive environment [6, 30]
10. … critically evaluate one's own decisions and their impact [6, 36]

4.2 Game Scenario

The game scenario is based on previous research in BPC, simulation games, and the digital transformation. Based on the literature, we derived fundamental principles and technical requirements for the implementation of the simulation game. Furthermore, following the design science approach as previously described, we iteratively discussed the game design and its technical requirements. Overall, this led to the following fundamental principles for our simulation game:

- The students work together in teams and compete against other teams in a common market [6]. Collaboration within the team is thus required to manage the game successfully [37, 38].
- The central tasks in the game comprise decisions regarding changing business processes induced by the digital transformation [39]. The students should divide tasks among their teams to analyze the different decisions, discuss them, and come up with a common solution afterwards [40].
- For all decisions, the students work with the interface of a modern ERP system, in this case SAP S/4HANA, in order to analyze the different alternatives and make decisions based on a real ERP system [6, 8, 33, 40].

We embedded the game into the storyline of a bike manufacturing company, as this is a frequently used example for a model company in education to teach business processes [41]. Especially in the context of the digital transformation, this storyline is highly suitable for students in IS education, as it provides a concrete example for an industry affected by the digital transformation, which can still be easily understood without extensive technical knowledge, e.g. about production processes. Our main idea was inspired by findings in the literature that see the Internet of Things (IoT) as an important concept when teaching the digital transformation [42]. Furthermore, the combination of products and services in a rental model, also called Product Service Systems (PSS), is an important topic for teaching changing business processes [43] and therefore is also considered as part of our game.

In our game, we use the scenario that a bike manufacturing company decided to introduce a new bike with IoT components to the market. In a first step, the new bike received positive feedback from test customers, who really liked the new IoT components. Therefore, the company reorganizes the production process to bring these new bikes to the market. However, despite positive customer feedback, the company is experiencing problems with the sales numbers due to the high product price of the IoT bikes. To address this problem, the executives decide to extend the company's business model and to offer bike-sharing services to private customers on the top of the current business. For this, additional components for the bike, e.g. an onboard application to manage bike rentals is necessary. Overall, the tasks within the game comprise the management of the necessary changes within the production process and ensuring that the new business model is running properly.

Overall, the different changes the bike company undergoes in the digital transformation are split up into four phases of transformation, which are depicted in the game in four rounds:

1. **Phase 1**. There is an initial demand of 10.000 bikes on the market. The teams have the possibility to buy additional assembly lines for production of the new IoT bikes and determine a price for their sales.
2. **Phase 2.** The demand increases to 60.000 bikes and the teams can now introduce quality management to improve the production process. Furthermore, new automatic assembly lines can be bought to increase the production capacity.
3. **Phase 3.** The bike company decides to offer bike-sharing services with their IoT bikes. Therefore, the demand increases to 350.000 bikes. The teams have to integrate application development into their process to be able to offer the bike-sharing services. Additionally, they can buy new assembly lines using predictive maintenance, which have a higher capacity and lower rejection rate.
4. **Phase 4.** In the final round, the demand is 400.000 bikes. The teams can introduce additional sales and distribution channels for their offerings and need to establish their offerings in competition with the other teams.

As basic process for the described scenario, we use a bike production process that consists of ten steps. As a foundation, we used a sample production process for bikes as described by Magal & Word [41]. However, we additionally considered the attachment of IoT components to the bike during production, such as sensors, a motor, or a battery [44]. This leads to the business process in Business Process Model and Notation (BPMN) shown in Figure 1.

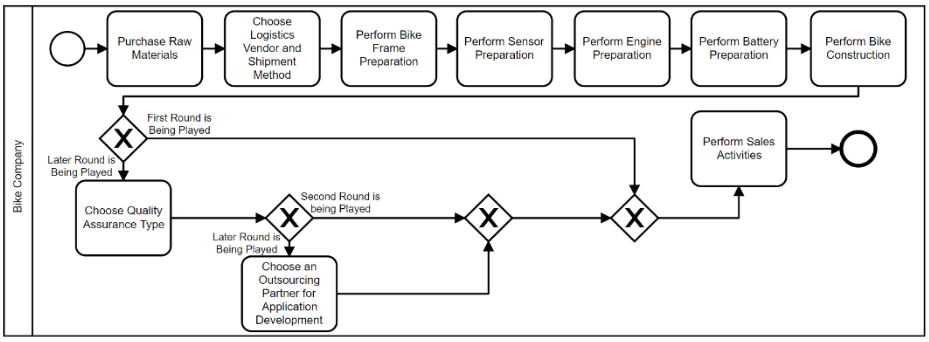

Figure 1. Process Scenario for the Simulation Game

First, there is the purchasing of raw materials, in which the teams can choose between different vendors offering the required materials and can decide which quality they should have. This is followed by logistics, which comprises company-internal logistics and allows the teams to choose between different shipment methods. In the next four steps, which are frame, sensor, engine, and battery preparation, the participants have to choose between different assembly lines. In each transformation phase, new assembly lines can be bought, depending on the current state of the digital transformation. This provides the ability to choose production lines with different capacities and align the production capacity to the overall demand on the market. As the seventh step, the bike construction follows, in which the teams can again select from different types of assembly lines. However, this step is very important, as it determines the final number of bikes the company will produce. Afterwards, there is quality assurance, which does not exist from the beginning, but can be implemented in the second transformation phase and improves the quality of the bikes. The ninth step is application development, which becomes important when the bike company decides to offer bike-sharing services in the third transformation phase. There, the teams have to choose an outsourcing provider for application development in order to manage bike-sharing services with their IoT bikes. Finally, there are the sales activities, which determine the price of the bikes and allow additional decisions that have an effect on the revenue, such as introduction of new distribution channels or sales branches. This last step also determines how many bikes are sold at the chosen price and therefore results in the overall profit of the company.

4.3 Technical Implementation

From a technical perspective, the application is based on the SAP ABAP (Advanced Business Application Programming) technology stack. It consists of three main components, which are the frontend, developed with the JavaScript framework SAPUI5, the backend, developed in ABAP, and an underlying SAP HANA database. The frontend consists of two subcomponents: administration and game. The first one can only be accessed by the instructor and is used to create a new game and to start the round simulation after the player entries have been confirmed. The players interact with the second subcomponent after they have been assigned to an active game. The frontend communicates with the backend for loading of master data, such as material data or vendor data, as well as for game data and round data submission.

In the design of the user interface, we followed the customer-centered approach as described by van Duyne et al. [45] to assure that all the game features are built in an understandable way. First, we have designed our user interface responsively, so that the game can be played using computers, tablets, and mobile phones. We divided the home page into a main section and navigation section, following the navigation bar pattern by van Duyne et al. [45]. From the main area, the players can access every process step shown in the process scenario in Figure 1. A side bar is used for navigating to the round results and to the help page, which describes the game rules and the differences between the rounds. The upper bar contains a button to end the round. Pressing it will disable the ability to change the decisions and will notify the instructor that the team the player is assigned to is finished with the current round.

For every process step, we developed a unified design, consisting of a header area and a decision-making area. Figure 2 shows this on the example of the “Frame preparation” process step. The header area consists of three sections: previous round data, showing the player’s decisions from the last round, current round data, showing what values have been saved for the current round, and cost accounting data, showing the influence of the player’s decisions on the budget, running cost, and total quality of the product. The header area also has the navigation button that returns the player to the home screen. The decision-making area is located under the header and has several input fields that have to be filled in by the player. Each field has a help button that briefly explains its meaning. All changes the players make are also reflected in the live cost accounting section. These values should aid the player through decision making by showing the impact of their decisions without having to save every change. The data needs to be saved only when the player is satisfied with his or her decisions and it is done by pressing the "Confirm" button in the footer of the page. The interface of the game also includes videos that explain the introduced innovations, e.g. robotic quality assurance or predictive maintenance. Located to the right of the live cost accounting, these videos are aimed at providing the player with better understanding of digitalization and automation and thus increasing the didactic value of the game.

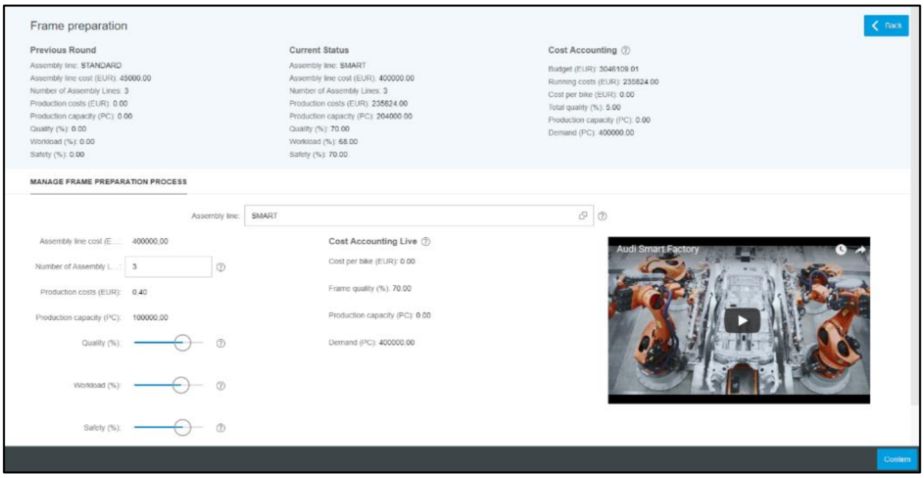

Figure 2. Sample Process Step of the Simulation Game

4.4 Fit Between Learning Objectives and Game Scenario

During the design and development of the game, the main goal was to implement a solution that addresses the learning objectives for teaching the digital transformation of business processes as described in Section 4.1. Table 1 illustrates the fit between the Learning Objectives (LO) and the game scenario from a conceptual perspective.

As illustrated, all learning objectives are covered by different aspects of the game scenario. LO1 and LO2, which focus on explaining and illustrating the business process and its interdependencies, are mainly addressed by the visualization of the basic process scenario in the starting screen of the game. Furthermore, common KPIs for all process steps, e.g. production capacity, create dependencies between the steps that the students have to understand to be successful in the game. LO3 to LO5, which focus on explaining the digital transformation in different contexts, are mainly met by the different activities that are available dependent on the transformation phase. In each phase, new technologies such as smart production lines become available, which have an impact on the efficiency and overall profit in the game. Additionally, new activities have to be handled by the students that are necessary to sustain the profitability, e.g. managing the quality assurance from the second phase on. As general rule, in each round, a new process step appears, which defines the current transformation phase and has to be managed to get a competitive advantage in the game. LO6 to LO8 focus on developing a strategy, adapting and changing the process accordingly, and analyzing and solving problems in a team. These learning objectives are addressed by a changing market demand based on the current round, which is accompanied by further changes regarding the business processes that have to be managed by the students. For this, teamwork is necessary, as new process steps become available in every round and tasks have to be split to react to all changes accordingly. Finally, LO9 and LO10 focus on making decisions in a changing environment and critically evaluating the impact of the decisions. For this, the demand changes in a flexible way based on the number of teams and the participants have to make decisions under time pressure to be competitive. Furthermore, the user interface provides a results screen, which allows students to evaluate their decisions and to reconsider their strategy for the following rounds.

Table 1. Fit Between Learning Objectives and Game Scenario

Learning Objective	*Aspects of the Game Scenario*
LO1	• Process presentation in the preparation phase of the game • Basic process scenario illustrated in the starting screen
LO2	• Interdependencies between the process steps through common KPIs
LO3	• Presentation of IoT components in the preparation phase • Impact of transformation phase on available process steps
LO4	• Impact of technological developments on the production capacity in the game
LO5	• Changes within process steps allow for more process efficiency • New process steps allow for more profit in the game
LO6	• Changing market demands based on the current round • Gameplay allows clear strategy for profit maximization
LO7	• Changes within process steps necessary in every new round • Additional process steps available in every new round
LO8	• Teamwork as fundamental principle of the game • Each team member is required to make decisions
LO9	• Demand changes based on number of teams • Limited time for decision making during the game rounds
LO10	• Results screen for each team to analyze decisions • Different strategies possible to win the game

Overall, regarding the revised Bloom's taxonomy for the definition of learning objectives, all categories are covered with the design of our simulation game. The taxonomy defines six cognitive processes, which are called Remembering, Understanding, Applying, Analyzing, Evaluating, and Creating [27]. While the majority of the learning objectives can be assigned to the processes of remembering (LO1 and LO2) and understanding (LO3-LO5), also applying is covered by our simulation game (LO7). Moreover, the process of analyzing is covered by LO8 and evaluating by LO9 and LO10. Finally, the process of creating is addressed with LO6. However, regarding Biggs' SOLO taxonomy, not all levels are covered by the game.

This taxonomy defines five levels of students' understanding. According to Biggs & Tang [26], four of them can be described with learning objectives, which are called the unistructural, multistructural, relational, and extended abstract level. Regarding the learning objectives of our game, the unistructural (LO1, LO3), multistructural (LO2, LO4-LO6, LO8 and LO9), and relational level (LO7, LO10) are covered. However, the extended abstract level is not addressed, meaning that the current game design is limited to the fact that students get a practical experience within the mentioned topic, but may not be able to transfer their experience to a theoretical level with the current version.

5 Results

5.1 Evaluation Scenario

For the evaluation of our simulation game, we conducted a pilot test with 13 students from IS education. The students were selected randomly from different courses in the IS master program and participated voluntarily. The age of the participants was between 19 and 37 and all of them had a basic understanding of business processes and the term "digital transformation" from previous lectures in their study program. We used a questionnaire including the SUS by Brooke [28] to evaluate the technical design of the game. The SUS is a reliable tool to measure the usability of a system or product and is valid to differentiate between usable and unusable systems [28]. It can be used on small sample sizes and still provide reliable results with regard to the usability of a system [28]. In our case, the SUS is beneficial as it provides a valid result for the utility of our simulation game despite the small number of participants in our pilot test. Based on the results, we can draw conclusions on the technical maturity of the implemented prototype and get a valid measure for the proper design of our game.

Overall, the pilot test took 90 minutes and consisted of three phases, inspired by the structure for simulation games proposed by Kern [16]:

1. **Preparation Phase.** In this phase, first the storyline of the bike manufacturing simulation was explained. The basic process as presented in the previous chapter was explained, as well as the new IoT components that can be added to the bike. Then, the game rules with four rounds, competing teams in a common market, and the fact that the team with the highest profits wins the game were described. Finally, the user interface was introduced to the participants, in order to prepare them for the first round. Overall, this introduction phase took about 20 minutes.
2. **Interaction Phase:** In this phase, the students played the four rounds with the different transformation phases as described in Section 4.2. Before every round, a short introduction to the available decisions was given. Afterwards, the students had ten minutes to make their decisions. After every round, a brief discussion of the intermediate results followed. Overall, the interaction phase took 60 minutes, with about 15 minutes per round.
3. **Evaluation Phase:** After the students played the game and discussed the results, they were asked to fill out an online questionnaire including the ten questions of the SUS. Afterwards, the pilot test was finished.

5.2 Evaluation Results

In general, the students rated the game very positively. The mean score of the SUS was 76.35, with a standard deviation of 11.59. Figure 3 shows the percentile ranking for all SUS scores of the 13 participants.

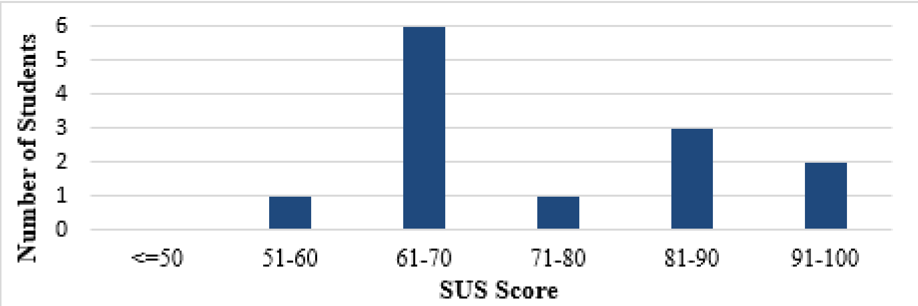

Figure 3. SUS Scores for the Simulation Game

The mean SUS score lies above the average of 68 and therefore is considered a good score [46]. According to the adjective rating score by Bangor et al. [47], the simulation game lies between "good" and "excellent". This indicates that our implementation in this state already has a good technical maturity. Most of the students agree that the simulation game is satisfactory and provides a good usability without needing much help of an instructor, which strengthens the purpose of using the simulation game as a learning system. Moreover, as the SUS not only serves to evaluate the usability, but also the learnability of systems or products [48], we can further derive that our implementation in general facilitates learning. Regarding the previously derived learning objectives, the results from the SUS does not allow drawing conclusions whether the students reached the single learning objectives. However, considering the results as feedback on the technical implementation, we can conclude that the game in general addresses the learning objectives with its technical functionalities. Therefore, the students' feedback through the SUS shows that the simulation game supports the purpose of teaching digital transformation of business processes.

6 Conclusion

In this paper, we have presented the design of a simulation game to teach the digital transformation of business processes within IS education. As basis, we derived learning objectives for teaching the mentioned topic from the literature and defined them for the purpose of our simulation game. The game was built based on the scenario of a bike manufacturing company that undergoes a digital transformation to a bike-sharing provider. We described the game scenario and the technical implementation in detail and argued whether the game design supports the predefined learning objectives. Thereby, we showed that our game is designed to address all level of the revised Bloom's taxonomy and supports the learning experience for students regarding the digital transformation of business processes. However, considering Biggs' SOLO taxonomy, our game design currently lacks the transfer of practical knowledge within the mentioned topic to a theoretical level. Hence, the current game design mainly aims to support students in getting practical experience with the digital transformation of business processes. In order to take the knowledge to a theoretical level, the game design has to be extended including more reflection by the students or a link to related research or literature focusing on further aspects of the digital transformation. Nevertheless, an evaluation using the SUS with 13 students from IS education showed the utility of our implementation from a technical perspective and the support of our technical solution to reach the defined learning objectives. However, a conclusion whether the single learning objectives have been reached by the students is not yet possible. Hence, a more extensive evaluation with a higher number of students can provide further insights on the achievement of the learning objectives. For example, this can include an assessment in which the students have to show their acquired knowledge after they played the game. Moreover, as further evaluation, observations by experienced lecturers may be suitable to measure the learning experience.

In conclusion, with this work, we propose a method for teaching the digital transformation of business processes from a practical perspective. The game can be used by lecturers in their practical courses and thereby extend the learning experience of their students. Furthermore, it provides a recommendation how teaching in the context of the digital transformation can be enriched with more interactive methods. Thereby, we contribute both to the theory of teaching business processes in IS education and to practice by providing concrete guidelines to teach the digital transformation of business processes using a simulation game.

Conceptualizing Immersion for Individual Learning in Virtual Reality

Henrik Kampling[1], Anna Schwarze[1], Oliver Heger[1], and Bjoern Niehaves[1]

Abstract. Immersive virtual reality technology (VR) receives more and more attention, especially since the release of the Oculus Rift (development kit 2) in 2016. This technology is not only used in the gaming industry but also in serious contexts such as product design or education. The creation of high immersion is commonly said to be the special characteristic of VR. We consider two perspectives on immersion: firstly, immersion in the task and, secondly, immersion in the technology. Our work focuses on immersion as part of the learning related theory of cognitive absorption to examine the theoretical difference between task and technology immersion in the case of individual learning with immersive VR technology. We conducted an explorative Grounded Theory approach with 10 in-depth interviews based on first-hand experience with a self-developed immersive VR application. We propose theoretical and design implications for how VR can potentially enhance individual learning.

Keywords: immersion, virtual reality, individual learning, grounded theory

1 Introduction

Virtual Reality (VR) technologies are gaining more and more popularity, especially since the market entrance of Oculus Rift (Development Kit 2) in 2016 [1]. Nowadays, there are a couple of virtual reality head-mounted displays (HMDs), such as HTC Vive or PlayStation VR. VR technology is not only used for gaming contexts but in a variety of serious cases, such as product design and manufacturing [2, 3], urban spaces [4], (landscape) architecture and environmental planning [5], travel fair [6], rollercoasters [7], healthcare [8], or education [9]. The latter, for instance, shows an overview of educational perspectives and contexts. Liu et al. propose frameworks for design and implementation of learning [9, part I] and case studies of immersive learning (part II).

Such technologies facilitate new opportunities to improve education. Nowadays, many teaching formats and materials are supported by digital technology, such as massive open online courses, collaborative learning through social media, blended learning concepts, or other e-learning tools. Besides increasing the detachment from local and time restrictions, an essential objective of digitally supported learning is the improvement of individual learning outcome. Recent research in Information Systems (IS) investigates in how far innovative learning strategies [10] and environments [11]

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

can improve individuals or organizational learning outcomes, learning performance and the acceptance of e-learning technologies [e.g. 12].

VR environments based on head-mounted displays (HMD), such as Oculus Rift or HTC Vive, offer high potential to enrich learning experience and achieve better learning outcomes. In an immersive VR, the user is completely surrounded by an enclosing virtual space [13], which requires complex interfaces such as an HMD. Being in an immersive VR, users are entirely "beamed" to a virtual space, in which they interact with the environment using their entire body. Thus, the user is more strongly absorbed by immersive VR than in traditional non-immersive VR [14]. The use of HMDs in combination with the use of controllers allow users to interact with objects in a virtual environment in a more active and deeper fashion [15, 16].

Although we assume that HMD-based VR can significantly increase the immersion of its user compared to traditional screens and, in doing so, increase individual learning outcomes, to the best of our knowledge, no (empirical) research exists explaining interdependencies of immersion VR learning environments. Hence, the meaning and specific conditions of immersion in virtual reality learning environments have to be explored. Consequently, our study is guided by following research question:

RQ: How can immersion be conceptualized in the context of VR technology for individual learning?

Given its explorative nature, our study uses a Grounded Theory approach. In doing so, we use the literature on immersion, VR, and individual learning to get first insights into the subject. Afterwards, we propose our research method in which the interviewees of our study got first-hand experience with an immersive VR-HMD due to the novelty of the technology, i.e. a HTC Vive and a self-developed application. We then present and discuss our findings and provide implications for theory and design.

2 Background on Virtual Reality and Immersion

Virtual reality. In IS research, virtual reality systems are in the scope of interest. Since Oculus Rift (Development Kit 2) entered the market in 2016, the hype surrounding VR technology, particularly HMDs, grew [1]. VR is an interactive, computer-generated three-dimensional environment in which people become immersed [17]. VR applications within such an environment depend on the degree of immersion [13]. On the one hand, non-immersive VR refers most commonly to applications in desktop or laptop computers. On the other hand, immersive VR relates to users who are wearing complex interface technologies (e.g. head-mounted displays) and are completely surrounded by an enclosing virtual space. In addition, VR mostly refers to a single-user interaction in a virtual environment [18] and is typically limited to a single user session of 30 minutes [19]. An overview of current VR technologies, i.e. hardware and software, is provided in Anthes et al. [15].

Current research on VR is manifold and examines diverse topics and fields. A recent study on VR examines virtually high and low experiential products while shopping online [20]. Results show that consumer learn more about products, such as attitude and knowledge, in the virtually experiential high condition than in low condition.

Another study investigates virtual product experience and consumers' product understanding while it focuses on product presentation format and task complexity [21]. Further characteristics of immersive VR are arising through the use of HMDs and the use of controllers [22]. Both technological characteristics allow users to interact, create, and manipulate objects in a virtual environment [23, 24]. Against the background of VR and its origins in the consumer market with focus on gaming, VR is well-suited for applying gamification techniques for teaching cases within architecture and engineering 3D arts because it can help to engage into the learning process [25].

As mentioned above, an advantage of immersive VR is the increase of precision and permission of the visualization of objects and processes which are otherwise difficult or impossible to show in the real world which in addition allows to promote focused experiences, such as for the purpose of learning [14, 24]. Slater and Sanchez-Vives [14], for instance, describe four particular advantages immersive VR can have for educational purposes: First, VR can change abstract settings to tangible settings. For example, geometrical and mathematical concepts can be more easily understood in VR compared to traditional paper and pencil learning [26]. Second, VR settings allow a user/learner to actively engage than just observe how things work. For instance, surgical training, ideally paired with haptic feedback, can profit from practicing instead of observing handles [27]. Third, VR simulations allow to substitute methods that are desirable by teachers but practically infeasible or impossible in reality. If students have to study different elements such as Niagara Falls on week one and Stonehenge on week two, it will be infeasible to visit both places (due to time or resource restrictions) [28]. Fourth, VR environments are able to break the bounds of reality as part of exploration. Within such a virtual setting, physics can be manipulated such as changing gravity or making light speed and biological cell utilizing visible [29].

Immersion in the literature. A central component of VR generated, through the use of HMDs, is immersion [14]. In accordance with Slater [16], a user becomes immersed in a completely surrounding virtual setting (wearing a HMD) so that they can turn in any direction with head movements and motion parallax. Literature defines immersion, firstly, as task immersion (such as interactions and activities) "a mental state of being completely absorbed or engaged with something" [30] and, secondly, as technology immersion (such as software) "the experience of total engagement where other attentional demands are, in essence, ignored" [31]. Both are similar but have different research backgrounds and are measured differently. Within the context of learning, immersion is essential within the flow theory [32], and hence, it is a central component of Cognitive Absorption (CA) in the context of new information technology [31]. Both deal with an individual's mental state of absorption, a feeling of engagement and immersion, including intense concentration, a sense of being in control, a loss of self-consciousness, and a transformation of time [31, 32]. Hence, Flow and CA agree that the role of the flow experience shapes individual attitudes and behaviors when using information technology.

Cognitive absorption and flow have been the object of investigation in many studies. Flow, for instance, has been studied in relation to e-learning environments for higher education [12]. Here, processes of interactivity, imagery, and spatial presence influence flow (directly associated to intrinsic motivation) while the goal is to analyze the user's response towards a learning environment, such as continuance behavior. Another educational and more practical approach focuses on interaction and flow and its impact on e-learning acceptance by nurses [33]. The goal of the study is to analyze interaction factors (such as learner-system, instructor-learner, and learner-learner) and intrinsic (e.g. flow) as well as extrinsic motivators (e.g. TAM constructs, such as ease of use and usefulness) to explain the nurses' behavior of using an e-learning system for continuance intention.

Current studies of CA investigate it in relation to perceived learning in a mobile training scenario [34] and to individual learning in groups through text and video [35]. The first one found out that CA plays a significant role in affecting the deep involvement of users. The second one analyzed peer influenced learning and individual CA on learning outcomes (i.e. satisfaction, perceived understanding, and performance). With regards to a virtual environment, Goel et al. [11] examine the effect of CA on learning in collaborative tasks. They analyzed the effects of CA on perceived learning, learner satisfaction, and task participation in a virtual world. Collaborative learning and cognitive absorption have also been studied in an organizational context including individual learning [36]. The authors focus their work on group-level behavior that, in turn, can reduce (self-assessed) individual learning. Another work focusing on online learning environments investigates social presence and interest as antecedents of CA which, in turn, affects satisfaction [37]. Burton-Jones and Straub [38] present a contextualized model of system usage and individual short run task performance in which CA and deep structure usage are antecedents of system usage. Their results indicate that inappropriate choices of usage measures reduce explanations of performance.

In summary, much research on VR and immersion already exists. With regard to learning, only a couple of studies have examined the actual individual learning but mainly in group or collaborative tasks [11, 36–38]. Nevertheless, these studies do not consider a differentiate view on the construct of immersion, and in this way, flow and CA. On the one hand, immersion is outlined as task or interaction specific [e.g. 11, 32, 36], and on the other hand, it relates to technology [e.g. 31, 38]. Moreover, due to the characteristics of VR-HMD technology (such as the opportunity of enclosed virtual spaces which offer high potential for interactivity, creation, and manipulation of objects), we assume substantial potential in the context of learning. In turn, the meaning of immersion, particularly the differentiation between task/interaction and technology immersion has not been focused yet. In addition, we assume this missing theoretical differentiation as a gap which could be essential for individual learning within VR.

3 Research Design

Methodology. Due to the novelty of VR-HMDs, we are not surprised that no solid theoretical base exists that is able to explain the central construct and the interdependencies of immersion within the context of virtual learning environments. Taking this into account, the study at hand was conducted to get initial insights to comprehend this phenomenon. As a consequence, a deductive approach cannot be used to investigate this context because there is a lack of a reliable body of existing theory to inform extensive a priori theorizing [39, 40]. Due to the explorative nature, we follow an inductive Grounded Theory approach [41–43] to explore and examine the central component immersion in the context of individual learning with VR systems. Grounded Theory is well suitable for exploring theoretical insights [41] and can be characterized along six dimensions [44]: i) development of theory for describing and analyzing the phenomenon of interest; ii) continuous data comparisons against different viewpoints by constant growing analytical and theoretical aspects; iii) a step-by-step coding of data across multiple steps as emerging theory develops; iv) along upcoming differentiating dimensions the theoretical sampling of data; v) the handling of prejudices that prevent relying on any certain theory as a starting point; vi) "an inextricable link between data collection and analysis that incorporates further sampling as part of ongoing analysis and theorizing" [1].

Data Gathering. Against the background of the novelty of immersive virtual reality technologies, such as HTC Vive, Oculus Rift, or PlayStation VR, we conducted the interviews in a virtual reality lab. Here, all interviewees were able to get first-hand experience by using a virtual reality head-mounted display (i.e. HTC Vive). They used a self-developed VR environment (created with the Unreal Engine 4). First-hand experience guarantees that each interviewee is able to answer questions regarding virtual reality systems. The interviews were guided by questions which aim to reveal insights of VR-based learning technologies and of learning (theories) useful for immersive systems.

One major challenge of the interviews results from the fact that VR systems are (to the best of our knowledge) popular but not yet part of everyday life and, as a consequence, largely unknown (particularly with first-hand experience) among non-experts. Therefore, before the interview started, we provided each interviewee with time to use a virtual reality head-mounted display to get first-hand experience. As mentioned above, each interviewee was able to use a self-developed application (c.f. Figure. 1). Each participant was guided to an enclosed room to ensure a quiet and controlled environment without external distractions. Only people who actually used the VR system were interviewed to guarantee that each interviewee was able to answer questions regarding the VR system. Within the self-developed demo, each interviewee was confronted with a scenario to move freely in a virtual room. Here, the starting point was in a room where a door has to be opened by using a key. The key had to be taken with the help of the controller and led to the door, which then opened. The participant had to walk through the door by real walking movements and to follow instructions in order to hand over a parcel, by using the controller, from one point to another, where a virtual avatar was waiting. The system provides feedback to the user through visualizations, i.e. green for correct conduction and red for making a mistake. In case the user made a mistake, he or she could restart the process until they conduct it correctly. Afterwards, each interviewee was given time to explore the virtual setting, such as interacting, playing, or manipulating objects. The aim of the VR demo is a parcel delivery process in which a participant is able to learn a step-by-step process.

For instance, the demo oriented itself within a perspective of a postman who hands over a parcel.

Figure 1. Self-developed immersive VR application

The interviews had an average duration of 67 minutes, whereby 6 male and 4 female persons were interviewed with an average age of 29 years. Within our interview group, we had one ERP consultant, one management consultant, one innovation consultant, one practice nurse, one research associate, one student of teaching, one student of environmental science, two students of information systems, and one student of business administration.

The study at hand follows an interview guide approach because it is more comprehensive and systematic for data collection than a purely conversational interview. Each interview was open-ended to ensure all interviewees can add concerns that we did not cover in our guideline [45]. Each interviewee was able to ask questions about the immersive VR technology while they were using it. Here, we followed the guideline of Darke et al. [45] who suggest to conduct an interview with at least two interviewers. We recorded the interviews to minimize data loss and to provide all answers and insights given by the interviewees. All interviews were fully transcribed.

Data Analysis. For reviewing our interviews, we used MAXQDA 12. Here, we looked for indicators of immersive VR technology, particularly insights into immersion, and specific conditions of individual learning in VR environments. To analyze the indicators, we draw from well-known methods from grounded theory [41–43, 46, 47], i.e. open coding, axial coding, and selective coding. Hence, we had three phases of analysis. These phases were done iteratively by the first two authors of the paper at hand, including phases of independent coding and code-matching to come to a joint result. Within this initial phase, i.e. looking for emerging aspects (open coding), we specifically took care that within the procedure no themes were excluded due to previous experience or prejudice. We then applied axial coding by building clusters of similar codes. The axial coding allowed us to identify different insights relevant for our subject. In a third step, we searched for relations between the insights to better understand the themes and to derive theory implications, we reflected them by matching them with the literature (selective coding). After we conducted 10 interviews, we finished collecting data because no new insights were found (theoretical saturation).

For the following presentation of our findings, we chose quotations which were most suitable to represent the overall findings.

4 Findings

Feeling naturalness within immersive VR. An immersive VR leads to the feeling that you can act with the virtual environment similar to the real world. Acting in VR feels natural for the users, so that a feeling of reality arises. Naturally executed movements by users and that everything behaves in such a way a user expects support this feeling. Their expectations are based on the experiences of the real world. This real feeling also creates barriers that do not exist in the virtual setting but which are perceived by the participant as real, based on their real world experiences.

"The application was very exciting. Firstly, because you really had to interact with the objects as in reality, and you had to be able to rely on the virtual environment reacting exactly as you would have expected. So that the physical effects of the virtual scenario match those of the real world. [...] Ok, I have to say that I really don't have the need to step into the table because I think it will hurt my knee, it is like an invisible barrier. It feels like walking through thick water. Of course, you don't feel anything but it feels like as you can rest on it." (Interviewee 1, ERP consultant)

Another aspect mentioned to enhance a feeling of naturalness relies on acting with real hands rather than controllers. These, in turn, can enhance the engagement within a virtual space. For instance, it was mentioned that connected gloves or similar technologies which visualize hands and fingers within the virtual space could change the kind of interaction with objects and strengthen the feeling of real behavior.

"Only one grabbing mechanism is not enough, there have to be two times five fingers so that you act as if you were using the real hand. For example, in medical cases, you need sensitivity." (Interviewee 10, student of business administration)

"If you pull on a glove, one with some sensors on it would probably be even more natural. […] A hand would be cool. Because now I have operated with the controller, I have seen the controller in the virtual reality. I wish I had seen my hands like the controller. Simply to be able to estimate the distance correctly even if I want to grasp something. If I don't have hands I don't know if I grab at the right place" (Interviewee 2, innovation consultant)

Against the background of traditional teaching formats and teaching in VR, positive and negative perspectives were mentioned. For instance, the reason why a learner can recall information could rely on the medium it was taught in. As a consequence, a VR space can enhance a learner to be engaged to specific content-related details as they exist in a real world environment.

"[…], the details in a lecture are between the lines or are available in texts. The medium of these lectures is the lecturer or the slides, in which I have two sources of attraction from which I must draw the information myself. In VR, I don't have the opportunity to write down information. It was beyond my familiar environment, so my head is naturally much more active to look at details and learn." (Interviewee 4, student of information systems)

Dimensions of Immersion. Almost all interviewees explained that they forgot the outside environment because they had the feeling of being inside the virtual setting and to be cut off from the real world. So far, virtual reality settings allow users to ignore distractions from the real world and to focus on the VR environment. In conjunction with haptic stimuli, the novelty, and variety of (inter)actions delivered by VR technology, users are (again) able to draw their attention to the intended learning task. The part of immersion in technology is, as defined above, the total engagement to a system while all other impressions are ignored (from here we call it *technology immersion*). Due to the technology immersion, the participant is in the position to feel like a part of the game or system, i.e. to dive into the VR system. Through the sensory immersion and interaction within the virtual environment, a feeling of being involved arises. In turn, this would make it difficult for an individual to "escape" the learning context because the VR provides an enclosed surrounding, engages, and transfer the user into virtual space.

"So, you were just in the game [VR system], you couldn't just look at it from the outside, like in a normal computer game. You were just in the game as part of the game." (Interviewee 3, student of teaching)

"Virtual reality is very engaging. It surrounds you and gives you another room. If you combine different media, such as writing, video, or audio, under a certain goal, then you have a great beneficial application. In VR, you have a much wider field of vision than on a PC display. Even if you put three displays side by side, the VR can surround you with a 360-degree environment freely for yourself. […] I think the non-perception of passed time is about the new environment, I have focused on many little things, this took so much time. The virtual room invites you to deal with everything; this shifts the perception of time." (Interviewee 3, student of teaching)

"I know that nothing can happen to me, so I can interact with the virtual reality very interested." (Interviewee 6, research associate)

The psychological perspective of immersion is a mental state in which you are immersed in a certain task or activity (from here we call it *task immersion*). On the one hand, participants are curious and engaged in the content, and on the other hand, there are some hazards that the user loses himself while interacting within VR.

"Yes, the technology is also interesting but more interesting is the presented content." (Interviewee 8, student of environmental science)

"I am already very curious to see what the scenario will look like. With these glasses [the HMD is meant] it will be a very exciting and engaging experience." (Interviewee 2, innovation consultant)

"[…] but the risks that I see in this context is that people get lost in the virtual reality activities." (Interviewee 9, practice nurse)

An emerged issue within the interviews is the loss of the feeling of passed time. In case an individual does not recognize the spent time while being active in the VR, this could be positive for concentration as well as learning. In contrast, if one is not sensing the spent time during VR activities than this could lead to a loss of perceiving the real world.

"I think it has a positive context because the loss of a sense of time is in general a sign for concentration. Therefore, to cut out the surroundings, I would say this could be useful [for learning cases]." (Interviewee 5, student of information systems)

"I think it is a danger that you completely lose yourself in virtual reality activities and you do not notice at all how fast the time passes in reality. You can lose the relation to reality." (Interviewee 9, practice nurse)

Finally, our findings reveal an essential insight about the relationship of task and technology immersion. In the context of problem-solving, a VR system can enhance an individual to cut off real world surroundings and to focus on a specific task. Hence, a higher degree of technology immersion allows a user to be engaged with a mental activity (i.e. a higher task immersion).

"There are situations where you get into a flow. In these situations, you just do and do not think. The VR can probably support that more than if I still have the ambient noises or other things that distract me. The VR can already support this. If I just say, I have a problem here and I want to deal with it now, and then, I put on the headphones and hide the world. VR would be notch up one's performance, which then supports me to ignore the real world and I concentrate on one thing [learning task]." (Interviewee 6, research associate)

5 Discussion

Conceptualizing immersion in virtual learning environments. Against the background of our findings, we conceptualize immersion within the context of individual learning in VR environments as manifold and suitable for educational purposes and the kind of absorption (c.f. Figure 2). Based on these, task immersion and technology immersion are dependent on each other in virtual reality learning environments. Task immersion, as described above, is a mental state of being psychologically engaged with something [30, 32]. Here, interviewee 5 mentioned that the interactivities are engaging and supports one's own concentration. Technology immersion is the total engagement with a technology while other attentional demands are ignored [31]. For instance, in our VR setting, interviewee 3 states that the virtual space surrounds and transport oneself in another room. An antecedents of immersion is naturalness. This can be subdivided into content-related details which enhances task immersion because the knowledge transfer from a VR and real similar setting might be easier than from an unsimilar. The natural feeling of interactions with one's own hands and control of movements in a virtual space rise the sense of naturalness which enhances the feeling of immersion with the technology because the activities are unbiased to interactions in the real world. Individual learning can be related to different purposes in which immersive VR technology can be well-suited to measure performance and learning outcomes. On the one hand, within virtual settings a learner can acquire declarative (theoretical) knowledge, i.e. cognitive outcomes, or they can develop (practical) skills. On the other hand, a VR technology can be satisfying for the learner [10].

There is a vast amount of literature on individual learning outcomes and individual performance measures [e.g. 10, 11, 37, 38] as well as on immersion and its defined categories on task and technology immersion [e.g. 31, 33–36, 48]. As a complement to that, our findings (Interviews 5 and 6) indicate that immersion influences individual learning outcome. Consequently, immersion and its two manifestations are essential and need explanation within the usage of VR technology.

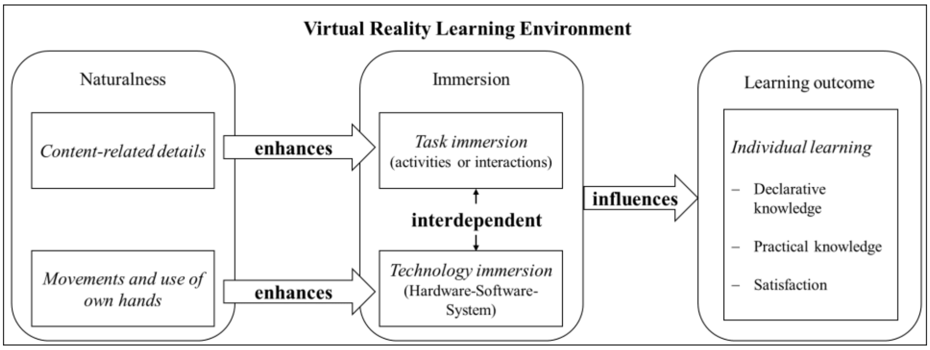

Figure 2. Conceptualization of Individual Learning in Immersive VR

Implications for theory and design. Immersive VR systems have the potential to improve individual learning through the specific characteristics underlying the VR medium. HMDs allow a user to dive into an enclosed virtual space and to interact, to create, and to manipulate objects by using controllers in the virtual environment. Moreover, immersion is essential for individual learning. Our research seeks to conceptualize this construct as a driver for learning outcomes (declarative, practical, and satifsaction). With regard to our RQ ("*How can immersion be conceptualized in the context of VR technology for individual learning?")*, we describe the manifoldness and meaning of immersion in the context of individual learning in VR (c.f. Fig. 2).

Our study provides several theoretical insights. We contribute to previous literature on individual learning outcomes and learning theory by extending the scope of analysis. Individual learning and/or immersion have been primarily investigated within group learning behavior [36], learner satisfaction [37], perceived learning, and task participation [e.g. 11, 34, 35], or from self-regulated learning strategy perspectives [10]. Yet, the use of immersive VR technology within learning contexts has not been focused broadly but already described from a subjective viewpoint [e.g. 9, 14]. We differentiate by interviewing direct user with first-hand experience in which way immersive VR technology can be used, what are preconditions for learning, and by examining the central aspect and the specifications of immersion.

There is an increasing amount of research on immersive VR with an educational purpose [e.g. 26–29]. Within such an environment, real but also abstract and unreal elements can be displayed with a diverse scope of interest. Here, we contribute to the literature by revealing the naturalness, and hence, the feeling of reality by using an immersive VR system that allows a user to develop and gain learning outcomes. Of course, the interviewees perception reveals these different possible outcomes but these are based on their own experience by using an immersive application with an underlying process which a user can learn.

In differentiating the theoretical construct of immersion in case of immersive VR technology for the purpose of individual learning, we contribute to literature by considering immersion in the learning task [e.g. 11, 32, 36, 49] and immersion in the technology [e.g. 31, 35, 37, 38]. Both play, as current literature suggests, an important role for IS educational purposes. From a theoretical perspective, it is worth to explore this phenomenon in more detail because we assume that a higher immersion to technology could decrease the immersion in the task what finally could result in a worse learning outcome. If one is more focusing the technology provided scenario (as a medium that provides the learner content) than the actual learning task, one might argue the learning task is less important or interesting, hence, a learner could be distracted through the technology. In turn, research also has shown that a too high immersion to a task can be detrimental because an intense absorption can lead an individual to ignore contextual cues in which they are immersed [50]. Moreover, if immersion is overemphasized, a learner is more likely to lose their concentration to their performing activity and, therefore, to suffer because of a disconnection from the contextual environment [51]. Here, a learner would rather focus the process than the activity itself. Furthermore, Illies and Reiter-Palmon [52] argue that a potential negative effect on individual learning arises by immersion because the learner might have a closed state of mind, in which they inhibit problem solving and information seeking.

As a consequence, there is a theoretical trade-off for research on immersive VR technology in the context of individual learning. On the one hand, we suggest that researchers should seek to consider this trade-off by focusing both kinds of immersion and taking these considerations into account. On the other hand, immersive VR technology has the potential to be beneficial for learning because such systems can be designed in a way that the antecedents of immersion are increased which, in turn, increases the immersion into the task as well as technology (for instance, design elements of presence [53]). Finally, our findings suggest that there is the opportunity that technology immersion can have a positive effect on task immersion because it can support a learner by ignoring the real world and to concentrate on the task activity.

In accordance with our theoretical implications, the theoretical trade-off can be addressed by designing certain aspects of an immersive VR setting. Users of such systems should be provided with a natural feeling when using the system. For instance, instead of using artificial controller for interacting within a virtual space, Schwind et al. [54] suggest the provision of a "leap motion" technology which could enable a leaner to use their own hands for interactions and perceiving presence. Another example for sensing naturalness refers to the idea that aspects within such a virtual setting has to be considered in a rich way, so that (expected) details are visualized. In contrast, a badly programmed virtual environment will decrease this sense of naturalness.

6 Limitations and Outlook

Our study has several limitations. First, this study is based on interviews, first-hand experiences with 10 participants following a convenient sampling strategy, and was conducted in central Europe. It does not cover how other cultures, certain professions, the elderly, or organizational backgrounds deal with topics around immersive VR technology and individual learning. The study could be extended to other cultures and backgrounds to get a broader perspective and deeper insights into the use of immersive virtual learning environments. Second, although the participants were provided with a VR-HMD experience before the interviews started, all of the participants were previously unfamiliar and inexperienced with such a technology. This first experience could have the effect of overemphasizing a feeling of curiosity or enjoyment with the technology which, in turn, could bias given answers.

As a consequence, this study offers potential for further research. For instance, within an experimental quantitative approach, the differentiation of immersion could be examined to develop a generalizable theory for individual learning (for instance, Jahn et al. [55] suggest in their research-in-progress article a theoretical model). Here, we assume an underlying potential for design theorizing with a focus on certain aspects of immersion to enhance the individual learning outcome. Different immersive VR-based design alternatives could be analyzed with regard to efficiency.

Abstract. Digital learning has become more than just a trend in the modern world. Blended learning concepts are well established in different areas of application. An important concept in this domain is the so-called flipped classroom. This approach repurposes class time to focus on application and discussion, while the acquisition of basic knowledge will happen at home, enabled by online lectures. In the past, research demonstrated and discussed the advantages of flipped classroom concepts within case studies. Still, standardized guidelines for the development of flipped classrooms are rare. However, it is necessary to learn from the past to improve future education. Thus, we analyzed reviews on flipped classroom research and used these to develop a generic process model for the realization of flipped classroom concepts. The model is based on phases taken from project management, which help to structure the procedure and associated tasks.

Keywords: Flipped Classroom, Course Development, Project Management, Process Model, Checklist

1 Introduction

The concept of a flipped classroom (FC), also known as inverted classroom, has gained rising attention over the last few years. It was primarily described by Bergmann and Sams in 2006 [1]. The number of publications as well as practical implementations are still increasing [2], [3]. A common understanding of the flipped classroom is that the activities of attendance time and time outside the classroom are switched [4]. Bishop and Verleger understand "the flipped classroom as an educational technique that consists of two parts: interactive group learning activities inside the classroom, and direct computer-based individual instruction outside the classroom." [3] The impacts of using this concept are widely discussed. Even though some approaches exist which conclude that FC does not improve class performance, compared to traditional lectures [5], [6], the majority of research results confirm positive impacts on student outcomes (like performance and satisfaction) as well as class participation when self-paced learning is in focus [3], [7-9].

Until now, only small parts of lectures are held as FC. One reason for this is a lack of knowledge about the design of these courses. Structural research providing an

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

overview of the topic is rare [10]. The dominating part of research available is case-based which leads to a “siloed” character of the research field, missing systematic approaches [2], [11]. This paper aims to present a process model for the course development from a lecturer’s perspective. We understand a process model as a guideline including basic tasks and milestones, which are successively being processed and are striving towards a clear goal. Theoretical guidelines can help to design and use FC and are recommended to be used for implementation [3]. To proceed systematically, we align the necessary steps to project management phases. To identify tasks and challenges associated with each phase, we conduct a review of literature reviews about FC that is later enriched by a forward and backward search. Additional information on important to do’s and possible questions are provided.

This paper contributes to research and practice by using a structural approach from another field of knowledge to systematize FC research. It also helps lecturers to design an FC. The focus lies on the development of a useful guideline for practitioners. In the next chapters, we present the research method and summarize findings from FC reviews, which are used for the development of the process model that is presented in chapter 4. We conclude by summarizing and discussing the findings on the phases. Lastly, the limitations of our paper and an outlook for further research are shown.

2 Method

We regard the conceptualization of an FC class as a process that follows all major project management phases (initialization, planning, execution and closing) according to the Project Management Body of Knowledge (PMBok) [12]. Using this concept is unusual as several teaching designs and concepts already exist [13]. Teaching and traditional instructional designs (e.g., ADDIE [14]) include aspects of the competences, group of learners, and teaching subjects [13]. However, their dominating parts focus on pedagogical issues rather than on processual aspects [15]. The process-oriented step by step guideline is (especially in the field of FC-Design) still underrepresented [10]. Therefore, we chose a project management guideline and added pedagogical insights, when appropriate. We assume that this approach is easy to apply and understand due to the few phases involved.

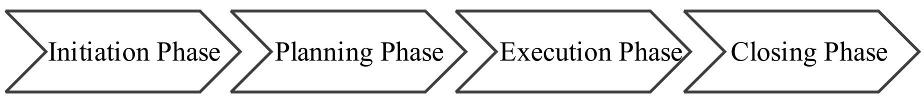

Figure 1. Project Management Phases

In general, different guidelines to define project phases exist and the number of phases varies [12]. Nevertheless, generic theoretical definitions can be applied to different kinds of projects. They all have in common that the phases are sequential and the degree and uncertainty are greatest in from the outset when stakeholders can best be involved [12]. We find many characteristics that are typical for projects within the creation of an FC course as the concept is new, of limited resources and limited time

[12]. Using a theoretical perspective, we define four key phases to develop, implement, proceed and evaluate an FC course (see figure 1). During the initiation phase, the idea of the project comes up and has to be evaluated. Risks and impacts are considered to prepare the decision about the project execution. In the second phase, the planning, required resources are identified and a plan for time, costs and performance is developed. The third phase is often presented in two sections (testing and execution). It describes the integration of products or services designed in the project. The closing phase includes an evaluation of the project and its output.

These phases are used to define activities for developing and implementing a flipped classroom. The activities are identified by conducting a literature search, that reflects the current knowledge base of FC [16]. To get the best possible overview, we decided to conduct a meta-review of existing literature reviews. The findings of the individual reviews can be compared and contrasted [17]. The reviews are used to (1) give an overview of the field of FC research, (2) find activities for the FC development phases and (3) start a forward and backward search. The forward and backward search leads to FC case studies describing the performed activities. The process model is developed in iterative steps. In each step, the identified activities are collected, discussed and assigned to the phases. Figure 1 shows how the research methods and the structure of the paper are linked.

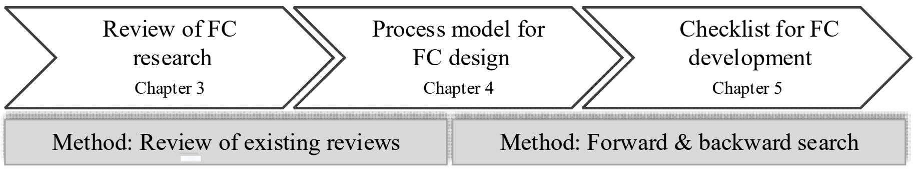

Figure 2. Research process

Our search was conducted in the following databases: Web of Science, Science Direct, Google Scholar, ERIC, AISNET and Scopus. We combined two research strings. The first describes FC to identify articles on the topic: „flipped classroom“ or „inverted classroom“ or “flip teaching”. The second research string is used to limit the results to review articles. Terms used are “review” or “state of the art” or “state-of-the-art” or “meta”. Both research strings are combined with an “and” function. We regard our work as a meta-analysis in the broadest sense [18], as we did not statistically analyze the databases.

The search resulted in 70 hits. Duplets and mere case-descriptions were sorted out which led to a total number of 21 articles, published between 2013 and 2018. We examined the focus of the reviews as well as the major findings. Moreover, we identified the kind of learners, the learning context and how the FC was implemented. The results of this analysis are used as a base to describe the state-of-the-art in FC research (see chapter 3). In a second step, we used the reviews to identify specific topics and tasks of the process of developing the FC. Articles, which showed evidence for at least one of the process' phases, were analyzed in-depth. Consequently, we enriched the reviews by findings from further literature in the field of FC. To decide if the papers are useful for identifying tasks for the phases, we used the following selection criteria:

a) Tasks during FC implementation must be mentioned or at least described; b) Clear alignment to the process phases of the development, when tasks were performed; c) The case was assessed as a representative example (no unusual designs); d) The articles had a clear relationship to FC as a concept described by Bergmann and Sams in 2012 [1]; e) The results described a positive influence of the FC. We are referring to an FC term in a broader sense, as articles with additional traditional lecture content have also been included.

3 Findings in Flipped Classroom Research

FC is a highly contemporary subject with a steady increase in publications. More than half of the identified reviews were published within the last two years, eight of them in 2018. Within our literature research, we identified 21 reviews in total. Six of them are meta-studies, e.g., [9], [7]. Eight reviews focus solely on teaching in health care, e.g., [6], [19] and three reviews examine FC courses in engineering [20–22]. Most reviews have been published in the Anglo-American region and focus on the US teaching system. One exception is a meta-study by Tan examining the effectiveness of FC in China. The author concludes that the satisfaction with FC in the Chinese study is significantly higher than in the Western countries and attributes this mainly to the different (teaching) culture in China, which traditionally entails less interaction with the students and limited exchange of opinions [23]. Regardless of the geographical location, several authors also observe a concentration of FC approaches on STEM (science, technology, engineering, math) and health students [2], [21], [9].

In most of the examined FC courses, videos are used to convey knowledge before the face-to-face session, allowing students to progress according to their own learning pace [24]. The attendance time is mainly used to apply that knowledge and to encourage group work and discussions [21]. Within the scope of digitization through FC, it is possible to introduce Learning Analytics (LA) which is defined as "the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning" [25]. Within the FCs, it can be used to enhance the development of targeted learning materials, monitor the success of in-class activities [26] and enrich the final evaluation [27].

The majority of reviews state that FC approaches have positive effects on the success of a course compared to traditional lectures. These include increased overall performance, more cooperative learning and increased student satisfaction as the format supports discussions between students and teachers [7], [20], [28], [29]. Furthermore, better learning habits and positive attitudes are observed [21]. Nevertheless, some authors criticize the lack of control groups in many studies and state that the results of some studies are not statistically significant [6], [34]. Due to the different design possibilities of the FC courses, comparability is difficult. There are also a few results which state that student outcomes are not better in FCs compared to traditional methods [6]. Accordingly, new approaches for the evaluation of FC courses which unequivocally prove the success of FC are needed [5], [19]. Moreover, the high initial costs and set-up times incurred when implementing an FC course, especially for the lecturers, are not yet sufficiently investigated [21], [30].

In sum, most reviews show the results of delimited case studies that focus strongly on individual disciplines. This leads to a siloed and perhaps anecdotal knowledge in the research field without any systematic approaches. Therefore, a more general systematic examination of current research is necessary [2], [11].

4 Process Model for the Design of a Flipped Classroom

In the following chapter, we will describe the activities to be carried out to run an FC course. Figure 3 shows the project phases and the respective milestones to mark the (intermediate) results of each phase. The *milestones* will be described in detail below within the following chapters. This summarizing overview provides the structure to understand the separate actions taken in each phase.

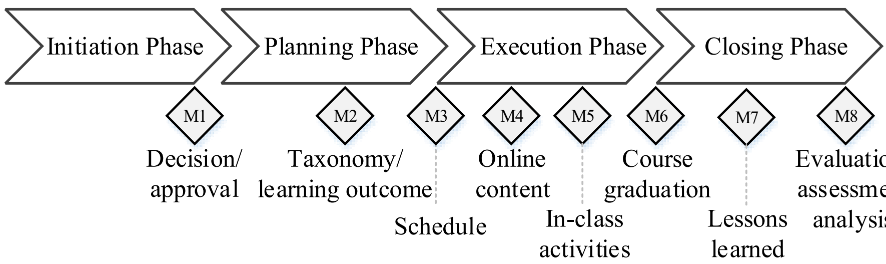

Figure 3. Milestones

4.1 Initiation Phase

The initiation phase aims to prepare a basis for deciding whether a course should be redesigned (or newly created) according to the FC method. Reasons for the redesign or creation could be the discontentment of teachers or students. The difficulties and problems of the current form of the lecture are investigated. Then solution proposals should be created, in this case, the transformation of the teaching form by the implementation of FC. The FC method can, for example, increase the student's motivation, performance, attendance and interaction during face-to-face sessions [20], [31]. It is useful to log the goals of the reorganization for the later evaluation. Once the goals which should be achieved by the FC have been determined, the time, staff and financial expenses of the implementation can roughly be estimated [12]. It should be checked whether necessary resources for a project team are available and to what extent costs for new acquisitions (e.g., learning management systems (LMS), video equipment) will be incurred [21], [30]. The affected stakeholders, as well as their benefits, challenges and barriers [12], must be identified. The stakeholders are the lecturers, students and the organization itself. All groups of stakeholders must be provided with the information needed. Teachers should familiarize themselves with the concept and may have to deal with a lack of skills and resources [30], [32].

Implementing the FC requires much effort, especially at the beginning, as the entire course has to be arranged in the FC format [21], [33]. Moreover, technical obstacles like cutting and uploading videos or the provision of self-learning tests on online platforms must be overcome [30]. Students can be actively involved in the redesign of the course by incorporating their feedback and ideas. However, according to Bishop, not all students are very fond of FC [3]. Students usually need more time to prepare for an FC course than to follow up on traditional lectures. It is therefore an important task to motivate the students to prepare the classes. This requires the implementation of appropriate structures. The gamification approach can be beneficial if it corresponds to the motivational structures and preferences of the students [34]. Short quiz questions to enter the next content or competitions between students can be useful to make self-study of class content easier and more appealing. [30], [38]. Here too, technical and skill related hurdles must be overcome as soon as possible [32]. Apart from teachers and students, stakeholders within the organization may also be addressed, such as administrative staff or IT support [35]. At some universities, there are competence centers for virtual teaching or higher education didactics, which accompany the conversion of courses and provide expert advice. Additionally, most organizations have a learning management system that can be used to make the multimedia files available to learners. During the initiation phase, a decision should also be made as to whether Learning Analytics is to be used and whether the technical and personnel requirements are met. The administration and the affected students must be informed and consent to the use of LA within the framework of existing data protection laws.

At the end of the initiation phase, it has to be pondered whether the benefits of FC merit the time and financial investments. If so, the phase ends with the milestone *decision (M1)* to implement an FC course.

4.2 Planning Phase

When the decision is made to implement the FC, the second phase begins. The goal is to plan the flipped classroom in general (adjustments to the curriculum, set the timetable, etc.) and in detail (design and tuning of the lectures). A lack of time is one of the most threatening challenges [30], [36]. Thoughtful planning is essential [11] for the success of the FC. The conception of the FC requires several resources [36], in addition to the pedagogical organization of the course, the instructor needs support to create virtual content and quiz questions. A FC can be conducted without supporting structures within the school. It is advantageous for the planning and implementation of a FC to build a team of people in order to share tasks and exchange experiences as well as results. For the training of the teachers, there is only limited structured information available about the pre-learning activities and duties [36]. Balan recommends the introduction of learner groups to provoke higher student motivation and to focus on individual learning motivation and outcome reviews [37].

Teachers need to get and give information before the execution about needed adjustments in curricula as the course (format) could also impact these [38]. It should also be checked if possible methods used for the FC meet the university's requirements, e.g., examination regulations. If the contents or the form of exams (e.g., digital exams) are to be changed in the context of the conversion, compliance must be ensured. This is also closely related to the *learning outcomes* which the lecturer wants to achieve within the course. Learning *taxonomies (M2)* are useful to structure the goals of the course [29], [39] and are therefore an important milestone in order to implement an FC. They are applied to split the content into reasonable sections and enable the tuning between the online and in-class courses [39]. There are different designs that represent a full flip or partial flip [3]. Furthermore, they reflect the different learning levels [40]. As the online-videos often cover basic contents, the in-class courses can be used for application, discussion, problem-solving and collaborative learning [41]. In this context, it is important to identify the group of students who will be taught. Teachers can develop FC classes for pupils, undergraduates [41], higher education students [11], and specific professional groups [8] from different disciplines.

Furthermore, different learning types need to be considered [3]. The development of the FC can be improved if the lecturer is aware of the diversity of the class. Gender differences can affect students` perceptions and learning outcomes [42]. To convince students of the new method, the concept of FC should be explained beforehand, including the content, goals and the procedure [30]. For the quality of the learning, the design of in-class and out-of-class activities is very important [22], [32]. Pre-class online lectures are of great value if they provide students with the basic knowledge to proceed with interesting in-class actions [36]. For the time out of class mostly prerecorded video lectures, podcasts or screencasts are used [3], [22], [43]. Herreid et al. surveyed FC teachers, with the result that most of them either chose sources like the Kahn Academy for precasted videos or produced the videos themselves, using programs like Camtasia or apps like Educreation [44]. As students can get easily distracted [45], it is recommended to use videos with a length of ten to 20 minutes [22]. The materials for the videos (e.g., slides) need to be planned beforehand [11] and produced step by step [46] before providing them to the students. For this purpose, subject areas have to be divided into several online contents [47]. The development of online courses is time-consuming. Researchers calculate the expenditure with approx. 1-2 hours per unit [33] and altogether 100 hours per course [48], whereby there is also the possibility of using already existing lectures [48]. The videos can be posted on platforms like YouTube, iTunes U, or on LMS like Blackboard and Moodle [44]. Lecturers should stay in contact with the IT support [30], [35] to guarantee easy access for the students [49]. It has proved to be beneficial to use existing technologies rather than developing new ones [50], [51]. As questions cannot be asked immediately [52] forums can enable discussions on the video content [53]. Regular quizzes that mirror the video content help to reduce distraction and ease the preparation for in-class activities [22], [45]. Out-of-class activities can be complemented by homework, pre-readings, automated tutoring systems or supplemental videos [11], [43]. Besides the planning of online lectures, lecturers need to decide which methods should be used in-class and prepare materials if needed. The pre-class preparation of an FC is much more time-consuming and complex than in traditional courses.

If the lecturer wants to use Learning Analytics to monitor student's activities, it has to be decided which data should be analyzed (e.g., trace data of the LMS like activation of course videos or solved online assessments), how the data is analyzed and how the results used [26]. Apart from FC specific planning, regular activities like scheduling in-class time and the reservation of rooms are necessary. The transition to the third phase takes place when the planned course starts. This is only possible when the milestone of *scheduling (M3)* is finished so that the course has a general structure.

4.3 Execution Phase

The actions proceeded during the term are subsumed within the execution phase. The phase mainly aims at the *supply of the video tutorials (M4)* and the *proceeding of the in-class lectures (M5)*. This phase is the one with the highest interaction between the students and the lecturer. This means the rules of the FC must be communicated beforehand [37], as students are less satisfied with unclear instructions and unknown situations [2]. The FC success depends mainly on the student's compliance [1], [30].

In-class courses can be designed as homework, quizzes, lectures, small group activities, presentations (e.g., case-based, student) and discussions (e.g., team-based, panel or expert-led) [3], [11], [43]. The activities chosen are very important as they differ in their effectiveness and conditions needed [43]. If the major goal is to enrich materials in class, more lecturer-oriented activities such as teacher-led discussions are useful. Interactive group work can be more suitable for the application of the material. Moreover, the course size has to be considered. While videos can be used for different group sizes, including large groups [54], the attendance time needs to be planned more carefully for larger groups, for example by forming smaller groups and/or using peer-learning [55], [56]. Attendance time activities are often accompanied by smartphone apps, pair-and-share activities or clicker assessments for immediate feedback to bridge expectations [37], misunderstandings and knowledge gaps [11]. Furthermore, accompanying in-class assessments make it possible to test previous knowledge and ensure quality [51]. Mid-term assessments are a common technique to evaluate learning success [22]. In-class and online-assessments, complement the flip model [51]. Therefore, clear accordance of video tutorials and in-class content (and assessments) is essential [2], [57]. Furthermore, the total student-workload should be considered [58]. The teacher must permanently control and steer the course regarding the students' needs, the planned results and the amount of work.

The kind and tone of interaction are important for the satisfaction emphasized by the learners [50]. The original FC model was designed as a flipped mastery model with little peer interaction and a focus on individual learning [59]. The role of the teacher changes in an FC environment [1], [45]. Recently, the share of team-based learnings and high group interaction increased [37], [59]. In team-based learning settings, the material for the in-class courses is processed iteratively. First, the individual student works with the material; then the individual results are discussed within the groups and finally debated with the teacher and presented in class [37] [59]. These iterations seem quite time-consuming to the students and can lead to a resistance to change [37]. In the worst case this results in absence from class. Some students also regard the in-class courses as obsolete, as they can learn the basic content of the class online. However, as intended by socio-constructivists, the group based learning in FC courses is essential for learning success [60].

In many studies learning success is directly linked to the exams. An FC design does not inevitably lead to a change in the way exams were carried out [61], but the high interaction and the available technical infrastructure enable changes [22]. Exams focused on problem-solving [62] or including bonus points [58] occur. In many cases exams mark the reaching of this milestone. The execution phase ends with *the graduation of the course (M6)*. This milestone marks the end of the interaction between the teacher and the students.

4.4 Closing Phase

The final phase of the FC process model is the closing phase. This is the time to evaluate the course, collect perceptions about the FC construct, content and overall implementation. The closing phase includes the analysis of data obtained on results and perceptions. The analysis is based on the teacher's experience, exam results and measurements of the students' attitude towards the concept [58]. Therefore, differentiation between summative (to measure the outcome) and formative (to formulate the lessons learned and re-design the concept) evaluations is necessary [39].

Most evaluations in FC research are based on self-reported scales using quantitative and qualitative data [22]. These scales often comprise perceptions of feelings, subjective experiences and satisfaction [60]. To assess the attitude towards the FC even scales, close to self-efficacy rate, are taken. We identified scales measuring enjoyment, self-confidence and perceived value of the content [60]. Furthermore, the evaluation of the learning success [11] and the students' effectiveness are important [31]. Many researchers claim the increase of the learning success using an FC scenario [41]. Often the students' performance as a whole increase in FC classes compared to traditional lectures [63]. Kerr mentions that even the middle and the lower third of the examination group increase their performance [20]. These results mainly aim at the exam-outcomes. Further positive statements regarding the problem-solving ability of students exist [7]. Only a few studies show opposite results [30]. Despite the measurable learning success, Foldnes [59] shows, that the increase of group interaction positively influences the learning outcomes. The great variety of evaluation designs shows that there is no standard tool for assessing FC neither formatively nor in a summative way. The evaluation can be further supplemented by LA, providing deeper insights into student's interaction and behavior throughout the whole course [26]. Only a few articles can be found that give room for the *lessons learned (M7)* to develop a sustainable culture of FC classes [9]. Teachers should use the closing phase to reconsider the contents and continuously work on the renewal of the contents and methods [11]. The pre-recorded online material should be critically revised [11]. In FC proceeding, the time made available for post-processing is limited. Nevertheless, it is important to collect thoughts, write down lessons learned and restructure future classes for sustainable success. These steps can improve the FC by design based approaches [9], [30]. This phase is finished with the *assessments and evaluations (M8)* which are held and analyzed. Results are shared with the organization and used for formative and summative re-organization of the course.

5 Discussion and Conclusion

For the deduction of the conceptual process model we chose a project management model based on four phases. We aligned the activities to initialize and implement an FC class. The structure helps to remember all duties and can be used as a checklist (see Figure 4) [12]. Figure 3, combined with the following chapters and the checklist, will give in-depth information about the activities performed, the important milestones and detailed description including further text references for a clear understanding of how to design and run an FC. Within the project initiation phase, both lecturer and institution decide about the introduction of an FC. During the planning phase, the rough and fine concept of the FC are developed. Besides the execution, the planning phase is the most demanding phase. In the execution phase the interaction with the students and the supply of online-material begins. When all in-class and out-of-class activities are finished, the evaluation phase starts. The activities, already described in more detail in chapter 4, are summarized in a checklist in Figure 4. The list is to be understood both as an overview and as a notepad so that all important activities are taken into account.

It is crucial to take enough time to set up an FC. The planning, content conception and coordination between online and attendance phases as well as the intermediate examinations and quizzes require a high level of professional competence. This is why the training of the teachers is so important. Surprisingly, little is reported about this in the literature found. Furthermore, there is a clear need for more conceptual models. Actual findings are dominated by anecdotal articles and presentations of cases [30]. Most articles imply somehow all phases but focus on different aspects. Future research could concentrate on single phases and the tasks or on single tasks covering all phases.

Despite our merits, the research is not free of restrictions and limitations. Review articles built the dominating part of our literature base. We cannot rule out the possibility that there may be some articles dealing with a more specific issue that we have only been able to address in a marginal way. Also, our model has to be evaluated. Regarding the results from our study, we acknowledge that FC is more for students than for pupils, as the learners need a self-paced learning experience. However, FC is not limited to any specified class of students [7].

For the evaluation of the model we plan to set up an FC for students based on the process model in order to gain further insights from our experience with the application of the model and to further concretize the individual steps. Also, we intend to interview FC teachers and students about our model and checklist in order to review our results and expand the model. A large and diverse set of data relating to the project management-centered design of an FC could provide interesting information that would allow the model to be evaluated and gains and barriers to be compared under different conditions and for different stakeholders.

Initiation

- ☐ Define needs and goals
- ☐ Estimate time, staff, and financial expenses
- ☐ Identify stakeholders (lecturers, students, institution)
- ☐ Weigh benefits and costs and make a decision whether FC is useful

Planning

- ☐ Activate project team
- ☐ Train teachers
- ☐ Check if changes/plans are in accordance with university requirements
- ☐ Identify group of learners (context, diversity)
- ☐ Define learning outcomes and levels with the help of taxonomies
- ☐ Inform students in advance
- ☐ Prepare and produce material (choose media type)
- ☐ Choose in-class activities and prepare material
- ☐ Tune in-class and online courses
- ☐ Prepare Learning Analytics
- ☐ Check and provide resources (rooms, technical equipment, LMS)

Execution

- ☐ Provide online material
- ☐ Continuous learning assessment
- ☐ Proceed in-class activities
- ☐ Monitor participants and learning success
- ☐ Steer according to students' needs

Closing

- ☐ Carry out exams
- ☐ Conduct formative evaluation (attitudes, perceptions) of stakeholders
- ☐ Conduct summative evaluation (learning success) of students
- ☐ Lessons learned

Abstract. Knowledge exchange and combination build the core of innovative activity. However, the processes of knowledge exchange and combination are inherently associated with risk. Consequently, for knowledge exchange and combination to occur in an organizational setting, the organization members must be encouraged towards risk-taking. Organizational cultural norms promote a certain behavior among organization members. Accordingly, this study focuses on risk-taking an organizational cultural norm and investigates risk-taking's influence on knowledge exchange and combination.

Keywords: Organizational culture, risk-taking, innovation, knowledge exchange and combination, knowledge management.

1 Introduction

In organization science, knowledge has gained great attention and a "legitimate and important role" [1] has been attributed to it [1, 2]. Knowledge is not only an essential asset for its owners but also an important source of sustainable competitive advantage [3, 4]. Specifically knowledge creation "is essential for the success and survival of firms competing in dynamic environments" [5], and can be considered "the precursor of innovation" [6]. From a knowledge-based perspective, innovation can be thought of as the "creation and application of knowledge to create new knowledge regarding novel products and processes" [6]. Knowledge creation involves two underlying processes, namely knowledge exchange and knowledge combination [7, 8]. These two build the core of any innovative activity which is in accordance with the Austrian School of Economics [8]. Knowledge exchange refers to "interchanging knowledge and information" [9] located in the organization and its members. Knowledge combination, on the contrary, depicts establishing connections between unconnected knowledge pieces or developing new types of connections [7].

Yet, innovative activity is inherently associated with risk [10] and represents a complex endeavor marked by uncertainty [11]. Similarly, knowledge exchange and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

combination are related to risk, and for organization members to engage in exchange and combination, they need to be willing to take risks [7]. In this regard, risk-taking – which is defined as a mindset that encourages the members of an organization to be open towards risks [12] – is essential. Accordingly, extant literature deals with risk-taking in the light of knowledge-related subjects [13], and risk-taking appears to be particularly relevant for knowledge exchange and combination [5, 7]. Research commonly states that risk-taking largely depends on organizational context factors (e.g. [14, 15]). A plethora of studies take the organizational climate for risk-taking into account, and analyze its influence on knowledge creation (e.g. [5]). However, risk-taking might "manifest the cultural variables that exist in and dominate" [16] the organization. This is underlined by several organization scholars who point out that risk-taking is attached to organizational culture (e.g. [12, 17]). In line with current research (e.g. [18]), we consider risk-taking as a norm. Norms define appropriate attitudes and behaviors of organization members [19]. As they convey which conduct is expected and appropriate, they guide organization members' behavior [20]. Accordingly, risk-taking norms direct organization members towards being me more apt to take on risks. As norms are proposed to be influential with regards to knowledge exchange and combination, we assume that risk-taking norms may influence knowledge exchange and combination among organization members significantly. However, empirical research on the influence of risk-taking norms on knowledge exchange and combination is scant.

Considering the above research issues, this study analyzes how risk-taking relates to knowledge exchange and combination. Thereby, we address the following research question: *What is the influence of risk-taking on knowledge exchange and combination?* Drawing on social capital theory, we empirically examine risk-taking's influence on both knowledge exchange and knowledge combination.

2 Related Literature

2.1 Knowledge Exchange and Combination

Social capital theory by Nahapiet and Ghoshal [7] posits that social capital can facilitate knowledge creation which involves two underlying processes, namely knowledge exchange and combination.

Knowledge refers to "a high value form of information that is ready to apply to decisions and actions" [21]. The exchange of knowledge describes "interchanging knowledge and information residing in different organizational members and subunits" [9]. Obviously, knowledge can be located at myriad entities, and its exchange not merely involves, but, necessarily requires more than one sole party. Knowledge exchange continuously provides new knowledge which serves as the basis for new combinations. Combination is the process of bringing together "elements previously unconnected or by developing new ways of combining elements previously associated" [7].

Social capital refers to “the sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit” [7]. It is an important driver of knowledge exchange and combination [22] and researchers commonly identify three dimensions of social capital [7, 22, 23]: (1) the structural, (2) the cognitive, and (3) the relational dimension. The relational dimension concerns “assets created and leveraged through relationships” [7]. This dimension pertains to resources that bond the members of a social system and transmit influence on their behavior. One form of social capital that is attached to the relational dimension is norms. Norms represent “a degree of consensus in the social system” [7] such as an organization. Norms that are effectively in use impart collectively binding demands on the members’ conduct and can have a significant impact on their knowledge exchange and combination activities [7].

2.2 Risk-Taking as a Cultural Norm

Conform with Yates and Stone [50], we define risk as “the degree of uncertainty and potential loss that may follow from a given behavior or set of behaviors” [17]. People generally dislike risk – and risk ambiguity even more [24]. However, knowledge exchange and combination processes are associated with risk and organization members’ willingness to take risks is critical for these two processes. Risk-taking refers to taking bold actions, and not only involves venturing into the unknown but also dealing with insecurities [25]. Consequently, organizations need to support and encourage risk-taking so that the organization members can cope with risk [26], and consequently engage in knowledge exchange and combination.

Cultural norms represent “a degree of consensus in the social system” [7] such as an organization. Due to the fact that cultural norms are “socially created standards” [18], they are to be grasped as the collectively binding demands and expectations regarding the conduct within the organizations [19]. They give direction to behavior, and if effectively in use, norms have a powerful effect on organization members’ conduct [7]. Similarly, whether and to what extent organization members take the risk and engage in knowledge exchange and combination could be significantly affected by risk-taking norms. Accordingly, we assume that risk-taking positively affects both knowledge exchange and knowledge combination.

3 Research Method

A survey is used for the means of data collection. All variables are measured with multiple-item scales using a seven-point-Likert-scale ranging from “strongly disagree” to “strongly agree”. Risk-taking, our independent variable, is measured with seven items adapted from Tellis et al. (2009) [26], Hogan and Coote (2014) [27], and Miller and Friesen (1982) [28]. Knowledge exchange (first dependent variable) is measured with 4 items and knowledge combination (second dependent variable) with 5 different items which are all adapted from Shu et al. (2009) [9]. The questionnaire undergoes a preliminary test. Researchers as well as innovation-related employees from different sub-divisions of the organizational unit under investigation serve as a pilot for the survey, helping to ensure that the items are appropriate and clearly worded for this particular sample. Data source is an organizational unit of production control and logistics in a major German, and internationally operating automotive manufacturer. Informants range from top management to lower employees. This sample is appropriate because the organization unit and informants are concerned with knowledge-intense work. We seek to reach an overall sample size of approximately 400 participants. The data collection process consists of two phases. First, emails with the link to the online-questionnaire on the academic survey platform "Unipark" are sent out. In the second step, a reminder-email is sent out after two weeks.is sent out via email.

This study uses structural equation modelling (SEM) for estimating the research model. SEM is appropriate because it allows us to test the relationships between the variables simultaneously.

4 Expected Contribution

We will contribute to extant research by providing empirical insights on risk-taking's influence on both knowledge exchange and knowledge combination. This will shed light on the norm "risk-taking" – which we consider the form of social capital that has the power to shape organization members' behavior to a large extent – and its role for knowledge exchange and combination. Thereby, this study will help create a more thorough understanding of the significance of risk-taking norms for organizational innovation. The results of this study will inform practitioners about the importance of embedding risk-taking as a norm within the organizational culture in order to strengthen organization members' knowledge exchange and combination activities.

Gamified Feedback durch Avatare im Mobile Learning

Tim Schneider, Andreas Janson

Universität Kassel, Fachgebiet Wirtschaftsinformatik, Kassel, Deutschland
{tim.schneider,andreas.janson}@uni-kassel.de

Zusammenfassung. Viele Arbeitsprozesse in der Industrie werden zunehmend digitalisiert. Diese Entwicklung erfordert neue Kompetenzen, welche im Arbeitsprozess durch Ansätze wie mobile Applikationen erworben werden können. Aufgrund der Informationsfülle im Mobile Learning und den Spezifika solcher Endgeräte kann es zu einer kognitiven Überlastung des Lernenden kommenden, wodurch dieser Lerninhalte nicht mehr aufnehmen kann. Um diesen Herausforderungen zu begegnen, schlagen wir den Einsatz von Gamified Feedback durch Avatare vor, welche als Lehrerergänzung die notwendigen Hilfestellungen und Informationen bereitstellen können. Hierzu wird im Kurzbeitrag eine Studie zur Untersuchung der Wirkungsweise von Gamified Feedback auf Cognitive Load von Lernenden im Mobile Learning präsentiert.

Keywords: Gamification, Feedback, Mobile Learning

1 Einleitung

Die zunehmende Digitalisierung der Arbeitsprozesse in der Industrie erfordert neue Kompetenzen und Fähigkeiten seitens der Mitarbeiter [1]. Das McKinsey Global Institute geht davon aus, dass 2030 rund 14% der globalen Arbeitskräfte aufgrund der Digitalisierung eine Weiterbildung benötigen, um den neuen Anforderungen an Arbeitskräfte in Zeiten der Digitalisierung gewachsen zu sein [2]. Diese Entwicklung führt zu einem stärkeren Bedarf nach Maßnahmen der Aus- und Weiterbildung (AuW). Gleichzeitig läutet die Digitalisierung einen Paradigmenwechsel in der AuW ein, hin zu informationsgestützten, innovativen Lernsystemen [3]. Diese Lernsysteme weisen einen hohen Flexibilitätsgrad auf, welches insbesondere bei Mobile Learning (ML) zu einer weiten Anwendungsbreite führt und sich in den starken Wachstumsraten von jährlich 8% wiederspiegelt [4].

Jedoch erfordert diese Flexibilität seitens der Lernenden hohe selbstregulatorische Fähigkeiten, um den Lernprozess selbstständig zu organisieren [5]. Diese selbstständige Organisation kann zu einem Überforderungserleben führen, welches sich in Frust und schlechten Lernergebnissen ausdrückt [5]. Um diesen Umstand zu begegnen, wird der Lernprozess in traditionellen Lernsettings von einer Lehrperson begleitet, welche direkt und unmittelbar in den Lernprozess eingreifen kann [6]. Insbesondere Feedback (FB) kann in diesem Zusammenhang zur Verbesserung des Lernerfolgs eingesetzt werden [7]. In digitalen Umgebungen fehlt dieses Angebot durch eine Lehrperson jedoch oft oder ist zu unspezifisch [6]. Deshalb muss der Einsatz

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

von Feedback in ML auf diese Umgebung angepasst werden. Aus diesem Grund schlagen Zichermann und Cunningham [8] den Einsatz von Gamification Elementen in Kombination mit FB vor. Dieses Gamified Feedback kann die den Lernerfolg von Lernenden verbessern [9]. Wir schlagen deshalb den Einsatz eines Avatares als Gamification Element als virtueller Lehrer vor, welcher die Lernenden gezielt unterstützt und ihren Lernprozess strukturiert [10].

Jedoch ist unklar, wie solche Gamified Feedback Elemente gestaltet werden müssen, um eine möglichst effiziente Interaktion zwischen Avatar und Lernenden zu ermöglichen und damit den Lernerfolg bestmöglich zu erhöhen. Zusätzlich ist unklar, wie diese Elemente im Rahmen von Mobile Learning eingesetzt werden müssen, da bspw. die geringe Displaygröße besondere Anforderung an die Gestaltung der Elemente setzt. Hierbei ist im speziellen die kognitive Last (Cognitive Load – CL) der Lernenden zu beachten [11]. Vor diesem Hintergrund beschäftigt sich diese Arbeit mit der folgenden übergeordneten Forschungsfrage (RQ):

RQ: *Wie muss Gamified Feedback durch Avatare im Mobile Learning gestaltet werden, damit der Lernerfolg von Lernenden gesteigert werden kann?*

Um diese Frage zu beantworten präsentieren wir in diesem Kurzbeitrag ein 2x2 Experiment, welches auf Grundlage einer ML Applikation (MLA) für die AuW den Effekt verschiedener Gamified Feedbacktypen untersucht. Dabei ist die Konzeption der MLA in ein größeres Design Science Research (DSR) Projekt [12] eingebettet.

2 Theoretischer Hintergrund

FB wird sowohl in der Offline als auch in der Online Welt zur Steigerung des Lernerfolgs eingesetzt [13], um u.a. die Verbesserung der selbstregulatorischen Fähigkeiten einer Person zu ermöglichen [14]. Dabei ist FB eine der wichtigsten Mittel zur Verbesserung von Motivation, Erfolg und Effizienz [14]. FB wird in formatives (FB während des Lernprozesses) und summatives (FB nach dem Lernprozess) FB unterteilt [7]. Das FB wird über eine Lehrperson an den Lernenden weitergegeben. Jedoch ist in vielen digitalen Lernplattformen ein unmittelbarer Zugang zu einer Lehrperson nicht verfügbar [15]. Durch die Zeit- und Ortsunabhängigkeit im ML [16] ist es besonders herausfordernd FB und Gamification Elemente so zu gestalten, dass sie gut vom Lernenden aufgenommen werden können und als nützlich angesehen werden. Durch die Übertragung von FB auf den Gamification Ansatz soll die Wirkung von FB verstärkt werden [17]. Dabei stellt Gamification einen Ansatz dar, welcher spieltypische Elemente in einem nicht Spielekontext einsetzt, um die Motivation und die Leistung von Nutzern zu steigern [18]. Gamification Elemente können in Spielmechaniken, -dynamiken und -motive eingeteilt werden [8, 19]. Vor diesem Hintergrund definieren wir Gamified Feedback als die Nutzung von spieltypischen Elementen zur Verstärkung der Wirkung von Feedback.

Die Cognitive Load Theory bietet in diesem Kontext ein Rahmenwerk, wie Instruktionsmaterialien gestaltet werden können [11], um die kognitiven Kapazitäten einer Person nicht zu überlasten. Durch die begrenzten Kapazitäten müssen die FB Materialien in der MLA so gestaltet werden, sodass diese bestmöglich vom kognitiven

System des Lernenden aufgenommen werden können. Deshalb müssen Elemente identifiziert werden, welche für Gamified formatives und summatives FB relevant sind, um eine effiziente Informationsweiterleitung zu ermöglichen.

3 Gestaltungsansatz für die Mobile Lernanwendung

Um die Wirkung von Gamified FB mittels Avatar in einer MLA zu evaluieren, wird im ersten Schritt ein Prototyp im Rahmen eines gestaltungsorientierten Projekts in der industriellen Fertigung entwickelt. In diesem Zuge soll die Wirkung von summativen und formativen Gamified FB auf den Lernenden bzgl. des Lernerfolgs und CL untersucht werden. Abbildung 1 zeigt die prototypische Implementierung der MLA.

Abbildung 1: Prototypische Implementierung der MLA

Der Avatar erscheint, sobald sich der Lernende die MLA betritt. Dieser begleitet ihn durch die Anwendung und gibt ihm nach seinem individuellen Fortschritt FB entweder während (formativ) oder nach dem Arbeitsprozess (summativ). Dabei bietet der Avatare u.a. kurze Lernvideos, Bilder oder text- und mediengestützte Quizelemente an. Zudem regt der Avatar die Probanden dazu an, sich selbstständig Lernziele zu setzen, indem er ihnen Nachfragen zu ihrem Lernprozess stellt. Gleichzeitig bietet der Avatar nur die Informationen an, welche für den Arbeitsprozess wichtig sind, um eine Überforderung der Lernenden zu vermeiden. Um dies zu ermöglichen und die MLA auf den neusten Stand bzgl. des Arbeitsprozesses zu halten, verbindet sich diese mittels einer NFC Schnittstelle mit der Maschine, an welcher die Person momentan arbeitet. Diese Schnittstelle ist die Grundlage für das aufgabenbezogene FB. Dadurch soll gewährleistet werden, dass der Lernende situationsbezogenes und relevantes FB für seinen Arbeitsprozess erhält.

4 Vorgehen und Ausblick

Zur Untersuchung von Gamified Feedback in einer MLA in der industriellen AuW wird ein 2x2 Pre-Post Experiment (summatives X formatives Feedback) mit einer Kontrollgruppe durchgeführt. Dabei wird das Feedback durch einen Avatar an die Lernenden vermittelt. Die Kontrollgruppe erhält kein Gamified Feedback vom Avatar. Dabei wird der Lernerfolg mittels des von Keller [20] entwickelten ARCS-Modells, sowie der CL mittels einer objektiven, indirekten Messmethode [21] untersucht.

Während des Experiments durchlaufen die Lernenden den gleichen Arbeits- und Lernprozess (vgl. Abbildung 2).

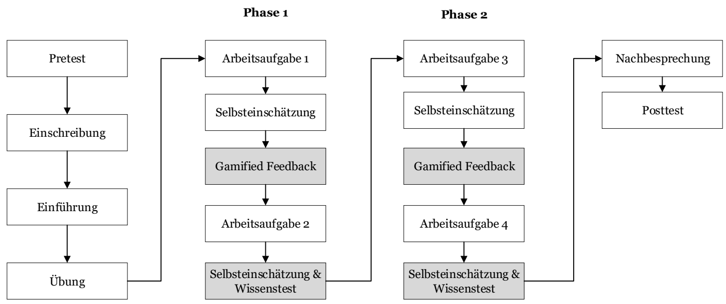

Abbildung 2: Ablauf des Experiments (basierend auf [22])

Die Evaluation wird in Berufsschulen mit industriellem Hintergrund mit Industriemechanikern durchgeführt. In einem Pre-Test werden die Demographika wie Geschlecht oder Vorwissen abgefragt [16]. Zusätzlich wird das Vorwissen bzgl. des Arbeitsprozesses und Erfahrungen bzgl. FB aufgenommen [23]. Darüber hinaus erfassen wir die Kontrollfähigkeit zum selbstorganisierten Lernen [24] .Der CL wird durch eine objektive, indirekte Methodik erfasst [21]. Danach werden die Teilnehmer randomisiert einen der vier Gruppen zugeteilt und müssen vordefinierte Aufgaben lösen. Dabei unterscheiden sich die Gruppen in der Art des Feedbacks. Die Kontrollgruppe erhält kein Gamified FB. Das Feedback wird entweder automatisch während, nach oder proaktiv auf Anforderung des Lernenden angeboten. Der Zeitpunkt der FB Bereitstellung wird hierbei durch die NFC Schnittstelle an die momentane Arbeitssituation angepasst. Dadurch soll sichergestellt werden, dass der Lernende arbeitsprozessbezogenes FB erhält. Für die weitere Vorgehensweise ist ein zweiphasiges Vorgehen geplant. Im ersten Schritt soll die hier vorgestellte experimentelle Analyse erste Aufschlüsse liefern, welche zur Umsetzung eines Feld Experiments in der zweiten Phase genutzt werden können. Durch dieses Vorgehen wollen wir zu Beginn kurzfristige und in der zweiten Phase auch langfristigere Auswirkungen des MLA auf den Lernenden untersuchen.

Basierend auf den von Seaborn und Fels [25] identifizierten Forschungslücken ist der theoretische Beitrag dieser Studie zweigeteilt. Zum einen möchten wir dazu beitragen, dass Verständnis von Gamified FB in ML und deren Auswirkungen auf Lernende besser zu verstehen. Zum anderen wollen wir im Rahmen des DSR Ansatzes präskriptives Wissen für die effektive Gestaltung von Gamified FB in ML gewinnen [26]. Der praktische Beitrag bezieht sich hierbei auf das Gestaltungswissen, welchen MLA Entwicklern helfen soll, wirkungsvolle Anwendungen für die AuW zu designen.

Abstract. In recent decades, the number of students per lecturer at universities has constantly risen. In these learning scenarios, individual lecturer support for helping students actively acquiring new knowledge is hardly possible. However, active student behavior is necessary for successful learning. Smart Personal Assistants such as Amazon's Alexa or Google's Home promise to fill this gap by being students' individual tutors. In order to understand what students expect from Smart Personal Assistants as tutors and how they interact with them, we will carry out an experiment. In this research in progress paper, we present our experiment design, where we observe the individual interaction between students and a Smart Personal Assistant tutor and between students and a human tutor applying the same methods in both cases. Drawing on the concepts of parasocial interaction and trust, we derive hypotheses, present the Smart Personal Assistant development and explain the experiment process in detail.

Keywords: computer tutor, Smart Personal Assistant, education, experimental design,

1 Introduction

In recent decades, the number of students per lecturer at universities has constantly risen [1, 2]. In these learning scenarios, lecturers are often forced to present their learning content to the students in a one-directional way with nearly no support for students before and after the lecture. However, the predominant constructivist learning theory states that learning only occurs when students actively acquire new knowledge [3]. This happens best in learning environments where lecturers individually scaffold students' understanding of new learning content [4]. This kind of support is hardly possible due to universities' financial and organizational restrictions. According to the

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

OECD, the number of students at universities rose from 2005 to 2014 by 15 percentage points in the US and 29 in Germany while public spending for education decreased in the same period by 7 percentage points in the US and 1 in Germany [5]. Smart Personal Assistants (SPA) such as Amazon's Alexa or Google's Assistant that are based on current technological developments in artificial intelligence and natural language processing have the potential to fill this gap. SPAs are software programs that communicate with an individual via natural language (voice and text) helping users to perform tasks [6]. Until now, there is no empirical evidence whether and under what conditions students accept SPAs as their personal tutors. Moreover, in past research, SPAs have been mostly used for rather simple and short tasks such as setting an alarm, restaurant reservations, etc. We therefore try to answer the following research questions:

RQ1: How do students accept Smart Personal Assistants as their tutors in complex problem task environments?

RQ2: How does interaction mode (voice vs. text) influence the acceptance of Smart Personal Assistants as tutors in complex problem task environments?

We employ a 2 x 2 (human vs. SPA and voice vs. text) between-subject experiment design with an actual SPA powered with current technology to address these research questions. By this means, our study contributes to literature in the following ways: (1) To the best of our knowledge, this study is amongst the first that empirically investigate the value of SPAs as personal tutors within complex problem task environments. (2) We extend past research of human and computer tutoring by directly comparing four types of tutoring (human text vs. human voice vs. computer text vs. computer voice).

2 Theoretical Background and Hypotheses

2.1 The ICAP-Framework in the Context of Tutoring

The ICAP-Framework is based on the constructivist learning theory. It helps classifying students' cognitive engagement behaviour during learning with four categories: *interactive, constructive, active, or passive* and predicts that they can be ordered by effectiveness *(better learning outcomes)* as **interactive > constructive > active > passive**. A *passive* student behaviour would be attending to the presented instructional information without additional physical activity (e.g. reading a text). An *active* student behaviour includes "doing something physically" (e.g. taking notes). A *constructive* student behaviour requires "producing outputs that contain ideas that go beyond the presented information" (e.g. self-explaining a text). An *interactive* behaviour requires "dialoguing extensively on the same topic, and not ignoring a partner's contribution [7]. One-on-one tutoring with human tutors mostly elicit interactive student behaviour including co-construction and other collaborative spoken activities leading to an increased understanding of learning content and an increased learning process satisfaction [8]. This way of interaction is currently beyond the state of the art in computer tutoring. Nevertheless, recent developments in artificial intelligence, natural language processing and machine learning let us believe that Smart Personal Assistants are able to replace human tutors to some extent. We therefore propose:

H1. There is no difference in acceptance levels between Smart Personal Assistants and human tutors.

2.2 Voice-based vs. Text-based Smart Personal Assistants

Voice-based discourse is the primary form of human-human communication, hence, computer interfaces that communicate via voice provide a more efficient, meaningful, and naturalistic interaction experience [9]. Within the context of tutoring, there are a lot of theoretical positions supporting that spoken interaction is important in tutorial dialogue, compared to communication through typing and printing [10, 11]. One reason for that might be that the gap between thought and speech is much less than the gap between thought and writing, because voice-based discourse is the language of the "mother tongue" [12]. However, studies also showed that people feel uncomfortable when talking with SPAs in public [13]. Nevertheless, voice-based interactions have the potential to foster relationship building between students and tutors [14]. We therefore propose:

H2. Voice-based Smart Personal Assistants show increased acceptance levels compared to text-based Smart Personal Assistants.

2.3 The mediated role of Parasocial Interaction and Trust

The concept of parasocial interaction was first introduced by Horton and Wohl [15], ahead of ubiquitous interactive computer technology. When computers such as robots or AI came to have human-like interfaces, researchers have started to use this concept to investigate the existence of emotional relationship (e.g. feelings of friendship) between people and computers [16]. Furthermore, Trust is vital in one's acceptance of technology [17]. Many studies found out that users must have trust in a technology before they show willingness to adopt it [17, 18]. Especially the affective dimension of trust may be very important for tutors' acceptance. It explains the confidence one places in a partner on the basis of feelings generated by the level of care and concern the partner demonstrates [19]. We therefore hypothesize that type of tutor as well as interaction mode can be mediated by these constructs.

H3a. The effect of type of tutor on tutor's acceptance is mediated by parasocial interaction.

H3b. The effect of type of tutor on tutor's acceptance is mediated by trust.

H3c. The effect of interaction mode on tutor's acceptance is mediated by parasocial interaction.

H3d. The effect of interaction mode on tutor's acceptance is mediated by trust.

3 Overall Experiment Procedure and Treatment Design

To test our hypotheses, we run a laboratory experiment where participants have to individually conduct a 30-minute complex problem task with the help of a SPA or a human tutor. Table 1 shows our treatment design. The human tutor can be perceived as an expert in tutoring (gold-standard). We include a control group that has no tutor. The sample consists of graduate and undergraduate students attending a Swiss business school.

Table 1. Treatment Design (randomly assigned groups)

		Type of tutor		
		No tutor (control)	**SPA tutor**	**Human tutor**
Interaction mode	**Voice-based**	T0 (N=35)	T1 (N=35)	T2 (N=35)
	Text-based		T3 (N=35)	T4 (N=35)

4 Task Design and SPA Development

We decided to choose a complex problem task comparable to the types of problems people face every day. We therefore first derived task requirements from complexity theory and problem-based learning theory [20, 21]. By this means, we chose a task that was already tested in a study on the effectiveness of problem-based learning [22]:

Increasing traffic flow has led to a significant increase in the number of accidents at a major intersection in your city. Several deaths have occurred in recent years. What should the city do about it?

We used Amazon's Alexa and its Skill Development Kit 2.0 with nodeJS to develop our voice-based and text-based SPA. The interaction model and the corresponding instructions of Alexa is based on the problem-solving steps of Kim and Hannafin [23]: *(a) problem identification, (b) problem exploration, (c) problem reconstruction, (d) presentation and communication, (e) reflection and negotiation*. We conducted a pretest with twenty students in order to test the functionality of our programmed SPAs and noted their change requests.

5 Measurement, Analysis and Conclusion

This experiment will be measured with the help of a posttest-questionnaire. *Tutors' acceptance* will be measured with the help of the technology acceptance model proposed by Davis et al. [24]. In specific, we will adapt items from perceived usefulness and perceived ease of use. Furthermore, we will measure the construct *parasocial interaction* with Rubin et al.'s [25] PSI (Parasocial Interaction) Scale. The construct *trust* will be measured with items proposed by Lee and Choi [26]. For analysis, we will use traditional t-tests to show mean differences between the treatment groups.

We are currently analyzing the data of the experiment. First results show that audio-based SPAs are significantly better than text-based SPAs in terms of acceptance. Our expected results from the experiment have a twofold contribution. To the best of our knowledge, this study is amongst the first that empirically investigate the value of SPAs as tutors for complex problem tasks. As this kind of task support has the potential to increasingly enter education in future, it is important to understand how students accept SPAs as their tutors. Moreover, we extend past research on human and computer tutoring that mainly focused on one type of tutoring.

Abstract. Course assignment is a widespread problem in education. Often students have preferences for course schedules over the week. First-Come First-Served (FCFS) is the most widely used rule to assign students to courses in practice, but recent research led to alternatives with attractive properties. Bundled Probabilistic Serial (BPS) is a randomized mechanism satisfying ordinal efficiency, envy-freeness, weak strategy-proofness, and polynomial runtime. We report a first application of BPS in a large-scale course assignment application and discuss advantages over FCFS comparing a number of metrics such as the size, the average rank, the profile, and the popularity of the assignments. The exponential number of possible course schedules is a central problem in the implementation of combinatorial assignment mechanisms. We propose a new way to elicit preferences, which limits the number of parameters a student needs to provide. This yields a computationally very effective tool to solve course assignment problems with thousands of students in practice.

Keywords: Course Allocation, Combinatorial Assignment Problem, Randomization, Field Study

1 Introduction

Course assignment is arguably one of the most widespread assignment problems where money cannot be used to allocate scarce resources. Those problems of assigning students to different courses or whole schedules of courses appear at most educational institutions. Matching with preferences has received significant attention in the recent years. While simple first-come first-served (FCFS) rules are still wide-spread, many organizations adopted matching mechanisms such as the deferred acceptance algorithm [1, 2] or course bidding [3, 4] to allocate scarce course seats. Although many course assignment problems are similar to the widely studied school choice problems with students private preferences for one out of many courses, other applications differ significantly. In particular, students are often interested in schedules of courses across the week. Assigning schedules of courses has been referred to as the combinatorial assignment problem (CAP) [5]. Similar problems arise when siblings should be

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

assigned to the same schools in school choice [6], or couples in the context of the hospital residency matching [7]. Overall, the CAP can be seen as a general form of a distributed scheduling problem.

Although there is a huge body of literature on scheduling, the CAP is specific in a number of ways. First, we can only elicit ordinal preferences and no money must exchange hands. Second, students have private preferences over course schedules and we want to have mechanisms that incentivize students to reveal these preferences truthfully. Third, apart from efficiency, fairness of the allocation is an important concern in matching with preferences [8]. Fourth, the allocation of course schedules is a computationally hard (NP-hard) problem and for the problem sizes with hundreds of students, an exact solution might not be tractable.

The need to assign course schedules rather than courses individually became apparent in an application of matching with preferences at the Technical University of Munich (TUM) that we will discuss. In the initial three semesters, there are large courses with hundreds of students (e.g. on linear algebra or algorithms). These courses include a lecture and small tutor groups. Students need to attend one tutor group for three to four courses in each semester and they have timely preferences over course schedules that need to be considered, which makes it a combinatorial assignment problem. These problems are widespread in academia.

A first and seminal approach to address this challenging problem, the *approximate competitive equilibrium from equal incomes mechanism* (A-CEEI), was published by Budish [5]. In A-CEEI students report their complete preferences over schedules of courses, the mechanism assigns a budget of fake money to each student that she can use to purchase packages (or schedules) of courses. Then an optimization-based mechanism computes approximate competitive equilibrium prices, and the student is allocated her most preferred bundle given the preferences, budgets, and prices. A-CEEI is relaxing design goals such as strategy-proofness and envy-freeness to approximate notions, which makes it a remarkable and practical contribution to a fundamentally hard problem. The mechanism has been shown to be approximately strategy-proof, approximately envy-free, and Pareto efficient. Budish, Cachon, Kessler and Othman [9] reports the empirical results at the Wharton School of Business. In addition, Budish and Kessler [10] summarize the results of lab experiments.

The work was breaking new ground, but the A-CEEI mechanism is also challenging. First, it is not guaranteed that a price vector and course allocation exists that satisfies all capacity constraints. This is not surprising given that prices are linear and anonymous. Second, the problem of computing the allocation problem in A-CEEI is PPAD-complete and the algorithms proposed might not scale to larger problem sizes required in the field [11]. Third, students might not be able to rank-order an exponential set of bundles, which is a well-known problem (aka. missing bids problem) in the literature on combinatorial auctions (with money) [12-14]. The latter is a general problem in CAP not restricted to A-CEEI, which we will discuss in much more detail below.

Randomization can be a powerful tool in the design of algorithms, but also in the design of economic mechanisms. Nguyen, Peivandi and Vohra [15] recently provided two randomized mechanisms for one-sided matching problems, one with cardinal and one with ordinal preferences for bundles of objects. The mechanism for ordinal preferences is a generalization of probabilistic serial [16] called Bundled Probabilistic Serial (BPS). Nguyen, Peivandi and Vohra [15] show that this randomized mechanism is ordinally efficient, envy-free, and weakly strategy-proof. These appealing properties come at the expense of feasibility, but the constraint violations are limited by the size of the packages. In course assignment problems the size of the packages is typically small (e.g., packages with three to four tutor groups) compared to the capacity of the courses or tutor groups (around 30 seats or more). There is no need for prices or budgets, and computationally the mechanism runs in polynomial time, which is important for large instances of the course allocation problem that can frequently be found. This makes BPS a practical approach to many problems that appear in practice.

1.1 Contribution

We report on a field study and address issues in the implementation of mechanisms for the combinatorial assignment problem that are beyond a purely theoretical treatment. In particular, preference elicitation is a central concern in combinatorial mechanisms with a fully expressive bid language. Theoretical contributions of assignment mechanisms largely focus on envy-freeness and efficiency as primary design desiderata. We also report on properties such as their size, their average rank, the probability of matching, the profile, and the popularity. These properties often matter in the choice of mechanisms beyond traditional ways to measure fairness and efficiency. For market designers it is important to understand the trade-offs.

Overall, we report on the assignment of 1415 students in the summer term 2017 to 67 tutor groups for four classes and the assignment of 1736 students in the winter term 2017/2018 to 66 tutor groups for four classes at the TUM using BPS.[1] For such a large application, we could not elicit preferences of students for BPS and let them participate in FCFS simultaneously. Instead, we simulated FCFS via a version of Random Serial Dictatorship that allows for bundles (BRSD), which is of independent interest as an assignment mechanism.

Finally, we contribute an approach that is applicable in a wide array of CAP applications where timely preferences matter. We elicit a small number of parameters about breaks and preferred times and days of the week. Together with some prior knowledge about student preferences, this allows us to score and rank-order all possible packages

2 The Combinatorial Assignment Problem

Let us now define the combinatorial assignment problem (CAP) in the context of course assignment applications, desirable properties, and randomized mechanisms.

---

[1] Not all students submitted a non-empty preference list. Therefore, we consider in our evaluation not all of the participating students (1439 in summer term, 1778 in winter term).

2.1 The Problem

Assigning objects to agents with preferences but without money is a fundamental problem referred to as *assignment problem* or *one-sided matching with preferences*. We will use the term assignment or matching interchangeably. In course assignment, students express ordinal preferences, which need to be considered in the assignment. A *one-sided one-to-many course assignment problem* consists of a finite set of n students (or agents) S and a finite set of m courses (or objects) C with the *maximum capacities* $q = (q_1, q_2, \ldots, q_m)$.

In the *combinatorial assignment problem* in the context of course allocation, every student $i \in S$ has a complete and transitive preference relation over subsets (or bundles) of elements of C. A preference profile $\succcurlyeq \in \wp^{|S|}$ is an n-tuple of preference relations.

We can model the demand of the students with binary vectors $b \in \{0,1\}^m$, where $b_j = 1$ if course j is included in b. We define the size of a bundle b with $size(b) = \sum_{j=1}^{m} b_j$, the number of different courses included in the bundle. Let B be the set of all feasible bundles b. Let $x_{ib} \in \{0,1\}$ be a binary variable describing if bundle b is assigned to student i. Then we can model the demand and supply as linear constraints. The supply constraints make sure that the capacity of the courses are not exceeded, and the demand constraints determine that each student can win at most one bundle.

$$\sum_{i \in I, b \in B} x_{ib} b_j \leq q_j, \qquad \forall \text{ j} \in \text{C}, \qquad (Supply)$$

$$\sum_{b \in B} x_{ib} \leq 1, \qquad \forall\, i \in S, \qquad (Demand)$$

Courses in our application are actually tutor groups and each tutor group belongs to one of ℓ classes. Students in our application can only select bundles with at most one tutor group in each of these classes. As a result, the possible size of a bundle b is $size(b) \leq \ell \ll m$.

A *deterministic combinatorial assignment* (deterministic matching) is a mapping $M \subset S \times B$ of students S and bundles B of courses C. $\mathcal{M}$ describes the set of all deterministic matchings. A matching is *feasible* if it is a feasible integer solution to the constraints (Demand) and (Supply).

Random combinatorial assignments (random matchings) are related to fractional assignments with $0 \leq x_{ib} \leq 1$ and random assignment mechanisms can be used to fractionally allocate bundles of course seats to students.

For (non-combinatorial) assignment problems with single-unit demands the Birkhoff-von-Neumann theorem [17, 18] says that any random assignment can be implemented as a lottery over feasible deterministic assignments, such that the expected outcome of this lottery equals the random assignment. However, the Birkhoff-von-Neumann theorem fails when students submit preferences for bundles of course seats. Nguyen, Peivandi and Vohra [15] generalize this result and show that any fractional solution respecting the (Demand) and (Supply) constraints can be implemented as a lottery over integral allocations that violate the (Supply) constraints only by at most $\ell - 1$ course seats.

2.2 First-Order Design Desiderata

Efficiency, envy-freeness, and strategy-proofness are design desiderata of first-order importance typically considered in the theoretical literature on deterministic assignment problems. For randomized mechanisms one has to reconsider these design desiderata and we will briefly introduce relevant definitions in this section. Stochastic dominance (SD) is the key concept among all of these definitions as it provides a natural way to compare random assignments. Let Δ describe the set of all possible random matchings. With p_i we refer to the assignment of student i in the random matching p, and denote with p_{ib} the probability that student i gets allocated bundle b. We will omit the subscript i when it is clear which student is meant. Given two random assignments $p, q \in \Delta$, student i SD-prefers p to q if, for every bundle b, the probability that p yields a bundle at least as good as b is at least as large as the probability that q yields a bundle at least as good as b. More formally, a student $i \in S$ SD-prefers an assignment $p \in \Delta$ over $q \in \Delta$, $p \succcurlyeq_i^{SD} q$, if $\sum_{b' \succcurlyeq_i b} p_{ib'} \geq \sum_{b' \succcurlyeq_i b} q_{ib'}, \forall b \in B$. In other words, a student i prefers the random assignment p to the random assignment q if p_i stochastically dominates q_i. Note, that $\succcurlyeq^{SD}$ is not a complete relation. That is there might be assignments p and q, which are not comparable with this relation.

One desirable property of matchings is *(Pareto) efficiency* such that no student can be made better off without making any other student worse off. That is, a random assignment $p \in \Delta$ is *ex post efficient*, if p can be implemented into a lottery over Pareto efficient deterministic assignments. A random assignment $p \in \Delta$ is *ordinally efficient*, if there exists no random assignment q such that q stochastically dominates p, i.e. $\nexists q \in \Delta: \forall i \in S: q \succcurlyeq_i^{SD} p$ and $\exists i \in S: q \succ_i^{SD} p$. Ordinal efficiency comes from the Pareto ordering induced by the stochastic dominance relations of individual students. It can be shown that ordinal efficiency implies ex post efficiency [16].

Fairness is another important design goal. A basic notion of fairness for randomized assignments is the *equal treatment of equals*, i.e. students with identical preferences receive identical (symmetric) random allocations. Envy-freeness is stronger. A random assignment $p \in \Delta$ is *(strongly) SD-envy-free*, if $\forall i, j \in S: p_i \succcurlyeq_i^{SD} p_j$. We call p *weakly SD-envy-free*, if $\nexists i, j \in S: p_j \succ_i^{SD} p_i$. SD-envy-freeness means that student i weakly SD-prefers the random matching she is faced with to the random assignment offered to any other student, i.e., a student's allocation stochastically dominates the outcome of every other student. For weak SD-envy freeness it is only demanded that no student's allocation is stochastically dominated by the allocation of another student. SD-envy-freeness implies equal treatment of equals.

A *randomized assignment mechanism* is a function $\psi: \mathcal{P}^{|S|} \rightarrow \Delta$ that returns a random matching $p \in \Delta$. The mechanism $\psi(\succcurlyeq) = p$ is *ordinally efficient* if it produces ordinally efficient allocations. In terms of fairness, one could aim for a matching where equals are treated equally. We call a randomized matching mechanism *ψ symmetric*, if for every pair of students i and j with $\succcurlyeq_i = \succcurlyeq_j$ also $p_i = p_j$. This means that students who have the same preference profile also have the same outcome in expectation. A randomized mechanism is *envy-free* if it always selects an envy-free matching.

An important property of a mechanism is *strategy-proofness*. This means, that there is no incentive for any student not to submit his truthful preferences, no matter which preferences the other students report. A random assignment mechanism is (strongly) SD-strategy-proof if for every preference profile $\succcurlyeq$, and for all $i \in S$ and $\succcurlyeq_i'$ we have $\psi(\succcurlyeq_i, \succcurlyeq_{-i}) \succcurlyeq_i^{SD} \psi(\succcurlyeq_i', \succcurlyeq_{-i})$.

A random assignment rule ψ is *weakly* SD-strategy-proof if for every preference profile $\succcurlyeq$, there exists no $\succcurlyeq'$ *for some* student $i \in S$ such that $\psi(\succcurlyeq_i', \succcurlyeq_{-i}) \succcurlyeq_i^{SD} \psi(\succcurlyeq_i, \succcurlyeq_{-i})$. We will omit the prefix SD for brevity in the following. It has been shown that participants in strategy-proof mechanisms such as the Vickrey auction do not necessarily bid truthfully in practice. Therefore, there was a recent discussion about obvious strategy-proofness of extensive form games [19].

Definition 1: OSP [19]. A strategy σ is obviously dominant if, for all other strategies σ', at any earliest information set where σ and σ' diverge, the best possible outcome from σ' is no better than the worst possible outcome from σ. A mechanism is obviously strategy-proof (OSP) if it has an equilibrium in obviously dominant strategies.

In section 4.1 we introduce a number of additional design goals that often matter in the practice and that we analyze empirically.

2.3 Mechanisms

A lot is known about assignment problems with single-unit demand. Random Serial Dictatorship (RSD) selects a permutation of the agents uniformly at random and then sequentially allows agents to pick their favorite course among the remaining ones. Gibbard [20] showed that random dictatorship is the only anonymous and symmetric, strongly SD-strategy-proof, and ex post efficient assignment rule when preferences are strict. Pycia and Troyan [21] prove that RSD is a unique mechanism that is obviously strategy-proof, efficient, and symmetric in mechanisms without transfers. However, RSD is not always ordinally efficient, only ex post efficient [16]. Zhou [22] actually showed that no random mechanism for assigning objects to agents could satisfy strong notions of strategy-proofness, ordinal efficiency, and symmetry simultaneously with more than three objects and agents. So, we also cannot hope for these properties in combinatorial assignment problems. RSD can also be applied to the combinatorial assignment problem. The Bundled Random Serial Dictatorship (BRSD) orders the students randomly and assigns the most preferred bundle, which is still available to each student in this order. Although the package preferences take some toll on the runtime, it is still very fast.

First-come first-served (FCFS) can be seen as a serial dictatorship. Students login at a certain registration and then reserve the most preferred bundle of courses that is still available. Although the arrival process is not uniform at random, students have little control over who arrives first. While there is a certain time when the registration starts, hundreds of students log in simultaneously to get course seats and it is almost random who arrives first. We will simulate FCFS via BRSD and run the algorithm repeatedly to get estimates for performance metrics of FCFS.

Probabilistic Serial (PS) [16] produces an envy-free assignment with respect to the reported unit-demand preferences, and it is ordinally efficient, but it is only weakly SD-strategy-proof. Bundled Probabilistic Serial (BPS) by Nguyen, Peivandi and Vohra [15] is a generalization of PS to the combinatorial assignment problem and computes a fractional solution to (Demand) and (Supply). The BPS mechanism is also ordinally efficient, envy-free, and weakly strategy-proof if preferences are strict.

Informally, in BPS all agents *eat* their most preferred bundle in the time interval $[0,1]$ simultaneously with the same speed as long as all included objects are available. As soon as one object is exhausted, every bundle containing this object is deleted and the agents continue eating the next available bundle in their preference list. The duration with which every bundle was eaten by an agent specifies the probability for assigning this bundle to this agent. After a fractional solution x^* was found via BPS, it is implemented as a lottery over integral matchings satisfying the (Demand) and the relaxed (Supply) constraints, as described in [15].

3 Preference Elicitation

The Department of Informatics has been using stable matching mechanisms for the assignment of students to courses since 2014 [2]. The system provides a web-based user interface and every semester almost 1500 students are being matched to lab courses or seminars via the deferred acceptance algorithm for two-sided matching or random serial dictatorship for one-sided matching problems.

In the context of the study reported in this paper, the web-based software was extended with BPS, the lottery mechanism for decomposing fractional solutions, and BRSD. During the winter term 2017/2018, 1778 computer science and information systems students in their third semester participated in the matching and could choose bundles of tutor groups out of four classes. A computer science student could have more than 700,000 different bundles.[2]

A naive approach would be to let the students rank bundles on their own by choosing the time slots they want to have in their preference list. This would take a lot of time and lead to a substantial missing bids problem.

Budish, Cachon, Kessler and Othman [9] describe the preference elicitation used at the Wharton School of Business. Students could report cardinal item values on a scale of 1 to 100 for any course they were interested in taking. In addition, they could report adjustments for pairs of courses, which assigned an additional value to schedules that had both course sections together. Afterwards courses were scored and transformed into an ordinal ranking over feasible schedules. The authors argue that they felt that “adding more ways to express non-additive preferences would make the language too complicated”. Wharton also provided a decision support tool listing the 10 most-preferred bundles, which allowed students to inspect top-ranked schedules and modify the cardinal values.

[2] The computer science students need tutorials from all four classes ($< 22 \cdot 25 \cdot 26 \cdot 52$).

However, our course allocation problem has a more special structure such that we can allow preferences that are more complex without asking for different weights for the courses. We developed an algorithm that allows to rank-order all possible packages based on a few parameters that students need to specify. For this, we can leverage prior knowledge about timely preferences of students for schedules of tutorials and lectures.

Students' preferences mainly concern their commute and the possibility to free large contiguous blocks of time (e.g., a day or a half-day) that they can plan for other activities (e.g., a part-time job). In larger cities such as Munich, the time that students spend for commuting is significant. Also long waiting times between courses are perceived as a waste of time as it is often hard for them to work productively in several one- or two-hour breaks without appropriate office facilities available. For example, if a student had a tutorial on linear algebra in the morning, a lunch break, and then the tutorials for algorithms and software engineering in the afternoon of the same day with the minimal time for breaks specified, this would be considered ideal. The desired length for breaks between tutorials and for the lunch break are considered parameters with default values in the preference elicitation.

First, students choose the lectures and tutorials they are interested in. The selected lectures will be considered in the bundle generation as constraints, i.e. if a time slot of a tutorial overlaps with the time of a selected lecture, then it will no longer be considered in order to allow students to participate in the lecture. In a second step, the student marks available time ranges in a *weekly schedule*. The day is partitioned into weekdays and time blocks of 30 minutes from 8:00 AM to 8:30 PM. If a tutorial is selected, all time slots of this tutorial will be highlighted with a specific color. Thus, students learn when the tutorials and lectures of interest take place.

A student can set a minimal amount of time for a lunch break and a minimal amount of time in-between two events (default value is 15 minutes). We also allow students to provide weights $\{1, \ldots, 5\}$ for the different days. That is, the students can express preferences over the days. The main web page and the main steps a student had to take are summarized in Figure 1.

The preferences elicited on this screen are input for an algorithm that uses prior knowledge about student preferences to rank-order all possible packages. The algorithm first generates bundles that satisfy all constraints and then ranks them. Finding the bundles that do not violate constraints (e.g., lectures to be attended) of the students can be cast as a *constraint satisfaction problem*. After the feasible bundles are generated, we rank these bundles. For this, we assign a score to each bundle that considers how many days a student needs to come to the university per week in total, the preference ordering over the days, the total time a student has to stay at the university each day, and the length of the lunch breaks between courses.

On the ranking page, we display the 30 top rated pre-ranked bundles and the students can adapt this ranking manually, go back to the previous screen and adapt the input parameters, or just accept the ranking with a single click (see Figure 2).

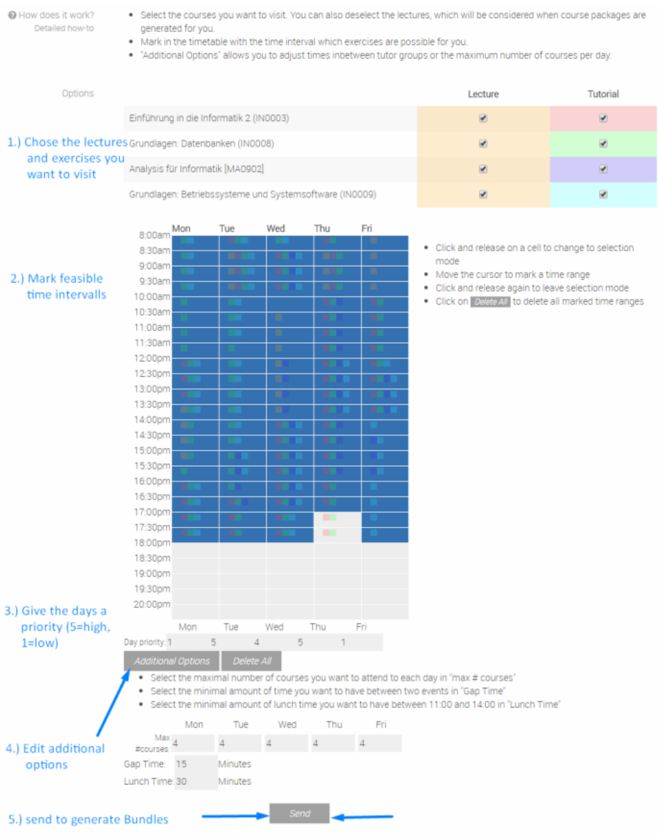

Figure 1. Process to rank-order packages

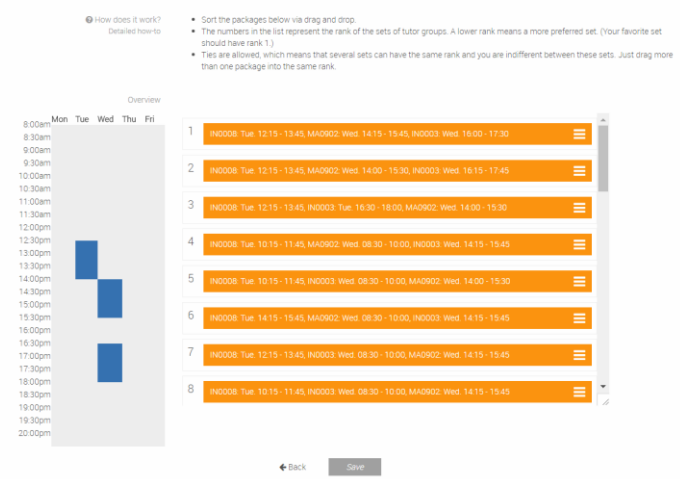

Figure 2. Page with top-ranked packages

Note that $\approx 90\%$ of the students received one of their top ten ranked packages and only a few students received a package with a rank less than 30. So, if a student inspects and confirms the ranking of the first 10-30 packages, this covers the most important quantile of the overall ranking list. We generated a ranking over 200 bundles for each student in advance based on the pre-specified parameters and further preferences only if necessary[3].

4 Results

In Section 2.2 we have summarized first-order design goals for assignment problems: strategy-proofness, fairness, and efficiency. Now we introduce second-order design goals and respective metrics allowing us to compare the assignments of BPS and FCFS empirically and provide numeric results of our two matching instances.

4.1 Metrics

Apart from efficiency, fairness, and strategy-proofness, *popularity* was raised as a design goal. An assignment is called popular if there is no other assignment that is preferred by a majority of the agents. Popular deterministic assignments might not always exist, but popular random assignments exist and can be computed in polynomial time [23]. However, Brandt, Hofbauer and Suderland [24] prove that popularity is incompatible with very weak notions of strategy-proofness and envy-freeness, but it is interesting to understand the popularity of BPS vs. BRSD. In our empirical evaluation, we analyze whether BPS or FCFS are more popular. To measure popularity we first define the function $\phi_i(b,b'): B \times B \to \{\pm 1, 0\}$ associated with the preference relations, where $\phi_i(b,b') = 1$ if $b \succ_i b'$, -1 if $b' \succ_i b$ and 0 in any other case.

Definition 2: Popularity. A random assignment $p \in \Delta$ is *more popular* than an assignment q, denoted $p \rhd q$, if $pop(p,q) > 0$ with $pop(p,q) = \sum_{i \in S} \sum_{b,b' \in B} p_{ib} \cdot q_{ib'} \cdot \phi_i(b,b')$. A random assignment p is *popular*, if $\nexists q \in \Delta: q \rhd p$.

Apart from popularity, the size and the average or median rank are of interest. The *size* of a matching simply describes the number of matched agents. The *average rank* is only meaningful in combination with the size of the matching, because a smaller matching could easily have a smaller average rank. We report the average rank, because it has been used as a metric to gauge the difference in welfare of matching algorithms in [9] and [25], two of the few experimental papers on matching mechanisms.

The *profile* contains more information as it compares how many students were (fractionally) assigned to their first choice, how many to their second choice, and so on.

[3] So far, we described the user interface for the winter term 2017/18. The user interface in the summer term 2017 required students to explicitly drag and drop the pre-ranked packages on a screen. This was considered tedious such that in the winter term the generated ranking was suggested to students right away without any drag-and-drop activities required and could be confirmed without much effort.

The profile of two matchings is not straightforward to compare. We want to compare multiple profiles based on a single metric, and decided to use a metric similar to the *Area under the Curve of a Receiver Operating Characteristic* in signal processing [26], which was already used by [27]. With R denoting the number of possible ranks and $b \in B$, the *Area Under the Profile Curve Ratio (AUPCR)* for matching M can be defined as:

$$AUPCR(M) = \frac{1}{R}\sum_{r=1}^{R} \frac{|\{(i,b) \in M \mid rank(i,b) \leq r\}|}{|S|}$$

4.2 Empirical Results

Due to space constraints, we only analyze the results for the matching in winter term 2017/2018. This application comprised 1736 students and 66 courses (see Table 1). Overall, we had a list of 20,845 different bundles. We simulated FCFS via BRSD on the preferences collected for the BPS. BPS is weakly strategy-proof and in such a large application, it is fair to assume that students do not have sufficient information about the preferences of others, which would be necessary to strategically misreport their preferences. To compare the result of BPS and BRSD we actually would have to run the BRSD for all permutations of the students. Note that computing probabilities of alternatives in RSD explicitly is **#P**-complete [28]. We ran BRSD 1000 to 1,000,000 times with the same preferences but random permutations of the order of students and derived estimates for the different metrics. These estimates are close (see Table 1).

For our data, BPS is more popular than BRSD(1000000). 754 students prefer BPS to FCFS, while 120 students prefer FCFS to BPS (see Table 2). A positive popularity score as described in Definition 2 means, that BPS is more popular than the BRSD outcome and the score for BPS is 3.41 (compared to BRSD(1000000)).

Table 1. Summary statistics for the winter term 2017/2018.

Metric	*BPS*	*BRSD(1000)*	*BRSD(1000000)*
exp rank	1.97372	1.9784	1.97873
exp size	1603.01	1601.03	1600.84
prob match (top 100)	0.923394	0.922253	0.922142
AUPCR	0.889512	0.888184	0.888058
weak envy	0	427	451
strong envy	0	1050	1202

Table 2. Popularity and stochastic dominance of BPS vs. BRSD. The syntax for the SD-preference is the number of students preferring (BPS | BRSD(x)).

Metric	*BRSD(1000)*	*BRSD(1000000)*
popularity winter	1.93061	3.41499
SD-prefer winter	(690|299)	(754|120)

Table 1 reports that for all metrics BPS achieves better results. In the BPS outcome 89.047% of the students receive an assignment ranked in their top ten while in BRSD 88.891% receive such an outcome (see Table 3 for BPS and 4 for BRSD with 1 mio. permultations of the students). The computation times were negligible for BRSD (0.013 seconds per run). BPS required 0.382 seconds, but the lottery algorithm around 30 minutes due to the high number of bundles generated in the winter term.

Table 3. Rank profiles for BPS in winter term 2017/2018.

Rank	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*
Prob match (%)	73.596	7.083	3.392	1.660	1.041	0.698	0.465	0.447	0.366	0.299
AUPC in (%)	73.596	80.678	84.070	85.730	86.772	87.470	87.935	88.381	88.747	89.047

Table 4. Rank profiles for BRSD(1000000)in winter term 2017/2018.

Rank	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*
Prob match (%)	73.452	7.046	3.382	1.673	1.040	0.704	0.486	0.443	0.358	0.307
AUPC in (%)	73.452	80.497	83.879	85.553	86.593	87.297	87.783	88.226	88.584	88.891

Our experiments confirm the theoretical result that BPS is (strongly) envy-free. BRSD is neither weakly nor strongly envy-free. In the winter term 1202 students do not SD-prefer their outcome over the outcomes of every other student, and 451 of those students even prefer an outcome of another student (see BRSD(1000000) in Table 1).

4.3 Discussion of Differences

The results from our field experiments and the survey reveal a number of interesting insights. Overall, BPS dominates BRSD on all metrics from our empirical evaluation in both field studies. It has a better average rank, a higher average size and a higher probability of matching, and it does not exhibit envy. However, the differences in average rank, average size, and the profile curve (AUPCR) are small, which is interesting given the fact that only a small number of preferences per student are considered via FCFS.

There are a number of reasons that help to explain the close performance of BPS and FCFS in these metrics. First, Che and Kojima [29] find that random serial dictatorship and probabilistic serial become equivalent when the market becomes large, i.e. the random assignments in these mechanisms converge to each other as the number of copies of each object type grows, and the inefficiency of RSD becomes small. Our empirical results suggest that differences might also be small in large combinatorial assignment markets with limited complementarities.

Second, ordinal preferences do not allow expressing the intensity of preferences. Suppose there are two students who both prefer course c_1 to c_2, each having one course seat only. No matter who gets course c_1, the average rank and size of the matching as well as the profile will be the same even though one student might desperately want to attend c_1, while the second student only has a mild preference for c_1. Without cardinal information about the intensity of a preference, the differences in aggregate metrics can be small.

5 Conclusions

We report two large field studies and show that BPS performs well on a number of additional criteria including average rank, average size, probability of a matching among the first 100 ranks, and the overall profile of ranks (in terms of AUPC of a specific rank) assuming a complete, truthful, and strict ranking of all packages. The matching based on BPS is also more popular than BRSD based on the preferences submitted for BPS. The level of envy in FCFS is significant, even though the size of the packages that can be submitted is limited to the number of classes (three to four groups per package).

The assignment of tutor groups is specific as preferences are mainly about times of the week. The preferred time slots in a week are different from student to student. However, the way how tutor groups should be ordered within these time slots (e.g., time for breaks) can be described with a few parameters such that it was possible to generate packages according to a score.

The paper highlights basic trade-offs in market design without money: FCFS can be seen as a version of serial dictatorship, which is ex post efficient, and obviously strategy-proof and treats students equally. It is also transparent and simple to implement and to understand for students. BPS is a new randomized mechanism that is only weakly strategy-proof, but envy-free, and ordinally efficient. Note that these properties hinge on the availability of strict preferences over all, exponentially many, bundles.

Even if the missing bids problem can be addressed, two important problems remain: First, in contrast to FCFS the BPS mechanism is not obviously strategy-proof[4]. Second, the assumption of strict preferences is strong in the presence of exponentially many bundles. Unfortunately, extending PS or BPS to preferences with ties is not without loss. On the one hand, Katta and Sethuraman [30] extended PS to preferences with indifferences and showed that it is not possible for any mechanism to find an envy-free, ordinally efficient assignment that satisfies even weak strategy-proofness as in the strict preference domain. On the other hand, with indifferences and random tie breaking efficiency cannot be guaranteed. Our preference elicitation technique generates a strict and complete ranking of course bundles based on a few input parameters and is one way to address these issues.

The key difference between BPS and FCFS is the absence of envy. The level of envy in FCFS is significant. Note, that it might be even more pronounced if students were allowed to pick larger packages. If envy-freeness matters, the elegant BPS mechanism has a number of attractive properties and is computationally much less expensive compared to A-CEEI.

[4] Remember that our empirical comparisons are based on the preferences reported in BPS. A part of these preferences might not have reflected the true preferences of participants, and the comparison might be biased towards BPS.

Abstract. In recent years, novel deep learning techniques, greater data availability, and a significant growth in computing powers have enabled AI researchers to tackle problems that had remained unassailable for many years. Furthermore, the advent of comprehensive AI frameworks offers the unique opportunity for adopting these new tools in applied fields. Information systems research can play a vital role in bridging the gap to practice. To this end, we conceptualize guidelines for applied image recognition spanning task definition, neural net configuration and training procedures. We showcase our guidelines by means of a biomedical research project for image recognition.

Keywords: Deep learning, Image Recognition, Object Detection, Instance Segmentation, Artificial Intelligence.

1 Introduction

In recent years, novel deep learning techniques, greater data availability, and a significant growth in computing powers have enabled AI researchers to tackle problems that had remained unassailable for many years. This holds especially true for voice or image recognition tasks where deep learning has demonstrated its remarkable capability of revealing structures in unstructured high-dimensional data. Given the wide availability of such data, deep learning applications can be used in many areas of science, business and administration [1]. At this point, a *McKinsey* study estimates the potential of AI applications to create between $3.5 trillion and $5.8 trillion in value annually across nine business functions in 19 industries [2].

A case in point for image recognition applications is the health care sector where deep learning in conjunction may offer a critical complement to the gold standard of randomized controlled trials by supporting massive observational studies that were not feasible before [3]. While there are already many successful biomedical applications enabled by deep learning applications, there is still a great need for innovative solutions. *Grand Challenge* [4] lists 167 data science competitions for biomedical image analysis over the last decade. These challenges comprise a wide range of applications, from ultra sound nerve segmentation, determination of skeletal age, and multiple sclerosis segmentation to different sorts of cancer detection and classification. A recent example

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

is the *Kaggle Data Science Bowl 2018* [5] that aims to develop algorithms to speed up research for almost every disease, from lung cancer and heart disease to rare disorders or to the common cold. While the IS community actively engages in various healthcare-oriented fields such as health care management [6], health care services [7] or mental health therapy programs [8], there has been little activity towards supporting researchers with cutting-edge tools such as advanced image recognition. Yet, our community should assume a more active role in this field as it is "uniquely positioned to provide the appropriate mix of rigor along with humanistic and instrumental relevance" [9].

In recent years, comprehensive new AI frameworks such as *Keras* [10] have emerged. They focus on fast experimentation and prototyping through user-friendliness, modularity, and extensibility. The corresponding democratization of AI allows non-AI researches to easily access powerful deep learning applications. This shifts the focus of attention from the technology to the use case. We feel that this development offers a unique opportunity for information systems researchers in facilitating the use of these tools in practical applications. Alongside this development, the availability of unstructured data, notably image data, is increasing dramatically. Images are not only present on social media platforms (Instagram, Facebook), video platforms (YouTube), satellite images (such as Planet.com), but also a growing constituent in scientific research [11]. As the volume of image data has vastly exceeded the capacity of manual analysis, AI is henceforth a key component for automated evaluation [12].

For research purposes AI applications, as with traditional machine learning applications, are typically embedded in data mining pipelines. Existing data mining frameworks such as the guidelines put forward by Müller et al. [13] or CRISP-DM [14] only vaguely describe machine learning applications as part of the *modeling* phase, whereas they focus on tasks such as feature engineering in the data *preparation* phase and the data mining process itself. However, modeling is a critical and extremely complex task for the distinctive nature of deep learning (AI) methods.

To this end, we seek to outline the current state of advanced image recognition and contribute to the literature by providing tangible guidelines for non-AI researchers on how to incorporate state-of-the-art AI algorithms into data mining pipelines. Thereby, we follow up on the call for embracing the value of unstructured data in the design of analytical information system put forward by Müller et al. [13].

2 Building Blocks for Image Recognition Applications

Supervised learning for image recognition requires a data set of labeled images (e.g., magnetic resonance or microscopy images labelled healthy or infected) [1].[1] To facilitate the usage by researchers outside the AI world we want to establish general guidelines for setting up computer vision projects.

[1] In the following, we assume the availability of such data and do not address the also challenging collection task in the remainder of this paper.

To this end, we break down the image recognition into its main building blocks - task definition, the design of the neural network and finally the training approach. The design task features several sub-tasks (choice of architecture, loss function, evaluation metric). To offer concise recommendations for these highly technical sub-tasks we link the design of the neural net to the initial task definition.

2.1 Defining the Task

In order to effectively address the abundance of image recognition applications, it is imperative to understand the underlying problem set. Consequently, any applied computer vision project must ultimately start with a proper definition of the image recognition task at hand. The majority of applications are capture by the following main task categories:

- *Image classification* [15] assigns the whole image to a particular class.
- *Semantic segmentation* (also referred to as pixel-wise classification) identifies every pixel that is part of a specific class, while neglecting distinct instances [12], [17].
- *Object classification* (also referred to as object detection) distinguishes between different objects (instances) of classes in a picture, returning their approximate location using a bounding box [18].
- *Instance segmentation* localizes objects on a pixel basis [19].

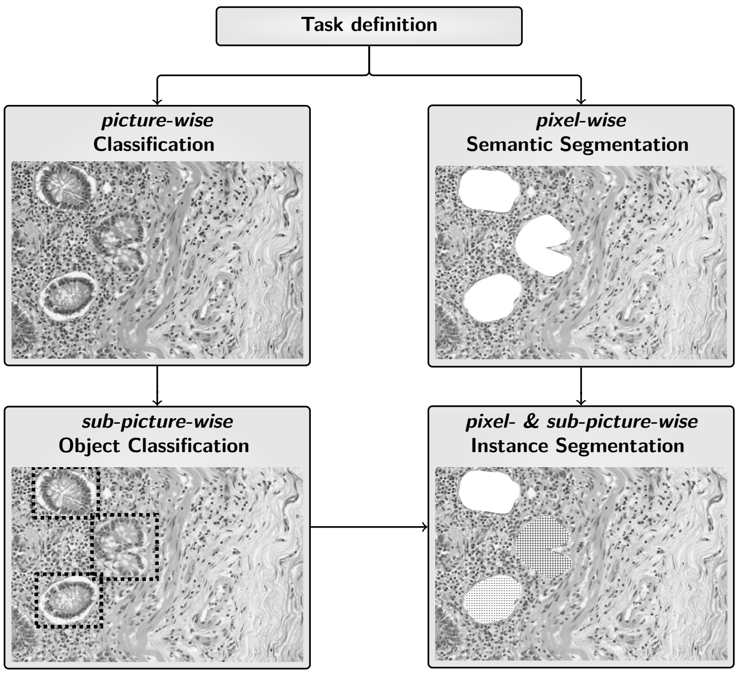

Figure 1. Taxonomy of image recognition tasks using the example of histology images that show cancer cells.

We want to illustrate these categories by means of a histology image containing cancer cells (Fig. 1). The histology images were adapted from "The GlaS Challenge Contest" data set [20]. Depending on the focus of the study the following questions can be addressed using image recognition:

- Classification: Does this image contain any cancer cells? If yes, assign this image to the class “cancer”.
- Semantic Segmentation: What pixels belong to the class “cancer”?
- Object Classification: How many cancer cells are in the image and what is their approximate location?
- Instance segmentation: How many cancer cells are in the image and what is the exact (pixel) position?

2.2 Composing the Neural Network

Having identified the image recognition task, the underlying neural network for image analysis must be set up. Unlike other classification or regression techniques, this is a highly non-trivial task and requires interacting with oftentimes cryptic concepts and an overwhelming number of design options.

While artificial neural networks, i.e., multilayer perceptrons, have been successfully applied to various tasks since the 1980s, convolutional neural networks (CNN) have emerged as the standard for image recognition in the last decade [1]. Consequently, we focus on explaining the essential building blocks of this class of neural networks and establish best practices for each task category.

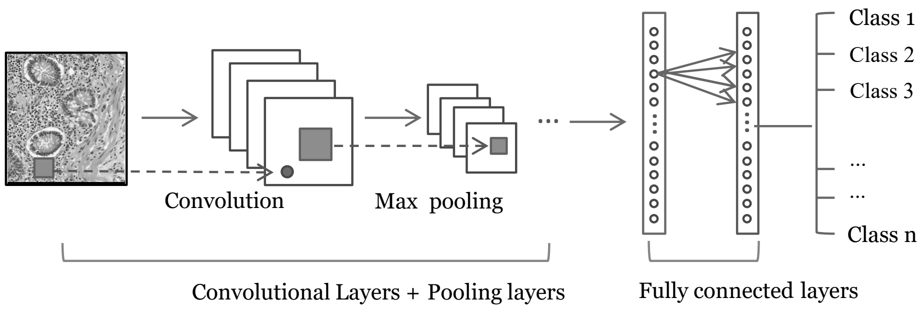

Figure 2. Example of a CNN Architecture

Architectures for Convolutional Neural Networks. The general CNN architecture is composed of three main neural layers, namely convolutional, pooling and fully connected layers as shown in Fig. 2 [1]. Convolutional layers consist of filters (“neurons”) and feature maps to discover conspicuous local pattern-like edges, lines, and other visual elements. Pooling layers are typically considered as a technique to compress or generalize feature representations and reduce the overfitting on the training data by the model [21]. Fully connected layers are used at the end of the network after feature extraction and consolidation by the convolutional and pooling layers. They integrate all feature responses and provide the final classification results [21].

The overwhelming success of AlexNet [21], a large CNN for image classification, in the ILSVRC 2012 challenge [22] has sparked significant interest in the CNN approach. Since then a vast number of architecture tweaks have emerged, each offering incremental improvements of image classification for different data sets. By using their original configuration, these networks perform the task of image classification. Due to their remarkable ability to extract features from images, they are also used as a *backbone* architecture for other image recognition tasks. Fig. 3 provides an overview of the current main architecture choices.

The basic VGG family, introduced by [23], is typically used for its simple and easily understandable architecture (see Fig. 3).

The *Inception* family of networks (introduced by [24]) relies on Inception modules (Fig. 3), where the input is processed by several parallel convolutional layers of different sizes whose outputs are then merged back. This enables the network itself to converge towards an optimal level of abstraction to represent a feature. Finally, the *ResNet* family [25] introduces residual blocks to the CNN (see Fig. 3). Their special features are shortcut connections parallel to the convolutional layers. This facilitates the efficient training of even deeper and more powerful networks [25]. Moreover, these architectures are frequently used as a foundation to tailor *customized* CNN architectures towards a specific use.

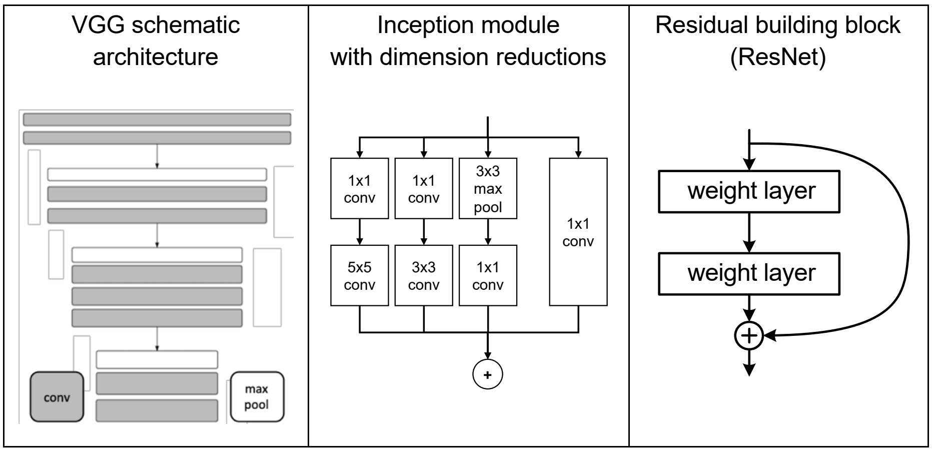

Figure 3. Backbone architecture characteristics

Next, we want to match CNN architectures to the image recognition task categories. These suggestions should provide an informative starting point for determining a suitable architecture:

- Classification: At present, the best performing classification models are, e.g., Inception-Resnet-V2 [26] different version of ResNet (i.e., ResNet51, ResNet101) or VGG.

- Semantic segmentation: Depending on the purpose, variants of the U-Net [27] (using a VGG backbone) perform well on biomedical images such as 2D light microscopy cell segmentation. The 3D version of the U-Net is called V-Net [28]. For more general purpose applications we suggest a VGG based architecture such as a Fully Convolutional Network (FCN) [16].
- Object classification and instance segmentation: As the approach of Mask R-CNN [19] allows both object detection and instance segmentation within the same setting it is the best option for most multi-class segmentation applications. However, the U-Net variants can be extended by additional post-processing steps to enable instance segmentation. In particular, this approach showed very strong performance in the *Kaggle Data Science Bowl 2018* [5]. Depending on the problem at hand, it can be rewarding to implement and evaluate both approaches.

Loss Function and Optimizer. The loss function (objective) and optimizer are the main components to configuring the learning process of a neural network. During the learning phase the weights are adjusted so that the loss decreases. The loss function has to be chosen according to the task, the number of classes or potential class imbalances. Due to its robustness and ability to handle nonlinear effects, the binary cross entropy loss is commonly used as the standard loss for binary classification tasks (picture- or sub-picture-wise). Accordingly, the categorical cross entropy loss works well for all multi-class classification tasks.

In pixel-wise segmentation tasks there is typically an imbalance between pixel classes (i.e., many background pixels and few foreground pixels). There are two common approaches to cope with this problem. On the one hand, [27] propose the use of the weighted cross entropy loss. On the other hand, the dice coefficient loss yields promising results as it handles true negatives as uninteresting defaults [28].

The optimizer determines the update process of the CNN by calculating the gradient. To tackle the high volumes of image recognition tasks, it is of paramount importance that the optimizer computational efficient, has little memory usage and requires little tuning. We suggest to use the optimizer Adam as it outperforms other common choices (e.g., SGD, AdaDelta and RMSProp) with respect to computational overhead [29].

Evaluation Metrics. A suitable evaluation metric is needed to assess a model's performance on the image recognition task. In contrast to the loss function, metrics do neither require to be mathematically differentiable nor used to train the model. Understanding the importance of the evaluation metric is fundamental for every data science project [30], including image recognition tasks.

Accuracy and the area under the curve (AUC) are metrics to evaluate the quality of classification results. For class-imbalanced problems, the Mathew correlation coefficient (MCC) is considered a robust measure [31]. Recall, precision and F-Measure focus on the positive examples to capture information about the rates and kinds of errors made. The intersection-over-union (IoU) metric measures the similarity between the predicted region and the ground-truth region for an object present in the set of images. This is particularly suited for pixel-wise image segmentation tasks. There is clearly no gold standard for evaluation metrics, as they have to account for the specific properties of the given task and underlying data set. We suggest using a combination of different metrics in order to cover different aspects of the evaluation requirements. An exemplary combination of metrics for instance segmentation could be the IoU and recall. While the IoU measures the quality of the segmentation task, the recall accounts for the ability to detect all relevant instances.

2.3 Training Strategy

Having determined the composition of the neural network (by choosing an appropriate CNN architecture, loss function, optimizer and evaluation metric) the final task of training this network on the data needs to be tackled. To this end, we introduce different concepts and best practices for model generalization, hyperparameter optimization, and hardware requirements.

Model Generalization. The advantage of deep and complex CNN architectures is to better extract information from unstructured data. However, a large number of available parameters (weights) renders these networks prone to overfitting which prevents the model from generalizing well to unseen instances [32]. We consider *data-oriented techniques*, *transfer learning*, and *architectural tweaks* to limit the overfitting tendencies of a model.

Data-oriented techniques prevent overfitting by restricting full access of the network to the training data. To this end we apply methods such as data splitting and data augmentation. Data splitting partitions the data set into two subsets: training and validation. The model is then trained on the training data and evaluated on the validation data. Thus, it is possible to stop the training as soon as overfitting occurs. In a k-fold cross validation this procedure is repeated k times [33].

Data augmentation artificially generates additional data without incurring extra labeling costs. In the case of image recognition this is easily achieved by means of transformative methods, such as rotation, shearing, translation, flipping, elastic deformations, and random intensity jitter. This is especially useful for small data sets [21]. Depending on the data set, some transformations should not be performed, i.e., in case of an object recognition task where objects are characterized by their shape, the shape should not be distorted.

Moreover, transfer learning leverages a pre-trained model as feature extractor. To this end, the CNN is initialized with pre-trained parameters of a network that has been trained on another data set such as ImageNet [22] or MS COCO [34]. There are plenty of pre-trained models publicly available, e.g., in the repository of *Keras* [10]. The pre-trained model is fine-tuned subsequently. Thereby, the pre-trained parameters of the initialized network are gradually adjusted to the new images during additional training steps. Depending on the problem, oftentimes the parameters of the majority of the layers are fixed while only a few parameters on top layers[2] are adjusted. Optionally, some custom layers can be introduced and trained in parallel to fine-tune these layers

2 Here, we define *top layers* as the layers close to the input layer of the CNN.

on the new data set. In general, transfer learning accelerates the learning process and improves the generalization ability of a network [32].

Finally, architectural considerations such as dropout layers [35] can incorporate generalization approaches within the CNN composition. Dropout layers prevent the network from overfitting by randomly deactivating a share of the neurons during the training phase. Thereby, the model is forced to learn the same patterns using different neurons. During the prediction phase the dropout is deactivated and all neurons can be utilized.

Hyperparameter Optimization. There are numerous configuration settings in a CNN that can be tuned to improve the performance. Such parameters include, e.g., the activation function, learning rate, the number of training epochs, the batch size, the, initial weight choices and many more.

- Each weight layer in a CNN is typically ensued by a non-linear *activation function*. The simplest activation function for binary classification decisions is the sigmoid function which is bounded between 0 and 1. The ReLU (Rectified Linear Unit) activation function [36] is commonly used for all layers except for the output layer in practice because of the constant slope for positive values.
- The *learning rate* controls the magnitude weights adjustment after each iteration. If the learning rate is low, the training progresses slowly. In contrast, a high learning rate can prevent from converging to a possible minimum loss.
- One *epoch* is when an entire dataset is passed through the neural network for training.
- The *batch size* defines the number of samples propagated through the network in each step of gradient descent, i.e., learning.

Given the vast number of parameters manual tuning is impossible. Consequently, we suggest to conduct an automated hyperparameter search based on either a random grid search [37] or a Bayesian optimization search [38] to identify the promising parameter choices.

Hardware Requirements. The training of CNNs requires a vast number of convolutional operations resulting in an enormous demand for computing power. Training the model on purpose-built hardware such as GPUs or TPUs are far more efficient than training on a universal CPU. The increased availability and reliability of cloud-computing services provides a strategic dynamic capability to scale up or down the IT infrastructure [39]. Therefore, we suggest using Machine Learning as a Service (MLaaS) solutions. Such services are offered by all leading cloud operators.

3 Applying the Guidelines: A Biomedical Case Study

We illustrate the execution of an image recognition project based on the guidelines put forward above. To this end, we report learnings from a research collaboration with a group of neuroscientists. In a joint project we developed an data mining pipeline to automatically detect fluorescently stained neurons in tissue images of mice brains [40].

3.1 Defining the Task

To define the task, we first need to understand the underlying problem and data set. Fig. 4 shows an excerpt of image dataset obtained using a confocal microscope. The data comprises three different sub-regions of the dorsal hippocampus: dentate gyrus (DG), Cornu ammonis 1 (CA1) and CA3. As there is no ground truth for fluorescent signal segmentation, neurons are determined by their relative brightness (signal strength) to the background. For this purpose, the resulting segmentation maps are generated either by means of a heuristic, manual identification process or by means of a (partially) automated threshold-based analysis. Due to the low signal-to-noise ratio of the data, threshold-based approaches do not work reliably as they fail to detect most of the fluorescent areas (see Fig. 4).

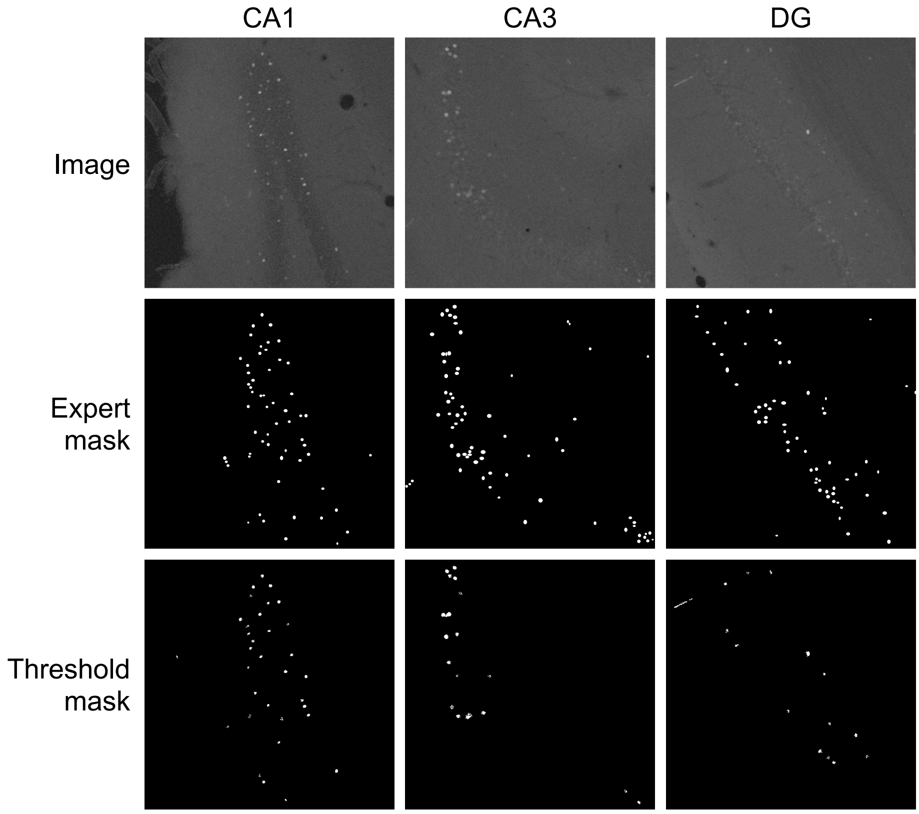

Figure 4. Different sub-regions of the dorsal hippocampus and the corresponding segmentation masks (here, the threshold only considers the 5% brightest pixels per image).

The goal of our image recognition is to automatically detect fluorescent neurons within a microscopy image. For biomedical evaluation, researches require the position, size and signal intensity of fluorescent neurons. Thus, our model needs to identify (i) object instances as well as (ii) the exact area (segmentation mask) rendering instance segmentation suitable for our task.

3.2 Composing the Neural Network

CNN Architecture. According to the task definition we first used the Mask R-CNN approach based on a ResNet backbone architecture for instance segmentation. This already yielded reasonably good results but also required a huge amount of computational resources. We also tried a U-Net based approach similar to the winning solution of the *Kaggle Data Science Bowl 2018* [5]. In this particular case, instance segmentation is achieved by (i) performing pixel-wise binary classification with the U-Net and (ii) post-processing the resulting binary segmentation map. The post-processing pipeline includes a Watershed algorithm [41] and the removal of biological implausible regions (i.e., too small or misshapen). As the U-Net approach yields the better results we continue with it for the remainder of the study.

Loss and Optimizer. As shown in Fig. 4 the total number of fluorescent neurons (positive pixel class) is far less than the background (negative pixel class) resulting in high class imbalances among the whole dataset. Thus, we optimize (Adam algorithm) our model by minimizing a weighted combination of the cross-entropy loss and the dice loss to take advantage of their respective benefits. Here, the dice coefficient loss is particularly valuable as it handles true negatives as uninteresting defaults. We found that the outcome of the whole pipeline depends on a well-suited loss function.

Metrics. To evaluate the quality of our model we compare the expert segmentation masks to the post-processed output masks of our network. This comparison can either be performed pixel-wise or on an aggregated neuron level. For the pixel-wise comparison we need to take the class imbalance into account. Hence, we leverage the IoU as we are mainly interested in identifying instances of the positive class (fluorescent neurons).

Considering the biomedical use case, researches are particularly interested in position and size of each neuron. However, in high resolution images the exact boundaries of the neurons are difficult to define for human experts on a pixel level. As a result, there are often minimal deviations on pixel level even though the same neuron is detected. To address this issue, we introduce another comparison process that (i) matches the corresponding neurons of two segmentation masks and (ii) calculates the accuracy as the proportion of matches divided by the total number of unique neurons found on both segmentation masks.

3.3 Training Strategy

Due to the high cost for both manual labeling and mice experiments, only a limited amount of training samples are available. Thus, we apply data augmentation as a combination of randomly rotating, flipping and shifting the original image-mask pairs. As the shape of the neurons is important in the identification process, we do not use techniques that distort the shape (e.g., shearing). Fig. 5 exemplifies this process with random parameters. Here, the original image-mask pair is horizontally flipped, rotated by 90 degrees clockwise and 20 percent shifted to the top and right. In light of the small dataset, data augmentation prevents from overfitting and generalizes the model, e.g. by learning to detect neurons independent of their position.

To further remedy the issue of limited training data we pre-trained our model on the Kaggle Data Science Bowl 2018 [5] data set, which contains similar microscopy tissue images. To tune the parameters of the network we use a Bayesian optimization search. The model is trained and evaluated on multiple Nvidia Tesla V-100 GPUs.

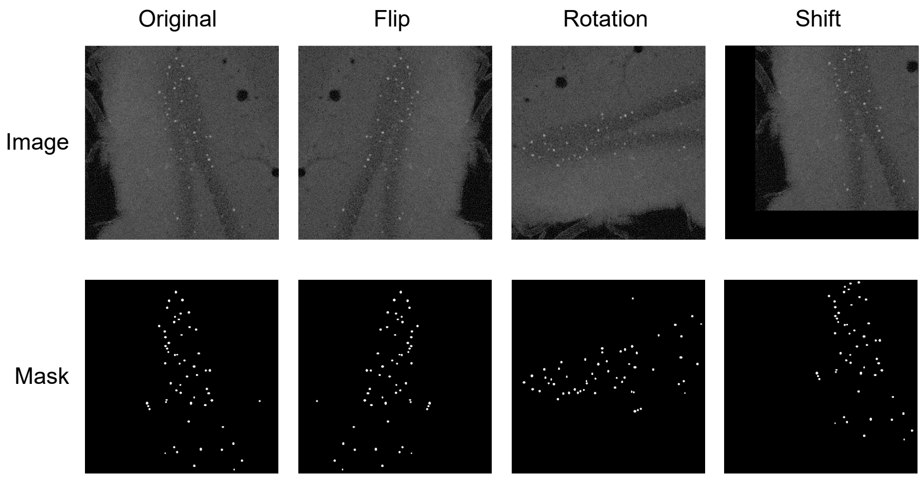

Figure 5. Data augmentation methods used in our project.

The detailed findings of our research project are described by Segebarth et al. [40] and the code is publicly available on *GitHub*[3]. In order to communicate our research, we provide a Jupyter-Notebook with free access to high computing power on *Google Colab*[4]. The execution of the notebook requires no machine learning and almost no programming expertise.

4 Conclusion and Outlook

In this study, we outline the current state of advanced image recognition and provide guidelines for non-AI researchers on how to incorporate state-of-the-art AI algorithms into data mining pipelines. We showcase the application of the proposed guidelines on a case study in the field of biomedical image recognition.

In particular, our research aims to make several contributions to the literature. First, we structure the variety of existing image recognition approaches and put forward a taxonomy for image recognition tasks based on the relevant literature. Second, our proposed guidelines are expected to extend data mining frameworks such as CRISP-DM. The *modeling* phase for machine learning applications is only vaguely described here, although it is a complex challenge for deep learning models. Finally, our presented case study demonstrates the potential of AI in biomedical applications. The automation of the conventional (manual) image analysis process reduces workload and enables highly qualified researchers to focus on important activities instead of tedious image labeling work.

To tap into these benefits, some limitations of our guidelines need to be considered. In the rapidly materializing field of AI and deep learning, the proposed model architectures and recommendations only represent a snapshot of the current developments and need to be updated continuously. However, the taxonomy for image recognition tasks will also apply to new technologies. In addition, modeling deep learning applications may require additional specific domain knowledge as depicted in our case study. Another difficulty is to identify the appropriate degree of abstraction for our guidelines when addressing scholars with different levels of prior knowledge.

In future research, we plan to generalize and refine our proposed guidelines by means of an evaluation on use cases from different domains. Possible topics may comprise but are not limited to fashion trend detection, satellite image analysis to predict future resource requirements and the diagnosis and management of diseases.

Abstract. In various applications, the counting of objects based on image data plays a pivotal role. In this paper we first conducted a literature review to display the state of the art in counting objects and summarized the results by extracting several important concepts that describe the counting problem as well as the solution. In a second step we applied this knowledge to yield prognosis in vineyards, where we used Deep Learning models to detect the objects. While these methods used in the detection step are state of the art and perform very well, several problems are usually introduced by the constraint of only counting an object once in the counting step. We provide a solution for this common problem by identifying unique objects and tracking them throughout a sequence of images in order to avoid counting objects more than once, resulting in an automated yield prognosis model for vineyards.

Keywords: deep learning, counting, image data, vineyard management

1 Introduction

The forecasting of economical features like profit plays an important role in predictive analytics in the age of digitization. In addition to the service and manufacturing industry, the commodities sectors, especially the field of agrarian management can benefit a lot from disruptive and innovative processes that follow up the digital transformation process [1]. Especially the scientific field of artificial (AI) with its subsidiary field of machine learning (ML) aims to provide a solution to problems that are either very cumbersome for humans to tackle or simply impossible [2]. However, there are still some fields, where artificial intelligence can help to tackle problems that are otherwise cumbersome to tackle.

One of these fields is yield prognosis in the context of agrarian management [3, 4]. The yield prognosis task within vineyard management is often times very labor intensive and subject to errors generated by bad and subjective sampling [5]. In addition to that the manual labor sampling techniques have very poor scaling behavior towards larger vineyards. While there are some automatic approaches using complex lighting

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

camera techniques to provide image data for statistical models, they are for the most part even more costly than the actual manual labor sampling process and have to be reapplied every time since the models are subject to various spatial and temporal factors like terrain, season and time of day.

While the problem of decision support systems that excel in the task of predicting profits based on yield prognosis is well established in IS-research, companies often times fail to leverage new analytic tools to harness business values from growing amounts of data [6–8]. While most systems promise improved results in terms of prediction performance, they come with high barriers in terms of application interpretability and required computational power [9, 10]. Therefore, the construction and evaluation of AI technologies like deep learning systems (DLS) in the context of business problems should be considered a vital research interest in IS research [11]. We construct such systems by transferring known algorithms for object counting to the problem of yield prognosis.

The task at hand can therefore be reformulated as finding a model that is able to count agrarian entities like grape berries and whole plants of grape vines. This task adds an additional and important step in the data analysis process: Besides the usual description of data selection, data preparation, modeling and evaluation we add a counting step after the model phase since basic detection is not enough to provide a yield prognosis.

Our goal is to provide several solutions to solve the underlying problems of object detection (modeling phase) and yield prognosis (counting phase) and we therefore employ a two-step-approach: Following a proposed IS research gap by Gordon et al. 2013, we review related work on intelligent systems based on Artificial Neural Networks (ANN) for the task of both object detection and counting the identified objects, propose a systematization of the whole context and secondly evaluate state-of-the-art existing approaches for object recognition in combination with novel approaches for the counting step using image data collected from different vineyards throughout Europe. The paper is therefore structured as follows: In the next section we provide a description of the criteria for our literature review and the subsequent conceptualization of approaches for object counting.

We then proceed to describe the underlying data and analysis process for our data science study in Section 3. In Section 4 the results are provided and discussed with regard to the problem at hand. The last section provides a summary as well as research limitations and an outlook.

2 Preliminaries and related work

The task of counting objects based on image data has a wide variety of application domains, for example, counting cells on microscopic images or the surveillance of large people crowds as well as counting life stock or plants and trees from satellite or drone images [13]. Counting objects on various images is an exhausting and failure heavy process for humans, especially when the data sources contain multiple images (e.g., from video data) that needs to subject to automation for the reason of efficiency [14].

However using intelligent systems to count provides a lot of obstacles to overcome like hidden objects, fuzzy borders between objects or change of perspective [15]. Often times the counting process needs to provide additional information like the number of objects in a certain area (e.g., in air surveillance or agricultural analysis of plant positioning). Loy et al. differentiate between three basic approaches to counting: counting by detection, counting by segmentation and counting by regression [16]. Counting by detection is a two-step approach that first uses localization through object detection (e.g., through the use of a detection model like a convolutional neural network) and then proceeding to counting the detected objects. Counting by segmentation uses multiple images and groups consistent motions throughout the images to estimate the object number. Counting by regression is modeled after the human counting techniques for estimating or "guessing" object numbers without complete enumeration. The growing field of Artificial Intelligence (AI) and Deep learning (DL) enables the application of Artificial Neural networks (ANN), especially convolutional neural networks (CNN) for counting objects. While recent benchmarks suggest that counting by regression outperforms the standard counting by detection it is very cumbersome in the model development phase, since relevant features that help "guessing" the right number have to be crafted by hand for every situation. A CNN requires only labeled training sets and can learn higher order features by itself [17]. A well trained CNN can also be generalized in its architecture to be applied to different objects, e.g., a model that is used to count apples can be trained to count cars without changing the model structure [17]. Related surveys on these topics for both manually generated features and automated feature generation with deep neural networks are provided by [16] and [18] respectively. The surveys provide insights in the effectiveness of the different counting methods. It is suggested that standard counting by detection, while the most precise, fails to live up to the task in cases of images containing a large number of objects. The disadvantage of counting by segmentation is obviously that it cannot be applied to single picture data but needs a consistent stream of pictures with time stamps as they would be generated by videos. While counting by regressions seems to overcome both disadvantages, it often times requires the extraction of low-level features in order to estimate a density function on the domain of those features that reflects the density of objects for every pixel in an image. Integrating then leads to a cumulative function that produces an estimate of the total number of objects in an image [18]. However with the use of DL a certain degree of automation and general applicability can be achieved [19]. Before we evaluate some of the above mentioned approaches for the problem of yield prognosis in the agrarian management of vineyards, we provide a general overview over DL and ANN based algorithms for object counting by conducting a structured literature review.

3 Research Methodology and Literature Review

3.1 Research method

The research goal (RG) of this paper is (1) to provide an extensive state of the art overview of neural network based counting algorithms and (2) provide and evaluate a set of methods to overcome some of the problems that are inherent to counting by detection using data from a case of agrarian management of vineyards.

In order to provide a survey of related literature as formulated in RG (1) we employed a literature review with content analysis [20]. For the data science study formulated in RG (2), we use a study design as suggested by [21]. The structure of our data science study follows the KDDM approach by [22]. It is divided into six basic phases: *i) domain understanding*, *ii) data understanding*, iii) *data preparation*, iv) *modeling*, v) *evaluation*, and vi) *deployment*. Since the system we developed is a non-productive system without deployment we omit this phase from our research process.

As mentioned earlier we add a counting phase after the modeling phase, since using ANN algorithms to detect the objects is not enough. The counting step confronts us with the problem of unique entity counting, meaning that every object should only be counted once in order to provide a valid yield prognosis. We supply solutions to solve both problems – object detection as well as unique counting in our data science study for yield prognosis of vineyards.

For the identification of relevant literature we conducted a search with the terms "count" and either of the keywords "deep learning" or "neural network" in the databases Science Direct, EBSCOhost, IEEE Xplore and arXiv. Both the terms and the database choices cover the area of interest as suggested by RG (1). The search was conducted in a way, that the terms had to be present in at least one of the following meta data of the paper: abstract, title or keywords, where we explicitly defined the search string in a way that the term "count" had to be present in the title as a necessary condition. Initially 321 relevant papers were identified. We then proceeded to apply subjective filtering by screening the title (131) and then the abstract (87) for relevance. After removing duplicates and conducting a backward search we finally yield 99 relevant papers. A forward search based on the 99 papers revealed no additional results. The subjective filter was implemented based on some relevancy checks: (A) counting objects had to be a core topic of the paper, which prevented the inclusion object tracking or object recognition heavy papers; (B) the paper needed to be an original work rather than a survey, so that only papers that describe a method in-depth will be included in the overview; (C) the method was based on image rather than video data; (D) the article had to include neural networks (either standard or deep learning), since that was the focus of our research goal.

From our result set we were able to extract six core concepts that describe the various existing counting methods and their application environments: *architecture, number of objects, density of objects, background dynamics, output, training data* and *type of counting.* In the next section we provide the description of those concepts with the respective results from the literature review.

3.2 Literature Review results

Architecture. This concept distinguishes the counting methods based on extent and type of elements in the data analysis process responsible for counting. First we distinguish systems that only use one step processes (22/99), resulting in a single ANN that can be trained as a whole. Typically those networks were based on CNN architectures (e.g., [23–25]). Those methods typically use local and/or global features (Type of Counting is feature based) to determine the object density per pixel or partial and whole images. Another one step ANN involves classification whether an object is present in a given part of the image or not (Type of counting = Detection based) (e.g., [26]). Secondly there are counting systems that use multi steps that only involve ANN algorithms (16/99). Often times this extraction of partial images and then using it within a regression model (e.g., [27–29]). This machine based feature extraction provides advantages in scenarios with overlapping and strong variations in object size [30]. Other only ANN based multi-step approaches involve sequential models like Long-Term-Short-Term networks (e.g., [31]) or parallel architectures that use multiple networks as base learners while having a final "deciding network" in the second step (e.g. [30, 32, 33]). The last characteristic involves ANNs as well as other methods (61/99). This category acts as a collection for the versatile preprocessing possibilities of ANNs and other image processing methods. ANNs are used to either manipulate images to achieve better results (e.g., scaling or color related features), extract features (e.g. abstract or low level features like edges or texture) and for regression and combination of previous results.

Number of objects. This concept, while it should not be considered isolated, gives us a description of the counting problem at hand that we try to solve using ANN algorithms. The success of various counting methods depend largely on that concept, e.g., for counting of crowds of people we can use detection based methods for a small number of objects but not if we have large crowds present in images. We would then rather use feature based methods. We divided the found literature up into small number of objects ranging from 0-50 (55/99 papers), medium sized 50-200 (21/99 papers), large 200-1000 (14/99) and "outlier" or "extra-large" with the number of objects being larger than 1000 (4/99). Some methods were built to be more flexible and can be applied to various object numbers. In our review we took average numbers of objects based on the used image datasets. We could however not determine such numbers for five publications, since there was no indication regarding the number of objects.

Density of objects. The concept of density is another characteristic attribute of the counting problem and we can distinguish between no overlapping objects (31/99) and overlapping objects (68/99). It was found that for counting problems with considerable overlapping, feature based methods are preferred and more successful in predicting object numbers [13].

Background Dynamic. Another important influence factor found in the literature is the background dynamic which can be distinguished into static (43/99) and dynamic backgrounds (56/99). Static can have multiple meanings in this context: We can assume that over a sequence of images only the foreground changes (e.g., fixed surveillance cameras) where we can ignore the background and remove it via background subtraction methods (e.g., [34–36]) or as another option for static backgrounds we can assume a region of interest as a part of an image that is henceforth declared as foreground (e.g., [37, 38]). The assumption of static background is necessary for some methods to distinguish between foreground and background.

Output. The counting methods found in the literature offer a range of different outputs, depending on the specifics of the problem at hand. In some cases the methods only supply a rough estimate (10/99) without positioning or a total count. This is the case for public transportation surveillance where only a rough percentage estimate is needed, e.g., of how crowded a departure platform is (e.g., [39, 40]), reaching from 0-100%. Some methods output an estimate of the total number of objects in an image (59/99), again without positioning information. To circumvent this problem some approaches divide the image and count the total number of objects by region (8/99). With using overlapping regions, more robust models are generated (e.g., [14, 41]). Other output methods that take positioning into account involve determining a count per pixel by either returning a unique coordinate for each object centroid (2/99) or by using a bounding box that forms a rectangular shape around the object (4/99). Another approach to give an estimate per pixel is using a density function (15/99) as depicted by a heat map in Figure 1, where a higher pixel density is expressed by red color whereas low densities are expressed by blue color (e.g., [13, 25, 42]).

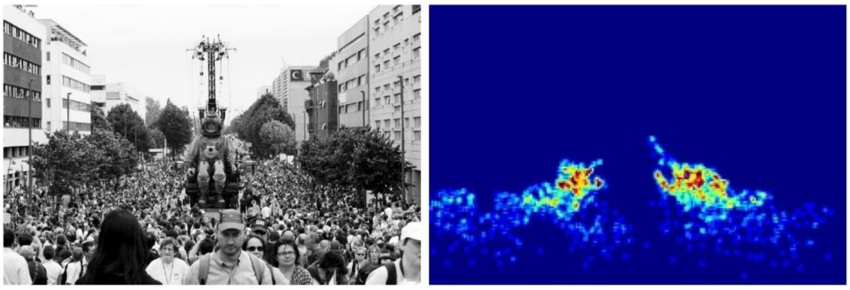

Figure 1. Example of density based count per pixel method ([28])

Training Data. The different options of available training data can be characterized by the effort of annotation of the unlabeled data. The first annotation tier with the lowest effort is given by annotating the total count (38/99). This is particularly useful when we only need an estimate or the total number as output without positioning information. For the purpose of annotating with positioning information we need the centroid coordinate (35/99), where every object is manually annotated with a dot in the center. This type of training data can be used for all output types since some outputs require the image to be divided up into regions, which in turn requires positioning information such as centroid coordinates (e.g., [28]). It was also found that this kind of data is needed in order to create density maps using Gaussian filter techniques (e.g. [30]). There are also approaches that do not require the annotation of training data at all (19/99) like segmentation based counting (e.g., [43, 44]) or detection based counting which instead of annotations needs example images of the objects that are to be counted (e.g., [44]).

Type of counting. The last concept as extracted from the literature review gives an insight on how the different approaches work. The first option is to use segmentation methods (15/99). After background and noise removal, which are essential preprocessing steps for this kind of approach, every foreground segment is declared as one object instance (e.g., [43]). The foreground/background segmentation is either conducted by a classification algorithm or by a threshold transforming images into binary black and white images with white pixels representing foreground objects [45]. The detection based methods (15/99) use a multi-step approach where objects are detected first and then localized and counted afterwards. Depending on the task at hand the detector is either trained to recognize the whole object (e.g. [44]) or only parts of it (e.g., only the head of a human body). The detectors are trained with single image training data to determine whether the object of interest is present or not. However a shortcoming of those approaches is that they cannot successfully be used with strong overlapping and large number of objects [16, 18]. Feature based methods (69/99) can circumvent that downside by extracting local and/or global features of the image. This can either be done by manually crafting features (e.g., [46]) or to use annotated data to train feature extractors (e.g., [23, 27]). Manually extracted features include shape, color, area, diameter, roughness of texture (e.g. [47]) or even additional meta annotations like perspective or weather data [48]. After feature extraction common machine learning algorithms like SVM, linear regression or ANNs are used to predict the desired output. In the next section we introduce a data science study that describes a data analysis process to provide an estimate for counting vines and grapes in order to produce a yield prediction to support decisions in vineyard management.

4 Data Science Study

4.1 Domain and Data Understanding

The management task in the context of agrarian management of vineyards is faced coherent spatial variability in the production systems, making crop and yield vigour an essential information [49]. Temporal variations of crop stability lead to unpredictable and nonstable yields, so that even the information of current yield during any phase of the crop development is vital.

In our data science study we gathered image data from three different vineyards in Germany at three different stages of the crop process (early, mid and late). The data gathering process was designed to be as cost efficient as possible, utilizing already existing equipment and avoiding complex lighting procedures and other high-cost image capturing in order to determine if a system can be designed that solves the counting task with only average to weak image quality data. We therefore combined already available mobile harvesting equipment like tractors with image capturing devices like full-HD cameras that generated a sequence of single images along a field of vine crops. We gathered three hours of video material in HD quality[1] and some Ultra-

[1] Taken with a GoPro Hero5 that was attached to the harvesting equipment

HD examples for testing purposes. Some important constraints when facing our task are a generalizable model that can predict yield under different conditions like weather, time of day and vineyard structure (e.g., slope or soil structure) and the necessity of avoiding to count an object more than once.

Since we can only use image data to train the model we transformed the video material into approximately 50 GB of image data sequences. We then judged the quality of the resulting images and especially the information content and removed poor quality images and images with no information content. Every image was captured from a frontal perspective facing the vines and we excluded other perspectives. We also excluded special vine crop structures like blue protection grids in order to keep generalizability (those vines have the same basic structure as other vine crops and are therefore detected just fine later on).

We can describe our counting problem in terms of the concepts extracted earlier in the literature review as a *small number of objects problem (0-50)* with *clear distinction* between the objects in terms of object density and for the most part *static backgrounds* with only small variations (e.g., cloud movement). We employ a *multi-step approach combining ANNs*. Since the object number is quiet high and we have some overlapping on the grapes, we use feature based detection. However we do not identify the image features ourselves but instead minimize the feature selection process by letting state-of-the-art image detection networks engineer the features, which further reduces manual labor on the part of the vineyard management. The concepts of output, training data and type of counting are given in the subsequent sections.

4.2 Preprocessing

For the labeling process we used the concept of *bounding boxes* for the training data as they are a supported format by deep learning frameworks like TensorFlow[2] and are our designated form of output for the modeling stages. We also labeled metal and wood rods that are occasionally used in vineyards in order to avoid confusing the algorithm. In other preprocessing steps we applied noise removal and feature extraction to highlight different parts of an image using thresholds and the background/foreground distinction resulting in black and white images, picturing vines with white pixels. For noise removal and isolation of objects of interest we further applied erosion on the transformed b/w images utilizing the OpenCV programming library and added Canny Edge Detection to better distinguish grape vines from the rest.[50]. Figure 2 gives a visualization of those preprocessing steps.

[2] https://www.tensorflow.org/

Figure 2. Selection criteria for input image data

For evaluation, we divided the data set into 70/30 train and validation data partitions.

4.3 Modeling

Given our counting task problem and the results of our literature review, we decided on a *detection based* type of counting by using automated feature extraction to minimize the manual effort in model building. There exist a lot of algorithms for efficient object detection and TensorFlow provides a collection of some of the state-of-the-art algorithms for that task [51]. We utilized the three common architectures for object detection ANNs: Single Shot Multi-Box Detector (SSD), Faster Region-Convolutional Neural Network (Faster R-CNN) and Region-based Fully Convolutional Networks (R-FCN). As a basis for our model training we used models that were pre-trained on the common benchmarking datasets: COCO (common objects in context), KITTI (images that capture traffic situations) and OID (an open Image dataset with 9 million images[3]).

We then continued training for the pre-trained models based on our training and test datasets. The results of the detection step in terms of model loss are given in Table 1. For evaluation purpose we compared the ground truth labeling bounding boxes with the model output boxes and used the mean average precision (mAP) as a metric [52]. In order for the comparison to be conclusive we use the degree of intersection between the two bounding boxes (ground truth vs. model output), also defined as Intersection over Union (IoU). The minimum threshold suggested by [52] is declared as an IoU of 50%. Since the original threshold was meant for more than 100 image object classes and we only have three classes (vine, metalstick, woodenstick), so we used an IoU of 70%.

Table 1. Object Detection Model Results

Model Architecture/ pre-training	Average Precision			Mean AP@0.5 IoU
	Vine	Wood	Metal	
F.R-CNN/coco	0.9887	0.9995	0.9992	0.9962
F.R.-CNN/kitti	0.8775	0.9081	0.9523	0.9126
F.R.-CNN/oid	0.9839	0.9991	0.9702	0.9847
SSD/coco	0.6027	0.6910	0.4433	0.5790
R-FCN/coco	0.9729	0.9982	0.9997	0.9910

[3] https://github.com/openimages/dataset

We can see that the task of vine detection executed successfully by all models except the SSD. For grape detection we therefore only used R-FCN and F.R-CNN models. Detecting single grapes was a nearly impossible task, since even with filtering the labeling of berries by humans was cumbersome and not always successful. We obtained average mAP values ranging from 0.2670 to 0.822, with the highest values only being reached when using some UHD quality images. Since obtaining and analyzing UHD images for a whole vineyard is beyond our economical reasonable goal definition of automated, cheap counting methods, we decided to cluster the berries up to grape vines and obtained mAP values ranging from 0.7576 to 0.9811 using an even higher IoU of 75%. The F.R-CNN/oid performed best with detecting grape vines.

4.4 Counting

As mentioned before we encounter several problems despite the successful detection of vines and grapes, since we cannot allow to count objects more than once. Using sequential image data we can define a simple predecessor – successor tracking process by giving an ID to a random box starting in frame 0 and then identifying that box in the next frame by drawing the same box from the previous frame and calculating overlapping percentage to all other boxes in the frame. The box with the most overlapping is called the successor and gets the same item ID. This creates a chain and identifies a single vine throughout the sequence. The process resets when there is no successor defined (when the end of the chain is reached) anymore and another box from frame 0 get a new ID. If all boxes already have an ID the process starts at frame 1 and so on, until all the vines have unique IDs. Sometimes the camera moves to fast or the camera reaches the end of the chain, so that we implemented a distance check that calculates the mean distance between two boxes. Whenever this distance is larger than the threshold of 150, no successor is defined, which lets the tracking process start again as explained above. The process is simplified and depicted in Figure 3 with the successor frames shown as red rectangles in frame n+1. A problem when using this method arises when we have (a) either missing vines in reality (e.g. vines that were removed because of crop sickness) or we (b) failed to detect a vine because it was hidden behind some other object (e.g. leaves or other plants).

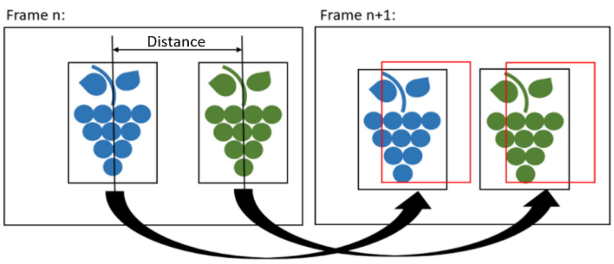

Figure 3. Tracking with overlapping and average distance between objects

In this case our method would not determine a successor object and counting would stop. But since we can track the vine throughout a sequence of images, we can determine the position the vine would have been at in that particular frame where case (a) or (b) applies. In case (a) we applied a 1.5 times threshold to the average distance measure as depicted in Figure 4 between two different IDs. For example if we calculate an average distance between two different vines (=different IDs) of 261 pixels, the threshold would be 391.5 pixels, resulting in the declaration of a missing vine whenever the distance between two bounding boxes exceeds that threshold. In case (b) we can correct the position where the successor should be by adding the average predecessor-successor difference to the previous position. If the object is out of bounce regarding to the frame coordinates we have simply reached the end of the row, otherwise we have imputed a vine which was not detected by our DL algorithm in the first place because of reason (b). This way we can solve the unique counting problem and also detect missing vines to give feedback to vineyard managers. This can have positive impacts especially when combined with agrarian management information like logs as to why vines were removed, so that we can prevent sickness from spreading or isolating certain crops in the development process.

We applied our process to every row we gathered video material from and the average deviation between model count and true vine count was 0.12 per row, with extreme values of 0 and 2. The average deviation for the count of grape vines per row was 1.87 with extreme values of 0 and 4. The extreme values can be explained by bad detection model performance on some objects, where the distance based algorithm just assumed there is either a missing vine or the end of row is reached. It is important to note that the counting process performance itself does not result in an error state itself, only when the object detection framework fails to classify an object. In comparison with other mechanics like motion tracking [25] or neural network based tracking [53] this combination is easier to use in the vine counting scenario as we described by using the extracted concepts from the literature review: medium number of objects, no overlapping, low density which is not the case in most benchmark scenarios of tracking in literature, where often times people are tracked in large crowds, facing problems of blur, high density and large amounts of overlapping, which requires far more advanced approaches [54]. However, in this case, it is sufficient in terms of the economic application to use a simple distance based method, since in comparison to the people tracking benchmarks we have a scenario with only slight perspective changes, distinguishable or static background and the overall scene is the same in every vineyard, apart from some details that have to be learned by the detection model.

5 Discussion & Outlook

We provided a literature review to describe both: the counting problem itself and the solution using various concepts like number of objects or type of counting. We then implemented a data science study to count objects like vines and grapes based on vineyard image data in order to provide a yield prognosis. While the detection of vines and grapes was very successful, the models failed to detect the single berries for non-

UHD picture material. We also provided a tracking solution for the counting step, to fulfill the constraint of unique object counting. However we only used a simple approach here that was based on subjective thresholds that might be subject to change on other vineyard architectures. Possibilities to circumvent this problem is the application of motion tracking straight onto the video material. While we made sure we had GPS data while gathering the image material we did not utilize it, which could be done in a next step and combined with aerial footage to map out the vineyard and provide more useful information like disease spreading factors to vineyard management, all of which would be automated and would not require human intervention once fully implemented. The process and the ideas provided in this paper are generally very robust to change of environment, especially the pre-trained networks can work on similar image data or can be re-trained in only a short amount of time, so that this process could be generalized onto various agrarian management situations were a similar counting problem structure can be found in terms of number of objects, density and background dynamics.

achatz@uni-passau.de

Abstract. While qualitative research is experiencing broad acceptance in the information systems discipline, growing volumes of heterogeneous data pose challenges to manual qualitative analysis. We introduce an unsupervised machine learning approach based on graph partitioning to detect hidden information and structure in qualitative data samples. With the clustering technique, we map coded data to a graph and formulate a partitioning problem which is solved by integer linear programming. As a result, clusters of information sources are identified based on similarities given in the coded data. We demonstrate the approaches' ability to detect hidden information in coded qualitative data by application on coded interview transcripts. With the approach, we draw on a technique from the operations research discipline and expand the repertoire of approaches being used to analyze qualitative data in the context of information systems.

Keywords: qualitative data mining, clustering, graph partitioning, unsupervised learning, integer linear programming.

1 Introduction

Since 2005 one can see a significant growth in qualitative research publications in information system (IS) journals which shows the growing relevance of qualitative research in the IS discipline [1]. Besides studies that are applying qualitative methods to investigate research topics (e.g. [2–4]), a lot of work is focusing on guidelines regarding how qualitative research should be conducted within the IS discipline (e.g. [5–7]). Additionally, qualitative research is often seen as a minor discipline because of findings which are said to be accompanied with biases (e.g. subjectivity) regarding the common quality standards [8].

Qualitative research in IS aims to gather a deep understanding of behavioral and technical issues regarding the role of information technology (IT) and often supplements quantitative studies in a mixed method approach [9]. Referring to Romano Jr. et al. (2003) with an increasing amount of available qualitative data it becomes

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

necessary to develop approaches to analyze growing volumes [10]. In the context of qualitative data, especially clustering mechanisms have been discussed in literature (e.g. [11]) but still remain underused [12]. In the case of clustering being used, researchers typically perform manual techniques to detect groups based on codes (i.e. marker for a relevant information given in qualitative data) in qualitative data which requires extensive resource commitments [13]. Due to this there is a growing field of scholars who are applying machine-learning techniques on qualitative data. Within this field, automatic coding techniques based on natural language processing and graph theory (e.g. [14, 15]) as well as clustering approaches (e.g. [16]) were applied on qualitative data. However, the clustering techniques are mostly used to cluster participants with similar profiles of codes instead of clustering codes based on their relationship to each other. Following this research stream, the paper investigates the research question how hidden structure in qualitative data sets can be detected automatically based on code similarities? Answering this question, we develop an unsupervised learning technique called *CodeClust* based on the concept of graph partitioning. We draw on a technique which we developed to solve clustering problems in the operations research (OR) domain and adopt it to mine and analyze coded qualitative data. With performing the approach, results are generated that grant additional and hidden insights regarding the structure and affiliation of qualitative data constructs. With this, we intend to expand the repertoire of approaches that are used in qualitative IS research and contribute to future studies by providing a new approach to analyze qualitative data samples.

The remainder of paper is structured as follows: First, we give a brief overview of data collection, coding techniques and existing quality criteria in qualitative research. This leads to the third chapter in which we outline fundamentals and related work in the domain and present *CodeClust*. Besides describing data preparation and essential features of the approach, we illustrate how to use the technique on coded data from expert interviews. The paper concludes in a discussion of the approach and gives an outlook towards future research directions.

2 Data Collection, Coding Techniques and Essential Quality Criteria in Qualitative Research

There exist different techniques of data collection to gather empirical material for the purpose of data analysis. Non-numeric information is usually collected directly in form of interviews or indirectly from secondary sources like text documents [17]. This results in textual information sources like interview transcripts and case descriptions which serve as a foundation for further analysis. For a detailed view of different methods, data collection techniques, modes of analysis and quality criteria used in qualitative IS research, see Keller (2017) [18].

After the data has been collected, the information sources have to be structured for further analysis in a next step. Grounded theory is a widely used approach and serves as a foundation to structure textual information based on coding techniques [19]. The aim of the coding is to highlight segments of textual data that contain relevant information in regard to the underlying research question [20]. Therefore, codes represent information given in the data and serve as a generalization of information. In this field, Gläser and Laudel (2013) provide a detailed view on coding techniques and variations in objectives related to coding [19].

In most cases, the coding process itself is done manually. To ensure the quality of the results, the data sources are coded by different coders and their outputs are merged and evaluated for similarities. Within this coding process, software tools (e.g., *NVivo, Atlas.Ti, HyperResearch, MaxQDA*) are used by the coders and support in attaching codes to relevant text segments. Additionally, the tools provide functionalities in form of quantifications and visualizations to process the results.

In terms of quality criteria in qualitative research, validity and reliability are differently characterized than in the quantitative domain [21].
Although validity aims to ensure the quality and information value, Flick (2014) argues that flexibility is one major strength of qualitative approaches [22]. Therefore, communicative validation is a common approach to ensure credibility and accuracy in qualitative research [21, 23].
Reliability stands for the robustness of findings and the consistency of an approach. However, in qualitative research identical findings do not always represent reliable results (e.g. identical responses in interviews may point to prepared answers) [24]. In order to draw consistent conclusions in qualitative studies, the specific context and the data collection process itself must be described in very detail. With this, one can ensure traceability from an intersubjective point of view [25, 26].

In addition, credibility describes the internal validity of qualitative research which can be ensured by triangulation and negative case analysis [21]. As the researcher functions as a central part in the research process (i.e. data collection, coding, analysis, interpretation) some degree of bias is induced because of his personal perception which may lead to the problem of subjectivity [27, 28]. Therefore, qualitative research processes should be supplemented with standardized techniques to ensure a non-subjective evaluation and interpretation of qualitative data. Sarker et al. (2013) support this point of view by mentioning the strong "[…] need for clarity in the logic underlying data analysis […]" [29] in qualitative IS research.

3 Clustering Coded Qualitative Data

In qualitative research, scholars are interested in identifying behavioral or structural pattern to understand the studied phenomenon in the research context. For this purpose, the available heterogeneous qualitative data must be gathered and processed to structure the observed information. As mentioned in the last section, one central aspect of this systematic structuring process is the assignment of codes to specific information. While most of this processing is done manually in qualitative research, the machine learning (also referred as statistical learning) domain provides some techniques to predict and structure categorical information in an automated manner on the one side and offers approaches to scale up the coding process on the other side [30].

3.1 Foundations and Related Work

When predicting categories (i.e. discrete variables with nominal or ordinal scale) two different approaches can be distinguished due to the underlying structure of available data: (i) supervised learning describes techniques for classification of information based on labeled data. (ii) unsupervised learning techniques process unlabeled data to detect structure within the given information. Labeled data refers to a sample that has been tagged with labels and hence includes information about categories. Therefore, in supervised learning labeled training samples are used to train different classifiers (e.g. naïve bayes, support vector machines or decision trees) aiming to categorize information according to the training data. In contrast, unsupervised learning aims to detect information in form of clusters (e.g. k-means) or topics (e.g. latent dirichlet allocation) in unlabeled samples without any prior knowledge about categories. Figure 1 shows the difference between the two approaches of machine learning and gives some examples.

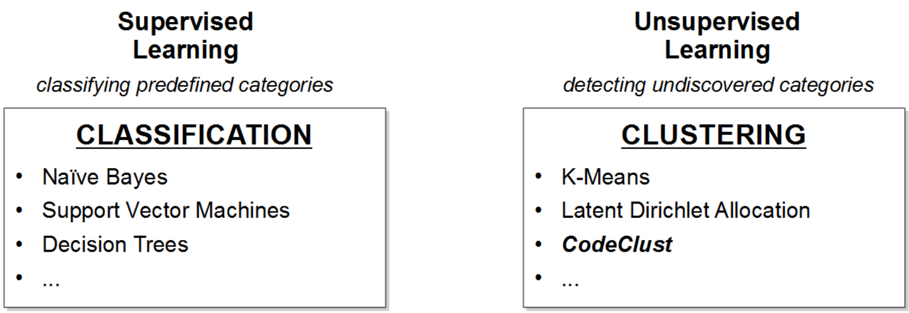

Figure 1. Unsupervised vs. Supervised Prediction of Categories.

As we aim to detect hidden information in qualitative data samples, this paper focuses on unsupervised learning in form of clustering. Clusters are defined as sets of objects (e.g. text documents) which are grouped based on similarities. Most prior work in this field has its origin in text mining, where documents are clustered based on the similarity of words to identify certain semantic topics [31, 32]. Besides emphasizing content representation, clustering is also used to identify dominant information in given samples [33].

The foundation of previous research is in general based on partitional clustering methods like K-Means [34] or graph-partitioning approaches [35] where an object belongs in exactly one cluster and the number of clusters is given in advance. Besides that, hierarchical clustering techniques are used where a set of nested clusters is built by successive merging or splitting [36, 37]. In general, hierarchical clustering strategies fall into two types: (i) the agglomerative or bottom up approach where clusters are merged on every hierarchy level and (ii) the divisive or top down approach in which splits are performed on every hierarchy level. Another approach is called topic modeling which decomposes information sources into topics and links the information sources to the identified topics based on certain probabilities. Latent dirichlet allocation introduced by Blei et al. (2003) is a common technique for topic modeling and is applicable in most textual based clustering scenarios [39, 40].

Most of the previous work has in common that the occurrence, frequency and/or combination of words are taken into consideration when building clusters. However, in qualitative research additional information in form of codes is available which can be considered in the clustering to detect hidden information. With this paper, we propose a clustering technique that grasps the relation of codes to each other.

3.2 Concept

Meeting the needs for an automated clustering technique based on the coded qualitative data, we develop a graph-partitioning approach called *CodeClust.* The presented technique is built upon existing clustering approaches and embraces the numerical structure of coded data which results from the assignment of text segments to codes (e.g. coding process in grounded theory and content analysis). The intention of the approach lies in clustering information sources and codes. As Marton (2013) points out, this is necessary because "[…] collected data needs to be grouped […] in order to form relevant corpora for comparison" [41]. Such additional information about groups serves as a basis and guidance for detailed interpretation and supports the analysis of subgroups [16, 42].

In our scenario, we assume that these similarities are based on information sources (e.g. interview transcripts) expressing the same ideas and therefore standing in relation to each other. For example, groups of experts can be identified in interviews which are considered to be similar relating to their statements. As *CodeClust* is a partitional clustering each object is assigned to one cluster.

The provided graph-theoretic approach has originally been developed to simplify the complexity of staff scheduling problems in the OR discipline [43]. We adopt our method from this domain and adapt it to analyze qualitative data to cluster affiliated information sources in groups with regard to their coding. Before describing the approach table 1 defines the used mathematical notations.

Table 1. Mathematical Notations and Definition

Notation	Definition
n	Total number of information sources
m	Total number of codes
i	Index of information sources, $i \in \{1, \ldots, n\}$
V	Set of nodes within a graph, with $\|V\|$ being the total number of nodes
E	Set of edges between nodes of V within a graph
c	Index of codes, $c \in \{1, \ldots, m\}$
f_{ci}	Code-frequency of code c within information source i, $f_{ci} \in \mathbb{N}_0$
b_{ci}	Binary value for a code being coded above average within i

In a first step, the coded qualitative data must be represented as a graph to use the technique. Therefore, the codes c are represented as nodes V in a graph $G = (V, E)$. The total number of nodes $|V|$ is m, representing the total number of codes given in the data set. E represents a set of edges between nodes c and c' of V. An edge between two nodes exists, if both codes represented by the nodes are coded above average within at least one information source. This is modeled with the binary value b_{ci} that takes the following two states:

$$b_{ci} = \begin{cases} 1, if\ f_{ci} > \left[\frac{1}{|V|}\sum_{c'=1}^{|V|} f_{c'i}\right] \\ 0, otherwise \end{cases}$$

These binary values b_{ci} determine the graph, which serves as a basis for the partitioning technique. In addition, each edge of the graph contains a weight $g_{cc'}$ that stands for the number of information sources in which the two codes c and c' are coded above average:

$$g_{cc'} = \sum_{i=1}^{n} b_{ci}\, b_{c'i}$$

The graph partitioning problem is solved with integer linear programming (ILP) to identify two disjunctive sets of nodes $G_1 = (V_1, E_1)$ and $G_2 = (V_2, E_2)$. For the ILP two binary auxiliary variables are introduced:

$$z_c = \begin{cases} 1, if\ the\ first\ set\ of\ nodes\ contains\ c \\ 0, otherwise \end{cases}$$

$$y_{cc'} = \begin{cases} 1, if\ an\ edge\ between\ c\ and\ c'\ leads\ from\ one\ subgraph\ to\ the\ other \\ 0, otherwise \end{cases}$$

The partitioning aims to minimize the weights of edges which lead from subgraph G_1 to G_2. To solve this minimization problem, the objective function is formulated under four constraints:

$$\min \sum_{(c,c')\in E} g_{cc'}\, y_{cc'}$$

$$(1) \qquad z_c - z_{c'} - y_{cc'} \leq 0 \qquad \forall (c,c') \in E$$

$$(2) \qquad z_{c'} - z_c - y_{cc'} \leq 0 \qquad \forall (c,c') \in E$$

$$(3) \qquad \sum_{c\,\in\,V} z_c \geq \frac{|V|}{4}$$

$$(4) \qquad \sum_{c\,\in\,V} z_c \leq \frac{3|V|}{4}$$

Constraints 1 and 2 ensure that the weights of edges are considered in the objective function if the particular edge leads from one subgraph into the other. E.g. the first and second constraint forces $y_{cc'}$ to be 1 when c and c' are nodes of different subsets (e.g. $z_c = 1$; $z_{c'} = 0$). Hence the weight of the related edge between c and c' $g_{cc'}$ is considered in the objective function. In the approach, the constraints 3 and 4 are used to prevent the clusters from becoming very small or vice versa very large. With the actual setting, it is ensured that a cluster contains at least the fourth part of the total amount of nodes. These boundaries can be set according to the individual preferences on the minimum cluster size.

In figure 2, an example is given which shows a graph G holding six nodes with different weights on edges between the nodes. After solving the ILP for the given example two subgraphs $G_1$and G_2 could be identified where two edges with a weight of 1 are leading from subgraph G_1 to the subgraph G_2 and vice versa. In the example the minimal solution of the objective function results in $g_{2\,3} + g_{1\,5} = 2$.

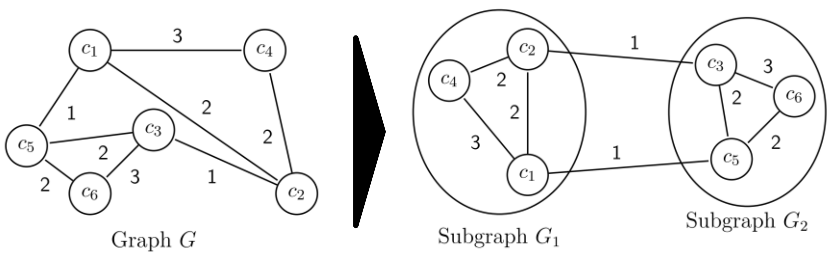

Figure 2. Example of Graph Partitioning

As shown in Achatz (1999) the technique can also be performed multiple times on large datasets to generate more than two subgraphs [43]. As multiple iterations can be performed by using the output from one iteration as input for the next one, large qualitative data samples can be analyzed with the approach in an automated manner. In settings where a code is not mentioned above average, one can either (i) exclude the code from the partitioning, (ii) assign code to smaller partition or (iii) assign code to larger partition. In scenarios where every node must be assigned to a cluster option (ii) or (iii) would be applied. However, in terms of clustering codes, we recommend using the first option. The specific code is excluded from the partitioning. This does not mean that the code should be excluded from further analysis. The information from the general coding can still be valuable for later interpretation.
As in each iteration the sample is only split into two clusters, the appropriate amount of clusters can be determined with existing measures like the elbow curve method [44] or a silhouette analysis [45]. In the first method the percentage of variance explained is used to find the appropriate number of clusters. The second method provides a graphical representation in form of silhouettes and measures how well an object fits to its cluster compared to other clusters. Identifying the correct number of clusters, however, is not a trivial task and there exists a multitude of cluster quality indicators (e.g. [46, 47]).

Regarding the behavior of the approach in higher orders of magnitude, there does not exist a high sensitivity to the number of observations. However, larger sample sizes will increase the runtime to solve the formulated partitioning problem with ILP.

3.3 Interpretation

The results from the clustering technique help to answer the question which set of information sources mention which specific codes. Hence, groups can be identified that include information sources based on the similarity of their coding. The clustering serves as an additional insight and makes it possible to identify structure in form of dependencies between information sources and codes. By just considering the codes, which are mentioned above average within the information source, the method uses the code-frequency for clustering. Therefore, it is assumed that information sources that mention the same codes above average are related to each other. This relation results from the fact that the information sources contain similar content regarding the research objective. E.g. if the information sources are interviews one can build groups of experts based on the similarity of their content-related statements. As a result, it can be identified which group of experts emphasizes which codes. Combining this with additional information about experts one can generate specific insights regarding the meaning and affiliation of identified codes.

4 Application to Field Data

The approach has been used on data from interviews with entrepreneurship experts to identify success indicators for IT-start-ups [48]. Besides entrepreneurs and investors, business angels were chosen as experts to generate a holistic view on the topic. In total eleven interview transcripts were coded on the basis of the methodology proposed from Steigleder (2008) [49]. The theory orientated content coding technique results in 22 codes. Each code represents a separate success indicator in the domain. The data set in table 2 represents the results of the coding process of textual data from the interviews.

Table 2. Data Set of Coded Qualitative Data from Interviews

			Interview i										
	c	Success Indicator	1	2	3	4	5	6	7	8	9	10	11
Code c	1	Sales competence and marketing power	2	3	5	2	0	2	1	2	3	0	1
	2	Perseverance	0	0	0	1	2	2	1	1	0	0	0
	3	Value orientated thinking	4	1	0	0	2	2	0	0	0	0	0
	4	Entrepreneurship and professional experience	2	1	1	2	2	2	2	2	0	0	2
	5	Industry specific competence	2	0	3	3	1	0	1	3	1	0	0
	6	ICT competence	1	2	0	2	1	1	1	4	2	0	0
	7	Conversion capability and speed	3	0	2	1	0	0	0	0	1	0	2
	8	Staff management skills	2	1	0	1	1	0	0	0	1	0	3
	9	Scalability and market ability	2	2	0	1	0	2	3	1	3	0	0
	10	Proof of feasibility and verification	0	0	1	0	1	4	0	1	0	2	0
	11	Business model flexibility and independence	2	3	0	0	2	0	0	2	1	1	2
	12	Team composition	1	1	1	2	2	0	0	2	2	3	0
	13	Industry specific financing	1	0	1	7	0	1	1	6	0	2	0
	14	Accelerator or incubator program	0	0	7	0	0	0	0	0	1	2	0
	15	R&D cooperations	0	0	0	3	1	4	2	2	0	0	1
	16	Seed-customer and technology partner	1	5	0	0	5	1	1	2	1	0	1
	17	Handling of market conditions	0	7	0	1	4	1	4	5	1	0	0
	18	Political and regulatory business environment	0	1	0	3	5	0	0	2	3	0	1
	19	Industry specific norms and requirements	0	4	0	3	3	0	1	2	3	0	0
	20	Customer orientated problem solving	0	1	3	1	3	3	0	2	2	2	1
	21	Feedback driven product development	0	2	1	0	3	0	0	5	3	1	1
	22	Prototype orientated product development	1	0	0	2	7	0	1	1	1	2	1

The values given in the matrix stand for the code-frequency of a particular code in an information source (f_{ci}). E.g. code *c=1* is coded two times in interview *i=1* which results in f_{11} equals 2. The variable b_{ci} is a binary value which equals 1 if a code *c* is coded above average in an information source *i*. If this is not the case, b_{ci} is set to 0.

Before performing the approach, the graph must be generated based on the values of b_{ci}. An edge between two nodes (i.e. codes) *c* and *c'* exists, if for at least one information source i the multiplication of b_{ic} and $b_{ic'}$ equals 1. The number of information sources i for which this is true represents the weight $g_{cc'}$ of a particular edge between the nodes *c* and *c'*. As represented in figure 3 on the next page the three codes (*c*=10; *c*=15; *c*=20) are mentioned above average in the sixth interview (i=6) which results in $b_{10\,6} = b_{15\,6} = b_{20\,6} = 1$. Besides that, information sources 6 and 10 mention the codes 10 and 20 above average. Therefore, the weight of $g_{20\,10}$ equals 2.

In figure 3 the input and the output of the approach is visualized. The matrix on the left side shows an unsorted data set of binary values b_{ci} based on the qualitative data given in table 2. This represents the graph which serves as an input for the presented approach. The matrix on the right side in figure 3 represents the data set sorted into two groups based on the graph partitioning. The first group contains the sources 1, 3, 6 and 10 as well as the codes 20, 12, 10, 14 and 3. The second group is determined by the rest of sources and codes, while code 2 is an artefact that cannot be assigned to any group because it is not mentioned above average in any information source. One can see that no source of the second group mentions a code of the first group above average, which means that each code of the first group is uniquely assigned to it.

Group 1 Group 2

Figure 3. Results Generated by the Clustering Technique

Using the approach, we identified that in the first group experts are clustered which have a strong relation to phases at the beginning of the start-up life cycle. In this group is one business angel supporting start-ups in the seed and start-up phase and the rest of experts are entrepreneurs standing at the beginning of their ventures. This observation is accompanied with the fact that the codes of the first group represent success indicators which are important when founding and developing the firm. E.g. *team composition* (c=12) and *accelerator or incubator program* (c=14) are aspects entrepreneurs must deal with at the very start of a venture.

In contrast, experts in the second cluster handle start-up firms in the growth and expansion phase (e.g. investors, advanced founders). Looking at the codes it becomes evident that the success indicators *handling of market conditions* (c=17) and *political and regulatory business environment* (c=18) are related to advanced phases in the start-up lifecycle as well. Additionally, no expert of group two is mentioning success indicators of group one above average. In contrast, some experts of group one do mention codes of group two. This shows that no expert in group two (i.e. expert related to advanced start-up life cycle phases) emphasizes the success indicators of early start-up phases because they seem to be less relevant. Experts in group one (i.e. experts related to early start-up life cycle phases) consider the future by focusing not only on success indicators for the beginning of a venture but also on success indicators of advanced phases of the start-up lifecycle.

While choosing start-up stakeholders as experts we did not focus on their affiliation regarding different start-up lifecycle phases. With performing the clustering, we are able to detect hidden structure in form of subgroups which generates valuable findings concerning the affiliation of success indicators to lifecycle phases.

5 Limitations and Future Research

As shown in the example the approach provides valuable results and assists in the detection of hidden structure in qualitative data samples. However, the technique is subject to some limitations.

First, it is depending on the underlying data. This means, that the results generated can only be as good as the quality of the gathered qualitative data. Therefore, the clustering should only be performed on top of a robust data collection and coding process.

Second, although it is transparent how clusters are generated, the findings might still be biased by a subjectivity in data pre-processing steps and by a wrong interpretation of clustering results. Therefore, it is important to mention that the clustering results offer guidance for interpretation and subgroup analysis but should not be applied as strict decision guidelines.

Third, like other techniques analyzing qualitative data, the approach provides an indication for the affiliation of codes with regard to the underlying research subject. In contrast to "[…] statistical methods which require representative data, cluster analysis does not find generalizable characteristics" [12]. Hence, it is suitable for qualitative research which aims to understand complex phenomena regarding a specific topic of interest.

Fourth, although the used code-frequency is a suitable measure to create the graph of codes it can make sense to include other aspects like the context a code is related to or actual speech such as laughter. Hence, the frequency measure could be enhanced or replaced with other subject related aspects.

Fifth, like in other clustering techniques, it has to be considered that there may be settings where the clustering does not result in interpretable results. This is indicated by a high value for the objective function related to the sum of all weights of edges. In this case, there exist outliers which indicate an unstable clustering. Therefore, we recommend combining multiple manual and automated clustering techniques to confirm accuracy of generated cluster solutions.

Regarding the limitations, future research should investigate how the approach can be combined with already existing qualitative data analysis techniques. Especially the possibilities for complementation should be considered to validate findings on the one side and supplement them on the other. In addition, the behavior of the presented approach could be studied in more detail. E.g. the clustering technique can be tested with a variation of the underlying data. With this the behavior of the partitioning

procedure can be evaluated with focus on the robustness of the clustering. Furthermore, we intentionally applied a small data example to introduce the approach in a simple and understanding manner. Although the clustering delivers stable results for larger data samples in its original discipline [43], further research should investigate the behavior with different dimensions of volume. A benchmark of the approach against other techniques can be based on agreement measures like the Cohen's kappa [50, 51]. In a next step, the technique could also be compared to traditional connectivity-based clustering techniques like hierarchical clustering. As distance metric the proposed $g_{cc'}$ will be considered to identify similarity of codes.
In addition, the approach is not only suitable in qualitative research scenarios but should also be considered in the domain of business analytics. Although in these scenarios the data modeling might be different, the problem formulation remains the same.

6 Conclusion

We introduced a machine learning approach to detect hidden information and structure in qualitative data samples. Therefore, we used a clustering technique based on a graph theory to group information sources based on the similarity of codes. With the approach, we map the coded data to a graph and formulate a graph partitioning problem which is solved with ILP. As a result, the technique separates the graph into different clusters based on the similarities given in the coded data. The technique is designed to be used on textual qualitative data which results from any kind of qualitative coding process. Hence, the approach can be performed independently of the underlying methodology and does not replace any existing procedures but complements them.

Until now interpretation of qualitative data mostly relies on the system of codes, their assigned textual passages and different frequency measures. Most clustering in this context is performed manually or semi-automated which is contradictory to the essential quality criteria of intersubjective traceability [22, 29]. Hence, with the presented automated approach we present a new data modeling and clustering technique which adds to the existing repertoire of qualitative data analysis methods in IS. Although the data pre-processing (i.e. data collection, transcription and coding process) might still be biased by subjectivity, the approach could increase the reliability of qualitative research approaches regarding interpretation. However, the clustering should guide and support the researcher in context informed interpretation and code relationship analysis but should not be used in form of decision rules to split qualitative data sets.
Referring to Sarker et al. (2012) about 60% of qualitative studies in the IS discipline use coding procedures to analyze empirical data [1]. Because of this, our approach could address and complement many existing and future qualitative studies in the IS domain in terms of applying a mixed methods approach to answer research questions. Especially when dealing with large volumes of empirical data, the potential of the clustering could be exploited.

Abstract. Online auctions are a viable alternative to conventional posted price mechanisms. Agrawal, Wang, and Ye [1] have proposed two primal-dual algorithms for revenue-maximizing multi-item allocation tasks. Although promising in terms of theoretical properties and competitive ratios, there is a lack of evidence regarding the real-world practicability of these mechanisms, for instance referring to online auction-based tickets sales. In this paper, we conduct an experimental study on both the *One-Time Learning Algorithm* (OLA) and the *Dynamic Learning Algorithm* (DLA) based on synthetic data, revealing the remarkable aptitude of the latter for non-trivial online auctions. Being robust to most input variations, the inherent dynamic update of dual thresholds achieves a superior balance with respect to the trade-off between objective function values and runtimes. We address critical sensitivities quantitatively and draft several small extensions by incorporating input distribution knowledge.

Keywords: Online Auctions, Online Ticket Sales, Experimental Study

1 Introduction

Online auctions and auction-type mechanisms become increasingly popular for revenue-maximizing allocations of scarce resources. While display ad auctions and sponsored search are always based on bidders revealing their willingness-to-pay prior to the actual allocation, many B2C business models still rely on conventional posted prices. For instance, ticket sales for cultural events or sports competitions are often conducted with a fixed-price policy, occasionally replaced by concepts of revenue management or dynamic pricing. In this case, however, sellers have little knowledge on the willingness-to-pay or consumer surplus of the bidders, potentially preventing higher revenues. In contrast, auction-type allocations in an online fashion can enable a better absorption of buying power and hence a more efficient allocation. Recently, in the aviation or hotel industry it can be observed that companies experiment with their established pricing models by gradually substituting conventional posted price

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

mechanisms with online open auctions. Such auctions might also be of particular interest for ticket sales in order to reduce black market activity. Aside from the online arrival of bidders, however, ticket allocation problems often exhibit additional complexity as a result of excess demand, heterogeneous willingness-to-pay and short processing times, calling for performant and fast decision-making algorithms.

We examine a notable contribution by [1] in the context of online resource allocation. Based on a primal-dual approach, the authors state theoretical properties and postulate a broad applicability of their two algorithms vis-a-vis auction-type allocations. As with many primal-dual frameworks, however, little is known about the implementation, real-world feasibility or practical challenges of these mechanisms.

This paper seeks to examine this gap between theory and practicability by assessing the empirical applicability of both the *One-Time Learning Algorithm* (OLA), which calculates a single set of dual threshold prices, and the *Dynamic Learning Algorithm* (DLA), which continuously updates dual prices at geometric time intervals. Optimizing the revenue against a stationary bidding process, we perform numerical experiments on both algorithms based on synthetic data and compare the runtimes and objective values to three benchmarks. Furthermore, we examine reasonable parameter combinations and investigate the algorithms' sensitivity with respect to their input parameters. We find a strong trade-off between outcome quality and runtime, whereas the DLA produces superior outputs while maintaining moderate runtimes for almost all cases. Our experiments provide evidence that the DLA is especially suited for complex allocation tasks with resource scarcity, heterogeneous bidders and limited ex-ante knowledge. Moreover, addressing the most critical sensitivity, we suggest several extensions utilizing priorly known input distribution information and thus improving the practical applicability for online auctions.

The remainder of this paper is structured as follows. Section 2 begins by reviewing recent contributions in the online resource allocation literature. We also explain the algorithms of [1] in more detail. We present our implementation and experimental design in section 3.1. Section 3.2 provides the experimental observations and states key results. We discuss our findings with respect to extensions and put emphasis on enhancing the practicability. Section 4 concludes and suggests further research.

2 Review of Literature and Research

Optimizing the allocation of given resources with respect to revenue or social welfare is a core element of a variety of scientific contributions. A popular approach is to actively control the availability of resources, often referred to as revenue management [16]. Closely related is the concept of dynamic pricing, in particular dynamically adjusting posted prices for the purpose of revenue maximization. Comprehensive literature overviews for value-based pricing techniques are, for instance, provided by [12] or [16]. Although these concepts ultimately aim at exploiting differences in customer willingness-to-pay, one key drawback of such techniques is the failure to explicitly record willingness-to-pay and hereby enhance the producer surplus.

Another domain of resource allocation is auction theory. While other objectives such as efficiency or states of equilibria can certainly exist, revenue maximizations might also be pursued through auctions. Since bidders reveal their true willingness-to-pay in incentive-compatible mechanisms, sellers might be able to absorb a larger proportion of the consumer surplus, thus increasing revenue. Traditional auction theory usually refers to a single point in time with comprehensive knowledge of demand and supply. However, an increasing number of digital markets are dynamic, meaning that bidders reveal their willingness-to-pay sequentially, requiring an immediate allocation decision by the auctioneer. The growing field of online auctions focuses – amongst others – on the algorithmic design for this class of problems. Examples include, for instance, [2], [14], and [17]. [13] specifically address the case of online ticket sales and design a fully stochastic and dynamic algorithm in order to compute an optimal online auction mechanism. [9] demonstrate that posted price mechanisms can indeed match competitive ratios of combinatorial auction principles, provided that stochastic information of the bidders' valuations is available.

Among a variety of algorithmic frameworks, one popular approach for online allocations is the utilization of dual threshold prices. Reasons for this include, for instance, a wide field of application, simple interpretability as well as the ease of implementation. In essence, this concept makes use of shadow prices of an ex-ante linear program as weights for subsequent decision-making. An incoming request can thus only be accepted if the weighted resource consumption is exceeded by the communicated willingness-to-pay. For instance, [8] investigate the AdWords problem within a similar framework as [1]. Under a random permutation assumption with known number of bidders and a specific right-hand side condition, they retrieve a $(1-\varepsilon)$-competitive algorithm. In a similar manner, but assuming an i.i.d. input with unknown and changing distributions, [7] develops dual-based resource allocation algorithms for stochastic AdWords problems. In a series of interrelated contributions, [3-5] use primal-dual approaches to match and prove several competitive ratios for various kinds of online problems, for example ad-auctions. Other examples using dual approaches include [10-11] for display ads or [6] in a Bayesian auction setting.

However, some contributions, for example those relating to the AdWords problem, do not permit multidimensional demand vectors, in particular the possibility to request several resources simultaneously, and are thus not directly applicable to ticket sales or similar B2C businesses. In contrast, the algorithms proposed by [1] explicitly refer to classical multi-item revenue maximization problems. The authors also demonstrate a superiority with respect to the theoretical competitive ratios compared to related online auction frameworks.

In order to allocate resources in an online auction fashion [1] use online linear programming, where the constraint matrix and corresponding objective function coefficients are revealed column by column over time. The linear program is calculated based on the input received so far and without any information about future requests. However, all subsequent decisions are based on this solution. More precisely, consider the following linear program:

$$\begin{aligned} &\text{maximize } \textstyle\sum_{j=1}^{n} \pi_j x_j \\ &\text{subject to } \textstyle\sum_{j=1}^{n} a_{ij} x_j \leq b_i \qquad && i = 1, \dots, m \qquad (1) \\ &x_j \in [0,1] && j = 1, \dots, n, \end{aligned}$$

where m denotes the number of capacity constraints and n represents the number of columns. While a_{ij} stands for the requested items by bidder j regarding resource i with capacity b_i, the term π_j denotes the willingness-to-pay for the total package. In an online auction the coefficients $(\pi_j, \boldsymbol{a_j})$ are revealed consecutively over time. The contribution of [1] is to compute the dual solution of a partial linear program and use it as a decision rule for future incoming bidders. The key idea is to set threshold prices $\boldsymbol{p} = (p_i)_{i=1,..,m}$ for each resource i equal to the dual prices of a linear program that is solved after a fraction of $\varepsilon \in (0,1)$ columns are revealed. Subsequent incoming bids $(\pi_j, \boldsymbol{a_j})$ will be compared to the current threshold prices $\boldsymbol{p}$. A bid will only be accepted if π_j exceeds $\boldsymbol{p^T a_j}$ and if no resource constraint is violated, meaning the problem remains feasible with $x_j = 1$.

OLA:	DLA:	(2)
maximize $\sum_{j=1}^{s} \pi_j x_j$	maximize $\sum_{j=1}^{l} \pi_j x_j$	
s.t. $\sum_{j=1}^{s} a_{ij} x_j \leq (1-\varepsilon)\frac{s}{n} b_i$	s.t. $\sum_{j=1}^{l} a_{ij} x_j \leq (1-h_l)\frac{l}{n} b_i$	$i = 1, \dots, m$
$x_j \in [0,1]$	$x_j \in [0,1]$	$j = 1, \dots, s$

[1] present two algorithms: the so called *One-Time Learning Algorithm* (OLA) and the *Dynamic Learning Algorithm* (DLA). The respective partial linear programs for retrieving the sets of dual prices are denoted above. The OLA learns a single threshold price vector at time $s = \varepsilon n$, applicable to all following bids. All incoming requests until s are only used to calculate the threshold prices and will always be rejected. Assuming that n is known and $(\pi_j, \boldsymbol{a_j})$ arrive in random order, [1] show that the OLA exhibits $(1 - 6\varepsilon)$-competitiveness against the ex-post optimum (OPT) under the right-hand side condition $B = \min_i b_i \geq \frac{6m\log(n/\varepsilon)}{\varepsilon^3}$.

The DLA updates dual prices in geometric intervals at $\varepsilon n, 2\varepsilon n, 4\varepsilon n, 8\varepsilon n, \dots$, in particular for each $l = \lceil 2^r \varepsilon n \rceil$ with the largest integer r such that $l < j$. The right-hand side of the partial linear programs is modified by a factor $h_l = \varepsilon\sqrt{\frac{n}{l}}$. The DLA is $1 - O(\varepsilon)$ competitive given a milder condition $B = \min_i b_i \geq \frac{m\log(n/\varepsilon)}{\varepsilon^2}$.

Note that both algorithms are distribution-free. However, [1] need ex-ante knowledge about the size of n in order to calculate the learning fractions of the respective algorithm. Furthermore, [1] assume that the bids $(\pi_j, \boldsymbol{a_j})$ arrive in random order. The latter assumption seems reasonable from a practical perspective, as the order of columns usually appears to be independent of the columns' content.

3 Experimental Analysis

3.1 Experimental Design

The main contribution of [1] is the introduction and (theoretical) analysis of these two algorithms for solving online allocation problems. However, they do not feature any specific implementation or application. This paper intends to examine the implied allocation mechanism from a practical perspective and to analyze sensitivities.

For this purpose, the algorithms are implemented and systematically tested in numerical experiments. In particular, all input parameters are varied in an orderly fashion to isolate important influencing factors on the algorithms' outcome and runtime. The treatment variables include the number of resources m, resource capacities b, initial learning fraction ε as well as number of bidders n. Moreover, building on the distribution-free property of the algorithms, we examine the robustness with respect to different stationary input distributions or distribution parameters regarding the willingness-to-pay π_j and the item requests a_{ij}.

Table 1. Parameters and Treatment Variables

	Description	*Values and Distributions*
Parameters	Simulations per Configuration	10
	Permutations per Simulation	100
	$\max(a_{ij})$	5
	a_{1j}, a_{2j}, a_{3j}	$N(0.4, 0.3), N(0.5, 0.6), N(0.6, 0.9)$
	$\pi_{1j}, \pi_{2j}, \pi_{3j}$	$N(100, 30), N(75, 20), N(50, 10)$
Treatment Variables	Resources m	$\{1; 2; \mathbf{3}; 5; 10\}$
	Capacity b	$\{50; 100; \mathbf{200}; 300; 400; 500; 600; 700; 800; 900; 1{,}000\}$
	Fraction ε	$\{0.001; \mathbf{0.01}; 0.02; 0.03; 0.04; 0.05; 0.075; 0.1; 0.125; 0.15; 0.2; 0.25\}$
	Bidders n	$\{200; 400; 600; 800; \mathbf{1{,}000}; 1{,}200; 1{,}400; 1{,}600; 1{,}800; 2{,}000; 5{,}000; 10{,}000\}$

The treatments are analyzed with respect to runtimes as well as objective function values, i.e. the revenue generated from the allocation in percent of the ex-post optimum. We define a baseline treatment which serves as a reference point for the subsequent ceteris paribus variation of treatment variables. The values and ranges for each parameter and variable are summarized in Table 1. The respective baseline configuration ($m = 3$, $b = 200$, $\varepsilon = 0.01$, $n = 1{,}000$) is highlighted in bold characters. All resources are assumed to have an identical capacity $b_i = b$. The parameter a_{ij} is required to be an integer value between zero and a pre-specified upper limit. In order to map distinct resource classes, the parameter a_{ij} follows a normal distribution with stepwise mean-variance-tuples. Similarly, the willingness-to-pay decrease over the different resources and are summed up to an aggregate π_j. Every bidder j is obligated to request at least one item.

Each treatment variable is considered in an isolated fashion. Under the ceteris paribus assumption, each input parameter is varied according to Table 1 using the baseline configuration as a starting point. Hence, our experimental design comprises 40 treatment combinations. For each configuration, 10 instances are created. Since [1] consider expected values over all permutations, each instance consists of 100 sub-instances, representing different permutations of the set of bidders.

Regarding the runtime evaluation, it should be noted that single permutations might be subject to noise distorting the measured runtimes. However, since averages are taken over a multitude of permutations, valid statements on general trends are ensured. Furthermore, we only intend to examine diverging runtime magnitudes and to identify common patterns. In order to explicitly exclude the possibility of invalid runtimes, we checked the results against larger problem instances. Essentially, we scaled the test configurations up by a factor of 100 (e.g. $b = 20{,}000$, $n = 100{,}000$ with 10 permutations and 5 simulations as the baseline treatment) and computed the respective ratios of runtimes. These ratios also took values of the up-scaling factor of 100, which we found to be consistent with our previous runtime analysis. Absolute runtimes should, however, always be handled with care according to [15].

In order to evaluate the objective function values and runtimes of both the OLA and the DLA, several simple benchmarks have been implemented as alternative measures. The most simplistic mechanism would be to accept any incoming request, as long as no constraint is violated. This quick and easy allocation principle is referred to as *Greedy Algorithm* in our context. In contrast, a so-called *Interval Learner* updates dual prices at constant 10%-intervals with respect to the ex-ante known number of incoming bids n. This benchmark is expected to always exhibit longer runtimes. The last benchmark, the *Willingness-To-Pay (WTP) Learner,* is based on the idea that it might be reasonable to update dual prices whenever the average over all bids per item changes by a certain magnitude, in our case by at least 5% in absolute terms. That is, if the pool of bidders appears to become more heterogeneous, different threshold prices might be deemed appropriate, calling for a re-calibration of dual prices. A fraction of 10% of the bids is used to calculate the initial dual prices.

The simulations were implemented in Python 3.6. Linear programs were solved using the interface to Gurobi 8.0. All simulations were performed on an Intel Core i7 7700K 4.20GHz quad-core machine with 32 GB of RAM.

3.2 Results

Starting with the baseline treatment, the well-known trade-off between approximation capabilities regarding the OPT and average runtimes already becomes visible. The numerical results indicate that the DLA excels in terms of the objective function (93.68% of the OPT). Evidently, the frequent update of dual prices incorporated into the DLA generates considerably better objective function values as opposed to the simpler OLA (69.42%), at least given the input parameters at hand. Furthermore, in spite of several updating steps of dual prices, the DLA certainly seems to be able to balance objective function output and runtime ($126.47ms$; OLA: $8.36ms$) reasonably. In contrast, while the *Greedy Algorithm* ($80.27\%; 1.53ms$) and the *WTP Learner* ($86.25\%; 97.31ms$) are executed faster, they cannot provide comparable approximations of the OPT due to their naivety. Likewise, the *Interval Learner* may come closer to the DLA vis-à-vis the objective (88.96%), but requires significantly more runtime ($405.35ms$). The OLA only proves to be competitive for large problem instances. Most notably, its approximation ratio increases to 95.16% in the up-scaled control scenario, potentially because the number of bids εn used for learning the dual prices is bigger in absolute terms. Therefore, the calibrated thresholds might be more valid than in the small-scale case.

Result 1. *The DLA provides a superior balance between objective function values and average runtimes. While several re-calibrations of dual thresholds enable good approximations of the ex-post optimum, the geometric updating intervals shift the majority of computational intensity toward small-scale optimization problems.*

Under the ceteris paribus condition, a variation of the total number of resources m, each having a capacity of 200 units, does not significantly affect the approximation performance of either the OLA or the DLA, as can be seen in Table 2. Employing a very little or a very large number of resources does not deteriorate the outcome substantially, potentially since each added resource inevitably comes along with new demand, as guaranteed by the simulation specifics. The performance of the *Greedy Algorithm*, however, constantly drops with an increasing number of resources. Table 2 also reports linear regression slope coefficients and adjusted R^2 figures for the objective function and the runtime. Regarding these coefficients, note that the dependent variables are denoted in percent and milliseconds (ms), respectively. Moreover, a significance level of 1% is chosen. The negative linear objective function sensitivity of the *Greedy Algorithm* may be ascribed to growing heterogeneity among bidders as a result of more resources and hence more scope of simulation. Since more deliberate decisions are necessary for a diverse pool of bidders, the naïve *Greedy Algorithm* cannot sustain its approximation ratio. The runtimes for almost all mechanisms increase significantly and in a linear fashion once new resources are added.

Because an increase in the number of resources goes hand in hand with newly generated demand, resource scarcity or abundance can better be reflected by changing the available capacities b. As displayed in Table 3, the *Greedy Algorithm*, the DLA, and the OLA ultimately converge to the OPT in terms of the objective function value when resources are excessively available. In particular, a 100%-approximation of the *Greedy Algorithm* indicates that all incoming bidders can be served. In this case, shadow prices may be close to zero and the other mechanisms exhibit a gap to the OPT mainly due to the initial calibration period, where all requests are rejected. When resources are scarce, however, the algorithms show significant discrepancies. As items need to be assigned with consideration, simple allocation mechanisms, as implied by the OLA or the *Greedy Algorithm*, produce below average results. The OLA, however, exhibits the steepest linear growth with increasing resource capacity. In contrast, the DLA already performs very well for limited availabilities. It also exhibits a slightly quadratic relationship, i.e. performing a quadratic regression increases the $\bar{R}^2$ from 86.45% in the linear case to 96.49% with the quadratic regression coefficient being statistically significant at the 1% level. That is, the DLA dominates all other benchmarks as long as resources are exposed to scarcity to some extent. It also exceeds the *WTP Learner* and the *Interval Learner*, where the first 10% of the bidders will always be rejected. Changing b does not significantly affect the average runtimes aside from the OLA and the *Greedy Algorithm*. That is, if more resource capacities are available, more bidders can be served, leading to a consistent upward trend in runtime, albeit on a small level. For the other mechanisms, this effect does not become visible, as it is only a tiny proportion of the total runtime.

The fraction ε represents an interesting lever for training-based algorithms, determining the number of bids initially required for calibrating the thresholds. As can be seen in Table 4, the three benchmarks exhibit zero sensitivity, as they do not make use of this parameter. In terms of the objective function value, the DLA shows the greatest dependence with respect to ε. Generally speaking, the smaller this fraction is chosen, the more learning instances are executed by the algorithm, enabling a better approximation of the OPT. For large ε, the OLA produces better results than the dynamic mechanism, indicating that the DLA is considerably restricted by the modifying right-hand side factor postulated by [1], artificially increasing the dual prices at each re-calibration for too large fractions. At the same time, unlike the DLA exhibiting a linearly decreasing behavior, the OLA produces its best results for a medium $\varepsilon = 0.05$. Since it only learns dual prices at a single time, a very small fraction of the sample will not be representative enough and thus result in a poor or incalculable performance. Therefore, in order to produce a proper outcome, a certain minimum share of bids needs to constitute the training set. The OLA thus exhibits a significant quadratic relationship with an $\bar{R}^2$ of 85.69%. Furthermore, the tests reveal linearly increasing OLA runtimes, since the single optimization problems will encompass more elements with increasing ε. As evident from the numerical results, the shape of the DLA runtime function is rather serrated. Holding the total number of required optimization steps constant, the runtime would increase with growing ε for the same reasons as the OLA. However, once ε exceeds some threshold, one former optimization step is not feasible anymore, thereby reducing the total number of dual price updates and significantly decreasing the average runtime.

Table 2. Numerical Results for Treatment Variable m

Resources m	*1*	*2*	*3*	*5*	*10*	β	$\bar{R}^2$
DLA	91.06%	93.64%	93.77%	92.49%	88.69%	-	-
	118.20ms	165.96ms	209.76ms	291.21ms	503.05ms	42.43	99.96%
OLA	70.21%	71.20%	69.24%	69.27%	65.08%	-	-

Changing the number of stationary bidders n competing for the fixed resource capacities, the DLA once again proves to be robust. This can be seen in Table 5. While it becomes increasingly difficult to select the ex-post optimal requests from a larger set of bidders, the drop in performance is not as significant as with other benchmarks. The *Greedy Algorithm*, for instance, cannot maintain its approximation ratio. The *WTP Learner* and the *Interval Learner* remain robust to a certain extent, yet never reaching the performance of the DLA. The OLA, in turn, is more sensitive towards changes in n. With a growing number of requests, a single learning step is not sufficient due to the multitude of bidders arriving subsequent to the calibration. The average runtimes of all algorithms naturally increase with problem size. The functional relationship concerning the runtimes is linear for all mechanisms.

We validated the observations of these ceteris paribus analyses with a multivariate parameter grid and were not able to detect major deviations. The results above might, however, also be contingent upon the distribution assumptions. In general, there are six levers to be tested with respect to the stationary input processes: mean and standard deviation of the willingness-to-pay π_j and of the requests a_{ij}, given a normality assumption, as well as the underlying distributions of the simulated parameters themselves. As pointed out by [1], the DLA stands out due to its distribution-free property and thus robustness to all tuning parameters. Conversely, the *Greedy Algorithm* benefits from homogeneous pools of bidders, exhibiting major improvements for decreasing standard deviations of π_j. It is also most sensitive to changes of the underlying distributions of π_j and a_{ij}. The normality assumption appears to be most suitable for achieving little runtimes. If the distribution parameters fluctuate within a simulation run, the DLAs performance deteriorates, yet is still competitive to the benchmarks.

Result 2. *The DLA proves to be robust regarding changes of most input parameters. Its capability to produce near-optimal objective function values remains widely unaffected by changes in the number of resources, available resource capacities, number of bidders, or distribution assumptions. The DLA thus seems to be applicable to any kind of online auction configuration with a revenue maximization objective.*

Result 3. *The average runtimes of the DLA depend linearly on the number of resources and bidders. They are stable with respect to resource capacities. These statements also apply to the OLA and more naïve benchmarks.*

Result 4. *The initial learning fraction ε represents the most critical sensitivity for the DLA. Small fractions are necessary in terms of the objective function value, but come at the cost of more computing time. The indispensable refusal of the first εn bidders is a key drawback with respect to the practical applicability of the DLA.*

Given these experimental results, several interesting inferences can be drawn with respect to the practical applicability of the DLA. In terms of the approximation of the OPT, the findings above indicate that large capacities b, small fractions ε, reasonable numbers of resources m, and few bidders n favor the DLA. The positive discrepancy towards other mechanisms, however, seems to increase for smaller b and larger n, i.e. conditions of resource scarcity and excess demand. Customer heterogeneity, implemented through larger standard deviations for π_j, also contributes to the superiority of this mechanism. In order to validate these statements, a modified baseline treatment is defined with the main purpose of making the DLA the most dominant algorithm. Here, excess demand ($n = 2{,}000$) together with a little learning fraction ($\varepsilon = 0.001$) and more heterogeneous bidders ($\sigma_{\pi_{ij}} = (60{,}40{,}20)\ \forall j$) are selected, while all other input figures remain identical to the initial baseline treatment. In this configuration, the DLA distinctly outperforms all other benchmarks with a 94.60%-approximation of the OPT. The *Interval Learner* follows with a ratio of 89.10%, but with more than thrice the runtime of the DLA. While the *WTP Learner* reaches 86.42%, the *Greedy Algorithm* and the OLA only produce 64.56% and 64.51%, respectively. Hence, the DLA excels in terms of OPT-approximation when the allocation is complex, e.g. if resources are scarce and bidders heterogeneous, and thus complies well with the nature of the generic online tickets sales problem. The average runtimes do not differ from our initial findings.

Result 5. *The DLA is especially suited for non-trivial online auction problems, in particular for scenarios with resource scarcity and excess demand by heterogeneous bidders. Its degree of optimality is highly contingent upon the choice of the initial learning fraction ε. Subject to these limitations, the exemplary case of online ticket sales appears to be a viable and expedient area of application.*

The key drawback of the DLA seems to be the unconditional refusal of the first εn bidders, as this fraction is required to learn the first set of threshold prices. Especially for large ε, it might be advantageous to define initial threshold prices to not lose revenue from the learning fraction. Moreover, the right-hand side modifier introduced by [1] artificially increases the dual prices, leading to overly restrictive thresholds for very large ε. Early-arriving bidders might also feel discriminated due to their arbitrary rejection. Since limited computing power or other conceivable reasons might prohibit the employment of sufficiently small learning fractions, this downside needs to be addressed in order to improve the applicability of the DLA for practical use cases, for instance for online auction-based ticket sales.

As explained by [1], the DLA is explicitly designed as a distribution-free mechanism. This seems a particularly useful property if no knowledge is available about the incoming bidders. If the allocation is repeated regularly, however, it might be possible to infer estimators for distribution parameters from historical data. In this case, one should define some initial threshold prices based on the given information about the stationary input processes in order to mitigate the problems associated with a big ε. Therefore, a deterministic linear program (LP), in particular replacing stochastic variables with their expected values, might be utilized for estimating meaningful thresholds. Dual prices can be accessed after solving the LP with expected willingness-to-pay and item requests. These shadow prices should be good references points for initial thresholds as they mirror expected values. Because all bidders are homogeneous in expectation, the LP can be solved by accepting all requests as long as no capacity restrictions are violated, just like the *Greedy Algorithm*. Since two resources will still be available when the third one is exhausted due to our assumption of stepwise demands, only one dual price will take a positive value in our setting.

If the allocation problem has to be solved repeatedly with similar input features, it might also be reasonable to use an average over past dual prices as initial thresholds. In particular, when input distributions are known, several simulations can be executed prior to the actual allocation task. For each simulation run, the first set of dual prices after εn bidders is stored. The average over this set of shadow prices, in our case over 10 simulations, can serve as initial thresholds for the actual allocation.

Alternatively, more naïve initial threshold prices are the expected values of the known input distributions for the willingness-to-pay for each resource. All bids, exceeding these prices will be accepted as long as the problem remains feasible.

Table 6. OPT-Approximations with Initial Thresholds

ε	*Baseline Treatment*	*LP Thresholds*	*Simulated Thresholds*	*Expected Values of Distributions*
0.001	94.54%	94.41%	94.74%	94.44%
0.01	93.67%	94.23%	94.84%	94.53%
0.03	90.06%	92.86%	91.66%	93.49%
0.05	86.32%	91.69%	91.10%	92.31%
0.1	75.88%	87.33%	85.75%	89.44%
0.15	65.16%	82.63%	77.95%	86.10%
0.25	47.25%	74.93%	63.51%	80.85%

The results of these different approaches for different ε are presented in Table 6. While the conventional DLA begins to rapidly deteriorate for $\varepsilon \geq 0.05$, initial thresholds keep the performance on a higher level. In particular, using thresholds does not seem to be disadvantageous for any ε. Simulated dual prices appear to be too instance-specific, making it difficult to rely on a limited set of past thresholds for future allocations. Retrieving initial thresholds from solving a LP produces better approximations of the OPT. This especially applies to scenarios where large fractions ε are chosen. Simply employing expected values of the distributions, however, further improves the approximation capabilities and should even be preferred to the more sophisticated alternatives. Again, it should be emphasized that this extension does not come along with any essential drawbacks. For small ε only few bidders are affected, whereas initial thresholds enable major gains for large fractions.

The DLA together with well-defined initial thresholds can therefore be deemed appropriate for complex allocation tasks. It represents a viable alternative to online ticket sales or other multi-item B2C businesses, achieving superior approximations of the OPT while maintaining satisfactory runtimes at the same time.

Result 6. *Defining initial threshold prices by using available information on the input distributions mitigates the drawbacks of the DLA associated with very large learning fractions ε. Matching the thresholds with the expected willingness-to-pay until the first calibration of dual prices already aids in alleviating revenue loss. It can also improve on the perceived fairness in handling the bidders and thus enhances the practical applicability of the DLA substantially.*

4 Conclusion

Online auctions represent a promising alternative to conventional posted price mechanisms, potentially enabling a more effective exploitation of customer willingness-to-pay. Based on the notion of ticket sales, we conducted an experimental study on two seminal algorithms proposed by [1] and put special emphasis on the practicability of their underlying primal-dual framework. Both the OLA and the DLA were implemented for the purpose of simulation-based experimental testing, along with some intuitive benchmarks, ranging from a quick-and-easy *Greedy Algorithm* to a computationally intensive *Interval Learner*.

There is a fundamental trade-off between the capability to approximate the ex-post optimal revenue and the average computational runtime. We ran extensive numerical experiments to discover dependencies and sensitivities of these opposing objectives. Through precisely defined re-calibrations of dual threshold prices, the DLA is able to approximate the OPT very well against a stationary process of bids. At the same time, it maintains reasonable runtimes, since dual updates occur more frequently at early stages of the allocation process. Our experiments illustrate that the DLA reacts robust to changes in many input parameters and proves to be extraordinarily dominant in situations of resource scarcity and excess demand. In this case, the decision rules implied by the DLA enable deliberate allocations through accurately determined thresholds.

Addressing the problem of generally rejecting bids in the first learning phase, we drafted several extensions, making use of known distribution information and aiming at the definition of some initial thresholds that could be employed until the first ordinary calibration. While retrieving a set of dual prices from a deterministic linear model seems an elegant solution, simply using the expected values of the known input distributions as initial thresholds proves to be an easy and well-performing alternative. Initial threshold prices permit major enhancements with respect to the real-world applicability of the DLA. Together with its robustness regarding other treatment variables, the DLA can thus be viewed as an expedient alternative when it comes to online ticket sales or other revenue-maximizing multi-item allocation tasks.

The basic idea underlying this research paper can be extended in various ways. An empirical validation with real-world data would, for instance, be desirable. Especially the context of online ticket sales seems to be a suitable use case. Furthermore, the algorithms have only been benchmarked with rather straightforward mechanisms. A more extensive experimental study with alternative sophisticated algorithms might provide useful insights into the applicability of different online auction mechanisms. Including risk considerations or non-monetary objectives would only be two possible extensions referring to the DLA.

Abstract. Many online review platforms such as Google Maps or TripAdvisor have implemented a reward program where reviewers receive points for posting online reviews. Based on the Self-Determination Theory, we hypothesize that introducing multiple reward levels and incentives for detailing online reviews have a positive effect on review quantity and effort. We test our hypotheses for Google's reward program 'Local Guides' which introduced new design features in June 2017. At this date, more badges (i.e., reward levels) were available and extra points for textual reviews (i.e., incentives for detailing online reviews) were provided. Based on a dataset of 43,988 online reviews on 40 sights across Europe, we find that multiple reward levels and incentives for detailing reviews significantly increase the number of reviews but counterintuitively decrease the effort invested by reviewers. Consequently, the introduction of extra points for textual reviews has not yield the intended effect on review effort.

Abstract. Traditional unsupervised topic modeling approaches like Latent Dirichlet Allocation (LDA) lack the ability to classify documents into a predefined set of topics. On the other hand, supervised methods require significant amounts of labeled data to perform well on such tasks. We develop a new unsupervised method based on word embeddings to classify documents into predefined topics. We evaluate the predictive performance of this novel approach and compare it to seeded LDA. We use a real-world dataset from online advertising, which is comprised of markedly short documents. Our results indicate the two methods may complement one another well, leading to remarkable sensitivity and precision scores of ensemble learners trained thereupon.

Keywords: topic modeling, word embeddings, LDA, seeded LDA

1 Introduction

With the increasing amount of textual data, the interest in text analysis has grown significantly in recent years and methods like topic modeling have become an integral part of research in computer science and information systems [1-3]. Topic modeling aims at finding topics in a collection of text documents.

One popular unsupervised method in the field is Latent Dirichlet Allocation (LDA), which is a probabilistic model that infers a document's topic based on the distribution of words therein, building upon the underlying assumption that topics generate words, which in turn generate documents. It was developed from probabilistic latent semantic analysis (PLSA) by Blei et al. [4] and has since been one of the most widely adopted approaches to topic modeling, which is mirrored by its readily-available implementations in many programming languages and environments.

However, in some scenarios, one may — possibly due to domain knowledge — already know about a specific set of topics that is present within the corpus or that one would like to classify documents into for other reasons. Under such circumstances, unsupervised methods may fail to identify particularly those envisioned topics in a corpus of documents. Standard LDA, for example, takes input on only the *number* of topics to

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

discover but it does not necessarily find topics similar to those that one aims to classify into. Instead, the topics identified with the means of standard unsupervised methods would have to be further investigated by a human in order to identify the discovered topics' meaning, beyond them constituting a collection of associated documents, and possibly map them to a predefined topic scheme.

Supervised methods do not suffer from this problem since the labels establish the set of topics that can be discovered. Approaches of supervised learning suitable for topic modeling include the naive Bayes algorithm, support vector machines or decision tree models, which require attaching topic labels to words [5]. But also derivatives of LDA, namely supervised or discriminative LDA approaches (sLDA, DiscLDA) [6], [7], have been developed. However, all supervised models come at the cost of labeled data, which may be substantial, if not prohibitive in some cases. Moreover, in case the set of topics that one would like to categorize into changes, again significant amounts of newly generated labels or re-labeling of the data are required.

A solution to solve the dilemma of combining unsupervised methods with a predefined set of topics may lie in seeded LDA, a recent extension to the traditional form of LDA [8].

We develop an alternative method that employs recent developments in word vector representations. Our proposed method matches current undertakings in the field, as, for instance, Schwaiger et al. [9] and Murawski and Bick [10] have dealt with similar problems of classifying short documents into predefined sets. Schwaiger et al. [9] analyze social media posts and develop a classification tool, utilizing a dictionary-based approach combined with a multinomial Naive Bayes algorithm. In a similar endeavor, Murawski and Bick [10] employ LDA to sort job advertisements of data professionals into job sub-categories within specific job titles. However, their purely unsupervised approach yielded results that had to then be manually linked to the given category framework [10]. Further examples of topic modeling implementations are presented by Müller and Brocke [11] or Geva et al. [12]. In both papers, the authors use LDA to retrieve topics from a collection of documents. Müller and Brocke [11] apply LDA to further develop categories for an app store by analyzing the short descriptions provided for each application. Following a similar procedure, Geva et al. [12] analyze tweets to find patterns in the posting behavior of users.

Extended approaches to retrieve topic models are presented by few authors. Xu et al. [13] propose a combination of LDA and Clustering methods as a novel method to incorporate text associations. The approach is twofold. To find topic associations, a clustering algorithm based on the pairwise proximity of topics is applied. These associations are then linearly combined with LDA to enrich topic retrieval [13]. A very different direction for enriching topic modeling research is presented by Eickhoff and Wieneke [14]. Emphasizing the need to make sense of topics retrieved by topic modeling algorithms, they propose a mixed methods approach combining qualitative coding and quantitative clustering to decontextualize and evaluate topic models [14]. These examples underline the current focus on vanilla LDA, indicating a need for the development of specialized methods in topic modeling [1], [2].

We contribute to topic modeling research a novel alternative to (seeded) LDA, departing from the proven paths of generative probabilistic models. Our proposed method, which we present in section 2, is easy to set up and allows high performance classification of (very) short documents into predefined topic schemes and does not require labeled training data. In section 3, we verify our proposed approach on a dataset of 380,000 URL-based short documents that we obtain from an online retailer, where the classification of such documents into a predefined taxonomy allows for a better understanding of the websites on which online advertisement is served. Section 4 discusses the results, which suggest the proposed method may constitute a valuable addition to the existing topic modeling tool set. Section 5 concludes.

2 Methods

Section 2.1 provides an overview of related work from the field of (seeded) LDA. Subsequently, we present our novel approach to topic modeling which relies on word vector embeddings (section 2.2). We refer to this approach as topic embeddings.

2.1 Seeded LDA

Seeded Latent Dirichlet Allocation is a powerful probabilistic model in the field of unsupervised topic and text mining algorithms. It is an extension of the standard LDA model developed by Blei, Ng and Jordan [4]. In contrast to vector and matrix based text mining approaches such as latent semantic indexing or clustering, LDA algorithms not only reduce dimensionality, but also account for documents being composed by a mixture of topics [4], [15], [16]. The method is therefore suited for organizing large and unstructured text documents by extracting representative topic compositions [17]. Successful implementations are documented in a broad range of domains. In the field of information system research, examples include the analysis of social media to develop a tool categorizing social media activities or the analysis of computer science job advertisements, which we described in section 1 [9], [10], [15].

Jagarlamudi, Daumé and Udupa [8] developed the seeded LDA model for settings where true labels are not available but prior knowledge of topics inside the corpus can be used to steer the resulting topic assignments towards predefined topics. The general idea of seeded LDA is to feed the model with information about the nature of the topics to look for by integrating seed words. Setting such seeds in the LDA algorithm aims at guiding the extraction of topics by skewing the distributions on the document level as well as on the word level (document-topic distribution, topic-word distribution).

On the topic-word level, seed words enhance the probability of a topic to generate words which are associated with the seed words. The model is then extended by another topic-word distribution for each seed topic. Hence, a new layer is added, where each topic is assumed to be a mixture of its regular topic distribution and the related seed topic distribution. In addition to the topic-word level, seeded LDA guides the probability distributions in the document-topic layer. For each set of seeds, a distribution over the regular topics is built, which acts as a prior for drawing the document-topic distribution. Drawing a topic for each document is enhanced by an extra layer, where the first step is sampling a set of seeds and then using the corresponding distribution over topics as prior information to select the document topic mixtures [8].

In other words, seeded LDA is an unsupervised approach to direct topic mining towards a given set of categories. That is to say, it is a method which incorporates knowledge about desired labels in an unsupervised learning algorithm [8], [18]. However, it relies on a sufficiently large number of words per document to properly find topic models within a document collection. The algorithm is based on the probability of words to co-occur. As a result, the success of seeded LDA depends on the composition of the document collection and the quality of seed words, which not only have to differentiate a given topic from other topics but also must frequently occur in the corpus. However, for short documents or underrepresented topics, seeded LDA has its limitations.

2.2 Topic Embeddings

Word embeddings are high-dimensional representations of words in vector space. The words are translated into vectors of real numbers in such a way that semantically similar words result in similar vectors, where the translation is based upon evaluating how words co-occur with other words. Even though the basic idea of representing semantic similarities of words in vectors dates back to the 1960s, when the first attempts were made to use feature representations to capture such similarities between words [19], the interest in word embeddings was boosted recently when Mikolov et al. [20] introduced a neural networks-based model called word2vec in 2013, which permitted much faster training than previous models.

As words are translated into vectors, it becomes possible to determine numeric distances between words. Thus, one can calculate the distances between the words of a document and another term. This other term (or a collection of terms for that matter) could well constitute a topic, which leads to the core of our approach. It assigns each document to the closest topic in a given set of topics, where closeness is measured in the word embeddings' vector space. Thus, we dub our novel classification method *topic embeddings*.

However, not all words in a document are of equal importance. Stop words like "the" and other recurrent words add no value to determine a document's topic as they are neither unique nor characteristic to documents of any specific topic. To filter for the characteristic words that help to measure the distance between documents and topics, we use the *term frequency inverse document frequency (tf-idf)* metric. Tf-idf assigns weights to words within a corpus' documents and balances the relative frequency of a word within a document against the word's relative frequency in the whole corpus. High scores stand for characteristic words of a document which occur frequently (that is at least once) in the given document but relatively seldom in the corpus. To efficiently use tf-idf scores in our setting, we first compute a (sparse) document-term matrix that contains the tf-idf scores and normalize it row-wise so that the tf-idf scores per document sum up to 1, which makes them a suitable mean of weighting.

To assign a given document to a topic from a predefined set, we combine word embedding distances with tf-idf scores as follows: We measure the distances between all words in a given document and the terms describing a topic and combine these into a weighted sum, where the weights are contributed by the document words' normalized tf-idf scores.[1] We repeat this for all topics and assign the document to the closest topic:

Define `ClosestTopic`($\mathbf{x}$,$\mathbb{T}$,$\mathbb{C}$,F):
Require: $\mathbf{x}$, the input document with documents words $x^{(i)}$
Require: $\mathbb{T}$, the set of topics, consisting of topics $\boldsymbol{t}^{(j)}$ and topic words $t^{(j,k)}$
Require: $\mathbb{C}$, the corpus, comprised of a set of all documents
Require: *F(word, word)*, a distance function from a word embedding space
Calculate tf-idf document-word matrix $\mathbf{W}$ from $\mathbb{C}$.
Normalize $\mathbf{W}$ row-wise (per document) and extract $\mathbf{w}$ with weights $w^{(i)}$ for each document word $x^{(i)}$.
for j from 1 to $|\mathbb{T}|$ **do**

$$distance_j = \frac{\sum_{i=1}^{len(\boldsymbol{x})} \sum_{k=1}^{len(\boldsymbol{t})} w^{(i)} F(x^{(i)}, t^{(j,k)})}{len(\boldsymbol{t})}$$

$y \leftarrow argmin(distance_1, distance_2, \ldots, distance_{|\mathbb{T}|})$
Return topic $\boldsymbol{t}^{(y)}$

Words that are not in the vocabulary of the employed word embeddings model cannot be used, even though they may have high tf-idf scores. Documents that do not contain a single word from the word embedding model's vocabulary can thus not be classified at all.

Our approach shares elements with the work of De Boom et al. [21], who devise vector representations of fixed-length short documents with the help of idf-scores and word embeddings. Other approaches to obtain text representations include deep learning and skip-gram based methods. Multilayer perceptron and convolutional neural networks can be used to arrive at sentence representations as De Boom et al. [21] note. However, as De Boom et al. [21] point out, these methods necessitate inputs of the same length or aggregation operations. Other techniques to measure semantic sentence relationships by vector representations include skip-gram inspired Paragraph2vec (Le and Mikolov [22]) and RNN-backed methods introduced by Kiros et al. [23]. However, documents may oftentimes rather constitute a collection of words than collections of actual sentences as our use case shows. Moreover, most of these techniques require retraining when changing the word embeddings or when encountering unseen examples as De Boom et al. [21] point out.

Our method, however, can employ pre-trained word embedding models without retraining while also being able to handle documents with unknown words to a certain extent, as the following sections will show. Also note that our method does not require any labeled training pairs of documents and topics.

---

[1] Note that tf-idf-weighting topic descriptions may be useful if topic descriptions have words in common.

3 Use Case and Benchmark

The evaluation of advertisement effectiveness is a common undertaking in managing online retailers. For example, retailers may wish to analyze the content of ad serving websites that a web shop's audience is frequenting. Categorizing these websites may be helpful to oversee ad spending and to gain insights about the type of audience that the online retailer is attracting. However, sorting into arbitrary categories is usually not helpful as it hinders comparisons with established taxonomies. Hence, classifying into predefined categories is a necessity, rendering the classic LDA approach unfeasible. Labels on the other hand would be costly to acquire in such a setting since they require human input.

We evaluate the predictive performance of our topic embeddings approach against the seeded LDA approach on a dataset of URLs obtained from a German online retailer. The dataset contains approximately 380,000 records of URLs with a *.de* top-level domain, from which the vast majority are German-content websites, as a qualitative scan of the data reveals. For the word embeddings model, we follow Müller's procedure [24] to train a 300-dimensional German word2vec model. As data inputs, we use a corpora of German news articles from 2007-2013 [25] and a copy of the German Wikipedia (retrieved Dec 21, 2017).

In order to allow for a quantitative performance evaluation of both methods, we manually label a fraction of 2,488 randomly selected records, which we then randomly split into a test and holdout set in an 80:20 ratio. To get consistent labels, two authors labeled the first 500 documents together and consult each other in ambiguous cases during labelling of the remaining records.

3.1 Topic Taxonomy

We use the Google AdWords taxonomy to predefine 22 main topics [26], which are further divided into sub-, sub-sub and sub-sub-sub-categories. However, we restrict ourselves to classifying into the 22 main topics.

Table 1. Examples of the used topics and their corresponding seed words[2].

Topic	*Seed Words*
Dining & Nightlife	dining, nightlife, night club, disco, restaurant, menu, bar, drinks, DJ, party, dancing, going out
Computers & Consumer Electronics	computer, consumer electronics, pc, laptop, mouse, keyboard, game console, playstation, xbox, wii, nintendo
Food & Groceries	food, groceries, juices, soft drinks, alcohol, beverages, vegetables, fruits, pasta, rice, potatoes, supermarket, milk, cheese, eggs, butter, bread, household goods, detergents, consumer goods

[2] The originally used seed words are German and have been translated.

As the taxonomy is in English and our documents are in German, we first translate the 22 main categories and their 252 sub-categories. To create further seed words, we additionally enrich the topic descriptions with extensions as well as with some associated entities and proper names. As extensions we consider synonyms as well as words (mostly nouns) associated with a given topic, despite them not being direct translations of the original English topic. As associated entities we consider popular brands or institutions linked to certain topics. Table 1 lists seed words for three example categories. Also, we make sure to use each word in the description of only one topic and avoid words which could be associated with more than one topic altogether. In total, the final topic taxonomy consists of 421 words in the translation part, 656 words as extensions and 49 words in the associated entities section.[3]

3.2 Preprocessing: Constructing Documents from URLs

We build our documents from the word tokens inside each URL's host and path. However, in some cases, the URL is extremely short and does not provide much useful information. For example, the host may be a brand name or another non-word, combined with a very short or non-word only path. Thus, we use a web crawler to extend our URL documents by the corresponding website titles as well as description and keyword tags. We thus end up with a corpus of 384,285 documents with an average (and median) length of 24 words when building the documents from URL tokens as well as all three crawled information sources.

3.3 Grid Search: Optimization of the Hyperparameter Configuration

Our approach to classifying the URL documents is twofold and comprises of two stages: After the pre-processing stage in which the documents are build, we classify them with either one of the two methods described in section 2. Each stage includes several hyperparameters to be tuned, which influence the performance of the resulting models. To examine the influence of these parameters and to identify the best configurations for our two methods, we conduct a grid search. The specific configuration options are shown in Table 2.

Table 2. Hyperparameter space for grid search evaluation.

Area	*Options*	*Range of values*
Topics	Topic description sources	[Translations, Extensions, Entities]
	Include sub-category words	[True, False]
Documents	Source of document contents	[URL Tokens, Crawling Tokens]
	Crawling sources	[Title, Description, Keywords]
Seeded LDA	Seed Confidence	[0.2, 0.8]
	Replace non-vocabulary seeds	[True, False]
Topic Embeddings	Weight words with tf-idf	[True, False]

[3] Upon request we are happy to share the list with interested readers.

During pre-processing, the documents can be constructed from either only the words in the URL, the words obtained by the web crawler or combinations thereof. Specifically, we distinguish one URL word source, three crawling word sources (website title, description and keywords) and combinations thereof. This procedure also allows us to more closely examine the effects of including the additional information retrieved from the web crawler on our two models' predictive performances. The second part of the pre-processing stage is the aggregation of information about the topics from our taxonomy. As described in section 3.1, the taxonomy was translated and then extended by characteristic words and associated entities. For both models we test the effect of including each of these sources as well as their combinations to guide the learning process. Further, we vary the amount of information included in the topic descriptions by either combining all information from sub-categories into their respective main categories, which we want to predict on, or rather leaving out the information related to the sub-categories altogether. Also, both our classification techniques require a number of hyperparameters to be set. The seeded LDA algorithm provides a variety of choices for the seed sets: We test two options for the degree to which the initial distributions are skewed towards the seed words, comparing a very high confidence of 0.8 against a low one of 0.2. Additionally, we test for the effects of replacing seed words that are not contained in the document corpus' vocabulary with the help of the word embeddings model, by means of replacing the missing words with the most semantically similar in the corpus vocabulary. For the implementation of the topic embedding approach, we include the option of weighting the influence of each word in the document by the tf-idf score. In total, the grid search includes 384 hyperparameter combinations[4] that we evaluate on the labeled test set.

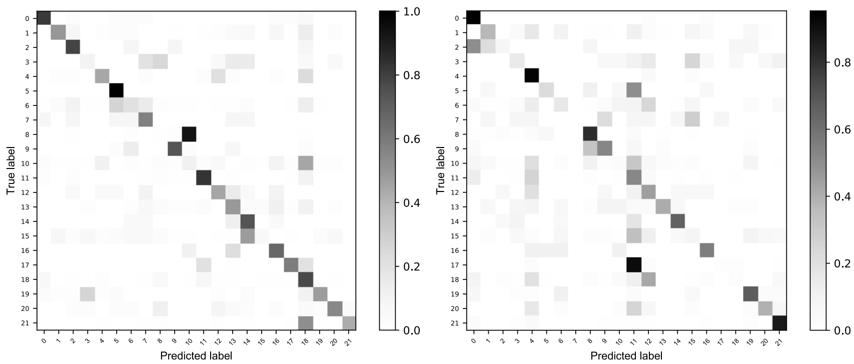

Figure 1. Confusion matrices of sensitivity-best models (left: Seeded LDA, right: Topic Embeddings). See Table 3 for topic names.

[4] We ignore combinations of topic description sources without translations since extensions and associated entities were less densely available and empty for some categories. Early trials indicated that using only extensions and/or associated entities leads to expectably poor results. Similarly, we exclude combinations of crawling sources that lack page titles because many crawled pages do not feature descriptions and/or keywords.

4 Results

The baseline for evaluating the results of the model is the effectiveness of simply predicting the most common category. To estimate this baseline score, we calculate the distribution of topics in the section of the dataset that we manually labeled. The most frequent label is "Vehicles" with a share of 18.8%. For the top-2 and top-3 scores the baseline is 30.9% and 42.3% respectively.

4.1 Seeded LDA Method

The seeded LDA approach correctly classifies a maximum of 45% of all instances in the test set in terms of sensitivity, which measures the share of correctly discovered topics, and reaches 55% in terms of precision, which indicates how useful the predicted labels are, i.e. how large the share of relevant labels is among the retrieved labels[5]. However, it shows poor performance on certain topics like “Food & Groceries”. Not using the web-crawled data decreases the performance by 13 percentage points, meaning that the sensitivity climaxes at 36% when the method only works on the tokens from the URL itself.[6] With regards to the possible combination of sources that describe the topics (translations, extensions, associated entities), it becomes clear that the extensions make a significant difference as they add 10 percentage points to the performance, while the inclusion of associated entities has no impact. Replacing seed words not found in the document corpus’ vocabulary makes no difference in our case, which is likely due to the fact that already a very large portion of the topic descriptions vocabulary is shared by the document corpus vocabulary. Further, the seeded LDA model’s top-2 and top-3 predictions cover the correct topic in 62% and 69% of all cases respectively.

4.2 Topic Embeddings Method

The topic embeddings approach reaches scores of 41% in sensitivity and 49% in precision. While it performs very well on certain topics like “Vehicles” (21), it does not do well on the “Hobbies & Leisure” (10) category and, as obvious from the confusion matrix in Figure 1b, frequently confuses "Home & Garden" (11) with "Real Estate" (17). Interestingly, the best topic embedding model relies only on data from the main categories as topic descriptions and excludes extensions and associated entities.[7] Adding the latter two or including the descriptions of sub-categories makes no difference aside from a stark increase in computation time as the number of required word to word distance calculations scales linearly with the length of the topic descriptions. The best

[5] The optimal configuration includes most document word sources (URL tokens as well as title and keywords from crawling results) and requires all seed word sources from main and sub-categories as topic descriptions.

[6] Topic descriptions again require all seed word sources and all words from main and sub-categories.

[7] The optimal model configuration further includes building documents from URL tokens as well as website keyword and title tags.

model uses tf-idf to weigh words but the influence of using tf-idf is, perhaps due to the shortness of the documents, very low. Restricting the compilation of documents from using the data obtained from the web crawler results in only a small performance drop of 3 percentage points in sensitivity and 1 percentage point in terms of precision. The topic embeddings' top-2 and top-3 scores cover the correct topic in 50% and 56% of all cases respectively, both including crawled data for document generation.

Table 3. Performance summary of the topic embedding and seeded LDA models evaluated on the test set.

			Topic Embeddings		*Seeded LDA*		
		Support	Sensitivity	Precision	Sensitivity	Precision	$\Delta_{Sensitivity}$
0	Apparel	43	0.95	0.31	0.84	0.55	0.11

4.3 Ensemble Learning: Combining Topic Embedding and seeded LDA

By comparing the two confusion matrices in Figure 1, one can easily discover that the two methods complement each other in parts. Thus, we train an ensemble learner whose results are depicted in Figure 2.

We combine the predictions of our two approaches in a decision tree, where the labels obtained during the grid search outlined in section 3.3 serve as features. We limit the

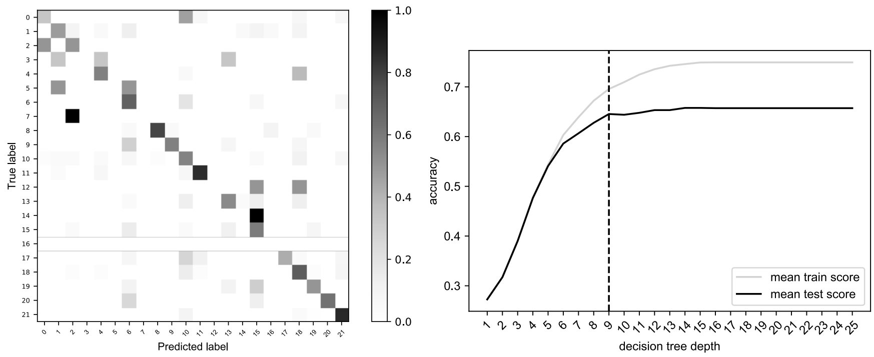

Figure 2. Left: Confusion matrix of ensemble learner evaluated on holdout-set (452 documents, none in topic 16). Right: Results of the grid search for the final ensemble learner.

resulting tree to take only two features as input due to the high computational cost of each feature, which we assume could otherwise be prohibitive in a realistic application scenario. We train a tree with all features and select the two most important ones. Not surprisingly, each of our two models contributes one feature. While the selected topic embeddings model is the best performing one described in section 4.2, the selected seeded LDA model is very similar to the best-performing one described in section 4.1 and only differs with respect to including the crawled website descriptions into the documents. Subsequently, we undertake an additional optimization endeavor with three-fold cross validation to identify the optimal tree in terms of test score, which is shaped by using entropy as a split criterion, an impurity decrease of 0 and an optimal depth of 13. We decide to further decrease the maximal depth to 9 to prevent overfitting and reduce complexity. We evaluate this final ensemble model on the holdout-set and reach scores of 65% sensitivity and 70% precision.[8]

Table 4. Performance summary for seeded LDA and topic embeddings evaluated on test-set and final ensemble learners evaluated on holdout-set.

	Options			
	Crawling		*No Crawling*	
	Sensitivity	*Precision*	*Sensitivity*	*Precision*
Seeded LDA	45%	55%	36%	49%
Topic Embeddings	41%	49%	38%	48%
Ensemble	65%	70%	50%	56%

Note: Topic word sources vary by method.

[8] See Table 4 for results of a crawl-data free ensemble learner fitted by the same procedure.

5 Discussion

We introduced a novel method for unsupervised topic modeling with predefined topics and evaluated its performance against the established seeded LDA model in a real-world application setting characterized by very short documents.

Our results emphasize that the seeded LDA method is very dependent on the length of its inputs and greatly benefits from additional data, both in terms of document length and in terms of topic description length. Since sufficiently long documents may not always be readily available as the case study demonstrates, this is one of the main shortcomings of the seeded LDA model. Nonetheless, it does perform very well when supplied with the required text volume. The topic embeddings model on the other hand does not profit from increased document length or topic descriptions. Its greatest strength is its robust performance that is almost on par with the seeded LDA model in a data-sparse environment of very short documents. The topic embeddings approach could easily be extended and possibly be refined in further research, for example by accounting for the varying performance of word embedding models depending on the word types. Rubinstein, Levi, Schwartz and Rappoport [27] show that on the one hand, word embedding models are limited with regards to learning attributive relationships like that between the words “fast” and “jet” while on the other hand they emphasize the strengths of such models regarding taxonomic relationships like that between “car” and “vehicle”. This hints at potential for performance improvements of the topic embeddings approach by only considering nouns while dropping everything else within a document. Another possible field of study lies in evaluating the effects of including bigram tokens in the model and, more far reaching, evaluating the robustness of the performance with regards to the chosen seed words. In addition, it would be interesting to compare the topic embeddings model performance against traditional classification methods in supervised settings. We suspect our method would naturally compete well against established models when training data is sparse since it has shown strong performance without learning from labeled examples, as outlined in section 4.2. However, with increasing amounts of training data, we believe it would be outperformed by traditional bag of words classifiers or other word embedding approaches like Facebook research’s fastText [28], which averages word embeddings of a document and passes the result through a softmax layer. While supervised classifiers obviously benefit from additional training data, our approach is independent of the amount of training data. It would be helpful to further investigate at which amount of data supervised learning algorithms take over.

However, one must keep in mind that both seeded LDA and the topic embeddings method are only unsupervised with regards to not requiring labeled document data. They obviously require input on the topics which one would like to classify into. Further research could possibly refine this area by investigating optimal discovery and selection strategies for seed words as well as determining which amount of information is optimal for maximum performance.

By combining both methods into an ensemble model, we showed how their individual strengths can complement each other. However, this requires one to pay the high price of labeling some data that essentially renders the whole undertaking a partly supervised method. Moreover, even the ensemble model struggles with very broad categories like "Hobbies & Leisure". Such diverse topics are problematic and further research is necessary to evaluate their handling, possibly by breaking them down into subcategories for classification and re-aggregating them afterwards.

Notable work on the combination of LDA and word vectors has been published in the past, e.g. by Nguyen et al. [29] and Moody [30]. While these combinations show strong performance, they lack our approach's ability to be steered towards a given taxonomy. Nonetheless, it would be valuable to investigate whether these existing models can be amended to allow for guiding towards given sets of categories.

To conclude, the topic embeddings model that we developed proves to be a valuable addition to current topic modeling research. Its relative independence of document length distinguishes it markedly from LDA approaches. Together with the ability to classify into given categories and its unsupervised nature, it marks one such specialized topic modeling technique that Eickhoff and Neuss [1] called for. Its strong performance on very short URL documents hints at further use cases in other areas where short documents are present, such as social media data or item descriptions in online shops. However, as language differs by context and evolves over time, one should keep in mind that the backbone of the approach, the word embeddings model, may need to be retrained on corpora of current, application-relevant text.

Abstract. Recently, traditional quality assurance methods, which often require human expertise, have been accompanied by more automated methods that use machine learning technology. These methods offer manufacturers to reduce error rates and, consequently, to increase margins as well. In particular, predictive quality assurance (PreQA) allows to minimize expenses by feeding back information from product returns and quality checks into the early product development. However, PreQA requires detailed information about previous quality problems which is not always readily available in a structured form. In this paper, we therefore discuss the potential of leveraging initially unstructured information in the form of images, taken either during quality checks or by customers when returning a product, to the end of product quality improvement. We furthermore show how this might be realized in practice using the case of fashion manufacturing as an example.

Keywords: quality assurance, image analysis, data science

1 Introduction

Manufacturers strive to avoid product defects as they have the potential to diminish margins and are detrimental to their public image. Traditionally, quality problems have been combatted by quality checks during production to avoid defective products slipping through to the customer and manual analyses of problem causes to avoid the initial bad decisions that might lead to quality problems further down the road [1]. Recently, these prevalent methods, which often require some form of human expertise, have been accompanied by more automated methods that use machine learning technology. In particular, the idea of predictive quality assurance (PreQA) [2] allows to minimize expenses due to product failures by feeding back information from product returns and quality checks into the early product development phase where then data-based predictions are made.

Predictive quality assurance requires as detailed information as possible about previous quality problems. However, quality checks are laborious and, for the case of product returns, while information is provided "for free" by the customer, it is often also very imprecise and coarse. A common situation is that of a customer taking

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

photographs of her defective product to point out the respective problems, but not using any kind of systematic annotation. This is the case for online purchases in particular as there is no sales staff to discuss issues with.

In such cases, information is available but not in a structured form so that it cannot be immediately used for machine learning purposes. To retrieve the knowledge hidden in photographs, structured information has to be mined from them. In this paper, we will discuss the potential of leveraging the initially unstructured information in the form of images, taken either during quality checks or by customers, to the end of product quality improvement, and how this might be realized in practice. The latter is demonstrated using the case of fashion manufacturing as an example.

After reviewing previous work in the next section, we summarize the predictive quality assurance approach [2] and discuss the role of unstructured data in that context (Sec. 3). In Sec. 4, we then outline an application scenario in fashion industry and show how a processing pipeline can use state-of-the-art image processing and vision methods to mine detailed information about product defects from photographs of different garments. First results presented in Sec. 5 underline the feasibility of the approach in practice. We conclude with an outlook towards future work on the topic (Sec. 6).

2 Previous Work

Existing literature overlapping with the topics of this paper comes from the domains of quality assurance, machine learning and computer vision.

2.1 Machine Learning for Quality Improvement

Applying machine learning to quality assurance is not a recent idea but has been around for a few decades. Early approaches however used to be rather passive in nature, focusing on the mere prediction of quality-related problems based on features and properties of a product and its production process. Examples include predicting whether a particular software component is error prone based on source code properties [4], or forecasting product quality in injection molding processes [5] and semiconductor manufacturing [6] given the manufacturing parameters. While such predictions can help to avoid producing low quality products they do not automatically lead to the production of higher quality products – for that, optimization approaches are necessary. E.g., given a model predicting the quality of an injection molding process in terms of properties of the resulting product, the process parameters may be tweaked automatically using a genetic algorithm [7]. Such pure optimization approaches have recently been accompanied by assistance systems which do not only allow to tweak existing products but which can already assist their users during product design and which allow the transfer of knowledge to completely new products instead of being tied to a specific process for a specific product. In particular, the predictive quality assurance architecture [2] provides a framework to implement such an assistance system. None of these existing approaches have however demonstrated how unstructured information about product quality problems can be mined and then used for an eventual quality improvement, so far.

2.2 Image Processing and Computer Vision

Research in image processing and computer vision has produced methods which are relevant to this work in two ways. First, there is a history of methods with a similar objective that use image processing to detect defects on objects either during maintenance or quality checks in production [8]. Second, for our proposed processing pipeline (Sec. 4), we transfer algorithms originally designed for different tasks such as people detection and pose estimation to serve a new, additional purpose as sub-steps in the mining of defect information from images.

For identifying defects and failures from images, there are both supervised methods, i.e. methods requiring a labeled data set to be trained on [9-11], and unsupervised methods [12-14], purely based on detecting statistical irregularities. Some aim at generic anomaly detection [14] while others have fixed application domains ranging from wood boards [13] to steel rails [11] to textiles [10]. The vast majority of those methods assumes their input images to be of a very regular nature, only showing a relevant patch of an object's surface texture, not the whole corresponding objects. This requires images to be taken under pre-defined conditions either automatically using calibrated equipment at a production site, e.g., at a fixed distance, angle and under pre-defined lighting conditions, or manually by an instructed expert. Consequently those approaches cannot easily be transferred to the much more irregular photographs taken by customers using varying hardware and showing different views of a full object or even just showing drastically varying complex objects such as different garments.

We post-pone the discussion of related work originally developed in other contexts, which we propose for different processing steps, to Sec. 4 where we will introduce our defect mining methodology.

3 Background

In this section we first summarize the main ideas behind the predictive quality assurance architecture [2] before going on to discuss the role and benefits that image data may provide in this context.

3.1 Predictive Quality Assurance

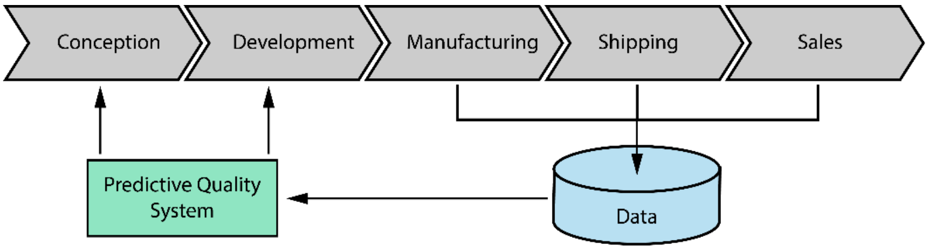

Figure 1. Predictive quality assurance: Data about products and the problems they exhibited previously is collected throughout the depicted process from conception to sales. The predictive quality system analyzes this data to gain insights which are fed back into the early process steps.

Predictive quality assurance (PreQA) uses historical data about manufactured goods and the defects they exhibited to eventually increase the quality of future products. At the core of the method are classification algorithms which are trained to predict the expected occurrence rates for different types of product defects, given a structured description of product features as input. In particular, predictions can also be made given only a subset of all possible features so that the method can already be applied in early stages of product development where not all existing features have been specified yet (Fig. 1). Using these predictions, issues such as bad product designs can be identified early-on. An integrated assistance component then allows to correct adverse decisions made about the product by suggesting alternative options with significantly lower expected probabilities of failure.

3.2 The Value of Image Data for Quality Assurance and Improvement

As PreQA is based on classification algorithms, the availability of a high quality dataset to train these algorithms on is crucial to the method's success. This not only concerns the level of detail found in the specifications of existing products, which should comprise a large set of expressive features, but furthermore especially the descriptions of previous cases of defect.

Using the case of fashion industry as an example, product defects can be of drastically varying nature: holes, stains, fragile seams, broken zippers, lost buttons, bleached colors or strong pilling all are reasons for a customer to return a piece of clothing. But they have very different causes. A bad material mix may affect pilling behavior but arguably has little influence on oil stains caused by a production machine. A weak thread can lead to loose buttons but will not cause problems with a zipper. Thus, if different types of failure are clustered together into a single class of defect, valuable potential for a detailed analysis and a subsequent reliable prediction and failure avoidance is lost irretrievably.

Unfortunately, when returning an item bought from a store due to a defect, customers are usually required to specify their reasons for doing so only in a very coarse way. This is because customers, on one hand, cannot be expected to analyze the specific nature of product failures as they are no domain experts and, on the other hand, because it would take additional time and lead to increased frustration at the customer's end. While the provided coarse defect information can give first insights into problems connected to specific products the imprecision makes it difficult to connect particular defects to individual product features using machine learning. This is reflected in the fact that the prediction confidence of PreQA is usually lower for unspecific defect labels while being higher for more specific ones [2].

Attaching unstructured data in the form of images to product return cases offers a way to mitigate this problem: A picture is worth a thousand words. Using photographs, we can generate detailed descriptions of situations in the fraction of a second. Taking a picture of her defective item takes the customer less effort than filling out a detailed return form by selecting appropriate defect descriptions from dropdown lists but still encodes virtually all information about the occurred problem into a compact visual description. The same applies to quality checks of final products performed in companies. While in this case the staff is specialized and experienced in assessing defects, just taking a photograph could significantly decrease the time required for checks which would allow a denser sampling of the full production yield given the same time budget and increase the quality of the items sold by itself.

3.3 Manual Visual Inspections in Fashion Companies

An automated analysis of images showing defective products should ideally produce output which is identical to the one expected from a human expert assessing the case manually. We will thus briefly describe the way visual inspections proceed for the exemplary case we are dealing with in this paper, the fashion industry.

While there are some industrial norms for quality checks in the form of ISO or DIN standards in clothing industry they mainly concern apparel which is used in safety-critical contexts. When it comes to quality checks of casual clothing, each company defines its own inspection protocols to follow. Nevertheless, there are certain best practices performed in most companies.

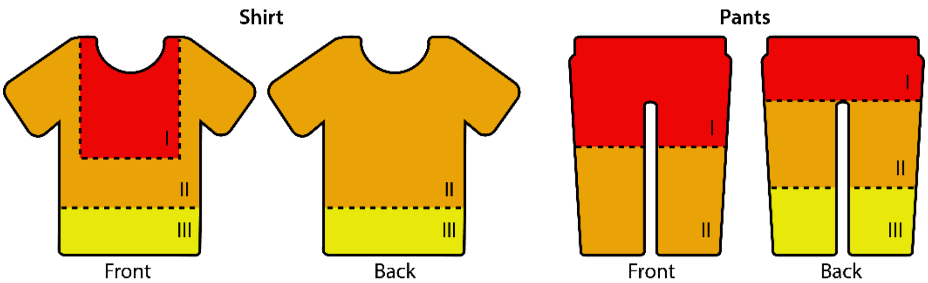

Figure 2. Typical defect zones used in visual garment inspections, according to [19]

First, a list of possible defects is defined. These potential quality flaws are then considered one by one during visual inspections. Second, garments are commonly subdivided into different zones called e.g., zone A to C or I to III, as depicted in Fig. 2.

These zones often correspond to different levels of visibility, and consequently also severity, of defects. Usually, the highest severity is assigned to parts visible when presenting the product in a store (Fig. 2, zones I), the second highest to areas more visible when wearing it (Fig. 2, zones II) and so on. Third, each company defines combinations of defect types and defect locations, in terms of zones, which lead to the rejection of a piece of clothing or its re-use in outlet stores, respectively.

4 A Processing Pipeline for Mining Textile Defects from Images

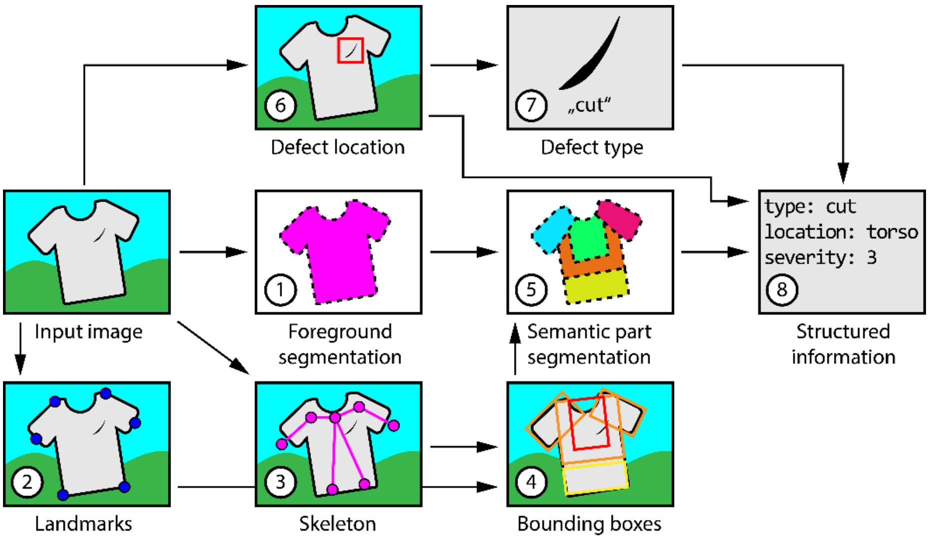

Figure 3. Image processing pipeline to mine details about product defects from images for the case of fashion industry. Steps are labelled by the order in which they are described.

We will now outline how computer vision techniques can be used to compose a processing pipeline to mine textile defects from photographs of pieces of clothing. An overview is shown in Fig. 3. It is inspired by the best practice approaches used in companies (Sec. 3.3) on one hand and the requirements set by machine learning algorithms on the other hand. The input to the pipeline is a photograph of a defective garment. No additional annotation is required. The output of the pipeline consists of a defect description regarding three properties: the type of the defect, its location with respect to the garment and a severity rating depending on the type and location which can be used to decide how to proceed further with the specific item. The pipeline consists of seven processing steps. For each of these steps, we will describe which output they compute, why they are necessary and which existing methods can be used to implement them.

4.1 Foreground Segmentation

Customers and customer care staff may take photographs of defective products in front of varying backgrounds. The first processing step therefore consists of segmenting the actual object of interest from that background (Fig. 3, step 1). In technical terms, each pixel of the original image is labeled as either belonging to the piece of clothing or to the background. This step is necessary for computing a more detailed segmentation of the object into different zones later on (Fig. 3, step 5) and also provides the precise areas of the image where defects can be expected to be localized later on (Fig. 3, step 6). There are several approaches which deal with this problem in different contexts, for example from the domains of image retrieval [15] or semantic scene description [16]. Some of them work best on photographs in which the clothing is worn by a person as they are based on detecting human features in a pre-processing step [15] while others are solely based on segmentation, such as the method by Borras et al. [16], and could therefore be applied in a more general setting.

4.2 Landmark Detection

In the second step, different semantic landmarks are detected (Fig. 3, step 2). Those are important image locations corresponding, e.g., to the end points of sleeves or of the collar. The output of this computation step is a list of detected landmarks – which may also correspond to only a subset of all known types of landmarks, depending on the type of garment and the specific view – and of their corresponding positions with respect to the image. The landmarks allow for a subsequent computation of 2D bounding geometry that then serves as guidance for the full semantic segmentation of the object (Fig. 3, step 5). Fashion landmark detection constitutes a very new area of research and has been introduced only recently by Liu et al. [17]. Their method employs deep neural networks and is robust regarding whether an image contains a person or not and whether the full item is depicted or only part of it (cf. Fig 4, second column).

4.3 Skeleton Fitting

In addition to the landmarks computed in step 2 which correspond to different extremal points of the pieces of clothing, further important key points can be derived using so-called pose estimation algorithms which try to fit an approximate skeleton to person depicted in an image (Fig. 3, step 3). These skeletons consist of a number of detected joints, connected by lines corresponding to different limbs (Fig. 4, third column). While those methods are originally used to determine the poses of humans in photographs or videos they often work surprisingly well for images without people in them (cf. Fig. 4, row 1) as the underlying neural networks have learned to use clothing as an important feature. Specifically, we employ OpenPose [20] to gather the additional pose information when possible. This framework outputs a number of human joint locations with respect to the input image. When particular joints cannot be detected reliably, only the subset which is detected confidently is output.

4.4 Fitting of Bounding Boxes

In the fourth processing step, the shape of the garment is approximated coarsely by a collection of two-dimensional boxes (Fig. 3, step 4). Fitting such so-called geometric proxies greatly simplifies the definition of rules to use by the semantic segmentation step following next. For example, in the case of an upper-body garment such as a shirt or jacket we first compute a box covering the torso region by fitting it to contain the four landmarks corresponding to the collar and the bottom of the torso. Boxes corresponding to the different defect zones within the torso region (Fig. 2) can then be derived from it: The zone III region typically corresponds to the lower 20% of the torso region while zone I covers 50% of the torso height and 70% of its width as it corresponds to the portion of the garment visible when folded and presented in a shop. To determine the height of the sleeves' bounding boxes we use the sleeve-ends landmarks in combination with the detected shoulder joints from step 3, if applicable, and fall back to using the collar landmarks from step 2 otherwise. The width of the sleeve boxes is derived from the horizontal distance between the collar landmarks. Results for this step are shown in the fourth column of Fig. 4.

4.5 Semantic Segmentation

Given the coarse shape approximation from step 4, as well as a mask segmenting the item of clothing from the background (step 1), the derivation of a complete segmentation (Fig. 3, step 5) can be defined using a set of processing rules: Each pixel is assigned to the semantic part corresponding to the closest box. In case a pixel is contained in multiple boxes, precedence is given to boxes corresponding to higher severity and main boxes are preferred over boxes corresponding to sleeves or legs. The resulting pixel-wise labelling is used to derive the location of the defect can then be used to rate its severity. While there are previous methods to solve this segmentation problem sometimes also referred to as clothes parsing [18] many of them strictly require the garments to be worn by a person [15, 18] and none take the typical zone assignment used in textile quality checks into account.

4.6 Anomaly Detection

Before we can classify textile defects into different categories, it is useful to first determine the image region where the defect is located (Fig. 3, step 6). The classification following in step 7 can then be applied to a cropped image showing only that region which significantly simplifies the problem as the cropped images to be classified are more regular. Assuming that most items of clothing are largely homogeneous regarding the fabric they are made of, we can employ unsupervised learning methods [12-14] which detect statistical irregularities and output a bounding box around the anomaly which can be used to determine the region to crop. By limiting the detection to the garment, using the segmentation from step 1, we can avoid irregularities being detected outside of the actual product.

4.7 Defect Classification

In the final image processing step (Fig. 3, step 7) we have to classify defects on an otherwise homogeneous image showing a textile patch. This problem has been previously tackled to automate visual quality checks of (raw) fabrics which constitute the feedstock for apparel manufacturing. There even is a standard benchmark, the TILDA dataset [21], which contains several hundred images of fabric patches with different defects and has been commonly used to assess different classification methods [22-24]. Those conventional methods are based on a two-step approach where first statistical features are computed in order to reduce the dimension of the input data (a patch of just 512 by 512 pixels with 3 color channels corresponds to a vector of 786,432 components) and then a classification only based on these features is performed.

However, recently, deep artificial neural network structures based on convolutional layers as the main computational units, called (deep) Convolutional Neural Networks (CNNs), have become very popular for various image processing and computer vision tasks [25]. In particular for classification tasks such as the annual ImageNet Large-Scale Visual Recognition Challenge (ILSVRC) [27] they have outperformed more traditional methods by a wide margin. We therefore compare their performance for the task of textile defect classification to that of existing methods [22-24] in Sec. 5.2.

4.8 Data Fusion

After we have gathered information about the different possible defect zones with respect to the piece of clothing (Step 5), the location of the defect (Step 6) and its type (Step 7), we can output corresponding structured information (Fig. 3, Step 8) which can then be used to train more precise classifiers for PreQA.

5 Results and Discussion

In this section we present initial results for several steps of our processing pipeline, specifically, the computation of bounding boxes and the final classification step.

5.1 Clothes Segmentation

Using the publicly available implementations of OpenPose [20] as well as of the fashion landmark detection of Liu et al. [17] we implemented steps 2-4 of our pipeline. Fig. 4 demonstrates the output of these steps for the case of four upper-body garments. Results are shown for both images with (Fig. 4, rows 2+3) and without humans (rows 1+4) and for the cases of both successful (rows 1+2) and unsuccessful (rows 3+4) pose detection.

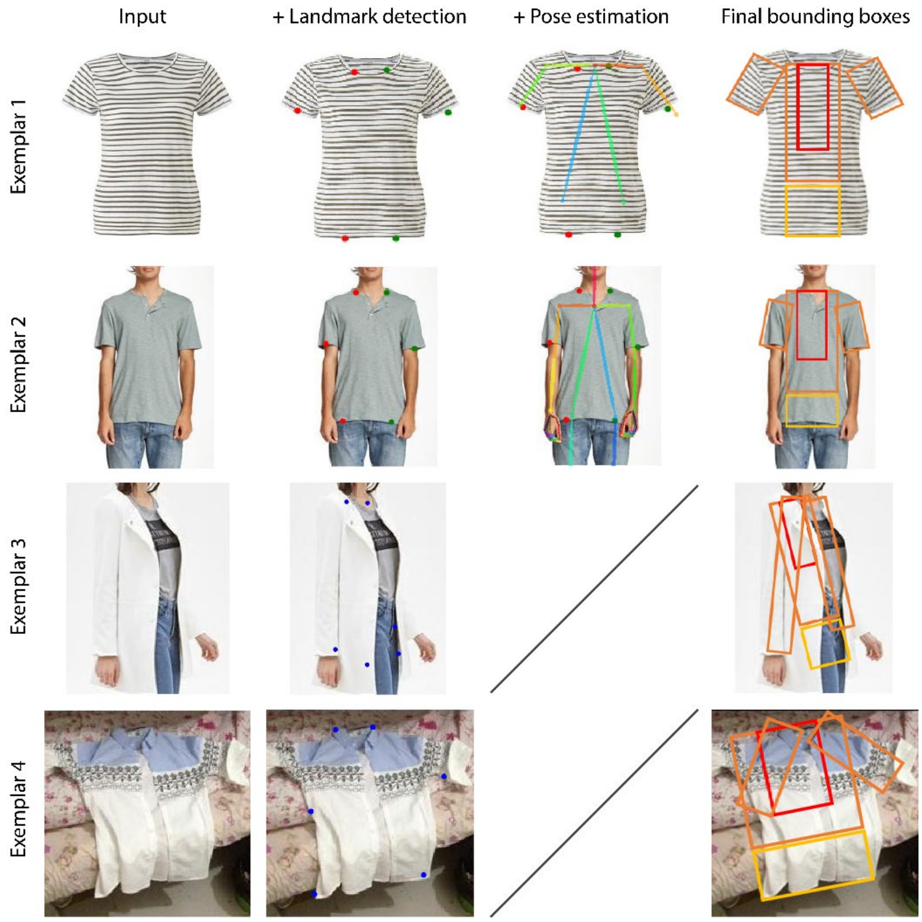

Figure 4. Pipeline input (first column) and outputs of processing steps 2 to 4 (second to fourth column) of our pipeline (Fig. 3). For rows three and four no full skeleton estimation was possible and the fallback approach (Sec 4.4) was used. The sample images have been taken from the fashion landmark detection benchmark dataset [17].

Table 1. Metrics achieved on the test set. As we deal with a multiclass classification problem the values have been averaged across the (evenly balanced) classes.

Metric	*Value*
Accuracy	90.1 %
Precision	87.8 %
Recall	87.6 %

5.2 Textile Defect Classification using Deep Learning

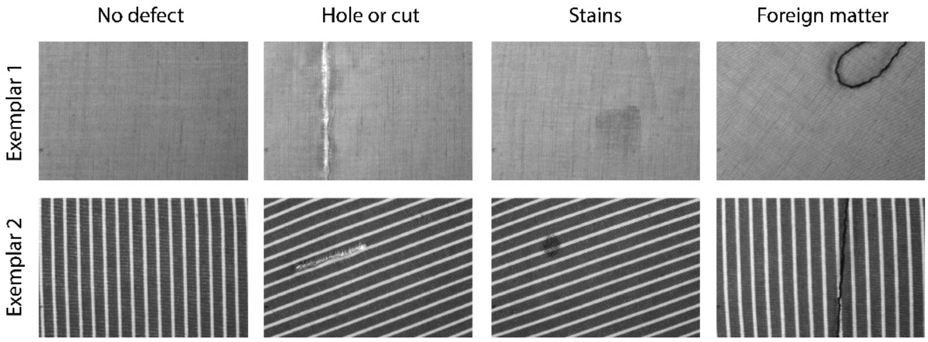

Figure 5. Sample images taken from the TILDA dataset [21] for four of the eight available classes (columns) and two of the included representatives (rows).

To evaluate the use of deep learning for textile defect classification, compared several popular network architectures from the ILSVRC contest [27], namely AlexNet [31], SqueezeNet [30] and GoogleNet [28]. We randomly split the TILDA dataset (cf. Fig. 5 for samples) into 90% of training and 10% of test images. The original balanced ratio of the classes (each class contributes 12.5%) was maintained. As TILDA only comprises about 3200 images, which is several orders of magnitude less than for most common deep learning datasets, we augmented our training data by adding mirrored and rotated copies of the original images. While TILDA contains high resolution images in a 4:3 format, all compared network architectures expect quadratic input images of lower resolution. We therefore padded images with white and then down-scaled them to the appropriate input resolution for each network. We first trained the candidate networks using the Adam solver [29] until their classification accuracy converged. As GoogleNet reached the highest initial accuracy, we selected it for further finetuning and increased the original drop-out rate to counteract potential overfitting to the small dataset, achieving an accuracy of 90% on the test set. A detailed evaluation using different common metrics is given in Table 1. This is on-par with values reported for competing methods [22] for which however no details, about whether a separate test set was used and which size it had, are given.

5.3 Discussion

The defect mining pipeline of Sec. 4 comprises eight steps, all of which constitute challenging problems by themselves. In the following, we discuss the current limitations of the most important steps and how these might be overcome in the future.

Fashion Landmark Detection While the method by Liu et al. applied by us for the problem of fashion landmark detection already achieves detection rates of about 70% when accepting only small misplacements of landmarks [17] this particular detection problem is a fairly new area of research. Improved, more robust methods can be expected to appear in the near future. This is also crucial for our defect mining approach as we use fashion landmarks as main guidance when constructing bounding geometry for different clothing zones.

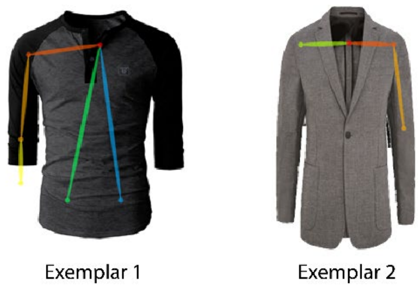

Figure 6. Two cases in which skeleton fitting failed for clothing-only images. The images shown are part of the fashion landmark detection benchmark dataset [17].

Skeleton Fitting We use skeleton fitting with OpenPose [20] as an additional input to help improve the subdivision of garments. While skeletons can sometimes also be derived for images where an item of clothing is not worn by a human (Fig. 4, first row), this cannot be expected to work in all cases. Fig. 6 shows two examples where skeleton fitting fails partially. Currently, we completely ignore the pose information in these cases. In future work, it might be useful to still extract available information for those parts of the skeleton that could be fit with significant confidence. For instance, for the left exemplar in Fig. 6, all joints but the ones corresponding to the left arm have been placed correctly and could have contributed information for fitting bounding boxes.

Bounding Boxes At the moment, we use simple boxes as the geometric proxies for different zones on pieces of clothing. This is sufficient in many cases but there are cases where a box provides a poor fit to the actual shape of the object, e.g., in cases where the sleeves of a shirt are not shown straight but bent. In such situations the fitting could be improved either by using multiple boxes, one for the upper and one for the lower part of a sleeve, or by replacing the boxes by more complex shapes such as two-dimensional generalized cylinders [26].

False Positive Anomalies We propose to use anomaly detection to spot locations of defects with respect to pieces of clothing. This assumes that their material is mostly homogeneous. While advanced detection methods also work for textured image regions, modern fashion sometimes uses defects such as holes or abrasion as design elements. Even for humans it is not always possible to decide with certainty whether a particular defect has been created voluntarily or not, unless additional exemplars of the same product are available to compare to. Consequently, it is debatable whether artificial intelligence can be expected to perform this kind of distinction more reliably.

6 Conclusion and Future Work

In this paper, we have discussed the importance of detailed training data when applying machine learning for quality improvement of manufactured goods by means of predictive quality assurance and demonstrated how image data can become a significant part in it. The latter was achieved by presenting the first pipeline to mine detailed structured defect information from images of defective products. While this pipeline is currently still of prototypical nature, preliminary results for several of the computational steps show its potential. Future work will see a full implementation of the described approach as well as a transfer to additional application scenarios in different industries, such as furniture manufacturing, where analogous methods to realize the individual processing steps, e.g., segmentation or anomaly detection, already exist within different contexts in computer vision research.

Decision Support for Real Estate Investors: Improving Real Estate Valuation with 3D City Models and Points of Interest

Markus Rosenfelder[1], Gunther Gust[1], and Dirk Neumann[1]

[1] Albert-Ludwigs-Universität Freiburg, Information Systems Research, Freiburg, Germany
{markus.rosenfelder,gunther.gust,dirk.neumann}@is.uni-freiburg.de

Abstract. Precise estimates of attainable revenue are essential for real estate investments. The large-scale availability of new data sources, combined with analytics, can help to improve price estimates in the real estate market, which is characterized by non-transparency. In this paper, we show how 3D city models and points of interest improve real estate valuations. We propose a hedonic pricing model with more than 100 features consisting of nearby points of interest as well as 3D digitized representations of buildings. We evaluate our model by means of a large showcase study in Berlin. The analysis shows that the combination of 3D data and points of interest reduces the prediction error considerably in comparison to standard approaches.

Knowledge Discovery from CVs:
A Topic Modeling Procedure

Alexander Schiller

University of Regensburg, Department of Management Information Systems, Regensburg, Germany
alexander.schiller@wiwi.uni-regensburg.de

Abstract. With a huge number of CVs available online, recruiting via the web has become an integral part of human resource management for companies. Automated text mining methods can be used to analyze large databases containing CVs. We present a topic modeling procedure consisting of five steps with the aim of identifying competences in CVs in an automated manner. Both the procedure and its exemplary application to CVs from IT experts are described in detail. The specific characteristics of CVs are considered in each step for optimal results. The exemplary application suggests that clearly interpretable topics describing fine-grained competences (e.g., Java programming, web design) can be discovered. This information can be used to rapidly assess the contents of a CV, categorize CVs and identify candidates for job offers. Furthermore, a topic-based search technique is evaluated to provide helpful decision support.

Keywords: Text Mining, Topic Modeling, Latent Dirichlet Allocation, Human Resource Management

1 Introduction

Acquiring the right personnel is one of the most critical success factors for companies [1, 2]. In this area, recruiting via the web has gained significant importance over the last years [3]. It is not only of practical interest, but has also received much scientific attention (cf., e.g., [4, 5]). Opportunities are, for example, provided by well-known professional online social networks such as *LinkedIn* and *XING*, which are becoming highly popular. For instance, as of Q2 2018, *LinkedIn* has more than 562 million members [6]. Recruiting via the web is further made possible by CVs provided not only on these networks, but also on private homepages and websites specializing in making available a wide range of CVs (e.g., *Indeed*, *CareerBuilder*, *Monster*). Overall, a huge number of CVs can be acquired online. Based on these CVs, companies have the prospect to identify promising job candidates and to conduct proactive recruiting.

However, to capitalize on this potential, a very large amount of semi- and unstructured data needs to be analyzed. While approaches for a manual analysis of document collections exist [7], this task becomes too time-consuming for large collections of complex documents (such as CVs) [8]. This issue is addressed by

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

automated text mining methods, which have already been used successfully for human resource management (HRM) [9, 10]. In particular, topic modeling approaches such as Latent Dirichlet Allocation (LDA) are promising in this application context. They are able to discover the hidden thematic structure present in a document collection [11]. Thus, they should be able to extract key information from CVs. More precisely, high-quality, fine-grained topics in a specialized topic model should represent skills, abilities, knowledge and work expertise (in the following subsumed by "competences" as in [12]). This information can then be used to, for instance, rapidly assess the contents of a CV, categorize CVs and identify candidates for job offers. Topic models offer unique advantages compared to a keyword search on existing platforms. However, research has not yet discussed the application of topic modeling to CVs, leaving open crucial issues (cf. Section 2.2). This paper thus focuses on the following research question: *How can topic modeling be used to discover knowledge from CVs?*

The remainder of the paper is structured as follows. In the next section, we discuss the problem context as well as related work and the research gap. In Section 3, we propose a procedure for knowledge discovery from CVs. Section 4 contains an application of the procedure and an evaluation of the results. Finally, we provide conclusions, limitations and directions for future research.

2 Background

In this section, we first briefly introduce topic modeling, LDA and evaluation methods for topic models. Then, we give an overview of related literature and discuss the research gap.

2.1 Problem Context

Topic modeling approaches aim to discover the latent thematic structure in a document collection and to identify thematically similar documents [11]. A topic model consists of a number of topics, each represented by terms strongly associated to the topic. Recently, probabilistic approaches have been highly popular. Here, topics can be seen as probability distributions over terms and documents as probability distributions over topics. In this paper, we focus on LDA [13], a probabilistic approach not relying on any kind of training data. It is the most widely-applied topic modeling approach [14]. Distributions are calculated using sampling or optimization procedures which take into account term-document-frequencies [15]. LDA is based on the bag-of-words model (i.e., the order of words in documents is ignored). This makes it particularly suitable for CVs, which often are formulated in note form instead of continuous text.

While an evaluation of topic models by humans is considered the gold standard [16], the required time effort has sparked the need for automated evaluations, especially for testing a large number of pre-processing and parameter configurations. Many criteria and methods have been proposed, discussing, for instance, the similarity [17], stability [14] or semantic coherence [18–20] of topics. While a negative correlation to human interpretability has been reported for some methods [16], semantic coherence has been shown to provide assessments of high quality [8, 19–21]. It is often calculated based on normalized pointwise mutual information (NPMI) [19, 21]. The idea is that a topic is of higher quality when the terms strongly associated to the topic often occur in close proximity in a text corpus. Following the discussion above, measuring semantic coherence by NPMI is used in this paper for assessing various topic model configurations before the final topic model is humanly interpreted.

2.2 Related Work and Research Gap

Topic modeling and in particular LDA is widely applicable to a large range of contexts and has been successfully employed to, for instance, consumer good reviews [8], research articles [22], hotel critiques [23] and even in BPM [24]. A tutorial for applying LDA in IS in general has been proposed as well [8]. However, the high degree of abstraction and flexibility also come at a price: An adaption to the application context is necessary to provide proper results. Despite much existing work to use text mining in HRM [9, 10], a literature search revealed that little of it has addressed topic modeling.

A notable exception is a work suggesting topic modeling for job offers [4]. The objective was to identify competences of importance in the construction industry. This research is similar to ours in the sense that a topic modeling approach was used for this task. However, the aim differs, because instead of CVs, job offers have been analyzed. Furthermore, no procedure for knowledge discovery is described.

In further research, *LinkedIn* profiles of BPM professionals are examined via topic modeling to investigate the role of gender in BPM [12]. While here, a topic modeling approach is applied to documents which are similar to CVs, the aim of the research is completely different to ours. Usability for recruiting is not discussed and no procedure for knowledge discovery is presented.

To sum up, none of the existing works has proposed a procedure for knowledge discovery from CVs using topic modeling. Thus, following existing literature in this regard leads to multiple crucial issues, which constitutes the research gap addressed by this paper: First, not considering the type and characteristics of documents to be analyzed produces non-optimal results. For instance, this is due to generic text pre-processing (e.g., in the case of CVs, no removal of author's contact details). Second, existing approaches cannot even be readily applied, as essential steps are not described. For example, the acquisition of CVs and their general pre-processing is not discussed in existing topic modeling literature. Finally, the goals of applying topic modeling to CVs are not considered in existing works. This means that, critically, it remains unclear how to use the topic modeling results for actual benefit in HRM (e.g., for recruiting).

3 Knowledge Discovery from CVs

Subsequently, our procedure for knowledge discovery from CVs is presented. Figure 1 illustrates the five steps of the procedure, adapted from the process for topic modeling in general IS as proposed in [8]. After the initial acquisition of CVs (i), general pre-processing (ii) and text pre-processing (iii) are required. Only then, the preprocessed CVs can be analyzed by applying LDA (iv). Finally, the results of the application can be interpreted and used (v). The five steps are described in detail in the following.

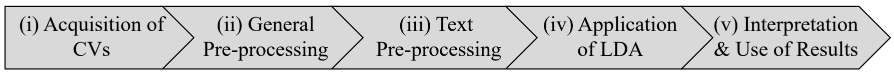

Figure 1. Steps for knowledge discovery from CVs

3.1 Acquisition of CVs

With unstructured data proliferating on the web, many options for acquiring CVs are available. The most prominent ones are utilizing (a) professional social networks such as *LinkedIn*, (b) specialized portals such as *Indeed* and (c) a web crawler.

(a): Professional social networks offer members the opportunity to present themselves to companies and recruiters via disclosing information on their profile. This includes, in particular, past work experience, education, skills, abilities, publications and interests as well as contact information. The information can be extracted from the profiles to generate CV-like documents. Internal and external tools for extraction are readily available for the most common professional social networks (e.g., *LinkedIn*, *XING*). For example, *LinkedIn* itself offers a native functionality to export member profiles as CVs in PDF format. Moreover, these portals allow members to directly upload their CVs, which can then be accessed and stored.

(b): Many job portals (e.g., *Indeed*, *CareerBuilder*, *Monster*) encourage their users to post their CV. These portals offer a (keyword) search engine which can be used to obtain CVs. For example, in Q2 2018, an exemplary search for CVs with "Data Scientist" as job title in New York City produced over 1,100 hits on *Indeed*. CVs resulting from a search can be accessed and, subsequently, stored in PDF format.

(c): Another opportunity for the acquisition of publicly available CVs is the use of a web crawler. A web crawler is an automated program able to navigate the web and store relevant information. Specifically, such a web crawler can be fed with desired search terms and programmed to find and store PDFs including these search terms. This allows the acquisition of CVs from the general searchable web. In particular, also CVs available on private homepages can be found and stored.

3.2 General Pre-processing

Once a sufficient quantity of PDFs containing CVs has been obtained, a general pre-processing of this collection of data is required to ready the collection for text pre-processing and further analyses. Depending on the way the PDFs were obtained, the common challenges (C1) or (C2) may need to be resolved:

(C1) The language of the documents does not match, causing problems for many text pre-processing routines. To address this issue, an approach for automatic language identification [25, 26] can be used. A high quality of automatic language identification can be achieved as CVs contain a substantial number of words.

(C2) The collection of data does not exclusively consist of CVs (e.g., when the PDFs were obtained using a web crawler). Obviously, this issue can lead to unsatisfactory results in the later stages of analysis, for instance, when a job offer instead of a CV is erroneously assessed to be the optimal match for a search query. A human is able to almost instantly decide whether a PDF is a CV or a non-CV with a very high degree of confidence. However, a manual distinction of CVs and non-CVs may still not be promising due to the substantial time effort required for assessing a large collection of data by hand. Thus, automated methods such as classification algorithms can be used.

In any case, PDFs should be converted to a more manageable format (such as TXT) for further analyses, and be fitted in a database for storage. As suggested in [8], an exploratory data analysis may be performed to detect possible data quality issues and to obtain a general understanding of the data to be analyzed.

3.3 Text Pre-processing

Meaningful text pre-processing before the application of a topic modeling approach is of high importance [8]. This is particularly the case for CVs, which contain many terms or even whole components irrelevant to the envisioned goal of knowledge discovery. There are simple and well-known pre-processing routines which are accepted to be valuable for (almost) all kinds of texts. Common examples are the removal of formatting tags and special characters, tokenization (i.e., splitting up documents into words), lowercasing and the removal of words occurring only in few documents. These routines can be looked up in renowned sources [27, 28]; in the following, we discuss routines which possess special characteristics with regard to CVs more explicitly.

N-gram-Creation. N-grams (expressions consisting of two or more words) instead of single words can be considered for further text analysis. For instance, many competence descriptions (e.g., ability in software such as Visual Studio) in CVs contain multiple words. Thus, a thorough creation of n-grams may be of importance. However, care needs to be taken because many skill descriptions in CVs are often used together but are not a real expression. For example, disclosing language skills in English and Spanish is common, which might lead to an incorrect 2-gram "English Spanish".

Stop Word Removal. Words that occur frequently, but are uninformative and decrease the quality and interpretability of topics need to be removed. To achieve this goal in the context of CVs, multiple types of words have to be eliminated. The first type includes general language-specific stop words, which usually are words that have only a grammatical or syntactical function such as propositions. The second type are CV-specific stop words, which are words commonly occurring in all kinds of CVs (e.g., "resume", "name"). The third type are stop words specific for the CV database at hand. To identify these stop words, word frequency lists can be used [27]. Finally, numbers may or may not also be seen as "stop words". When competences are to be modeled as topics, numbers tend to obscure the results; thus, they should also be filtered.

Part-of-speech Filtering. Research has provided varying results with respect to which parts of speech should be filtered using LDA [8, 29]. Against this background and taking into account that CVs contain a word distribution different from other types of documents (e.g., higher prevalence of nouns), part-of-speech filtering needs to be analyzed and adapted to obtain optimal results. In any case, nouns are not to be filtered as they transport essential information regarding competences.

Stemming & Lemmatization. Both stemming and lemmatization aim to decrease the number of considered terms by consolidating similar words. Stemming strives to truncate words to their stem, while lemmatization seeks to reduce words to their dictionary form. Stemming is seen as problematic for the application of LDA [27, 30, 31], for instance due to the danger that words with substantially different meaning are consolidated. Lemmatization, on the other hand, has mostly shown positive effects [29, 31]. However, CVs are structured differently than other types of documents, for example with respect to parts of speech; hence, the use of lemmatization should also be analyzed and adapted with respect to the database at hand to obtain optimal results.

Named Entity Recognition. Approaches for named entity recognition classify named entities in text into pre-defined categories (e.g., person names). The appearance of names in CVs is particular. CVs contain the name of the CV's author, possibly other person names (e.g., co-authors of publications), location names (referring to, e.g., company sites) and organization names. Location names may be useful in order to pinpoint expertise in certain areas such as the D-A-CH region. Organization names are of high relevance for many descriptions of competences (e.g., Microsoft Office). Person names, however, do not contribute to interpretable topics and should be filtered.

Overall, it has to be stated that – as it is usually the case in text mining – finding a very good pre-processing configuration for topic modeling of CVs is a non-trivial task. One has to experiment with different configurations to obtain optimal results with respect to the database at hand. Based on the discussion above, in the context of CVs, it seems particularly sensible to fix most steps but to experiment with n-gram creation, part-of-speech filtering and lemmatization.

3.4 Application of LDA

LDA requires as input two hyperparameters α and β as well as the total number of topics N. The shape of the CV-topic-distributions is determined by α [13]. When α is large, CVs are described by many topics and thus competences, whereas a small α leads to few topics per CV. Obviously, α should neither be too large (resulting in an unwieldy description of CVs which does not carve out the main competences) nor too small (resulting in only the most prominent competence being identified). The shape of the word-topic-distributions is controlled by β [13]. A large β implies that topics are widespread (i.e., competences are described broadly). A small β, in turn, leads to narrow topics and competences. In practice, α and β are often set to standard values (e.g., $1/N$) which have been shown to work well for a large range of application contexts [8]. Alternatively, an optimization can be performed [32].

If the number of topics N is too small, resulting topics may be general and widespread, representing a large variety of competences. For example, in a database containing CVs from IT experts, programming skills may constitute a single topic and not be differentiated further. As a result, topic distributions of CVs are not very meaningful: The competences of two persons portrayed by CVs with a similar topic distribution may still differ substantially. On the other hand, the more topics, the more challenging it is for humans to grasp all word-topic-distributions and to interpret CV-topic-distributions. Moreover, if N is too large, resulting topics may be very similar to each other. Thus, (almost) the same competences can be represented by multiple topics, leading to interpretation difficulties. The competences of two persons portrayed by CVs with a largely differing topic distribution may still be similar. To determine a favorable number of topics N, evaluation methods for topic models (cf. Section 2.1) can be used. Then, the resulting topics can be analyzed with regard to their human interpretability. In particular, it can be checked whether competences of interest are represented by topics or pre-processing configuration and LDA application need to be refined.

3.5 Interpretation & Use of Results

Once the topic model has been constructed, the actual knowledge discovery can begin. The topic model provides both word-topic-distributions and CV-topic-distributions.

The word-topic-distributions can be analyzed to obtain an understanding of the subjects generally present in the CVs. On a more fine-grained level, analyses of each topic – in particular, of the words with the highest probability in each topic – can be conducted to allow for their interpretation. Ideally, many of the topics clearly represent specific competences (e.g., web development). It is to be expected that also other topics representing, for instance, university or school career are contained in the model. In any case, as long as topics are interpretable, they should be labelled accordingly. Preferably, multiple persons label topics independently and compare their assessments afterwards.

The CV-topic-distributions offer a succinct description of each CV's topics. They allow to analyze CVs with respect to contained topics, in particular with respect to the competences of the portrayed person. This is especially helpful when topics have already been labelled. Then, the competences of a person portrayed by a CV can be assessed rapidly by observing the respective CV-topic-distribution and taking into account the labels associated to the most prevalent topics. Such an assessment is useful in HRM (e.g., for swift decision support in regard to the relevance of applicants for a job offer). Here, it is also important to note that using LDA, the topic distribution of a fresh CV can be determined quickly without re-running the whole model. Moreover, based on CV-topic-distributions, CVs may be categorized or tagged for future use. For example, all CVs which exhibit a proportion above 40% for a topic representing web development skills can be marked as relevant for future job offers in this area.

Furthermore, based on word-topic-distributions and CV-topic-distributions, techniques for post-processing LDA results can be applied. This includes in particular visualization approaches (e.g., [33, 34]) which assist analysts in gaining an overview and interpreting. For instance, LDAvis [34] provides clear illustrations of word-topic-distributions and offers to display terms particularly characteristic for a topic based on a relevance metric. This can be helpful to pinpoint rare but valuable competences occurring almost exclusively in a certain topic. If a specialist possessing this rare skill is required, the respective CV can then be retrieved quickly.

Obviously, there are further possibilities yet to be explored. We describe the following technique of a *topic-based search for CVs* as an exemplary idea. To facilitate this technique, in a first step, topics of interest and interpretable as competences are extracted from the LDA model and labelled. Based upon these topics, a query can be formulated which represents the desired competences in form of a search vector. For instance, if a Java developer with complementary competences in web development and web design is in demand, the emphasis may be 50% on Java programming, 30% on web development and 20% on web design. The search vector would thus include the values 0.5, 0.3 and 0.2 for topics representing Java programming, web development and web design respectively and 0 for all other topics. Then, the similarity between the search vector and the CV-topic-distributions of each CV can be calculated based on established similarity measures such as cosine similarity or Kullback-Leibler divergence for topics [17]. The most similar CVs can be manually screened and promising candidates can be contacted for recruiting. Such a topic-based search possesses clear advantages compared to a usual keyword search (e.g., also on platforms such as *LinkedIn* and *Indeed*), which can be illustrated by the example above:

1) The topic-based search allows to search for actual competences and not just for words which may or may not represent these competences reasonably well. For instance, a CV may not contain the term "web development" but the portrayed person may still report experience in JavaScript, HTML and PHP. The respective CV would be deemed irrelevant by a keyword search, whereas the topic-based search acknowledges the competence in web development.

2) In the topic-based search, it is possible to put emphasis on an aspect and the mere occurrence of a keyword is not enough for a CV to be relevant. For example, the specification that Java skills should make up for 50% of a CV's topic distribution means that CVs indeed need to contain a lot of Java-related terms to be assessed as relevant in the topic-based search. In contrast, a keyword search for terms such as Java is not very promising because a large number of CVs will claim at least some competence in Java.

3) The topic-based search allows to specify a weighting between different competences. In the example, Java programming is weighted with 50%, web development with 30% and web design with 20%. However, in a simple keyword search, each keyword would be treated as equally important. Weighting allows to more accurately identify the candidates which fit the requirements best (e.g., that Java development skills are most important and the other competences are complementary).

4 Application and Evaluation

In this section, we first describe how we exemplarily applied the procedure presented in Sections 3.1-3.5. In addition to this demonstration of practical applicability, we also evaluate the feasibility of the results within Section 4.5.

4.1 Acquisition of CVs

For our exemplary application, we decided to focus on CVs from IT experts for the following reasons. First, IT experts often possess diverse competences (e.g., programming languages, software, ...) which they report in their CVs. A topic modeling approach adapted to CVs should be able to identify these competences and categorize them into interpretable topics. Second, focusing on a single area provides a particular challenge for the procedure. CVs portraying persons with completely different competences are relatively easy to distinguish. However, a procedure that provides good results even when applied to CVs which are quite similar to each other – as in this case, CVs from IT experts – is of greater practical usefulness because more fine-grained distinctions can be made. Third, projects in companies often require IT experts with specific competences and thus, this application context is highly important.

To obtain CVs from IT experts, we used a web crawler (cf. Section 3.1, c)). This choice was made to allow the acquisition of CVs from private homepages, which many IT freelancers maintain. The web crawler was fed with search terms commonly used in IT (e.g., "Java") and including "CV". Based on these search terms and starting from the *Google* search, the web crawler stored approximately 27,000 PDFs.

4.2 General Pre-processing

To ready the collection for text pre-processing, we had to resolve the challenges (C1) and (C2) described in Section 3.2. PDFs were stored in a MongoDB database and converted to TXT for further analyses.

In order to address (C1) the diverse languages present in the collection, we performed automatic language identification and partitioned the collection accordingly. To this end, we used a Java open source tool [35]. On a manually inspected test sample of 100 documents, the approach did not produce any errors. We proceeded with German documents as those represented the largest proportion of the collection.

With regard to (C2), we observed that a quite large percentage of documents were not actually CVs. Thus, we manually classified documents into CVs and non-CVs to obtain a training dataset and built a classification model based on majority voting of the common classification methods logistic regression, support vector classification and random forests. The classification into CVs and non-CVs reached an accuracy of 95% on a test dataset of 1,291 documents and was applied to the remainder of the collection.

Overall, general pre-processing resulted in a database of 2,410 (presumed) CVs in German language which we used for further analyses. An exploratory data analysis was performed to obtain an overview. For instance, we determined the number of total (3,504,014) and unique (242,416) terms in the database and analyzed which terms occurred most frequently (all of them common stop words for German texts).

4.3 Text Pre-processing

The pre-processing routines with special characteristics in regard to CVs were set up as follows: In order to determine a comprehensive stop word list, we started by integrating established lists [36, 37]. Then, we modified this list by incorporating CV-specific stop words based on own reflections as well as an analysis of the 1,500 most frequent words in the database. The CV-specific stop words included in particular time specifications, legal forms of organizations and forms of address. Numbers were filtered as well. In contrast, terms such as "C" or "R" were removed from the list, as they represent ability in the respective programming languages in the given context.

To create n-grams, we used the NPMI-based method from the Python topic modeling library gensim [38]. 2-grams were created for terms with a NPMI value of at least 0.5 and a joint occurrence frequency of at least 100. Analogously, 3-grams were created from 2-grams (e.g., "Microsoft Visual" and "Visual Studio" were combined to "Microsoft Visual Studio") and so on. In this way, many n-grams were created, the most frequently used ones being "SQL Server", "SAP R3" and "MS Office".

Part-of-speech tagging was realized by the aggregated results of two taggers. We used TreeTagger [39], a tagger based on a probabilistic Markov model pre-trained for the German language, and the Natural Language Toolkit [40] tagger which was trained with the TIGER corpus [41]. On a manually inspected test sample of 400 words, tagging in this way exhibited an accuracy of 96%. TreeTagger was also used for lemmatization.

For named entity recognition, the Stanford NER Tagger [42] was used. Its results were then refined by publicly available lists of first names [43, 44] and a phone book for surnames, achieving a true positive rate of 97% in regard to filtered person names.

As suggested in Section 3.3, we fixed many of the pre-processing routines but let others vary and experimented in order to achieve optimal results. To be more precise, we always – and in this order – removed formatting tags and special characters, tokenized and lowercased the CVs and removed stop words and words occurring only in few documents. We experimented with n-gram-creation (yes/no), lemmatization (yes/no), part-of-speech filtering (possibly filtering adjectives and/or verbs and/or adverbs) as well as the threshold for words to occur in too few documents (50/40/30/20/10). Overall, this resulted in 160 pre-processing configurations.

For each configuration, LDA models were generated using the gensim libary [38] and each number of topics $N \in \{25,50,75,100\}$, following [32]. Convergence was tested as suggested in [15]. Subsequently, the generated LDA models were evaluated with respect to semantic coherence (cf. Section 2.1). We determined the configuration leading to the highest value of semantic coherence and used it for optimizing the LDA application (cf. Section 4.4). Thereafter, to verify the results, we re-ran the evaluation of all configurations with the optimized LDA model. The configuration leading to the highest value of semantic coherence (NPMI: 0.161) did not consider n-gram-creation and lemmatization, filtered adjectives as well as verbs and adverbs, and filtered all words occurring in less than 40 documents.

The results in regard to n-gram-creation and lemmatization may surprise at first. However, they are in line with previous research in other application contexts suggesting that LDA derives required semantic relations itself and stronger pre-processing reduces topic model quality [30]. Similarly, filtering all parts-of-speech except nouns has also already been shown to provide strong results [29] and is expected to be promising for CVs, with competences usually being described by nouns.

4.4 Application of LDA

The hyperparameters α and β were optimized similar to the pre-processing configuration, again following [32]. To determine the number of topics N, we generated LDA models for each $N \in \{2,4,6,...,100\}$ based on the optimal pre-processing configuration. We then analyzed semantic coherence for each N. This led to choosing

N=42, a number of topics manageable for humans. Thus, the respective topic model was examined further with respect to interpretability and use of results.

4.5 Interpretation & Use of Results

The interpretation of the topic model was conducted separately by two human coders to account for human subjectivity. Consolidating the interpretation only required to settle minor wording differences. The word-topic-distributions of each topic were analyzed to obtain an overview of the topic model. We observed that topics could generally be categorized into three groups: Group A, the largest group, contained topics describing specific IT-related competences and consisted of 23 topics. The four topics in Group B described competences concerning business & management. The remaining 15 topics in Group C were related to university or school career and, due to our focus on competences, not considered for further analysis. Some topics are shown exemplarily in Table 1. Thereby, a topic is represented by its seven words with highest probability in decreasing order and translations for German words are provided in square brackets. Please note that many English words are used frequently in German CVs, explaining their occurrence in topics.

Table 1. Exemplary topics from each of the groups A, B, C

ID	*Gr.*	*Topic (most probable words)*
1	A	java eclipse entwicklung[development] xml spring j2ee oracle
2	A	linux server administration unix system perl security
3	A	design adobe konzeption[conception] 3d web programmierung[programming] photoshop
4	A	entwicklung[development] web javascript php mysql css html
5	A	windows server ms microsoft support software office
6	A	c r analysis time solution network networks
7	B	management projekt[project] einführung[launch] analyse[analysis] projektmanagement[project management] business durchführung[execution]
8	C	university research school international european science german

Overall, the analysis yielded that most of the topics in Groups A and B are fine-grained topics clearly representing specific competences. More precisely, they do not describe competences rather general for CVs from IT experts such as programming skills, but more distinguishing competences such as programming skills in Java (cf. Topic 1). Employing the relevance metric of LDAvis [34], it was possible to differentiate topics even further and carve out competences highly characteristic for a topic. Usually, this concerned closely associated special frameworks, software or technologies. For instance, the most relevant words of Topic 1 (describing programming skills in Java) then were: jaxb, j2se, jpa, jax, ejb, hibernate, jms. All of them are Java-specific and occurred almost exclusively in Topic 1.

The results support that the topics possess a clear interpretation with respect to describing competences and are thus useful for HRM. Furthermore, based on these results, a topic-based search seemed promising. We labelled 21 of the 27 topics in Groups A and B with respect to the competence described (the remaining 6 topics were judged to not be as clearly interpretable and left out). Besides their use to rapidly assess the competences represented in a CV for HRM (cf. Section 3.5), the labels facilitated the topic-based search. Our prototypical implementation allows the specification of search queries as vectors containing the desired weight for each topic. Similarities between the search vector and the CV-topic-distributions of each CV are calculated based on Kullback-Leibler divergence [17]. The most similar CVs are shown together with their topic distribution. Figure 2 illustrates the GUI of the prototypical implementation with the search query from Section 3.5 and the first search result (CV #545). Clicking on a search result opens the respective CV.

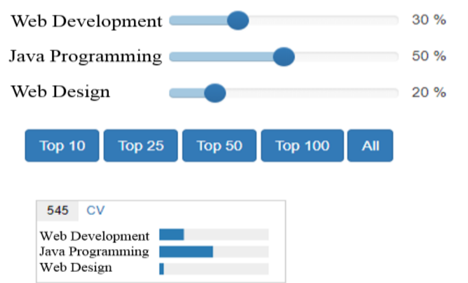

Figure 2. Topic-based search for CVs

CV #545 portrayed a senior Java developer with skills in a large number of Java-related technologies (Spring, Struts, JUnit, JEE, ...). The CV also claimed a lot of work expertise in web development such as the programming of web frontends using HTML and CSS. To a lesser extent, competences in web design and respective software (e.g., Photoshop, Gimp) were reported as well. Thus, the CV fit the job offer represented by the search query exceptionally well. The analysis of the other top 10 CVs which were determined to be the best match for the search query yielded similar results.

For comparison, we also performed a keyword search using the search term *java AND "web development" AND "web design"*. Here, we observed all 3 advantages of a topic-based search outlined in Section 3.5: With respect to 1), the keyword search only yielded 4 results because few CVs actually followed the exact wording dictated by the search term. In particular, many suitable CVs such as the ones found by our topic-based search were neglected by the keyword search. Regarding 2), the problem of merely focusing on keywords became obvious as the CV of a manager who once had conducted a Java project was included in the 4 results of the keyword search, but did in fact not fit the job offer. Concerning 3), the lack of weighting showed when the CV of a web developer specializing in PHP, HTML and JavaScript with basic Java abilities was assessed as relevant. Overall, none of the results of the keyword search fit the job offer well. Our topic-based search thus produced clearly superior results in this setting.

We further specified 8 more search queries and analyzed the respective CVs suggested by the topic-based search. In each case, the competences reported in the top

CVs coincided with the competences called for by the search query. To conclude, the topic-based search worked very well in this application and seems fit to provide helpful decision support for HRM.

5 Conclusion, Practical Implications and Directions for Future Work

In this paper, a topic modeling procedure consisting of five steps with the aim of discovering knowledge from CVs has been presented. CV-specific characteristics are considered in each step. An exemplary application to CVs from IT experts suggests that clearly interpretable topics describing fine-grained competences (e.g., Java programming, web design) can be discovered. This information can be used to rapidly assess the contents of a CV, categorize CVs and identify promising candidates for job offers, thus providing decision support in HRM.

The presented procedure allows for proactive recruiting. It can, for instance, be applied in HRM similar to how professional social networks are currently used in the recruitment process to rapidly source candidates before subsequent steps such as job interviews are conducted. However, it is not restricted to members of these networks as the analyzed CVs may stem from any origin. Additionally, the presented topic-based search possesses advantages compared to a keyword search on these platforms. Moreover, the CV-topic-distributions in conjunction with labels can be used to categorize and tag CVs for future use. In this way, companies can construct and steadily extend a database of interesting CVs. Another promising idea for companies is to also include CVs of own employees to promote internal recruiting. In any case, HRM and IT departments need to cooperate as skills from both areas are required to achieve a successful application of the procedure.

While the paper at hand offers a detailed description of a procedure for knowledge discovery from CVs, there are also limitations which provide directions for further research. First, an application to CVs from a different context should be conducted to validate feasibility. Second, a topic-based search technique has been presented and evaluated in an exemplary setting. However, it should be further assessed, for instance by a more detailed comparison to alternatives (e.g., with the help of a HRM expert) and an application to real job offers from a company. Finally, CV-specific visualization approaches should be developed, allowing for an easier overview and use of the results of the procedure. They should be included in a tool facilitating and partly automating the five steps of the procedure to further its practical use.

Online Product Descriptions – Boost for your Sales?

Tristan Wimmer[1], Michael Scholz[1]

[1] University of Passau, School of Business, Economics and Information Systems, Passau, Germany
{michael.scholz,tristan.wimmer}@uni-passau.de

Abstract. Product descriptions are a source of information online consumers can use to reduce product uncertainty. Recent research provides evidence that consumers favor using information from other consumers, such as customer reviews, over retailer or manufacturer provided information, such as product descriptions. We complement this research and show that the presence of product descriptions significantly influences products' sales and that this influence decreases with an increasing number of customer reviews. We furthermore demonstrate that a product description's information amount positively affects a product's sales. The number of customer reviews available for a product also moderates the effect of the information amount of a product description on sales.

Keywords: Product Description, Product Uncertainty, E-Commerce, Customer Reviews

1 Introduction

Online consumers face a barrier in physical experience of products. While consumers in offline markets can touch the product of their choice, online consumers hardly can evaluate a product's physical characteristics prior to purchase. Consumers in online as well as offline markets typically perceive uncertainty in purchase decision processes [1–3].

Pavlou et al. [4] investigated reasons for perceived product uncertainty by considering the relationship between sellers and consumers as a principal-agent problem. Amongst others, they identified information asymmetry as one of the most important determinants of perceived uncertainty. This information asymmetry refers to the seller or the product and finally leads to seller uncertainty or product uncertainty [4, 5]. Seller uncertainty is defined as consumer's difficulty to predict a seller's behavior in the future whereas product uncertainty refers to the difficulty to evaluate a product's quality prior to purchase [2, 6].

Product descriptions often are the only information source for consumers. Customer reviews and expert tests especially are not available for new products. In contrast to customer reviews, sellers furthermore can control the content of product descriptions. Thus, product descriptions likely will influence sales. However, product descriptions and their impact on sales have been sparsely addressed in recent research. We focus on

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

the effect of product descriptions on the reduction of product uncertainty. We follow Pavlou et al. [4] and assume that a lower product uncertainty leads to higher sales and analyze the impact of product descriptions on sales. The research question investigated in this paper therefore is as follows:

RQ: What is the effect of product descriptions on product sales?

Our empirical investigation shows that products with a product description generate higher sales than products without a description. We provide evidence that the information amount of product descriptions is positively correlated with products' sales.

With this paper, we contribute to recent research by (1) examining the effect of the presence and the information amount of product descriptions on sales, (2) distinguishing between the effect of product descriptions written by a retailer and product descriptions written by a manufacturer, (3) investigating the interaction effect of product descriptions and customer reviews on sales.

The remainder of this paper is organized as follows. In the next section, we review related research. We thereafter discuss the theoretical background on product uncertainty and its reduction. Afterwards, we describe our research model followed by a description of our empirical evaluation. We then present the result of the empirical evaluation and of some robustness checks. We conclude this paper with a summary of our results and a discussion of the implications for researchers and practitioners.

2 Related Research

Consumers in offline markets can inspect a product's physical characteristics and can get personal advice from the seller. Consumers in online stores, such as Amazon or Staples, predominantly have two sources of information to learn about a product's characteristics: customer reviews and product descriptions [7]. Consumers typically have a higher trust in information from other consumers than from a producer or a marketplace [8]. Recent research thus has intensively investigated the effect of customer reviews, as one source of information, on consumers' purchase decision processes and retailers' sales [9–11]. These studies demonstrate that customer reviews affect purchase decisions and ultimately sales to a large extent. Wang et al. [12] investigated customer reviews embedded in product descriptions and found, that embedded customer reviews rise sales.

The more reviews are available, the lower is a consumer's perceived product uncertainty [13, 14]. But if there are no or only a few customer reviews available, consumers tend to consult other information sources (e.g., Question and Answer (Q&A) technologies or product descriptions). Banerjee et al. [15] found evidence, that question and answer technologies can reduce a consumer's uncertainty, whether the product fits her needs, affecting the review quality. However, implementing such Q&A technologies is not costless and thus, most market places do not provide such technologies which in turn forces consumers to contact other information resources such as product descriptions. Dimoka et al. [2] found evidence that product descriptions reduce product uncertainty most significantly among several information sources, such as product descriptions, product inspections, history reports and product warranties. Further, Detlor et al. [16] found evidence, that product descriptions are important in pre-purchase online information seeking. Hence, product descriptions are another important source for reducing product uncertainty with two major advantages compared to customer reviews: First, product descriptions are also available in the absence of customer reviews, because they are provided by the seller. Thus, product descriptions are often the only source of information consumers can digest to learn about a product's characteristics prior to purchase. And second, sellers can control product descriptions and hence the extent to which they reduce product uncertainty.

We discuss the relationship between product uncertainty and sales and how to reduce product uncertainty in order to improve sales in the next section.

3 Theoretical Background

3.1 Product Uncertainty and Sales

Product uncertainty is defined as consumers' difficulty to evaluate a product's characteristics prior to purchase [17]. The higher the variance of product characteristics the higher is the perceived product uncertainty [6]. A consumer who wants to purchase a new electric toothbrush might feel uncertain about whether a particular toothbrush is controllable via a mobile application. If there is no toothbrush with mobile application support available, there is no variance for this characteristic. Thus, in the case that none of the toothbrushes provides mobile application support there is no product uncertainty. As soon as there are toothbrushes with and without mobile application support available, consumers perceive product uncertainty to a particular extent about the quality of that mobile application support.

Product uncertainty has negative implications for both, sellers and consumers. Recent research has demonstrated that the higher the product uncertainty, the lower is the price premium that can be charged for a particular product [2]. Product uncertainty furthermore negatively affects sales [4] and the number of product returns [6]. Consumers' transaction costs increase with the perceived product uncertainty because consumers need to invest search costs in order to reduce product uncertainty [18]. Furthermore, a rising product uncertainty decreases consumers' purchase intention significantly [4]. Thus, sellers and consumers have a keen interest in reducing product uncertainty. Therefore, sellers and consumers provide information in form of product descriptions or customer reviews to reduce product uncertainty in online stores.

Recent research provided evidence that sales significantly rise when consumers' uncertainty in product quality decreases. Given the positive relationship of low product uncertainty and sales [4], sellers seek to reduce product uncertainty in order to improve their sales. Besides motivating consumers to submit product reviews, sellers also can provide product descriptions that discuss important product features. In the next section, we discuss how sellers can reduce product uncertainty in order to improve their sales in more detail.

3.2 Reduction of Product Uncertainty in Online Stores for Improving Sales

Online consumers want to learn about a product's characteristics before purchase in order to reduce product uncertainty. In offline stores, consumers can reduce product uncertainty by inspecting a product itself and requesting individual advice from the seller. Inspecting products prior to purchase is typically not possible in online stores. Thus, online consumers gather information about a product's characteristics from different information sources, such as product descriptions and customer reviews [19, 20].

Customer reviews are peer-generated product evaluations that typically consist of a product rating and an optional textual description of the experiences with the product [21, 22]. Recent research has shown that the existence of customer reviews reduces product uncertainty and thereby improves consumers' purchase probability [20]. Customer reviews might vary significantly in the product characteristics they discuss. The probability that a consumer can learn about some certain characteristic increases with the number of provided customer reviews [23]. Mudambi and Schuff [21] furthermore find evidence that the length of the textual description of a customer review is positively correlated with the perceived helpfulness of the review. Longer reviews presumably discuss more product characteristics. Archak et al. [24] show that reviews discussing more product characteristics are more influential on consumers' purchase decisions. Similarly, Scholz and Dorner [22] find support that reviews with a higher information amount are more helpful for consumers. Reviews with a higher helpfulness are more likely to reduce product uncertainty [21]. Helpfulness has been furthermore shown to positively affect a retailer's sales [9]. In summary, product reviews are an important source of information. They influence consumers' decision-making processes by reducing information asymmetries and thus by reducing product uncertainty.

In contrast to customer reviews, the effect of product descriptions on reducing consumers' product uncertainty has been sparsely analyzed in existing research. Dimoka et al. [2] investigate the influence of product descriptions on product uncertainty in online car auctions. They provide evidence that the influence of product descriptions is nearly twice as much as that of third-party assurances, such as (car) inspections, history reports or product warranties. Ghose and Han [7] find evidence that the length of product descriptions is positively correlated with sales.

In summary, existing research demonstrates that customer reviews and product descriptions contribute to reduce product uncertainty. A positive impact of customer reviews on sales has also been found in several studies [25–28] . An investigation of the effect of the existence of product descriptions as well as the interaction of product descriptions and customer reviews on sales is missing so far.

4 Research Model

Recent research has illustrated that product uncertainty significantly influences sales [4]. Factors positively influencing product uncertainty are hence likely to negatively influence sales. In the following, we will use sales as proxy for product uncertainty because product sales are easily observable.

Product descriptions have been found to be one source for reducing product uncertainty [2]. If no or not enough information is available for reducing product uncertainty, consumers refrain to buy, especially high-priced products [29]. However, not all products do have a product description being available in an online store. Even the availability of product descriptions might help consumers to learn about product characteristics and thereby reduce product uncertainty and improve sales. We thus hypothesize a positive effect between the availability of a product description and the product's sales.

H1a: Products with a product description generate on average more sales than products without a product description.

The information amount transported in a product description significantly varies across the products. Descriptions discussing more product characteristics are more likely to help consumers reducing product uncertainty. Recent research has provided evidence that customer reviews, as another source of information for consumers, are perceived as more helpful if they discuss more product characteristics that are not widely discussed in other customer reviews [22, 30]. Such an effect has been shown for app descriptions [7]. We expect a similar effect also for product descriptions and thus hypothesize that a product's sales are increasing in the product description's information amount.

H1b: The higher the information amount of a product's description, the higher are its sales on average.

H1a can be seen as a special case of hypothesis H1b. A product description that is not available is equivalent to a product description with an information amount of zero.

Recent research provides ample evidence that the number of customer reviews available for a particular product positively influences this product's sales [14, 28]. Consumers prefer customer reviews over product descriptions because the retailer or manufacturer generates the latter [8]. Product descriptions communicate a positive picture about a product whereas customer reviews also point to a product's drawbacks. However, product descriptions exist, in contrast to customer reviews, even if no consumer has bought or evaluated the product. The more reviews are available, the higher is the probability that a particular consumer will find enough information to reduce product uncertainty and the higher will be the probability to purchase a product. Recent research has demonstrated that the number of reviews positively affects sales [9, 31]. We therefore propose a decreasing impact of a product's description on sales when there is an increasing number of customer reviews available.

H2: The influence of the availability of a product description on a product's sales is moderated by the number of reviews. The more reviews a product has, the lower is the effect of the availability of a description on sales.

Similarly, the impact of a description's information amount might be also moderated by the number of reviews available for a product.

H3: The influence of a description's information amount on sales is moderated by the number of reviews. The more reviews a product has, the lower is the effect of its descriptions' information amount on sales.

Existing research has demonstrated a positive effect of the number of reviews on sales [28]. More customer reviews lead to more sales and hence more customers that are prepared to write further customer reviews. We follow these findings and also propose a positive effect of the number of customer reviews on sales.

H4: The more customer reviews are available for a product the higher are this product's sales.

5 Empirical Evaluation

In order to prove our hypotheses, we collected data for three product categories from Amazon.com. We collected data about 84 backpacks, 131 pencils and 136 electric toothbrushes for a period of 39 days. For each product of each category and day, we gathered the price, the average rating and the number of reviews. Amazon provides typically two kinds of product descriptions: descriptions generated by the manufacturer and descriptions generated by the retailer (Amazon.com). Thus, we collected the product description provided by the manufacturer and the product description provided by Amazon.com for each product. Figure 2 represents an exemplary product description of an electric toothbrush.

The price range for each product category is rather large as shown in Table 1. On the one hand, each category has at least one product which doesn't have any customer reviews (ratings) and on the other hand, each category includes products with a lot of customer reviews (e.g., there are more than 1,000 reviews available for 10 of the electric toothbrushes in our dataset). An Amazon product description is available for 90% of the backpacks, 96% of the pencils and 96% of the electronic toothbrushes in our dataset. Manufacturer product descriptions are significantly less often available than Amazon product descriptions ($p < 0.001$). Only 23% of the collected backpacks, 3% of the pencils and 16% of the electronic toothbrushes provide a manufacturer product description. The mean lengths of Amazon and manufacturer product description differ. Amazon product descriptions furthermore consists of significantly more words than manufacturer descriptions ($p < 0.001$). Amazon descriptions on average are 91.76 words long whereas manufacturer descriptions only consist of 48.13 words. We will use product sales ranks as proxy for sales because sales figures are not available on Amazon.com. Schnapp and Allwine [32], Chevalier and Goolsbee [33], as well as Chevalier and Mayzlin [26] found a linear relationship between ln(sales) and ln(rank). We thus use ln(rank) as dependent variable in order to allow a more straightforward interpretation of the estimated effects on sales. The lower the sales rank of a product, the more instances of this product have been sold compared to other products in the same category. The mean sales rank for the backpacks in our dataset is 3911.85, that for pencils is 244.24 and the toothbrushes in our dataset or on average on rank 307.18. For each product category, we collected top sellers (i.e., products with a sales rank of

1) as well as well as niche products (i.e., products with a rather high category-specific sales rank).

Figure 2. Exemplary Manufacturer and Amazon Product Description of an Electronic Toothbrush

A summary of the collected data variables is provided in Table 1 and Table 2.

Table 1. Variables Overview

Variable	*Symbol*	*Description*
Price	p	Price of the product
Average Rating	avr	Average rating based on customer reviews
Number of Reviews	rev	Number of customer reviews
Amazon Product Description	apd	Availability of an Amazon product description
Manufacturer Product Description	mpd	Availability of a manufacturer product description
Sales Rank	rank	Sales rank of the product
Day	d	Day at which the data have been collected
Length Amazon Product Description	la	Number of words in the Amazon product description
Length manufacturer Product Description	lm	Number of words in the manufacturer product description

Table 2. Descriptive Statistics of the Variables in the Dataset

Variable	*p*	*avr*	*rev*	*apd*	*mpd*	*rank*	*la*	*lm*
Backpacks (min)	7.99	-	0	0	0	10	0	0
Backpacks (max)	447.5	5	2822	1	1	72690	307	377
Backpacks (mean)	65.82	4.28	388.97	0.91	0.23	3911.85	91.76	48.13

Toothbrushes (min)	3.8	-	0	0	0	1	0	0
Tooth-brushes (max)	199.99	5	6233	1	1	1466	510	1018
Tooth-brushes (mean)	44.55	3.95	316.47	0.95	0.16	307.18	145	93

6 Analysis and Results

6.1 Effect of Product Descriptions

In H1a, we hypothesized that products with an available product description generate on average more sales than products without a product description. According to H2, the number of customer reviews available for a product moderates this effect. H4 proposes a positive effect of the number of customer reviews on sales. In order to test H1a, H2 and H4, we estimate the effect of the presence of a product description binary-coded by the variables apd (Amazon product description) and mpd (manufacturer product description) on product i's sales rank rank at day d. We use price p, average rating avr and number of reviews rev as control variables, because they have been found to significantly affect sales ranks [11]. More specifically, we estimate the following model with fixed product and time effects for investigating H1a, H2 and H4:

$$\begin{aligned}\log\left(rank_{i,d}\right) = {} & \beta_1 \log(p_{i,d}) + \beta_2 avr_{i,d} + \beta_3 \log(rev_{i,d} + 1) + \beta_4 apd_{i,d} + \beta_5 mpd_{i,d} \\ & + \beta_6 \log(rev_{i,d} + 1) apd_{i,d} + \beta_7 \log(rev_{i,d} + 1) mpd_{i,d} \\ & + \beta_8 category + \gamma_1 d + \gamma_2 i + \varepsilon_{i,d}\end{aligned}$$

We use the logarithm of product i's price to model a diminishing effect of price on sales rank. A price difference between 200 and 210 Euros might be less relevant for a consumer than a price difference between 20 and 30 Euros. We also use the logarithm of each product's number of reviews to model a diminishing effect of this variable on the sales rank. Furthermore, we use the logarithm of each product's sales rank as dependent variable in order to model diminishing perceived differences between sales ranks [34]. Variance inflation factors of less than 2 indicate the absence of multicollinearity in our model. Based on a Durbin-Watson test, we did not find an indication for autocorrelated residuals (D = 1.9998, p = 0.497). The results of our regression model with robust standard errors are depicted in Table 3.

Table 3. Effect of Product Descriptions on log(Sales Rank)

Variable	*Estimate*	*Std. Error*	*t-Value*	*p-Value*
log(Price)	0.361	0.030	11.950	< 0.001
Average Rating	0.062	0.016	3.922	< 0.001
log(Number of Reviews+1)	-0.634	0.055	-11.506	< 0.001
Amazon Product Description	-0.778	0.159	-4.898	< 0.001
Manufacturer Product Description	-0.606	0.221	-2.742	0.006

log(Number of Reviews + 1) x Amazon Product Description	0.178	0.051	3.484	< 0.001
log(Number of Reviews + 1) x Manufacturer Product Description	0.083	0.028	2.926	0.003
Pencils	-3.163	0.106	-29.947	< 0.001
Toothbrushes	-2.496	0.134	-18.658	< 0.001
Adj. R^2 (full model)		0.960		
Adj. R^2 (projected model)		0.341		

As expected, Table 3 also shows that a lower price and a higher number of customer reviews result in a better sales rank. A somewhat counterintuitive result that emerges from Table 3 is that a better (higher) average rating increases the sales rank. One would expect that a better rating would decrease the sales rank. However, previous research has shown that there exists a negative relation between sales and average rating for some product categories [35]. Customer ratings typically follow a J-shape distribution with most ratings being very positive (i.e., they are 5-star ratings) [36]. Consumers might fear manipulated 5-star ratings and rather trust products being characterized not only by 5-star ratings, which ultimately might lead to a positive observed relation between sales rank and a product's average rating.

The results in Table 3 indicate that both types of product descriptions – Amazon and manufacturer descriptions – significantly influence a product's sales rank. The existence of an Amazon product description on average decreases the sales rank by 2.18 ranks whereas the existence of a manufacturer product description decreases 1.82 ranks. Amazon descriptions hence have a higher impact on a product's sales rank. Manufacturers should consequently create descriptions for their products in order to improve their sales. Our hypothesis H1, that the presence of a product description has a significantly positive influence on sales is therefore supported by our data.

In H2, we proposed that the effect of product descriptions on sales will diminish with an increasing number of customer reviews. Positive estimates of the interaction effects between the number of reviews and the availability of both, Amazon product descriptions and manufacturer product descriptions, show support for H2.

The negative estimate for the number of reviews indicates that more customer reviews lead to a better sales rank and hence more sales. This is in support of hypothesis H4.

Our results show a high importance of product descriptions for improving a product's sales. We will analyze the impact of the information amount of Amazon and manufacturer product descriptions in the next section.

6.2 Effect of Product Descriptions' Information Amount

In H1b, we hypothesized that a higher information amount in a product description will lead to a better sales rank. To test H1b, we use the number of words as a proxy for a description's information amount. H3 hypothesizes an interaction effect between the number of reviews and the information amount of product descriptions. We again test hypothesis H4 with this analysis. We use the following model to prove H1b, H3 and H4.

$$\log(rank_{i,d}) = \beta_1 \log(p_{i,d}) + \beta_2 avr_{i,d} + \beta_3 \log(rev_{i,d} + 1) + \beta_4 \log(la_{i,d} + 1) + \beta_5 \log(lm_{i,d} + 1) + \beta_6 \log(rev_{i,d} + 1) \log(la_{i,d} + 1) + \beta_7 \log(rev_{i,d} + 1) \log(lm_{i,d} + 1) + \beta_8 category + \gamma_1 d + \gamma_2 i + \varepsilon_{i,d}$$

With variance inflation factors of less than 2.1, we can assume that our model is not subject to multicollinearity. A Durbin-Watson test also indicated that our model is not subject to an autocorrelation problem (D = 1.9998, p = 0.496). The results in Table 4 again show that a lower price and a higher number of customer reviews result in a better sales rank. Table 4 also shows that the information amount of Amazon product descriptions has a significant positive influence on a product's sales rank (the higher the information amount, the lower is the sales rank). The effect of manufacturer descriptions is in the same direction but only weakly significant. Hypothesis H1b is hence supported partially.

H3 proposes a diminishing effect of the information amount of product descriptions on sales when the number of customer reviews increases. As shown in Table 4 and Figure 3, we found such a diminishing effect for both Amazon and manufacturer product descriptions. The interaction effect of the number of customer reviews and the information amount of manufacturer descriptions is, however, only weakly significant. The more customer reviews are available the higher is the estimate for the information amount indicating that a higher number of available customer reviews leads to a diminishing effect of the information amount on sales. Hypothesis H3 is therefore partially supported by our data.

Table 4. Effect of Product Descriptions' Information Amount on log(Sales Rank)

Variable	*Estimate*	*Std. Err.*	*t-Value*	*p-Value*
log(Price)	0.361	0.030	12.097	< 0.001
Average Rating	0.084	0.016	5.252	< 0.001
log(Number of Reviews + 1)	-0.744	0.051	-14.574	< 0.001
log(Length Amazon Description+1)	-0.209	0.030	-7.078	< 0.001
log(Length Manufacturer Description+1)	-0.088	0.048	-1.829	0.068
log(Number of Reviews + 1) x log(Length Amazon Description+1)	0.074	0.011	6.919	< 0.001
log(Number of Reviews + 1) x log(Length Manufacturer Description+1)	0.010	0.006	1.673	0.094
Pencils	-2.746	0.129	-21.218	< 0.001

Toothbrushes	-2.050	0.146	-14.043	< 0.001
Adj. R^2 (full model)			0.960	
Adj. R^2 (projected model)			0.344	

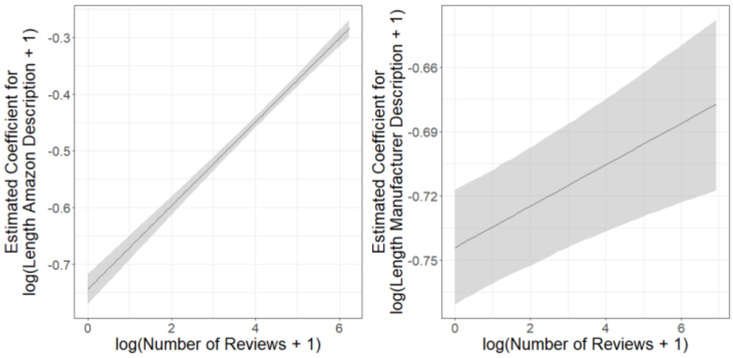

Figure 3. Interaction Effect Between the Availability of Product Descriptions and the Number of Reviews

We again found support for hypothesis H4. A higher number of customer reviews lowers the sales rank which is equivalent to an improvement in sales.

7 Robustness Check

We test the robustness of our results by investigating the effects of product descriptions on quantiles rather than average values of sales ranks. We found a very high variance of 13.075.579 for the sales ranks (2.547 for log(sales ranks)) in our data set indicating that our data set encompasses blockbusters as well as niche products. Thus, we analyze the effects of product descriptions on quantiles of sales ranks. More specifically, we run quantile regressions at the 25, 50 and 75% quantile of our dependent variable sales ranks. We estimate the regression model again with fixed product and time effects. Table 5 shows the results for the additional quantile regressions and the effect of the availability of product descriptions.

Table 5. Results of Quantile Regressions for Availability of Product Descriptions

Variable	Estimate 25% quantile	Estimate 50% quantile	Estimate 75% quantile
log(Price)	0.276***	0.289***	0.284***
Average Rating	-0.002	0.007	0.021
log(Number of Reviews + 1)	-0.530***	-0.553***	-0.562***
Amazon Product Description	-0.552***	-0.511**	-0.487**
Manufacturer Product Description	-0.711***	-0.759***	-0.744***

log(Number of Reviews + 1) x Amazon Product Description	0.104*	0.103*	0.101*
log(Number of Reviews + 1) x Manufacturer Product Description	0.057*	0.062**	0.058**
Pencils	-3.235***	-3.180***	-3.128***
Toothbrushes	-2.576***	-2.601***	-2.627***

Significance codes: *** $p < 0.001$, ** < 0.01, * < 0.05

Table 5 indicates that Amazon product descriptions as well as manufacturer descriptions significantly affect sales rank. The influence of manufacturer descriptions is higher than of Amazon descriptions and in opposite to the Amazon descriptions, the influence of manufacturer descriptions slightly increases for niche products. The biggest influence of Amazon product descriptions is for blockbusters. In summary, the effect of the existence of product descriptions is rather robust to products with different sales ranks.

Table 6 depicts the results for the quantile regressions and the effect of the information amount of product descriptions. All findings from Table 4 are supported by the results in Table 6. Thus, they are robust for products with different sales ranks.

Table 6. Results of Quantile Regressions for Information Amount of Product Descriptions

Variable	Estimate 25% quantile	Estimate 50% quantile	Estimate 75% quantile
log(Price)	0.266***	0.277***	0.273***
Average Rating	0.028	0.037*	0.050**
log(Number of Reviews + 1)	-0.629***	-0.645***	-0.660***
log(Length Amazon Description+1)	-0.168***	-0.150***	-0.156***
log(Length Manufacturer Description+1)	-0.144***	-0.153***	-0.153***
log(Number of Reviews + 1) x log(Length Amazon Description+1)	0.045***	0.043***	0.045***
log(Number of Reviews + 1) x log(Length Manufacturer Description+1)	0.012*	0.013*	0.013*
Pencils	-3.189***	-3.136***	-3.084***
Toothbrushes	-2.550***	-2.582***	-2.607***

Significance codes: *** $p < 0.001$, ** < 0.01, * < 0.05

8 Discussion

This paper examined the influence of product descriptions on sales. Based on empirical data from Amazon.com, we found that the existence of product descriptions positively affects sales. This finding is valid for descriptions generated by the manufacturer as well as by Amazon. Amazon descriptions have been found to have a slightly stronger influence on products' sales than descriptions generated by the manufacturer. Products offered online should hence be described by product descriptions.

We furthermore demonstrated that product descriptions that have a higher information amount are more influential on products' sales. The higher the information amount, the better the product description is prepared to reduce consumers' product uncertainty. We demonstrated that especially Amazon product descriptions positively influence sales rank. Finally, we analyzed the interplay between product descriptions and customer reviews and showed that Amazon-generated descriptions especially affect sales of products having no or only a few customer reviews. Manufacturer-generated product descriptions, in contrast, have been found to have a higher impact on sales for products having many reviews. This indicates that consumers might have a higher trust in Amazon descriptions. Further, our robustness check showed that the effect of the existence of product descriptions is independent of its sales rank.

Our research hence has four major managerial implications. First, we analyzed observational data from Amazon. We hence cannot exclude the problem of endogeneity. Manufacturers of successful products (i.e., products with a high number of sales) might have on average longer product descriptions then manufacturers of not successful products. The availability as well as the length of a product description thus can be consequence of the success of a product. Second, manufacturers and retailers should not only incentivize their consumers to provide reviews but also provide product descriptions on their own. We found that an Amazon-generated product description improves a product's sales rank by more than two positions on average.

Third, the longer a product description, the better it helps reducing product uncertainty and the more consumers finally buy the product. Following Mudambi & Schuff [21], we assume that longer product descriptions discuss more product characteristics and hence have a higher information amount.

And fourth, it is worthwhile to provide a product description also for products that already got many customer reviews. In the case of Amazon as online store, we found that especially product descriptions generated by manufacturers have a high impact on a product's sales if there are many customer reviews available.

Our research contributes to the ongoing stream of literature on the impact of information sources on consumers' purchase decisions. We demonstrate that the originator of the product description determines the impact of product descriptions on sales. Amazon-generated descriptions have been found to have a higher impact on sales than descriptions generated by the manufacturer.

Our investigation is subject to three major limitations. First, we analyzed the impact of product descriptions and customer reviews on sales only for three product categories – electric toothbrushes, backpacks and pencils. The influence of product descriptions on sales varies across different product categories. Future research should hence investigate further product categories. Second, we found a significant and positive effect of product descriptions on sales, which indicates that consumers use product descriptions to reduce product uncertainty. We, however, did not measure consumers' product uncertainty and instead assumed that product uncertainty has a strong impact on sales. Investigating the effect of product descriptions on consumers' stated product uncertainty and the effect of the stated product uncertainty on sales provides an interesting avenue for future research. And third, the econometric model we used in this study allows to analyze the correlation between sales and independent variables such as product descriptions and customer reviews. We hence cannot exclude that our results are subject to the problem of endogeneity. It might be the case that good sellers provide a product description whereas bad sellers do not. The difference in sales between sellers providing a product descriptions and sellers that do not is then a result of the sellers' quality rather than the availability of a product description. A seller's quality will be translated into sales. With additional robustness checks we show that our findings are valid for different levels of sales making the endogeneity issue not very likely.

Entscheidungsunterstützung durch historienbasierte Dienstreihenfolgeplanung mit Pattern

Lena Wolbeck[1], Bastian Amberg[1], und Natalia Kliewer[1]

[1] Department Wirtschaftsinformatik, Freie Universität Berlin, Berlin, Deutschland
{lena.wolbeck,bastian.amberg,natalia.kliewer}@fu-berlin.de

Abstract. Die Verwendung von Softwarelösungen zur Unterstützung der Personaleinsatzplanung personalintensiver Unternehmen ermöglicht Planungsabläufe zu erleichtern und Einsatzpläne zu optimieren. Dieser Beitrag zielt ab auf eine sozialverträglichere und effizientere Organisation des Personaleinsatzes bei Arbeit im Schichtdienst durch automatisierte Erstellung bestmöglicher Dienstreihenfolgepläne unter Fortschreibung historienbasierter Daten zu Arbeitszeiten und Wunscherfüllung der einzelnen Arbeitskräfte. Als Grundlage dieser Dienstreihenfolgeoptimierung dienen Pattern. Ein Pattern entspricht einem potenziellen Muster an Dienstreihenfolgen in einer Kalenderwoche, das individuell je Arbeitskraft hinsichtlich Gültigkeit, Arbeitszeit und Zufriedenheit bewertet wird. Eingebettet in ein Entscheidungsunterstützungssystem erfolgt die Planerstellung zweistufig. Zuerst werden potenzielle Pattern hinsichtlich der Planungsperiode generiert (Stufe 1). Anschließend erfolgt die Verknüpfung von Pattern und die Generierung eines Dienstreihenfolgeplanes, der den Bedarf an Arbeitskräften abdeckt, mit Hilfe eines Optimierungsmodells (Stufe 2). Der entwickelte Lösungsansatz wird anhand realer Daten eines Wohnheimes für Menschen mit Behinderung evaluiert. Bei maximalen Zufriedenheitswerten generiert das System Dienstreihenfolgepläne, die die Arbeitszeitkonten erheblich besser ausbalancieren als eine manuelle Planung.

Keywords: Entscheidungsunterstützungssystem, Dienstreihenfolge, Pattern, Personaleinsatzplanung, historische Daten

1 Einleitung und Motivation

Jede Einrichtung und jedes Unternehmen, das Dienstleistungen rund um die Uhr (24/7) anbietet, ist mit den Herausforderungen einer lückenlosen Dienstreihenfolgeplanung konfrontiert. Basierend auf längerfristigen Entscheidungen über den Bedarf an Arbeitskräften, die Zusammensetzung der Belegschaft sowie die Art der Schichttypen als Grundlage der Dienste gilt es für den operativen Einsatz der Arbeitskräfte die Dienstreihenfolgeplanung durchzuführen. Eine Dienstreihenfolge bezeichnet hierbei die Abfolge von Diensten und freien Tagen einer Arbeitskraft für eine Planungsperiode.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

1.1 Betrachtete Problemstellung

Bei einem Dienstreihenfolgeplanungsproblem (DRPP) wird folgendes Entscheidungsproblem betrachtet: Es wird eine Zuordnung von einer zu erfüllenden Menge an Diensten einer Planungsperiode zu einer vorgegebenen Menge an Arbeitskräften unter Einhaltung festgesetzter Regeln gesucht. Je nach Anwendungsfall differieren die Zielsetzungen eines DRPP. Unter Einbeziehung individueller Wünsche wird in diesem Beitrag bei der Lösung auf eine maximale Sozialverträglichkeit abgezielt. Quantifiziert wird diese mit Hilfe eines Zufriedenheitswertes sowie der Balance der entstehenden Über- und Unterstunden.

Ohne Beschränkung der Allgemeingültigkeit wird in diesem Beitrag als Planungsperiode ein Monat betrachtet und als Schichttypen zur Dienstbildung werden Frühschicht und Spätschicht berücksichtigt. Jede konkret durchzuführende Schicht entspricht daher einem notwendigen Dienst (pro Tag). Neben Wünschen hinsichtlich bestimmter Dienste bzw. freier Tage werden Urlaubstage und individuelle Arbeitszeitkonten (AZK) der einzelnen Arbeitskräfte beachtet. Bei der Planung sind übliche Regelungen hinsichtlich der Arbeits- und Ruhezeiten wie bspw. *keine Frühschicht nach einer Spätschicht*, *am Wochenende beide Tage frei oder beide Tage Dienst* sowie *Berücksichtigung minimaler und maximaler konsekutiver Arbeitstage* zu beachten.

Die Dienstreihenfolgeplanung ist aufgrund der vielfältigen Regeln eine komplexe Problemstellung und wird heutzutage weitgehend von informationstechnischen Systemen begleitet. Dabei reicht die Entscheidungsunterstützung bei der Planerstellung von simplen Excel-Tabellen zur Veranschaulichung der Pläne zur Erleichterung der manuellen Planung bis hin zu ausgereiften Softwarelösungen mit eingebundenen Optimierungskomponenten, die automatisiert mögliche Pläne vorschlagen. Ein DRPP weist als Optimierungsproblem eine hohe kombinatorische Komplexität auf, die sich aus der hohen Anzahl an möglichen Kombinationen von individuellen Dienstreihenfolgen ergibt. Gemäß [1] ist ein DRPP NP-schwer. Deswegen werden Problemformulierungen häufig vereinfacht, um die Laufzeit der Optimierung zu verringern. Eine simplifizierte Darstellung eines DRPPs kann zu einer Lösung führen, die nicht den realen Anforderungen genügt. Eine historienbasierte Planung, bei der Daten der vorherigen Planungsperiode(n) berücksichtigt werden, wird bspw. oftmals nicht ausgeführt. Die praktische Durchführbarkeit eines Dienstreihenfolgeplanes ist für die Akzeptanz und den Einsatz eines Verfahrens zur Entscheidungsunterstützung jedoch unabdingbar. Eine Anknüpfung an vergangene Perioden erlaubt zudem eine bessere Balance der individuellen AZK und somit eine höhere soziale Verträglichkeit der Pläne.

1.2 Zielsetzung des Beitrages

Dieser Beitrag widmet sich der Fragestellung, wie leitende Arbeitskräfte darin unterstützt werden können, unter Fortschreibung der historischen Daten aus den vorangegangenen Perioden einen optimalen Dienstreihenfolgeplan für eine Planungsperiode zu finden. Der Fokus liegt auf der Erstellung eines Planes, bei dem die Zufriedenheit der Arbeitskräfte sowie ein ausbalanciertes Verhältnis der Über- und Unterstunden innerhalb der Belegschaft als Zielgrößen definiert sind.

Zur Generierung eines optimalen sowie praktikablen Dienstreihenfolgeplanes wird ein zweistufiges Verfahren entwickelt. Die Basis bildet eine Pattern-basierte Planung, die als Instrument für die Planung potenzielle Muster für Dienstreihenfolgen verwendet. Ein Pattern umfasst eine potenzielle Reihenfolge von Diensten und freien Tagen in einem vorab definierten Zeitraum, z. B. eine Woche. Die erste Stufe umfasst die Generierung der potenziellen Pattern. In der zweiten Stufe wird mit Hilfe des entwickelten mathematischen Modells ein optimaler Dienstreihenfolgeplan generiert.

Dieser Ansatz zielt insbesondere auf einen Einsatz in der Praxis ab, weswegen die Berücksichtigung aller praxisrelevanten Restriktionen gewährleistet wird. Als Optimierungskomponente eingebettet in ein IT-System kann dieses Verfahren Dienstreihenfolgepläne empfehlen und die Planung unterstützen. Das mathematische Modell als auch die Implementierung als Entscheidungsunterstützungssystem (engl. *decision support system*, DSS) sind allgemein gehalten, so dass verschiedene zeitliche Planungsperioden sowie andere Schichttypen und Regeln abbildbar sind.

Als Fallbeispiel dient ein Pflegewohnheim für Menschen mit Behinderung. Der entwickelte Ansatz wird anhand dessen realer Daten evaluiert. Die Probleminstanzen für das DRPP umfassen bis zu 53 Arbeitskräfte, die in sechs Wohngruppen organisiert sind. Pro Tag sind bis zu 22 Dienste zu besetzen. Es wird eine heterogene Belegschaft berücksichtigt, da die Arbeitskräfte eine individuell vertraglich vereinbarte Anzahl an Arbeitsstunden pro Woche sowie individuelle Wünsche haben.

Der Beitrag ist wie folgt gegliedert: Abschnitt 2 ordnet diese Arbeit in den Stand der Forschung im Bereich der Dienstreihenfolgeplanung unter Verwendung von Pattern ein. Der entwickelte zweistufige Ansatz wird in Abschnitt 3 (Stufe 1: Pattern-Generierung) und Abschnitt 4 (Stufe 2: Optimierungsmodell) erläutert. Abschnitt 5 skizziert die Einbettung des Lösungsansatzes in ein DSS zur Unterstützung der Planung. Abschnitt 6 diskutiert numerische Ergebnisse eines Fallbeispiels. In Abschnitt 7 wird ein Fazit gezogen und es werden Implikationen für die Praxis abgeleitet.

2 Stand der Forschung – Ansätze für Pattern-basierte Dienstreihenfolgeplanung

Im Kontext der Personaleinsatzplanung gibt es eine Vielzahl an Veröffentlichungen zu Methoden und Lösungsansätzen für die Dienstreihenfolgeplanung, (engl. *rostering/ scheduling*), bei der zunehmend die Berücksichtigung von Wünschen der Arbeitskräfte für die Planbildung in den Fokus rückt. Für einen allgemeinen Literaturüberblick zu „rostering/scheduling“ wird auf [2] und [3] verwiesen.

Bei Problemen der Dienstreihenfolgeplanung sind Restriktionen wie bspw. zur Abdeckung aller benötigten Dienste ähnlich geartet [4]. Differierende Anforderungen und Regelungen hinsichtlich individueller Dienstreihenfolgen erschweren die Verallgemeinerung von Problemmodellierungen und stellen so ein Hindernis bezüglich des Einsatzes von DSS dar, die über eine Optimierungskomponente zur automatisierten Erstellung von Dienstreihenfolgeplänen verfügen. Eine Lösung dieser Schwierigkeit bieten Pattern, da mit ihnen verschiedene Regeln gleich gut abgebildet werden können (wie in Abschnitt 3 verdeutlicht). Da die Mehrzahl an Regeln durch passende

Patternbildung abgedeckt werden können [4], kann ihre Verwendung helfen, ein allgemeingültiges, einsatzfähiges Modell zu formulieren. In diesem Abschnitt liegt der Fokus somit auf exakten und heuristischen Ansätzen, die Pattern als Instrument bei der Dienstreihenfolgeplanung verwenden.

In [5] werden Pattern (engl. auch *stint*) aus konsekutiven Arbeitstagen und freien Tagen jeweils Kostenwerte zugewiesen. Netzwerkbasierte Formulierungen zur Optimierung eines *Nurse Scheduling Problems* mit Zielsetzung der Kostenminimierung liefern für kleine Probleminstanzen gute Ergebnisse. Aufgezeigt wird in [5] zudem, dass eine nicht-zyklische Modellierung von dem Dienstreihenfolgeproblem komplexer ist als ein zyklisches Modell. Basierend auf Pattern ausschließlich für Diensttage werden in [6] zyklische Dienstreihenfolgepläne an mittelgroßen Probleminstanzen mit einer homogenen Belegschaft optimiert. Zielgröße ist hierbei neben Wünschen und Regelungen zur Arbeit am Wochenende die Abfolge von verschiedenen Schichttypen. In [7] werden ebenfalls Pattern bestehend aus Diensten zur Lösung eines kleinen nicht-zyklischen Dienstreihenfolgeproblems genutzt. Diese Pattern sind äquivalent zu möglichen Abfolgen von Schichttypen an aufeinanderfolgenden Tagen. Modelliert als Set Partitioning Problem werden die Anzahl der Dienste bzw. entsprechende Kostenwerte minimiert. Basierend auf denselben Probleminstanzen werden Pattern aus zwei Schichttypen, die einer Kalenderwoche entsprechen, in [8] und [9] genutzt, um jährliche Dienstreihenfolgepläne zu generieren. Die Zielsetzung in diesen beiden Studien ist es, die Erfüllung der Wünsche der bis zu 30 Arbeitskräfte zu maximieren. In einem metaheuristischen Lösungsverfahren von [10] werden monatliche Pattern verwendet, um unter Berücksichtigung von Wünschen für kleine Probleminstanzen automatisiert Dienstreihenfolgepläne zu generieren.

Eine zyklische Planung ist insbesondere bei Planungsproblemen mit kontinuierlichem Bedarf, einer homogenen Belegschaft und Wünschen hinsichtlich Schichtreihenfolgen möglich [6]. Zyklisch zu planen bedeutet zwar die Berücksichtigung vorheriger Planungsperioden, es ist jedoch nicht möglich, Wünsche für spezifische Schichten und einzelne freie Tage zu berücksichtigen. Bei Ansätzen, die nicht historienbasiert sind, d. h. nicht die vorherigen Planungsperioden beachten, können die erzeugten Pläne insbesondere an den Übergängen zwischen den Perioden ungültig sein. Diese Problematik (siehe [7]) führt zu Dienstreihenfolgeplänen, die praktisch nicht einsetzbar sind. Eine fehlende Praktikabilität der mathematischen Lösungsansätze führt zu einer geringen Akzeptanz von Optimierungsmethoden im Bereich der Personaleinsatzplanung [11].

Dieser Beitrag erweitert den aktuellen Forschungsstand, indem der Fokus auf die Integration von historienbasierten Daten bei der Dienstreihenfolgeplanung und damit auf die praktische Einsetzbarkeit einer durch die Verwendung von Pattern verallgemeinerbaren Optimierungskomponente gelegt wird. Diesem identifizierten Problem wird mit einem zweistufigen Verfahren begegnet, das anhand realer Probleminstanzen eines DRPP evaluiert wird. In der ersten Stufe, die in Abschnitt 3 beschrieben wird, werden anhand der Input-Daten potenzielle Pattern generiert. Bei diesem regelbasierten Vorgehen wird eine heterogene Belegschaft berücksichtigt, um die individuell ausführbaren Dienstreihenfolgen sowie die jeweiligen Verknüpfungsmöglichkeiten zwischen den Pattern zu identifizieren. Die ermittelten Mengen an potenziellen Pattern dienen als Grundlage für die im Abschnitt 4 erläuterte zweite Stufe. Da in der ersten Stufe historische Daten explizit betrachtet werden und die zweite Stufe darauf aufbaut, berücksichtigt das weitere Vorgehen Daten der vorherigen Planungsperioden implizit. Mittels mathematischer Optimierung werden in der zweiten Stufe zugleich die individuellen Dienstreihenfolgen ausgewählt und zu einem Plan verknüpft. Das entwickelte DSS erlaubt die Erstellung von historienbasierten, nicht-zyklischen Dienstreihenfolgeplänen unter Berücksichtigung maximaler Sozialverträglichkeit durch Einbeziehen von Wünschen und ausbalancierter Arbeitszeiten.

3 Pattern als Instrument bei der Dienstreihenfolgeplanung

Angelehnt an das Vorgehen einer leitenden Arbeitskraft und aus Gründen der Nachvollziehbarkeit der automatisierten Erstellung eines Dienstreihenfolgeplanes sowie Regelungen hinsichtlich wöchentlicher Arbeitszeiten werden Pattern mit einer Länge von einer Kalenderwoche verwendet. Diese Länge der Pattern wird ebenfalls in [8], [9] und [12] genutzt. Die Zulässigkeit eines Patterns ist individuell je Arbeitskraft bestimmbar. So können beispielsweise Restriktionen hinsichtlich konsekutiver Arbeitstage die individuelle Menge von potenziellen Pattern pro Arbeitskraft verringern. Zudem erfolgt die Bewertung eines Patterns hinsichtlich der Über- und Unterstunden sowie des Zufriedenheitswertes individuell. In diesem Abschnitt wird erläutert, wie potenzielle Pattern individuell bewertet werden (siehe 3.1). In einem ersten Preprocessing-Schritt werden die Pattern basierend auf den Daten einer Probleminstanz hinsichtlich ihrer Zulässigkeit je Arbeitskraft und Woche gefiltert (siehe 3.2). Zudem werden Regeln zu Abhängigkeiten zwischen den Pattern und somit der Verknüpfung der Pattern zwischen den Kalenderwochen im zweiten Preprocessing-Schritt berücksichtigt (siehe 3.3). Dieses Vorgehen ermöglicht in der ersten Stufe des vorgeschlagenen Lösungsansatzes die Generierung von individuellen Patternmengen je Arbeitskraft. Es werden ausschließlich unzulässige Pattern entfernt, so dass keine (heuristische) Reduktion des Lösungsraumes geschieht. Die Komplexität des Entscheidungsproblems wird deutlich reduziert und somit kann die Rechenzeit der Optimierung vermindert werden.

3.1 Dienstreihenfolge als Pattern

Ein Pattern, das einer Dienstreihenfolge von sieben Tagen entspricht, beinhaltet neben Diensten auch freie Tage. In Abbildung 1 ist ein beispielhaftes Pattern dargestellt: Dienste bzw. Schichttypen (Zeile 1) werden den Wochentagen (Zeile 2) zugeordnet. Aufgrund der Betrachtung von zwei Schichttypen, gibt es die folgenden drei Ausprägungen: 'X' ist ein arbeitsfreier Tag, 'F' ist Frühschicht, 'S' ist Spätschicht.

Dienst	X	F	F	S	S	X	X
Wochentag	Mo.	Di.	Mi.	Do.	Fr.	Sa.	So.

Abbildung 1. Beispiel-Pattern

Bewertung der Arbeitszeit: Innerhalb der Pattern werden sowohl Tage, an denen Urlaub gewährt wird, als auch Tage, an denen ein arbeitsfreier Tag zugeteilt wurde, als generell arbeitsfreie Tage mit 'X' gekennzeichnet. Ein freier Tag leistet keinen Beitrag zur Arbeitszeit der Kalenderwoche. Ein Tag mit Urlaub wird bei der Bewertung der Über- bzw. Unterstunden beachtet und in Höhe von bspw. 1/5 der regulären wöchentlichen Arbeitszeit berücksichtigt. Zusätzlich zu Urlaubstagen werden die Arbeitsstunden der Dienste, die in dem Pattern beinhaltet sind, bei der Berechnung der Bewertung beachtet. Die Berechnung der Stundenanzahl eines Pattern sei beispielhaft an dem Pattern aus Abbildung 1 erläutert: Dieses Pattern beinhaltet vier Arbeitstage und drei freie Tage. Wird dieses Pattern anhand der Parameter der Arbeitskraft aus Abbildung 2 berechnet, muss der Urlaubstag 'U' am Montag (Zeile 1) einkalkuliert werden. Angenommen ein Dienst umfasst bspw. acht Stunden und diese Arbeitskraft hat eine wöchentliche Regelarbeitszeit von 38,5 Stunden, würden bei Auswahl dieses Patterns in der entsprechenden Woche 1,2[1] Überstunden anfallen.

Bewertung der Wunscherfüllung bzw. Zufriedenheit: Zusätzlich zu der Bewertung hinsichtlich der Über- bzw. Unterstunden wird einem Pattern ein Zufriedenheitswert abhängig von Arbeitskraft und Woche zugeordnet. Die Bewertung des individuellen Zufriedenheitswertes eines Patterns ist von der Zuteilung zu Diensten bzw. freien Tagen sowie den geäußerten Wünschen der Arbeitskraft abhängig. Liegen für die betrachtete Woche Wünsche für Dienste bzw. nach freien Tagen vor, erhöht ein erfüllter Wunsch den Zufriedenheitswert und ein widersprochener Wunsch hat folgerichtig einen negativen Einfluss. Die Bewertung der Wünsche ist parametrisiert, in der Regel wird einem Tag ein höherer Wert zugewiesen als einer einzelnen Schicht.[2]

Angenommen ein Wunsch eine spezifische Schicht betreffend wird mit (+/-) 10 Einheiten bewertet. Ist hingegen ein gesamter Tag betroffen, wird dieser Wunsch mit (+/-) 20 Einheiten bewertet. Werden keine Wünsche geäußert, wird der Zufriedenheitswert nicht verändert. Als Beispiel für die Bestimmung eines solchen Wertes seien die Wünsche einer Arbeitskraft aus Abbildung 2 verwendet. Für Dienstag ist ein früher Dienst und am Sonntag ein freier Tag gewünscht (Zeile 2). Das Beispiel-Pattern aus Abbildung 1 hat für diese spezifische Woche einen Zufriedenheitswert von +30, da beiden Wünschen entsprochen würde.

Fixierte Dienste/Urlaub	U			S			
Wünsche		F					X
Wochentag	Mo.	Di.	Mi.	Do.	Fr.	Sa.	So.

Abbildung 2. Individuelle fixierte Dienste, Urlaubstage und Wünsche einer Arbeitskraft

3.2 Pattern Preprocessing – Potenzielle Pattern pro Woche und Arbeitskraft

Bei einer Woche von sieben Tagen und drei Ausprägungsmöglichkeiten gibt es insgesamt $3^7 = 2187$ mögliche Pattern ohne Beachtung von Dienstreihenfolge-Regeln.

[1] $4 * 8 + 1/5 * 38{,}5 - 38{,}5 = 1{,}2$

[2] Diese Skalierung kann von einem Anwender des DSS angepasst werden

Da in den Pattern zwischen den Schichttypen und freien Tagen differenziert wird, können Regeln hinsichtlich eines Verbotes der Zuweisung eines Schichttyps an Tag *d* und eines Typs an Tag *d+1* bei der Anzahl der möglichen Pattern berücksichtigt werden. Diese Anzahl kann generell und weiterhin individuell pro Arbeitskraft und Woche bestimmt werden. Dafür werden die folgenden vier Operatoren verwendet:

(1) Kein 'F' nach 'S': Nach einer Spätschicht darf aufgrund der gesetzlich vorgeschriebenen Pausen- und Ruhezeiten keine Frühschicht folgen. In diesem Schritt werden daher alle Pattern, welche die Abfolge 'SF' enthalten, ausgeschlossen. Somit verringert sich die Anzahl der potenziellen Pattern pro Woche auf *567*.

(2a) Wochenende: Um der großen Belastung der Arbeitskräfte aufgrund von Arbeit am Wochenende entgegenzuwirken, gibt es die Regelung, dass entweder beide Tage des Wochenendes (Samstag und Sonntag) Arbeitstage sind oder beide Tage frei sind. Dementsprechend werden die Pattern, die dieser Regelung nicht entsprechen, von den potenziellen Pattern ausgeschlossen. Es sind nunmehr *288* Pattern pro Woche möglich.

(2b) Wochenende-Symmetrie: Zusätzlich zu den unter (2a) ausgeschlossenen Pattern sind Pattern mit der Abfolge 'FS' am Wochenende nicht möglich. Das Ausführen einer Frühschicht am Samstag und einer Spätschicht am Sonntag einer Arbeitskraft würde erzwingen, dass eine andere die konträre Kombination von 'SF' wahrnehmen müsste. Diese Schichtabfolge ist laut (1) nicht möglich. Daher werden weitere 32 Pattern entfernt, es verbleiben *256* potenzielle Pattern pro Woche.

(3) Individuelle konsekutive Arbeitstage: Um die individuellen Mengen an Pattern zu bestimmen, werden persönliche Regelungen zu minimalen und maximalen konsekutiven Arbeitstagen berücksichtigt. Muss eine Arbeitskraft bspw. mindestens zwei konsekutive Arbeitstage leisten, ist die Abfolge 'XFX' sowie 'XSX' verboten und die Anzahl der Pattern reduziert sich auf *161*. Dürfen bspw. nur zwischen zwei und fünf konsekutive Arbeitstage wahrgenommen werden, sind grundsätzlich nur *148* Pattern möglich. Die Beispiele verdeutlichen, dass die Anzahl potenzieller Pattern teilweise drastisch reduziert und daher die Komplexität des Entscheidungsproblems gesenkt werden kann.

Zusätzlich hat die Beachtung der letzten Woche der vorherigen Planungsperiode neben der Sicherstellung der praktischen Einsatzfähigkeit des Dienstreihenfolgeplanes Einfluss auf die Anzahl der individuell möglichen Pattern (siehe Abschnitt 3.3), wodurch die Anzahl an potenziellen Pattern weiter vermindert werden kann.[3] Weiterhin können die potenziellen Patternmengen aufgrund von Urlaubstagen oder anderweitigen Restriktionen zwischen den Wochen differieren.

3.3 Pattern Preprocessing – Abhängigkeiten zwischen den Pattern

Anschließend an die Aufbereitung der individuellen Patternmengen pro Woche werden Abhängigkeiten zwischen den jeweiligen Pattern betrachtet. Hierbei wird ähnlich wie in Schritt (1) und (3) des vorherigen Abschnittes vorgegangen. Die Zuweisung von einem späten Dienst folgend von einem frühen Dienst an zwei konsekutiven Tagen ist

[3] Bei der größten in diesem Beitrag betrachteten Probleminstanz (siehe Abschnitt 6) scheiden so 28,86% aller potenziellen Pattern für die erste Planungswoche aus.

nicht regelkonform. Ein Pattern, das montags mit einem frühen Dienst beginnt, darf nicht nach einem Pattern folgen, das mit einer Spätschicht am Sonntag endet. Darüber hinaus sind minimale und maximale konsekutive Arbeitstage über zwei bzw. drei Pattern hinweg zu beachten. Bei zwei aufeinanderfolgenden Pattern muss die Anzahl der konsekutiven Arbeitstage innerhalb der individuellen Grenzen liegen. Da ein freier Tag eine Folge von konsekutiven Arbeitstagen unterbricht, werden nur die Pattern mit sieben Arbeitstagen (7-Tage-Arbeitswochen, z. B. 'FFFFSSS') für die Abhängigkeiten mit einem vorhergehenden und nachfolgenden Pattern überprüft. Entsprechend der Regeln sind die Pattern und deren Verknüpfungen anzupassen. Abhängig von einem potenziellen Pattern p einer Arbeitskraft e in Woche w werden die nicht erlaubten Pattern für Woche $w+1$ identifiziert (Menge $P_{w+1}^{e,NOT}(p)$). In Kombination mit 7-Tage-Arbeitswochen sind bestimmte Pattern nicht in der vorigen Woche möglich. Für Pattern q (aus der Menge $P_{w-1}^{e}(p)$), die in der Woche $w-1$ vor einer 7-Tage-Arbeitswoche w mit Pattern p möglich sind, sind wiederum gewisse Pattern in der darauffolgenden Woche $w+1$ verboten (Menge $P_{w+1}^{e,NOT}(p,q)$). Als Ergebnis der ersten Stufe dienen diese Mengen als Input für das Optimierungsmodell, das in dem folgenden Abschnitt erläutert wird.

4 Mathematisches Modell zur historienbasierten Dienstreihenfolgeplanung mit Pattern

Als Grundlage für Stufe 2 dient die folgende abstrakte mathematische Modellierung zur Optimierung historienbasierter Dienstreihenfolgeplanung mit der Zielsetzung einer maximalen Sozialverträglichkeit (quantifiziert als Balance der Über- und Unterstunden, sowie dem Gesamtzufriedenheitswert). Ausgangspunkt für die Modellierung bildet die in Abschnitt 1.1 beschriebene Problemstellung. Der Bedarf an erforderlichen Diensten pro Tag ist festgelegt und muss ohne Abweichung erfüllt werden. Zur Verknüpfung mit der Historie liegen individuelle AZK sowie das letzte in der vorherigen Periode durchgeführte Pattern je Arbeitskraft vor. Zusätzlich ist die Anzahl der konsekutiven Arbeitstage am Ende der letzten Periode bekannt, sollte diese sieben überschreiten.

Für die aktuelle Planungsperiode sind neben dem Bedarf Wünsche, Urlaubstage und fixierte Dienstzuteilungen der Arbeitskräfte bekannt. Diese werden wie die zahlreichen Regelungen zu Dienstreihenfolgen mit Hilfe der individuellen Mengen an Pattern pro Kalenderwoche berücksichtigt. Wesentlich für die Modellbildung ist die automatisierte Generierung der individuellen Patternmengen als Eingabe für das Optimierungsproblem (Stufe 1). Durch die Festlegung dieser Mengen ergeben sich verschiedene Kombinationsmöglichkeiten von Dienstreihenfolgen und somit verschiedene zulässige Planlösungen. Einerseits existieren die generell pro Arbeitskraft und Woche möglichen Pattern (ermittelt gemäß Abschnitt 3.2), mit „7-Tage-Arbeitswoche“-Pattern als besondere Teilmenge. Zusätzlich existieren Patternmengen (ermittelt gemäß Abschnitt 3.3), die in Abhängigkeit der einzelnen Pattern einer Woche und Arbeitskraft mögliche oder verbotene wochenübergreifende Verknüpfungen zu anderen Pattern regeln.

Die Formulierung des mathematischen Modells erfolgt als gemischt-ganzzahliges Optimierungsproblem (engl. *Mixed-Integer Programming*, MIP) mit binären Entscheidungsvariablen über die konkrete Auswahl jedes möglichen Pattern und reellen Entscheidungsvariablen zur Abbildung der Zielfunktionsgrößen. Tabelle 1 fasst Mengen, Parameter und Entscheidungsvariablen des Modells zusammen.

Tabelle 1. Mengen, Parameter und Entscheidungsvariablen des Modells

Mengen:	
E	Menge der Arbeitskräfte, mit Index e
W	Menge der Wochen, mit Index w, {0, ... |W|}
D_w	Menge von Tagen, mit Index d, innerhalb Woche w
S	Menge der Schichttypen, mit Index s
P_w^e	Menge von Pattern für Arbeitskraft e in Woche w, Menge der Woche 0 besteht nur aus dem letzten durchgeführten Pattern
$\tilde{P}_w^e$	Menge der „7-Tage-Arbeitswoche" Pattern für Arbeitskraft e in Woche w, Teilmenge von P_w^e
$P_{w+1}^{e,NOT}(p)$	Menge von Pattern für Arbeitskraft e, die nicht in Woche $w+1$ zugewiesen werden können, aufgrund der Auswahl von Pattern p in Woche w
$P_{w-1}^e(p)$	Menge von Pattern für Arbeitskraft e, die in Woche w-1 zugewiesen werden können, in Kombination mit „7-Tage-Arbeitswoche" Pattern p aus Woche w
$P_{w+1}^{e,NOT}(p,q)$	Menge von Pattern für Arbeitskraft e, die nicht in Woche $w+1$ zugewiesen werden können, aufgrund der Auswahl von „7-Tage-Arbeitswoche" Pattern p in Woche w und der Auswahl von Pattern q in Woche w-1
Parameter:	
ϵ_{sat}	Mindestwert an Zufriedenheit, der erreicht werden soll
α	Bestrafungsfaktor in Zielfunktion für Abweichung von ϵ_{sat}
dem_{ds}	Bedarf an Diensten vom Schichttyp s an Tag d
sat_{ep}	Zufriedenheitswert von Pattern p für Arbeitskraft e, umfasst für das Pattern in der Woche 0, die bisher kumulierten Werte
eh_{ep}	Summe der Über- oder Unterstunden durch Pattern p für Arbeitskraft e, umfasst für das Pattern in der Woche 0, die bisher kumulierten Werte
a_{epds}	1, falls Pattern p von Arbeitskraft e den Schichttyp s an Tag d abdeckt, sonst 0
Entscheidungsvariablen:	
x_{ep}	1, falls Arbeitskraft e Pattern p ausüben soll, sonst 0 (binär)
u	Diskrepanz um vorgegebenen Zufriedenheitswert zu erfüllen (reelle Zahl)
eh_{max}	Höchste Überstundenanzahl von allen Arbeitskräften (reelle Zahl)
eh_{min}	Höchste Unterstundenanzahl von allen Arbeitskräften (reelle Zahl)

Zur gleichzeitigen Verfolgung beider Zielsetzungen zur Sozialverträglichkeit ist die Formulierung eines bikriteriellen Optimierungsproblems notwendig. Bei solchen Problemstellungen existiert in der Regel keine eindeutig optimale Lösung, sondern es gibt eine Menge von sogenannten „effizienten Lösungen". Diese können nicht verbessert werden, ohne dass sich die Ausprägung einer Zielsetzung verschlechtert (vgl. [13]). Die Menge effizienter Lösungen bildet somit die möglichen Kompromisse zwischen der Erfüllung der beiden Zielsetzungen ab. Sie kann mittels der ϵ-Constraint-Methode bestimmt werden, bei der die Ziele gemäß einer Rangfolge geordnet und aufeinander aufbauend einzelne Optimierungsprobleme gelöst werden. Die zuvor erreichte Zielsetzung wird dabei zu einer Nebenbedingung umformuliert, die im neuen Optimierungsproblem zu einem Mindestanteil, vorgegeben durch den ϵ-Wert, erfüllt werden muss. In dieser Arbeit wird zunächst ein Optimum für die Zielsetzung nach maximaler Zufriedenheit berechnet. Anschließend wird als zweite Zielsetzung die Ausgeglichenheit der Über- und Unterstunden unter der Voraussetzung optimiert, dass die maximal mögliche Zufriedenheit zu einem Mindestwert ϵ_{sat} erfüllt wird. Damit das entstehende MIP rechnerisch einfacher lösbar ist, wird dies als Nebenbedingung durch eine Elastic-ϵ-Constraint formuliert (vgl. [13]), bei der eine zusätzliche Diskrepanz-Variable mögliche Abweichungen auffangen kann. Durch Veränderung des zu erfüllenden Mindestwertes sind systematisch alle effizienten Lösungen bestimmbar. Beide Zielsetzungen sind gleichzeitig vollständig erfüllbar, wenn der maximal mögliche Zufriedenheitswert zu 100% (ohne Einsatz der Diskrepanz-Variable) erreicht wird und zugleich der berechnete Zielfunktionswert des Gesamtproblems den gleichen Wert wie bei Zielsetzung nach reiner Optimierung der Ausgeglichenheit annimmt.

Das mathematische Optimierungsmodell zur Dienstreihenfolgeplanung unter Fortschreibung historischer Daten vergangener Planungsperioden (*h-DRPP*$^{(eh,sat)}$) und zweifacher Zielsetzung kann wie folgt formuliert werden:

$$Minimiere\ (eh_{max} - eh_{min}) + \alpha * u \tag{1}$$

$$s.t \quad \sum_{e \in E} \sum_{w \in W} \sum_{p \in P_w^e} sat_{ep} x_{ep} + u \geq \epsilon_{sat} \tag{2}$$

$$\sum_{e \in E} \sum_{p \in P_w^e} a_{epds} x_{ep} = dem_{ds} \quad \forall w \in W \setminus \{0\}, \forall \mathrm{d} \in D_w, \forall s \in S \tag{3}$$

$$\sum_{p \in P_w^e} x_{ep} = 1 \qquad \forall e \in E, \forall w \in W \tag{4}$$

$$x_{ep} + \sum_{r \in P_{w+1}^{e,NOT}(p)} x_{er} \leq 1 \qquad \forall e \in E, \forall w \in W \setminus \{|W|\}, \forall p \in P_w^e \tag{5}$$

$$x_{ep} + x_{eq} + \sum_{r \in P_{w+1}^{e,NOT}(p,q)} x_{er} \leq 2 \ \ \forall e \in E, \forall w \in W \setminus \{0\}, \forall p \in \tilde{P}_w^e, \forall q \in P_{w-1}^e(p) \tag{6}$$

$$eh_{max} \geq \sum_{w \in W} \sum_{p \in P_w^e} eh_{ep} x_{ep} \quad \forall e \in E \tag{7}$$

$$eh_{min} \leq \sum_{w \in W} \sum_{p \in P_w^e} eh_{ep} x_{ep} \quad \forall e \in E \tag{8}$$

$$x_{ep} \in \{0,1\} \quad \forall e \in E, \forall w \in W, \forall p \in P_w^e \tag{9}$$

$$u, eh_{max}, eh_{min} \in \mathbb{R} \tag{10}$$

Mit der Zielfunktion (1) wird die Differenz zwischen der höchsten Überstundenzahl und der höchsten Unterstundenzahl von allen Arbeitskräften minimiert und gleichzeitig werden mögliche Abweichungen vom zu erfüllenden Zufriedenheitswert minimiert. Die Restriktion (2) stellt dabei sicher, dass ein Mindestmaß an vorgegebener Gesamtzufriedenheit erfüllt wird. Die Schwere möglicher Abweichungen von dieser Vorgabe wird in Abhängigkeit des Bestrafungsfaktors α in der Zielfunktion gesteuert.

Die Restriktionen (3) stellen die Bedarfserfüllung pro Tag und Schichttyp sicher. Restriktionen (4) gewährleisten, dass pro Arbeitskraft genau ein Pattern pro Woche ausgewählt wird. Mit den Restriktionen (5) wird die Durchführung von Pattern in aufeinanderfolgenden Wochen vermieden, die nicht miteinander verknüpft werden dürfen. Restriktionen (6) stellen sicher, dass die maximale Anzahl aufeinanderfolgender Arbeitstage pro Arbeitskraft eingehalten wird. Restriktionen (7) bzw. (8) bestimmen die maximale bzw. minimale Anzahl zu leistender Zusatzstunden der Arbeitskräfte. Restriktionen (9) und (10) legen die Wertebereiche der Entscheidungsvariablen fest.

Vorgaben zu dem Zufriedenheitswert ϵ_{sat} können durch ein abgewandeltes, vereinfachtes Modell berechnet werden. Dazu wird (1) durch die Zielfunktion (11) ersetzt. In Kombination mit den Restriktionen (3), (4), (5), (6) und (9) entsteht ein Optimierungsmodell (*h-DRPP*$^{(sat)}$), das ausschließlich die Gesamtzufriedenheit aller Arbeitskräfte maximiert. Der resultierende Dienstreihenfolgeplan ist für den Einsatz zulässig, ohne jedoch auf einen Ausgleich der Über- und Unterstunden abzuzielen. Die Lösung kann als Vorgabe für obiges Modell *h-DRPP*$^{(eh,sat)}$ einen maximal möglichen Zufriedenheitswert liefern, der entsprechend der Wahl von ϵ_{sat} berücksichtigt wird.

$$Maximiere\ \sum_{e\in E}\sum_{w\in W}\sum_{p\in P_w^e} sat_{ep}x_{ep} \qquad (11)$$

Weitere Modellvariationen: Für eine Dienstreihenfolgeplanung mit alleiniger Zielsetzung nach Ausgeglichenheit von Über- und Unterstunden (*h-DRPP*$^{(eh)}$) entfällt in der Formulierung (1)-(10) die Restriktion (2) und der korrespondierende Summand $\alpha * u$ in der Zielfunktion (1). Für eine Dienstreihenfolgeplanung ohne Verknüpfung zu vergangenen Planungsperioden kann die Formulierung (1)-(10) wie folgt zu einem Modell *DRPP*$^{(eh,sat)}$ angepasst werden: Als Eingabeparameter verändert sich die Wochenmenge W in die Menge $\{1,\ldots,|W|\}$. Zusätzlich sind die Restriktionen (6) über alle Wochen aus $W\backslash\{1\}$ statt aus $W\backslash\{0\}$ zu formulieren.

5 Einbettung in ein Entscheidungsunterstützungssystem

Der entwickelte Lösungsansatz kann wie in Abbildung 3 dargestellt in ein DSS eingebettet und für die Dienstreihenfolgeplanung verwendet werden (orientiert an der aktuellen Planung des in diesem Beitrag betrachteten Fallbeispiels). Als Eingabe aggregiert die leitende Arbeitskraft die notwendigen Daten zu Bedarf an Diensten, Arbeitskräften und deren Restriktionen sowie weiterer Regelungen in einer Excel-Datei. Die manuelle Planung wird anschließend durch das entwickelte Verfahren inklusive Optimierung ersetzt. Diese Optimierungskomponente ist in C# implementiert und verwendet als Solver CPLEX. Auf Grundlage der potenziellen Patternmengen werden optimale Dienstreihenfolgepläne generiert und ausgegeben – inklusive eines Lösungsreportes über den Optimierungsprozess. Der Datenaustausch zwischen den einzelnen Komponenten erfolgt durch strukturierte Textdateien (.csv). Die Lösungsgüte der Pläne kann neben einer tabellarischen Darstellung auch in einem Koordinatensystem im Hinblick auf die beiden Zielsetzungen visualisiert und miteinander verglichen werden. Schlussendlich kann aus den vorgeschlagenen Plänen ein geeigneter Plan ausgewählt und bei Bedarf manuell angepasst werden.

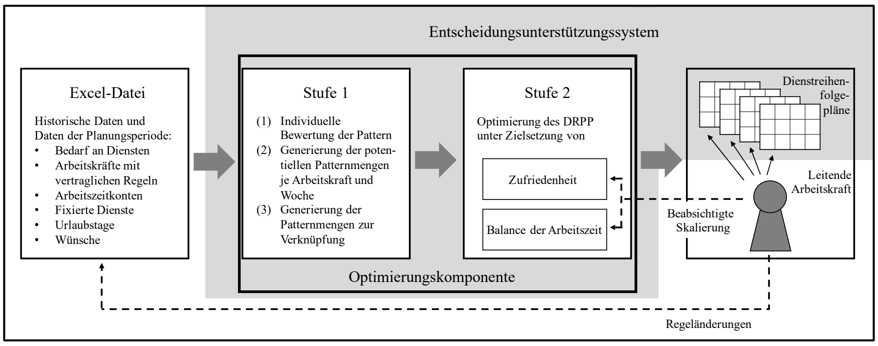

Abbildung 3. Entscheidungsunterstützungssystem für die Planung

Optimierungsbasierte DSS erfordern in der Regel eine aufwendige Einführungsphase. Im Rahmen von Einführungsprojekten wird auch eine Kalibrierung der Optimierungskomponenten vorgenommen. Gegenstand ist bspw. die Bewertung der Wünsche. Zudem wird dem Anwender des DSS als Interaktion ermöglicht, eine Skalierung zwischen Plänen mit maximalem Zufriedenheitswert und bestmöglicher Balance der Über- und Unterstunden auszuwählen (inklusive der Gewichtung möglicher Abweichungen von der gewünschten Zufriedenheit durch α) sowie ein Zeitlimit für die Optimierung vorzugeben. Anwendungsspezifisch eingestellt kann das entwickelte DSS dementsprechend in verschiedenen Fällen eingesetzt werden.

6 Numerische Ergebnisse eines Fallbeispiels

Der vorgestellte zweistufige Lösungsansatz zur Dienstreihenfolgeplanung wird anhand realer Daten eines Pflegewohnheims für Menschen mit Behinderung evaluiert. Dabei liegt der Fokus neben dem Vergleich historienbasierter Planung mit einer Planung ohne Bezug zur Vorperiode auf der Ermittlung des gesamten Potenzials optimierungsbasierter Planung. Das Pflegewohnheim umfasst sechs Wohngruppen, für die bisher einzelne Dienstreihenfolgepläne erstellt wurden. Eine Verteilung der Arbeitskräfte zwischen den Gruppen ist möglich bzw. häufig notwendig, wurde aber bisher aufgrund der nicht zu bewältigenden Komplexität einer manuellen Planung nicht ausgeführt. Generell sind im Wohnheim pro Tag 22 Dienste zu besetzen. Dabei ist eine heterogene Belegschaft zu berücksichtigen, da die insgesamt 53 Arbeitskräfte individuell vertraglich vereinbarte Wochenarbeitszeiten haben sowie individuelle Wünsche für Arbeits- bzw. Urlaubszeiten für die Planungsperiode geäußert werden können. Die Planungsperiode umfasst einen Monat. In diesem Beitrag werden 14 Probleminstanzen zur Dienstreihenfolgeplanung eines Monats betrachtet. Zum einen werden Dienstreihenfolgepläne separat für die sechs Wohngruppen erstellt wie es der bisherigen manuellen Planung entspricht. Einer Wohngruppe sind jeweils sechs bis elf Arbeitskräfte zugeordnet, pro Gruppe und Tag sind (mit einer Ausnahme) generell vier Dienste zu planen. Zum anderen wird ein gemeinsamer Dienstreihenfolgeplan über alle sechs Gruppen erstellt, um mögliches Potenzial aufzudecken, das bisher nicht erschließbar ist. Für diese sieben Instanzen werden Pläne sowohl historienbasiert als auch ohne Bezug zur Vorperiode erstellt (insgesamt 14). Für jede der Probleminstanzen werden mit den Modellen *(h-)DRPP*$^{(sat)}$ und *(h-)DRPP*$^{(eh)}$ die jeweils bestmögliche Ausprägung der Zielsetzung nach maximaler Wunscherfüllung und nach minimaler Abweichung von Über- und Unterstunden berechnet. Mit dem Modell *(h-)DRPP*$^{(eh,sat)}$ werden dann beide Zielsetzungen gleichzeitig verfolgt, wobei als generelle Vorgabe der maximale Zufriedenheitswert erreicht werden soll (mögliche Verletzungen werden mit α=1 bei der Berechnung des Zielfunktionswertes (1) bestraft, die Zusammensetzung der Zufriedenheitswerte pro Pattern ist skaliert wie in Abschnitt 3.1 beschrieben).[4]

Tabelle 2 zeigt die Zielfunktionswerte hinsichtlich Zufriedenheit sowie Ausgeglichenheit der Über- und Unterstunden exemplarisch für eine einzelne Wohngruppe (*planOpt_06*) sowie für das gesamte Wohnheim (*planOpt_gesamt*) bei historienbasierter Planung (*mit h*) bzw. bei Planung ohne Bezug zur Vorperiode (*ohne h*).

Tabelle 2. Zufriedenheitswerte sowie minimierte Differenz von Über-/Unterstunden in hh:mm

Instanz	*(h-)DRPP*$^{(sat)}$	*(h-)DRPP*$^{(eh)}$		*(h-)DRPP*$^{(eh,sat)}$		
	mit h und ohne h	*mit h*	*ohne h*	*mit h*	*ohne h*	*bei* ϵ_{sat}
planOpt_06	**490**	**112:17**	17:42	120:36	17:42	(100%) **490**
				112:17	17:42	(90%) 450
planOpt_gesamt	**1340**	**277:58**	30:52	**277:58**	30:52	(100%) **1340**

In den Tests hat sich gezeigt, dass (bis auf eine Ausnahme) für alle Instanzen gleichzeitig der höchste Zufriedenheitswert[5] bei minimal möglicher Differenz von eh_{max} und eh_{min} erreichbar ist. Wie in Tabelle 2 zu erkennen, gilt diese Beobachtung auch für die alle Wohngruppen umfassende Gesamtplanung (*planOpt_gesamt*). Ausnahme bildet die ebenfalls in Tabelle 2 aufgeführte historienbasierte Einzelplanung für die Wohngruppe 6, bei der neben der Historie vergleichsweise viele Wünsche der Arbeitskräfte im Planungszeitraum zu berücksichtigen sind. Der maximale Zufriedenheitswert von 490 (100%) ist nur mit einer leichten Erhöhung des minimierten Differenzwertes der Über- und Unterstunden erreichbar. Anders ausgedrückt, der optimale Zielfunktionswert der Über- und Unterstunden ist erst bei 90% Zufriedenheit erreichbar.

Anzumerken ist, dass die ohne Historie erstellten Pläne zwar sehr ausgeglichen mit in der Regel geringen Unterschieden in den individuellen AZK der Arbeitskräfte sind, bei einer Verknüpfung mit der Vorperiode allerdings zu Regelverletzungen führen

[4] Die Testläufe wurden auf einem Notebook mit Intel Core i7 Prozessor mit 2,6 Ghz und 16 GB Hauptspeicher durchgeführt. Für die historienbasierte Planung liegen alle Laufzeiten in der Regel unter 3 Minuten. Für reine Zufriedenheitsmaximierung liegen die Zeiten im geringen Sekundenbereich. Bei Planung ohne Bezug zur Historie kann der Optimalitätsbeweis beim Lösen andauern, die Laufzeiten liegen dabei in der Regel deutlich unter 30 Minuten. In allen Fällen wurden vom Solver bereits zu Beginn des Lösungsprozesses zulässige Pläne gefunden. Ein vom Anwender ausgeführter frühzeitiger Abbruch der Optimierung durch striktes Zeitlimit kann daher zwar nicht unbedingt zu optimalen, aber zu passablen Lösungen führen.

[5] Da keine Daten über die bisherige Wunscherfüllung vorliegen, sind die maximalen Zufriedenheitswerte bei Planung *mit h* und *ohne h* gleich.

würden. Bei separater Planung ergeben sich im Hinblick auf verbotene 'SF'-Wechsel, sowie einzuhaltende maximale und minimale konsekutiver Arbeitstage insgesamt 8 Regelverletzungen, bei Wohngruppen übergreifender Gesamtplanung sind es 10.

Tabelle 3. Ausgeglichenheit von Über-/Unterstunden bei manuellen und optimierten Plänen

Über- u. Unterstunden (Eh)	*vorher*	*planMan*	*planOpt_einzeln*	*planOpt_gesamt*
Maximum (eh_{max})	139:57	(+4%) 145:17	(-57%) 59:39	(-82%) 25:32
Minimum (eh_{min})	-356:02	(+34%) -478:18	(-29%) -252:26	(-29%) -252:26
Differenz von Max - Min	495:59	(+26%) 623:35	(-37%) 312:05	(-44%) 277:58
Summe Überstunden +	1575:03	(+16%) 1829:44	(-49%) 809:12	(-69%) 479:57
Summe Unterstunden -	-860:40	(+32%)-1140:33	(+72%)-1480:56	(+25%)-1079:41
Gesamtstunden +/-	2435:43	(+22%) 2970:17	(-6%) 2290:08	(-36%) 1559:38
Mittelwert je Arbeitskraft	13:29	13:00	-12:40	-11:19
Standardabweichung	68:35	87:50	55:40	48:32

Tabelle 3 vergleicht die Ergebnisse von Varianten historienbasierter Dienstreihenfolgeoptimierung sowie der manuellen Planung. Da bei der manuellen Planung sämtliche Wünsche erfüllt werden und bei Optimierung der maximale Zufriedenheitswert erreicht werden kann, liegt der Fokus auf Kennzahlen zur Ausgeglichenheit der AZK (*Über- u. Unterstunden*). Ausgehend von kumulierten Daten der Vorperioden (*vorher*) werden diese für manuelle Planung (*planMan*) sowie für die – zusammengefasste – separate Optimierung aller Wohngruppen (*planOpt_einzeln*) und die Wohngruppen übergreifende Gesamtoptimierung (*planOpt_gesamt*) aufgeschlüsselt mit jeweiligen prozentualen Veränderungen in Bezug auf die Vorperiode. Es wird deutlich, dass durch die Optimierung eine signifikante Steigerung der Sozialverträglichkeit erreicht werden kann. Vor dem Hintergrund maximaler Zufriedenheitswerte werden Überstunden drastisch abgebaut. Zusätzlich zeigt sich, dass die bisher nicht umsetzbare Gesamtplanung erhebliche Potenziale verglichen mit separater Planung besitzt.

7 Fazit und Ausblick

Dieser Beitrag beschreibt aktuelle Entwicklungen für die informationstechnische Unterstützung der Personaleinsatzplanung mit einem Fokus auf Praktikabilität der Lösungsverfahren und Akzeptanz der automatisiert erstellten Lösungen. Es wurde ein zweistufiges Verfahren zur Lösung eines DRPP vorgestellt, das insbesondere auf die Sozialverträglichkeit der erstellten Pläne abzielt und eine historienbasierte Anknüpfung an vorausgegangene Perioden ermöglicht. Nach der problemspezifischen Generierung der Mengen potenzieller Pattern können mit Hilfe eines Optimierungsmodells je nach Skalierung der Zielsetzungen verschiedene bestmögliche Pläne erstellt werden. Darüber hinaus ist das entwickelte Optimierungsmodell für verschiedene Varianten eines DRPP einsetzbar und leicht anpassbar, bspw. für andere Planungszeiträume, Schichttypen und Regeln sowie unterschiedliche Längen der Pattern.

Die Anwendbarkeit und der Nutzen des Ansatzes wurden evaluiert und dargestellt. Der Lösungsansatz liefert für ein Fallbeispiel sehr gute Ergebnisse. Unter Beibehaltung hoher Zufriedenheitswerte ist parallel eine deutliche Reduzierung der Überstunden möglich. Insgesamt zeigt sich, dass eine bessere Balance der Über- und Unterstunden bei einer historienbasierten Planung bewirkt werden kann. Es können darüber hinaus organisatorisch komplexere Problemstellungen betrachtet und zusätzliche Freiheitsgrade bei der Planung genutzt werden. Eine empirische Langzeitstudie kann die Auswirkungen der durch Optimierung unterstützten Planung auf die Belegschaft untersuchen. Da das DSS Wünsche leichter berücksichtigen kann als die manuelle Planung, wird erwartet, dass die Wunschanzahl im Zeitverlauf steigt.

Der Einfluss und das Zusammenspiel von Skalierung und Diversität der Wünsche sowie der Verschiedenartigkeit vorhandener AZK auf eine gute oder schlechte Lösbarkeit historienbasierter DRPP ist darüber hinaus als grundlegende Fragestellung weiter zu untersuchen. Hierfür und für einen möglichen Vergleich mit problem-spezifischen Heuristiken und metaheuristischen Ansätzen bietet das vorgestellte Modell und seine Anwendung im Rahmen eines DSS einen passenden Ansatzpunkt.

A Semi-Automated Approach for Generating Online Review Templates

Martin Poniatowski[1], Jürgen Neumann[1], Thomas Görzen[1], and Dennis Kundisch[1]

[1] Paderborn University, Business Administration and Economics, Paderborn, Germany
{martin.poniatowski,juergen.neumann,thomas.goerzen,
dennis.kundisch}@wiwi.uni-paderborn.de

Abstract. It is widely accepted that online customer reviews play a key role in influencing potential customers. Online shops and rating platforms face two important challenges: how to elicit reviews from existing customers, and how to maximize the helpfulness of these reviews. To address these challenges, online review systems require a design that facilitates the writing process and increases the reviews' informational value. It is an open question whether providing reviewers with review templates could support both of these objectives. In this study we propose a semi-automated approach for designing review templates, which uses machine-learning for the generation and crowdworkers for the evaluation of review templates. To identify product- or service-specific dimensions we use Latent Dirichlet Allocation on reviews considered helpful by readers. Further research is planned to establish whether the automated approach for deriving and evaluating templates is an effective method for improving review generation for specific products and services.

Abstract. In many industries, particularly discrete manufacturing, companies can benefit from conducting product-cost optimization as early as possible. Given the amount of data to be analyzed in the costing process, the lack of dedicated information system support, and the pressure to quickly estimate the cost of new products, the potential for cost optimization is often underexploited. In this paper, we present an approach for leveraging machine learning capabilities, including similarity and anomaly analysis, to improve the identification of product-cost optimization potentials and therefore, improve the quality of early cost estimates. For the approach to succeed, however, ongoing training of a model based on a high-quality dataset is crucial. Thus, we also propose the machine learning approach's integration with our long-term research project toward improving the management of cost optimization during product development.

Keywords: Product costing, product-cost optimization, machine learning, product development, measure management.

1 Problem Context

To ensure long-lasting economic success amid globalization, shortened product life cycles, and growing product diversity, companies seek support for conducting product-cost optimization [1], [2]. Despite the immense potential of early cost optimization [3], [4], our prior research has shown that early optimization lacks dedicated information system (IS) support [2], [5]. In response, our long-term research project grounded on design science research methodology [6], [7] aims to improve IS support for early cost optimization. Based on industry-evaluated requirements and IS implementation hurdles, we developed an approach that aims at improving the management of cost-optimization measures, supporting the phases of identifying, elaborating, evaluating, and implementing optimization measures. This measure management (MM) approach, including optimization examples, is depicted in [5] and [8] in detail.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

In this context, this paper takes up an idea that emerged from our research project: The automated identification of optimization potentials [2], [8]. Such a functionality is especially important in the discrete manufacturing industry, where products such as cars and special-purpose machines comprise up to 100,000 components. Due to this and further practical challenges [2], [8], the complexity of optimization is hardly manageable manually. Therefore, industry demands IS approaches to support the identification of optimization potentials by using available datasets [5], [9].

Thus, on the one hand, this paper showcases machine learning (ML) approaches for identifying optimization potentials. On the other hand, the paper identifies a means of improving the accuracy of ML algorithms by incorporating the MM approach from our long-term research project.

2 Machine Learning goes Measure Management

2.1 Measure Identification

To demonstrate the potential of ML for early product-cost optimization, we first introduce two exemplary optimization use cases from industry [5]. We use these to develop suitable approaches for self-optimizing algorithms. These approaches then form the foundation for demonstrating the interaction between the MM approach based on [8] and self-optimizing algorithms that support the identification of cost optimization potentials. This paper summarizes such self-optimizing algorithms under the term ML according to the definition in [10], which defines ML as a specific system design that allows the system to learn from data and improve with experience [10].

The first approach, a similar parts search, helps users locate similar but preferable (e.g., cheaper) materials [9]. For that, a user selects a certain material in a product costing structure. Based on dedicated material attributes like description, material number, weight, plant, etc., the approach starts the search for materials with similar attributes in the master data and previous costing structures. The single similar attributes are found using fuzzy search [11], with subsequent defining of the overall degree of similarity of the target and similar materials as a weighted sum of single similarity scores. The weight coefficients are defined using an optimization algorithm which analyzes the historical similar products. As result, the ML algorithm recommends a list of similar materials, ranked by their degree of similarity to the one selected [12]. This list of similar but possibly more suitable materials can be used to create an optimization measure as described in [5]. By creating such a measure, the user can accept the respective recommendation to replace the originally selected material.

The second approach involves plausibility checks, based on the work of Vosough and Vasyutynskyy [13], whose main goal was identifying potential user-made errors by assessing the validity and plausibility of items within a costing structure. Since only a small set of examples of such errors is known, which makes usage of the supervised ML approaches difficult, Vosough and Vasyutynskyy concentrated on the unsupervised model-based algorithms for anomaly detection. These algorithms detect potential errors in cost estimates as anomalies, i.e., significant deviations from the values of typical material attributes (e.g., price and weight) or typical costing structures, in which the attribute values and structures are learned from historical cost estimates. The detected anomalies are then converted into human readable messages [13], which can be used to create a dedicated optimization measure [5]. Different anomaly detection algorithms can be used [14], whereas we identified the adjusted approach based on the Z-Score of the data points as most robust for different use cases in our context. In this adjusted approach, the thresholds for anomaly detection are not constant, but are defined dynamically dependent on the number of samples, their statistical distribution as well as user-defined settings (patent filed [15]). The approach was validated and adjusted based on real data and feedback from four large, international companies.

Figure 1 drafts ML recommendations from our research project and how both approaches could potentially be integrated with IS for product costing. The left side shows the similar parts search containing the list of similar materials for a hexagonal screw, which can be replaced by either the same material from another plant (PT1) or another material (M16). The right side shows results of plausibility checks. In addition to the anomalies identified, the potential cost impact of these anomalies on the product-cost estimate are also calculated and displayed.

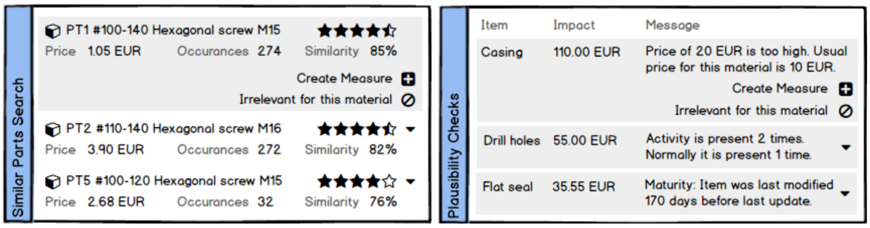

Figure 1. User interface mockups for the similar parts search and plausibility checks

2.2 Problem Case: Labeled Data

Both the similar parts search and plausibility checks can be realized with unsupervised [16] and supervised learning [17]. The latter requires a high quantity and quality of data (e.g., labels, master data, costing information, and bill of materials) to accurately train the ML model. As mentioned above, it is difficult to obtain the required large labeled datasets, given the need for extraordinary manual effort and the variety of potential errors in the costing structures [18]. Moreover, specific domain knowledge in product costing is required to accurately label the data [2], [9], [19].

To address those setbacks, which are quite common in ML [20], the presented approaches start with unsupervised learning using fuzzy search [11] as well as statistical and hierarchical algorithms [14]. Although these approaches are already a good support in improving the product-cost estimate quality, they require company-specific calibration and do not deal well with special use cases, which may result in false positives or missed errors. To combine the ML with the knowledge from the user without overwhelming the latter with additional efforts, we propose integrating the ML algorithms with our approach of MM [8]. We extend the approach with supervised learning to further improve the ML algorithms and thereby raise the quality of optimization recommendations (Figure 2).

With the initial ML model trained by unsupervised learning, we use inference to generate recommendations. The user now has the option to either mark the recommendations as irrelevant or, if it seems reasonable, initiate an optimization measure for further processing (Figure 1). All recommendations marked as irrelevant are flagged as false positives. With the initiation of an optimization measure, the respective recommendation is labeled implicitly as true positive and later labeled again after the measure has successfully been applied to the product [5].

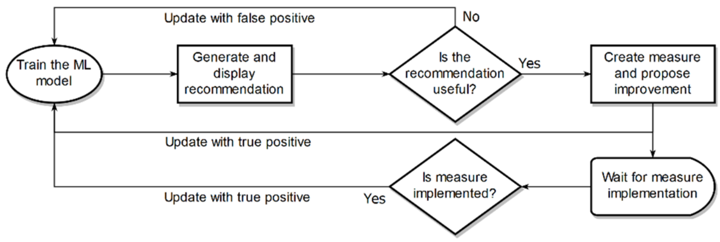

Figure 2. Measure management as an enabler of supervised learning

In sum, positive and negative feedback is used to retrain the models so future recommendations are more accurate (Figure 2). Thus, the user's feedback is reused without additional effort for labeling data. In that way, we can continuously improve learning results for both ML approaches and increase the accuracy of algorithms, even if optimization recommendations are not ultimately applied to the product.

3 Status Quo and Outlook

The initial unsupervised learning of the described optimization approaches has already been implemented in the context of our research partner's system SAP Product Lifecycle Costing (see [21]) to propose optimization potentials [12], [13]. To date, unsupervised learning has been performed with a set of real data representing four large, international companies in the discrete manufacturing industry, each with more than 10,000 employees. For them, plausibility checks detect anomalies and potential errors for up to 5% of all available line items in the provided costing structures. This error rate is surprisingly high, which can be explained on the one hand by undiscovered errors caused by manual editing of costing structures with up to 100,000 line items and on the other hand by the fact that the unsupervised approaches result in false positives in specific use cases. Therefore, we look forward to validating and further training of the ML models with the help of our presented approach.

With continuous improvement of the models and more profound results, further automation of the process is possible. For example, the most certain recommendations can be automatically implemented for entire product development projects with minimal manual effort. Even the creation of new costing structures based on identified typical costing structures and user-provided parameters is conceivable.

Bedeutung von Predictive Analytics für den theoretischen Erkenntnisgewinn in der IS-Forschung

Giacomo Welsch, Matthias Hauser, Frédéric Thiesse

Universität Würzburg, Wirtschaftswissenschaftliche Fakultät, Würzburg, Deutschland
{giacomo.welsch,matthias.hauser,frederic.thiesse}
@uni-wuerzburg.de

Abstract. Obgleich mehrere Forscher die Wichtigkeit von *Predictive Analytics* für den theoretischen Erkenntnisgewinn hervorgehoben haben, werden IS-Theorien der Verhaltensforschung in der Regel nicht auf ihre Vorhersagekraft getestet. Vor diesem Hintergrund soll in dem diesem Artikel zugrundeliegenden Forschungsprojekt am Beispiel der Technologieakzeptanzforschung aufgezeigt werden, dass der Einsatz von *Predictive Analytics* bei der Aufstellung von Theorien nicht nur wichtig ist, sondern sogar notwendig sein kann um die potenziellen Schwächen rein erklärender Modelle (insbesondere Vollständigkeit, Generalisierbarkeit und Praxisrelevanz) zu adressieren. Hierzu wird in diesem Artikel eine dreistufige Forschungsagenda zur Untersuchung und gegebenenfalls Modifizierung bestehender Modelle mithilfe von *Predictive Analytics* aufgezeigt.

Keywords: Technologieakzeptanzforschung, IS-Theorien, Predictive Analytics, Verhaltensforschung

1 Vorhersagemodelle in der IS-Forschung

Die Verhaltensforschung und die Design-Forschung gelten als die beiden Säulen der IS-Forschung [28]. Während sich Letztere in erster Linie mit dem Entwurf nützlicher Artefakte beschäftigt [4, 13], ist das Ziel der Verhaltensforschung die Aufdeckung von *Wahrheit* [19]. Theorien der Verhaltensforschung sollen hierbei insbesondere in der Lage sein, Verhalten einer bestimmten Zielgruppe (z.B. Kunden, Mitarbeiter oder Organisationen) gegenüber Artefakten zu erklären oder vorherzusagen [16].

Der Fokus dieser Arbeit liegt auf den Vorhersageeigenschaften von Modellen der Verhaltensforschung. Ausgangspunkt des Forschungsprojekts ist die Beobachtung, dass Theorien der Verhaltensforschung in der Regel nicht auf ihre Vorhersagekraft getestet werden [9, 23, 24]. Dies verwundert, da sich einflussreiche Forscher [12, 24] intensiv mit der Vorhersageeigenschaft von IS-Theorien auseinandergesetzt haben und von den *Grand Theories* sowohl Erklärungs- als auch Prognosefähigkeiten erwarten. Stattdessen werden Theorien der Verhaltensforschung in der Regel wie folgt entwickelt: Forscher stellen auf Basis theoretischer Überlegungen und bisheriger Forschungsergebnisse Hypothesen kausaler Zusammenhänge auf, die mithilfe einer Stichprobe an Daten überprüft werden. Werden die vermuteten Zusammenhänge im

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Zuge dessen als ausreichend stark und signifikant bewertet, gilt die jeweilige Theorie als bestätigt [5, 23]. Beispiele hierfür sind TAM [7] und UTAUT [26, 27].

Generell weist die IS-Forschung einen Mangel an Vorhersagemodellen auf [24]. Mehrere Forscher haben daher zu mehr Einsatz von *Predictive Analytics* aufgerufen, insbesondere weil sich mithilfe solcher Modelle theoretische Erkenntnisse gewinnen lassen können [1, 24]. In dem diesem Artikel zugrundeliegenden Projekt soll am Beispiel der Technologieakzeptanzforschung gezeigt werden, dass der Einsatz prädiktiver Verfahren bei der Aufstellung von Theorien notwendig ist. Darauf aufbauend soll ein Ansatz entwickelt werden, der aufzeigt, wie prädiktive Verfahren bei der Modifikation und Entwicklung von Theorien eingesetzt werden können.

2 Erklärungen und Vorhersagen in theoretischen Modellen

Theorien der Verhaltensforschung sollen Phänomene entweder beschreiben, erklären und/oder vorhersagen. Hierbei vernachlässigen rein beschreibende und rein prädiktive Theorien – im Gegensatz zu erklärenden Theorien – die Aufdeckung der latenten Mechanismen, die der Entstehung eines Phänomens zugrunde liegen [12]. Diese werden von dem Statistiker Breiman [5] als *Natur* beschrieben. Da rein beschreibende Theorien die einfachste Form einer Theorie sind und zum Einsatz kommen, wenn noch wenig über das zu betrachtende Phänomen bekannt ist [10], werden diese in diesem Artikel nicht näher betrachtet. Im Fokus liegen folglich Theorietypen zur (i) Erklärung, (ii) Vorhersage und (iii) Erklärung und Vorhersage (Abbildung 1).

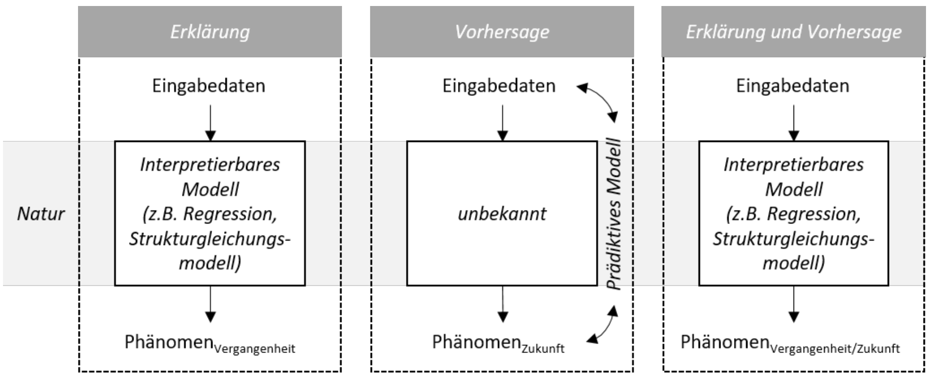

Abbildung 1: Theorietypen (in Anlehnung an Breiman [5] und Gregor [12])

Aus philosophischer Sicht unterscheiden sich Erklärungen und Vorhersagen dadurch, dass sich Erstere auf die Vergangenheit und Letztere auf die Zukunft beziehen [14, 20, 21]. Für die statistische Modellierung bedeutet dies folgendes:

- Bei Theorien zur reinen Erklärung werden für die Aufstellung eines Modells alle zu einem bestimmten Zeitpunkt verfügbaren Daten zu dem betrachteten Phänomen berücksichtigt, wobei insbesondere überprüft wird, ob die a priori vermuteten

Beziehungen in den Daten bestätigt werden können [5, 11, 23, 24]. Rein erklärende Modelle sind gut interpretierbar, liefern aber nicht per se gute Vorhersagen [5, 24].

- Rein prädiktive Modelle sind typischerweise das Ergebnis algorithmischer Verfahren wie beispielsweise Künstlicher Neuronaler Netze [5, 24]. Dabei sind die vorherzusagenden (Test-) Daten des Phänomens während der Aufstellung des Modells unbekannt. Es wird nur mit einem Teil der verfügbaren (Trainings-) Daten aufgestellt. Die Modellgüte wird bestimmt, indem überprüft wird, wie gut es die unbekannten Daten vorhersagen kann. Rein prädiktive Modelle sind in der Regel schwierig bis gar nicht interpretierbar, liefern jedoch sehr gute Vorhersagen [5].
- Für die Aufstellung von Modellen, die sowohl interpretierbar sind als auch gute Vorhersagen liefern, existiert kein eindeutiger Modellierungsansatz – entweder wird ein erklärendes Modell auf seine Vorhersagekraft getestet und gegebenenfalls modifiziert, um diese zu verbessern oder die Interpretierbarkeit eines prädiktiven Modells wird (zumeist auf Kosten der Vorhersagekraft) mithilfe entsprechender Methoden und Prädiktoren erhöht [24].

Laut Gregor [12] gehören *Grand Theories* wie TAM zu den Theorien der Vorhersage und Erklärung – dennoch werden sie im Rahmen ihrer Modellierung und Evaluation in der Regel wie rein erklärende Theorien behandelt [7, 24, 26, 27]. Auch wenn sich TAM und UTAUT in einer Vielzahl von Studien bewährt haben und im Rahmen dieser Arbeit nicht an ihrer Qualität gezweifelt werden soll, birgt rein erklärende Modellierung ohne prädiktive Evaluation Gefahren bezüglich der folgenden Kriterien:

- **Vollständigkeit.** Da der Fokus rein erklärender Modellierung auf der Bestätigung von Hypothesen liegt, besteht die Gefahr, dass die vollständige Aufdeckung der Mechanismen, die ein Phänomen verursachen, in den Hintergrund gerät. Fiedler [11] argumentiert daher, dass Studien, die den Fokus von der Bestätigung einzelner Zusammenhänge auf die vollständige Beschreibung eines Phänomens legen, ebenfalls notwendig sind. Solche Studien bezeichnet er als *phänomengetrieben*. Prädiktive, datengetriebene Studien legen den Fokus auf die Vorhersage von Phänomenen [24] und sind daher ideale Kandidaten für derartige Studien.
- **Generalisierbarkeit.** *Grand Theories* sollen weitestgehend ungebunden an Raum und Zeit sein [3]. Dies gilt in der Verhaltensforschung zwar nicht gleichermaßen wie in der naturwissenschaftlichen Forschung [2, 6, 18], eine möglichst generalisierbare Lösung sollte dennoch das Ziel sein [12]. Die größte Gefahr für die Generalisierbarkeit ist die *Überanpassung* (*Overfitting*) [23] – rein erklärende Modelle können auf die Daten ihrer Stichprobe überangepasst sein [17].
- **Praxisrelevanz.** Technologieakzeptanzmodelle sollen praxisrelevant sein – so soll UTAUT2 der Konsumgüterindustrie helfen, Technologien besser zu vermarkten [27]. Dazu ist es notwendig, dass die Erkenntnisse der Theorie auf die Zukunft übertragbar sind – hängt die Nutzungsabsicht in der Zukunft von anderen Faktoren ab als in der Vergangenheit, liefern die theoretischen Erkenntnisse keinen praktischen Mehrwert. Mithilfe prädiktiver Methoden kann daher die Praxisrelevanz von Theorien überprüft werden [24], mit rein erklärender Modellierung nicht zwingend.

3 Forschungsagenda

Im Rahmen dieses Projekts sollen Theorien der Technologieakzeptanzforschung auf ihre Vorhersagekraft überprüft und gegebenenfalls modifiziert werden, wobei die oben genannten Gefahren rein erklärender Modellierung vermieden werden sollen. Zu diesem Zweck sollen drei Studien durchgeführt werden:

1. **Vorhersagbarkeit der Nutzungsabsicht.** Mit *Predictive Analytics* kann die Vorhersagbarkeit von Phänomenen quantifiziert werden [8]. Lässt sich ein Phänomen mit einem prädiktiven Modell wesentlich besser vorhersagen als mit der zugrundeliegenden Theorie, spiegelt die Theorie die *Natur* noch nicht hinreichend wider [24]. Dabei kann sich ein prädiktives zu einem bestehenden theoretischen Modell dahingehend unterscheiden, dass es über weitere/alternative Prädiktoren verfügt und/oder mit anderen Methoden entwickelt wird. In einer explorativen Vorstudie zu diesem Forschungsprojekt konnte bereits eine entsprechende Prognosediskrepanz der Nutzungsabsicht zu einer etablierten Theorie der Technologieakzeptanzforschung mit einer kleinen Umfragestichprobe (N=249) festgestellt werden. Die verbesserte Vorhersage wurde dabei durch die Erweiterung und Kompression der von der Theorie suggerierten Prädiktoren unter Einsatz von *PLSpredict* und Kreuzvalidierung erzielt [25]. Da jedoch insbesondere die Analyse großer Datenmengen das Potenzial bietet, theoretische Erkenntnisse zu gewinnen [1, 24], soll in einer Folgestudie eine weit größere Stichprobe, die in Kooperation mit einem Praxispartner erhoben wird, mit maschinellen Lernverfahren analysiert werden. Ziel hierbei ist die Aufdeckung und Analyse einer substanziellen Diskrepanz zwischen den Vorhersagen des prädiktiven Modells und denen der Theorie sowie die Identifikation potenzieller neuer und alternativer Prädiktoren.
2. **Identifikation des *wahren* Modells.** Mithilfe einer Monte-Carlo-Simulation – ähnlich den Simulationen von Henseler et al. [15] und Rönkkö und Evermann [22] – sollen in einer zweiten Studie Daten eines *wahren* Strukturgleichungsmodells simuliert werden. Mit diesen Daten werden in einem ersten Schritt Strukturgleichungsmodelle aufgestellt, die das *wahre* Modell approximieren sollen. Anschließend werden diese Modelle jeweils auf ihre (i) erklärende und (ii) prädiktive Stärke überprüft. Hierbei werden im ersten Fall alle simulierten Daten herangezogen; im zweiten Fall wird der Datensatz in Trainings- und Testdaten partitioniert. Ziel der Studie ist zu zeigen, dass durch rein erklärende Evaluationen Modelle, die nicht dem *wahren* Modell entsprechen, bestätigt werden können. Darüber hinaus soll gezeigt werden, dass jenes Modell, das dem *wahren* Modell entspricht, bessere Vorhersagen liefert als die übrigen Modelle. Für die Berechnung der Vorhersagen werden verschiedene Ansätze der Strukturgleichungsmodellierung herangezogen.
3. **Vorgehen zur Modifikation von Theorien.** Ziel der dritten Studie ist mithilfe der Erkenntnisse der ersten beiden Studien einen Modellierungsansatz für die Aufstellung und Modifikation von Modellen zur Vorhersage und Erklärung zu entwickeln.

Abstract. Design knowledge on smart glasses-based systems is scarce. Utilizing literature analysis on software development publications, insights from the design and implementation of four smart glasses-based systems and expert interviews, we elicited 16 design principles to provide guidance in the development of future service support systems. Heuristic Theorizing is an abductive Design Science Research method, hitherto far too little known or little noticed, which was applied to conduct the research. We contribute to theory and practice with applicable design principles to support the development of smart glasses-based systems. Phenomena known to have an impact on the adoption of smart glasses are addressed by these design principles.

Keywords: Smart Glasses, Augmented Reality, Design Principles, Heuristic Theorizing, Instantiation

1 Introduction

Digital transformation is characterized by unavoidability, irreversibility, rapidity and uncertainty [1]. Thereby an essential driver for today's digitalization are mobile technologies [2]. In this domain Augmented Reality (AR) reached much attention in research and practice. Haborth [3] discovered that a dominant technical research focus exists and inevitably studies regarding user behavior are underrepresented. However, a holistic knowledge is essential for the adoption of new technologies [4].

One technology to take into consideration are smart glasses. Smart glasses-based systems are identified as an appropriate solution to assist services with intense information-needs [5], [6]. Based on three years of research and a certain amount of smart glasses-based prototypes we define the corresponding concept as a mobile eyewear having a display and further sensors installed, in sum called smart glasses, which proactively provides process information and instructions to the user or allows the user to collaborate with integrated IT-systems (Human-Computer Interaction) or other process participants. For example, by using integrated cameras the user is able to scan bar codes or to take pictures and videos while executing assigned tasks. As a

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

further benefit, a valid smart glasses-based system allows a hands-free interaction and therefore releases further efficiency. The underlying technology Augmented Reality is a generic technical concept, which describes displays that enhance the perceived real world by digital and virtual objects [7]. Smart glasses-based systems are discussed in particular to cope with the variety and wide range of service tasks [8].

New technical features exist that (amongst others) can track the user and take photos unnoticedly. Therefore, privacy is a vital issue not only in terms of compliance, but for user's trust and perceived privacy. Potential users refrain from the adoption of smart glasses as they criticize privacy risks as well as ergonomic and social consequences following the use of smart glasses [9]. To ensure the adoption of this promising support technology, iterative adjustments are required to design and implement smart glasses-based systems to encounter existing adoption barriers [10]. A research gap exists thereby because those systems are still under ongoing investigation and have not been fully implemented in practice to date. Due to a small number of cases, the factors and phenomena influencing the adoption and diffusion of smart glasses are not fully understood [11]. Hence, the research focus of this paper is embedded in a design science research (DSR) project that deals with the global research question:

(RQ) *How to design smart glasses-based systems for industrial service scenarios aiming to positively influence adoption and diffusion?*

During a three-year consortium research, we investigated the design and development of smart glasses-based systems. Uncertainties arose in terms of implementation, usability, privacy, acceptance, and project management resulting from the aforementioned research gap. Heuristic can be understood as an approach to handle situations where limited time and knowledge are involved in achieving with a high probability suitable solutions. This is in contrast with the imagination of unlimited rational thinking and resources to find out the optimum [12]. Marewski et al. [13] figured out that heuristics, i.e. simple cognitive approaches, can be in favor when uncertainty is involved due to omitting insignificant details. Heuristic Theorizing [14] is applied in this context to structure the problem space and generate regarding solution components in an iterative approach. Then, we combined our justificatory knowledge of smart glasses-based system development with design principles from IS literature.

Our presentation of research is structured as follows: To begin with, the theoretical background of smart glasses, their implications for service support systems and research projects, which applied Heuristic Theorizing are presented (cf. section 2). Afterwards, we introduce Heuristic Theorizing as our research approach and apply it to the initial research questions (cf. section 3). This is followed by detailed explanations of our execution (cf. section 4). Then we describe the derived design principles (cf. section 5) and state hardware guidelines (cf. section 6). We conclude with discussion and further research need statements (cf. section 7).

2 Related Work

Smart devices appear in everyday objects that become omnipresent and allow interconnection to a smart environment. Popular manifestations of smart devices are smart glasses [11]. The main advantage of smart glasses are the hands-free navigation and context-sensitive information provision [15], [16]. Smart glasses are in particular applicable to information-intensive and bi-manual tasks. However, potential users criticize privacy risks as well as ergonomic and social consequences following the use of smart glasses [9]. In IS research, several models and theories are applied to explain and measure the technology acceptance. Due to a small number of cases, the determinants for the acceptance of smart glasses are still not fully understood [11]. First articles in the IS domain present prototypical implementations of smart glasses-based service support systems and describe their individual and domain-specific design process (cf. [8], [17–22]). These researchers built on general guidelines for human-computer interaction (cf. [23–25]) or design guidelines provided by manufacturing companies such as Google [26] and Sony [27]. A few approaches aim to derive design principles for smart glasses-based service support systems, but again these are limited to individual use cases and domains [18], [28].

However, design guidelines and principles in human-computer interaction for an application must be extended and adapted to specific hardware Design knowledge on smart glasses-based service support systems is scarce and limited in their generalizability [cf. 28]. Design guidelines provided by the manufacturers are specific to individual models and focus on UI design [26], [27]. As this disruptive technology is part of a sociotechnical system, principles regarding the interaction, information provision and implementation in an existing system landscape are necessary. Design Principles convey prescriptive design knowledge provided by DSR [29]. This prescriptive knowledge results from the generalization of experiences and knowledge from individual implementations. In the course of research, we applied a heuristic approach to derive such design principles for smart glasses-based systems, because heuristic thinking is useful in design situations with high uncertainties [30]. For instance, Lienhard and Legner [31] used Heuristic Theorizing in a research project to evolve design principles for mobile health apps.

3 Research Approach

Heuristic Theorizing [14] was applied as a research strategy during an iterative system development grounded in a three-year consortium research. This DSR method is characterized by the use of heuristics to design a satisficing solution for an unstructured problem space. The design and implementation of smart glasses-based systems is such an unstructured problem space, because of the lack of design knowledge. Therefore, the entry point is the research gap for the design smart glasses-based systems. This problem space was structured continuously with reoccurring “problem structuring heuristics”. The findings are concretized and translated into action with the use of “design heuristics”. Results from heuristics are extracted through “heuristic synthesis”. The applied heuristics served to build a satisficing solution in the form of (i) four prototypes and (ii) 16 design principles to design and develop smart glasses-based systems. The alternating phases of heuristic synthesis and problem structuring/ design heuristics supported the course of research with dynamic problem-solving approaches.

Figure 1 states the methods applied as heuristics and the main artifacts that result from the synthesis. The sequence of steps that we passed through in order to derive design principles for smart glasses-based systems by using Heuristic Theorizing is traced with numbers in ascending order from (1) to (17). The designed principles are deduced from scarce design knowledge in IS literature [32], experiences made in the design and instantiation [33] of smart glasses-based systems and expert interviews [34] with AR software engineers.

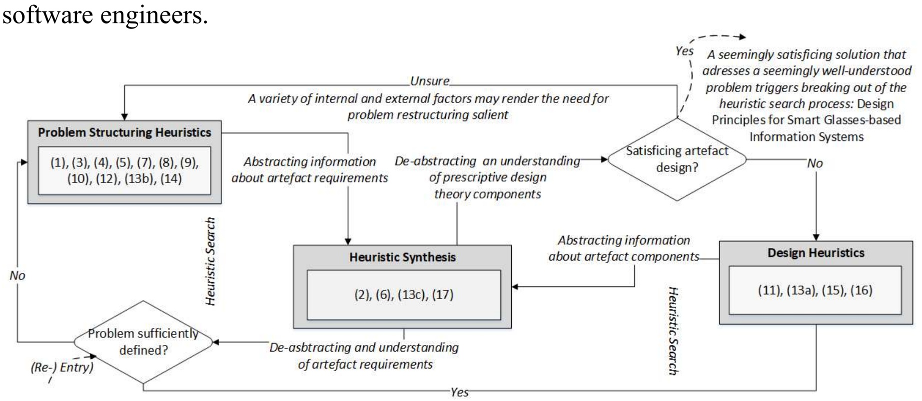

Figure 1. Applied process of Heuristic Theorizing

4 Executing Heuristic Theorizing

Overall, we applied nine different heuristics during research. To conduct the heuristic search, we used established *design science research methods and patterns* as published by Vaishnavi and Kuechler [35]. Initially, we *decomposed the research problem (1)* to identify the essential aspects of the research questions and to form the central problem class "design know-how for smart glasses-based systems" *(2)*. With an *interdisciplinary problem extrapolation (3),* we searched for existing solutions within other scientific disciplines such as law and psychology as well as solutions from practice. We found prototypes and studies from the field of logistics [36], manufacturing [37] and technical customer services [8], as well as design guides for user interfaces of AR or smart glasses [26], [27], [38]. Relevant knowledge was identified through *familiarization with the research community (4)* and the analysis of the *industry and practice awareness (5)* on smart glasses-based systems. The design then was enriched during the prototyping with insights from practice. We based our prototypes' design on already *published design solutions (6)*, both from research and from smart glasses producers [8], [26], [27], [39].

For the instantiation of our concept, we *identified a research domain (7)* and focused on a use case in logistics services as it inherits a linking function in the supply chain and provides numerous services, such as value-added services, which are highly intertwined with other industries. As we identified our research domain, we examined the *industry and practice awareness (8)* for smart glasses-based solutions in this specific sector again and collected requirements, challenges and potentials by conducting *expert interviews (9)* and a *systematic literature review (10)*. These expert interviews were conducted in the form of eight focus groups (two per prototype) consisting of three researchers (two from IS, one from logistics), two domain experts from logistics and two implementers of logistics systems. During these sessions, we discussed potential use cases for smart glasses in logistics and derived requirements for the prototyping. For an instantiation, the selection of the logistics domain is suitable as their workflows are characterized as information intense services with high flexibility [40]. Furthermore, smart glasses-based systems offer great potentials to improve logistic services. Potential use cases within the standard business processes in intralogistics have already been analyzed [41].

Software development activities, supported by design drafts *sketching possible solutions (11)*, were validated in four *expert interviews (12)* from the same group as before. Including the resulting feedback, four applications for smart glasses were developed through *iterative prototyping (13.a)*. In a cyclical attempt, we evaluated the applications using *experimentation and exploration (13.b)*. In a first step, students tested the applications and gave feedback. In a second step, the applications were tested with employees from logistics companies at real workstations. The feedback was collected in particular through discussions with the scientists involved and by applying the thinking aloud method. Four *smart glasses-based systems* for logistics support resulted from this approach *(13.c)*.

The four systems provide functionality for four different use cases. With system A, logistics workers can document damages of incoming goods by making use of the built-in camera. System B guides employees through the assembly processes of value-added services. System C provides a documentation method through a checklist-based approach for quality assurance, replacing paper-based lists. With system D, users can record processes while executing the respective tasks at the same time, which are then transformed into standardized process models automatically. While system A was developed for the Vuzix M100 smart glasses, the other three systems were built for its successor, the Vuzix M300. All four systems have been tested and evaluated by domain experts in real application cases. Major problems we identified in the course of research are the system's acceptance, usability, the ergonomic design, privacy and safety. We adapted the technical and functional design aspects regarding a modular architecture, measures to address acceptance and privacy compliance and included further aspects of the user interface and interaction patterns for smart glasses-based design. Unfortunately, adjustments for an improvement of the ergonomic design were limited due to the hardware. An example for the user interface and provided functionality of such system can be seen in Figure 2 (cf. section 5).

Investigating generalizability (14) of our design knowledge, we aggregated the similarities in problems and solutions among the four prototypes together with the participating developers to deduce the first set of *design principles (15)*. For evaluation this set was retrospectively discussed and was further supplemented in *interviews (16)*. One interview was conducted with the two implementation experts from the earlier interviews and one was conducted with two AR experts from a so far uninvolved software development company. The concepts and lessons learned from the development and implementation of the four systems were *embedded (17)* with the insights from literature and practice The three researchers mentioned have independently carried out a qualitative content analysis [42] and compared and integrated the results afterwards to develop a set of 16 design principles for smart glasses-based systems. Table 1 (cf. Appendix) states from which sources each design principle originates. In contrast to Niemöller et al [8], the proposed design principles are not based on a single implementation but integrate findings from four prototypical implementations and design knowledge from IS literature.

5 Design Principles

Overall, we identified 16 design principles, which we structure into four superordinate categories based on the architectural pattern of Model-View-Controller [43]. The category Interaction Design represents the controller (C), the category Software Design and Architecture serves as model (M). As smart glasses pose unique challenges concerning the presentation of data, the view-component (V) was divided into the categories Information Provision and User Interface, to state *which* and respectively information should be presented. Figure 2 states a summary of the proposed design principles. The design principles convey descriptive knowledge gained from the before mentioned DSR project and design knowledge from literature (cf. Table 1). This manifold design knowledge has been translated into action and materiality oriented [29] design principles. However, Information Provision deviates from this; these principles have been developed with a view to action as action-oriented design principles.

INTERACTION DESIGN (C)

(1) Simple and hands-free interaction utilizes value added by smart glasses. **(2)** Feedback from the system/ reciprocal and dynamic interaction generates steadyness for the user. **(3)** Take process and workplace safety requirements into account. **(4)** Using peripheral devices to optimize interoperability and the human computer-interface.

INFORMATION PROVISION (V)

(5) Focus on the essentials. **(6)** Match the user's qualification.
(7) Provide continuous navigation and orientation.

USER INTERFACE (V)

(8) Design a simple and consistent layout to avoid complexity. **(9)** Focus perceptible user interface design to ensure usability. **(10)** Offer customizable interfaces to respect individual user requirements.

SOFTWARE ARCHITECTURE AND DESIGN (M)

(11) Privacy is a design goal. **(12)** Use of Random Access Memory (RAM) economically. **(13)** Choose software components according to usage context. **(14)** Modular software design allows a customizable range of functions. **(15)** Scalable software architecture enables the future expansion of such young technology. **(16)** Use external sensors and interfaces to collaborate with others users and the overall.

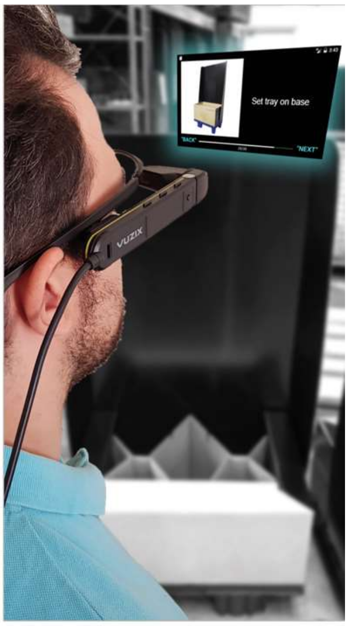

Figure 2. Design principles attributed to the model-view-controller paradigm

5.1 Interaction Design (C)

(1) Simple and hands-free interaction utilizes value added by smart glasses. To keep both hands free for bimanual tasks, e.g. picking of goods, voice control is favorable [21]. However in louder conditions, voice control can be distracted by noise or other voices. Alternative solutions such as gesture control or external control buttons should therefore also be provided.

(2) Feedback from the system/ reciprocal and dynamic interaction generates steadiness for the user. The feedback given by the smart glasses is important for the user's orientation among his tasks. To not lose track of the workflow, the user has to be informed about his handling errors and successful inputs [18], [21]. If voice control is deployed, the status of speech recognition should be displayed and an acoustic feedback could be implemented. We experienced confusion and mishandling if the user does not receive feedback on the status of data processing. If virtual objects are displayed in a smart glasses-based system with spatial localization, direction indicators should be implemented to guide the user to objects, which are placed outside his current field of view.

(3) Take process and workplace safety requirements into account. Smart glasses are deployed in industrial settings with potential dangerous conditions and processes. To safe the user from imminent danger, giving input during safety warnings should be disallowed. Regarding binocular devices, a half display mode, e.g. for forklift drivers, to ensure an unaffected perception of reality combined with larger font sizes during movement activities seem to increase the safety at work even further.

(4) Using peripheral devices to optimizes interoperability and the human-computer interface. Smart glasses as a standalone solution have limited resources. The connection of smart glasses with peripheral devices (e.g. telemetry sensors) increases the application potential and, for instance, enables smart services [8]. The possibility of a wireless connection to the internet makes online communication (e.g. video chat) possible [28]. Interoperability with other devices or the interaction with machines that are part of the user's working place can enhance the support of complex or collaborative tasks.

5.2 Information Provision (V)

(5) Focus on the essentials. Minimalistic and context-adaptive information provision and one main screen with crucial information about the task to fulfill, prevent the occurrence of information overload and cognitive stress [8]. Additional information of the displayed process should be attached and split into multiple screens if it is to complex or too much content [8]. To reduce confusion and to not lose track of the workflow, hierarchies should be kept flat, messages should be short and concise [27]. Complex structures also have to be avoided due to limited legibility and cognitive stress. Instead of this, physical objects seem suitable [38]. Finally, the navigation depth should be as small as possible to prevent information overflow and cognitive stress [8].

(6) Match the user's qualification. An information provision that matches the user's qualification leads to a higher acceptance and a better user experience. For example, novices might require additional information, while this additional information is redundant for experts. Moreover, the full workflow should be represented by one smart glasses device. This prevents media disruption and improves the acceptance and user experience [8].

(7) Provide continuous navigation and orientation. Avoiding the unexpected, e.g. sending content too frequently and at unexpected times, helps to increase acceptance and usability [26]. Providing a progress bar to keep track of information and always returning to the last shown step are also supporting acceptance and usability [8]. Recognizable icons guiding the user and let him know immediately about the meaning of the corresponding message. To allow direct feedback to one step is also improving the usability [8].

5.3 User Interface (V)

(8) Design a simple and consistent layout to avoid complexity. Complex and dynamic layouts impede the usage of smart glasses. The following features decrease such complexity: Virtual screens and look-around displays should have no more than three colors maximum [21], [26], [44]. The Information should be placed in the (lower) center of the screen [21], [44], navigation bars at the bottom [21], [26]. Intuitive elements, such as icons, find their place in the corners of the display [26]. A dark background for look-around displays or to display 2D objects is desirable. An adaptable mode for different usage contexts (e.g. day and night mode) is useful.

(9) Focus perceptible user interface design to ensure usability. To deliver a good perceptibility, it is important to use an appropriate font size and type [27]. Recognizable icons enhance an intuitive use and reduce complexity. In regards to AR glasses with spatial localization, depth cues for virtual objects and a well-suited field of view increase immersion and are crucial for a comfortable head movement [38]. Finally, real world objects should not be covered by virtual content. Digital objects should be placed in open spaces [38].

(10) Offer customizable interfaces to respect individual user requirements. The user should be allowed to adapt the colors and positioning of elements to match their individual requirements and information needs. As a consequence, stronger involvement of the user results and seem to lead to higher acceptance [28].

5.4 Software Design and Architecture (M)

(11) Privacy is a design goal. Security breaches and client insecurity, privacy risks as well as General Data Protection Regulation (GDPR) compliance are common problems with smart glasses that should be avoided. As a result privacy by design and default are central rules to be followed for smart glasses-based systems. Therefore, latest data security measures have to be taken [45]. Moreover, a transparent system architecture as well as a transparent data collection and storage increase the trust in the system and in doing so the users acceptance [27], [45].

(12) Use Random Access Memory (RAM) economically. The main goal of all measures regarding the economical use of RAM deals with a lack of battery power, heat generation, and speed reduction as well as stability problems. These issues are caused by still constrained hardware setups of latest smart glasses devices. The downscaling of images and the avoidance of unnecessary elements and activities reduce the extent of RAM use and therefore increase the performance as well as user experience of the smart glasses-based application.

(13) Choose software components according to the usage context. To meet the device properties and the system requirements, deploying a sufficient framework is important to meet the device properties and the system requirements. One the one hand significant factors for the choice of an implementation framework, are hardware, the complexity of the task, support and scalability. On the other hand, solution components may vary with the usage context and therefore require a certain level of flexibility. For example, in most cases integrated voice commands like a "Next" voice statement are sufficient to complete a task rather than implementing a cloud-based speech-to-text service (even causing further issues with regards to DP 11). According to the usage context of the resulting support system, corresponding applications may use different functions of the system. For example, different options of voice control can be applied (command vs. speech-to-text) instead of single commands (e.g. "say what you see" principle. Also, connectivity, algorithm, implementation effort and the level of maturity are the deciding factors for the choice of voice control as some require an internet connection.

(14) Modular software design allows for a customizable range of functions. A modular design of system components enhances scalability and customization. Turning off unnecessary functionalities (modules) for specific use cases, receives several benefits regarding privacy compliance, the complexity of the system and the extension of RAM usage.

(15) Scalable software architecture enables the future expansion of such young technology. The system should be maintainable, expandable and scalable to meet an increasing demand and technical evolution.

(16) Use external sensors and interfaces to collaborate with others users and the overall system environments. Based on an increasing amount of sensors around the company landscape, mainly driven by Internet-of-Things concepts, there is a great potential to access process data, e.g. watching live machine utilization or being informed in case a new truck is arriving. Furthermore special peripheral devices like hand-mounted scanners utilizing additional process performance.

6 Hardware-specific Guidelines

During the course of research we additionally identified actionable guidelines for the choice and preparation of hardware. As these hardware guidelines occurred as a byproduct of our discussions and information generating methods, they were not integrated into the previously presented design principles. Nevertheless, they serve as important insights concerning the choice and handling of smart glasses.

Ensure wearing comfort. Regarding the Hardware Design, ensuring the wearing comfort of smart glasses is the first identified guideline. Poorly balanced as well as a too heavy weighted devices may lead to muscular pain and discomfort during a long working day [46]. A flexible position of the display supports wearing comfort by providing a better individual perceptibility [18]. The stable attachment of the smart glasses at the head further enhances the wearing comfort during movement. To meet individual demands, the suitability of the devices for spectacle wearers and mounting options for both eyes are necessary.

Choose hardware usable in industrial settings. The application of smart glasses in an industrial context leads to specific requirements. The consideration of industry standards is crucial with regard to the acceptance of smart glasses [8], [28]. Certain working contexts such as outdoor or soiled environments require waterproof and shockproof housing. Clip-on solutions are favorable for mounting on existent equipment, to be compliant with safety regulations in many industries.

Minimalistic Hardware Design. Complex and fragile hardware impedes the adoption of smart glasses [8], [28]. Consequently, the functionalities should match the usage context, and unnecessary functions should be avoided. The outsourcing of computational power as well as the battery, combined with high mobility are also important factors to minimize the hardware. A modular system would comply with the privacy by design paradigm [45], because the built-in sensors and functionalities are limited to the usage scenario.

Ensure excellent legibility. The legibility of smart glasses displays depends on technical as well as environmental conditions and has to suit the individual requirements of the user. Adjustable brightness, high resolution, and protection against solar radiation are crucial for excellent legibility of the display [28], [38].

7 Discussion, Conclusion, and Outlook

Discussion. Through applying heuristic theorizing, we introduced design principles for smart glasses-based systems. These design principles enrich previous research [6], as they focus on how software for smart glasses should be designed and developed. We contribute to the limited knowledge-base of smart glasses-based system engineering by providing results from the successful application of Heuristic Theorizing [14], an appropriate method for systems engineering which hitherto is not very known in research. We designed and instantiated four systems on two different hardware models. Hitherto, an evaluation has been carried out in the form of an interview with implementation experts. The effectiveness of the proposed design principles was not part of previously documented studies, and hence needs to be addressed in subsequent steps. The design principles for look through devices with spatial localization originate from literature and expert interviews. Further instantiations are required to extend the specific design knowledge within the range of those smart glasses.

Conclusion. In a DSR approach, we utilized design knowledge published by IS scholars and smart glasses-producers, the design and instantiation of a smart glasses-based system and expanded these findings with knowledge provided by augmented reality software engineers. The lack of long-time experience with smart systems demands the adaption and extension of best practices to meet the requirements emerging with the implementation in business settings and to derive design knowledge for future implementations. Heuristic Theorizing enables the integration of scientific insights to meet the requirements of innovative technology. As an open and creative process, it contributes new insight and is beneficial to the artefacts for practical use.

With our research, we contribute to theory with design principles for smart glasses-based systems. The aggregated design principles address the phenomena of acceptance and privacy, as crucial factors for the fail of smart glasses on the consumer market, as well as usability and ergonomic design. Furthermore, the paper presents a respective domain that is affected by the digital transformation and demonstrates with the application of Heuristic Theorizing an approach to handle digitalization research projects.

Outlook. Technology acceptance and usability of pervasive computing such as smart glasses is not understood, yet. Especially impediments in smart gasses adoption such as acceptance [47] require further understanding. Therefore, influence factors regarding those devices need to be examined and integrated into theories for technology acceptance [11]. To spark future research, the presented design principles can further be validated, expanded and refined through further case studies. A combination of our findings with further insights from the research community and particularly from interdisciplinary areas, e.g. from cognitive science, psychology and ergonomics, is planned to deepen the understanding of phenomena influencing the adoption of smart glasses-based systems.

Appendix

Table 1. Design principles grounded in literature and design heuristics

Design Principle	Literature	Design Heuristics	Example
(1) Simple and hands-free interaction utilizes value added by smart glasses.	[8], [18], [21], [28]	Sketching Solution	For actual freehand use, only voice control comes into question. Gesture recognition or input using buttons temporarily require at least one hand.
(2) Feedback from the system/ reciprocal and dynamic interaction generates steadiness for the user.	[18]	Iterative Prototyping	Users were irritated when the system did not confirm a successful entry.
(3) Take process and workplace safety requirements into account.		Iterative Prototyping	Users handle chemicals and require instructions during the process.
(4) Using peripheral devices to optimizes interoperability and the human-computer interface.	[28]	Sketching Solution, Iterative Prototyping	Users faced problems to scan barcodes with the camera. Instead, a barcode scanner ring could be added to the system.
(5) Design a Simple and consistent layout to avoid complexity	[21], [26], [27], [8]	Sketching Solution, Iterative Prototyping	Strongly differing layouts and forms of presentation irritate the user.
(6) Focus perceptible user interface design to ensure usability.	[18], [21], [26], [27],	Embedding concepts and Techniques	Some manufacturers provide specific information for display on the devices, but these are not transferable to other products.

Design Principle	Literature	Design Heuristics	Example
(7) Offer customizable interface to respect individual user requirements.	[28]	Iterative Prototyping	During the evaluation of a prototype with different people, differing requirements were placed on the user interface.
(8) Focus on the essentials.	[8], [18]	Iterative Prototyping	Implementers with experience in app development for smartphones tend to design the user interface and the information to be displayed too complex for smart glasses-based systems.
(9) Match the user's qualification.	[8]	Sketching Solution	Different user groups require a differing degree of detailing and additional information for process support.
(10) Provide continuous navigation and orientation.	[8], [38]	Iterative Prototyping	A progress bar provides users with an overview of the process step in which they are.
(11) Privacy is a design goal.	[19], [28], [45]	Sketching Solution	The regulations of the GDRP must be complied with for industrial use. Privacy-by-design is a fundamental principle to be integrated into system development.
(12) Use of Random Access Memory (RAM) economically.		Iterative Prototyping	The application has a high latency time or the smart glasses have already heated up after a short period of use.
(13) Choose software components according to usage context.		Iterative Prototyping	For step-by-step instructions, a different language application and library is suitable than for speech-to-text scenarios.
(14) Modular software design allows a customizable range of functions	[19], [28]	Iterative Prototyping	Technical and functional modules of already existing prototypes could be integrated in the implementation of new use cases. Thus a registration mask or a video recording function of different prototypes has been realized with the same system module.
(15) Scalable software architecture enables the future expansion of such young technology.	[19]	Sketching Solution	So far, smart glasses have initially been used as prototypes. However, the corresponding solutions should be scalable in order to enable broad use in the future. So far
(16) Use external sensors and interfaces to collaborate with others users and the overall system environments		Sketching Solution	In order to develop smart services, external sensor data, e.g. from machines to be maintained, are required.

Mirroring E-service for Brick and Mortar Retail: An Assessment and Survey

Jan H. Betzing[1], Marco Niemann[1], Benjamin Barann[1],

Benedikt Hoffmeister[1], and Jörg Becker[1]

University of Münster, ERCIS, Münster, Germany,

Abstract. The digital transformation increasingly impacts the competitive retail market structure in favor of e-commerce and digital business models, while many Brick and Mortar (BaM) retailers are struggling to meet customers' expectations. Supported by the customer adaption of e-commerce and digital technologies, this paper applies the lens of channel complementary theory to BaM. We examine, which e-service touchpoints from e-commerce can be transferred to the physical servicescape of BaM retail to complement customer journeys. Drawing from the dominant design theory, we first assess leading e-commerce solutions to identify dominant e-service touchpoints, which are then mirrored for their application in BaM retail. Second, we surveyed 250 shoppers to elicit the likeliness of use regarding these touchpoints. Our results provide a foundation for both academia and retail to advance the knowledge of relevant e-service touchpoints in BaM.

Keywords: Brick and Mortar Retail, Omni-Channel, Touchpoint, Dominant Design Theory, Channel Complementary Theory

1 Introduction

The digital transformation is an ongoing organizational change process that leverages technology-enabled innovation to optimize existing business processes and to digitally (re-)engineer business models [1, 2]. In retail, the digital transformation increasingly impacts the competitive market structure in favor of e-commerce and digital retail business models and also bolsters customers' expectations towards e-service offerings in BaM [3–5]. In particular, small and medium-sized enterprise (SME) Brick and Mortar (BaM) retailers, which comprise the majority of stores in Germany, face strong competition with pure online players and large retail chains that embrace technological innovations [6, 7]. Over the last years, e-commerce in Germany steadily realized double-digit growth rates [8, 9], while SME retail turnovers are projected to decline by up to 30 % until 2020 in many cities [10]. To cope with the digital transformation, large retail chains are heavily investing in channel management to become omni-channel retailers that are able to seamlessly interact with customers through any physical and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

digital channel expected by them [11, 12]. While selecting appropriate channels and technologies to adopt for this purpose is already challenging for large retail corporations [13, 14], it can appear like a Herculean task for SME BaM retailers [7]. However, BaM retailers that are unable to develop new (digital) strategies to address customers' expectations, are threatened to become "amazon-ed" [15]. When asking customers for their reasons to choose e-commerce over BaM retail, comparably lower prices to BaM retail (36 %,[8])—contrary to popular belief—are only one aspect mentioned, while a considerable number of customers also names comfort and ease of use (50 %, [8]), 24/7 availability (39 %, [8]), and low purchasing efforts as motivators [8, 16]. Hence, non-financial levers do exist in e-commerce that could turn out to be beneficial in the BaM context (e.g., the integration of 24/7 e-service to increase BaM store visibility).

Particular to e-commerce is the offering of *e-service touchpoints*. An e-service is understood as the application of digital competencies "through deeds, processes, and performances for the benefit of another entity or the entity itself" [17, p.26], where the "delivery is mediated by information technology" (IT) [18, p.341]. Literature differentiates touchpoints into instances and classes [19]. The former touchpoints describe moments of contact, i.e., any "instance of communication between a customer and a service provider" [20, p.846]. This contact belongs to a touchpoint class, which denotes "an abstract interaction interface to the customer" [19, p.4]. When using the term (e-service) touchpoint, we refer to a touchpoint class. Established technologies that provide access to these touchpoints in the physical servicescape of BaM retail are, for example, smartphone and in-store terminal applications (apps) [21, 22]. Against this background, it is fair to assume that *mirroring*—adapting e-service touchpoints, originally provided in e-commerce, to the physical servicescape—represents a good starting point for BaM retailers to transition towards an omni-channel environment.

Still, retailers can select from a wide variety of conceivable e-service touchpoints to offer as value propositions that potentially create value for and with the customer [17, 23, 24]. In particular, it remains unclear, whether customers in the physical servicescape of BaM retail are likely to use the same e-service offerings they are used to in e-commerce. Empirical studies on omni-channel retail are sparse [13], and BaM retailers are lacking guidance regarding the selection and mirroring of e-service touchpoints [22]. To shed light on this matter, our research question reads as follows: *What e-service touchpoints, enabled by smartphone and in-store terminal applications, should be mirrored to the physical servicescape of brick and mortar retail?*

We followed a two-step approach to answer this question. First, we identify a set of major touchpoints offered by leading e-commerce platforms, group them, and mirror them for their application in a traditional BaM retail servicescape. Second, we surveyed 250 shoppers to elicit the likeliness of use regarding these touchpoints.

The remainder of this paper unfolds as follows: Section 2 positions our study within the body of knowledge. Section 3 presents the set of mirrored e-service offerings, whereas Section 4 introduces our survey research method and the survey results. Section 5 discusses our results and relates them back to theory. We close with an overview of our contributions and an outlook on future research in Section 6.

2 Theoretical Background

Customers have become accustomed to an increasing level of digital touchpoints in all facets of their lives [25], and also expect e-service offerings in traditional BaM environments [12, 21]. In this context, the term hybrid customer interaction is used to describe a behavior, where customers are present simultaneously in both the physical and digital worlds [26]. For example, customers use their smartphones in-store as a "second screen" to compare prices, while interacting with a salesperson [27]. Phenomena such as "showrooming" [5] or using e-service touchpoints by other service providers during the store visit can be cannibalizing for BaM retailers.

On the other hand, hybrid customer interaction can also be leveraged by retailers, when they are able to provide own e-service touchpoints for customers to use in-store [28]. Our reasoning follows channel complementary theory [29], which explains that traditional and new media formats for implementing communicative functions may exist alongside instead of replacing each other. The theory suggests that the function is a more important consumption driver than the medium itself [29]. In our context, e-service touchpoints can be understood as such communicative functions. Some authors provide evidence of channel synergies in retail [30] and suggest a "bricks-and-clicks" approach, where insights from the BaM channel are integrated into an online channel [28]. However, the opposite direction—adapting knowledge from e-commerce to the physical BaM servicescape—has not received much attention. Further, most omni-channel initiatives focus on integrating *existing* digital and physical channels and touchpoints [5, 11–13]. Yet, particularly traditional BaM retailers that only have the stationary sales channel lack information regarding which e-service touchpoints they should provide to their customers [30]. It remains unclear, which e-service touchpoints potentially yield value for customers and would likely be used by them [31]. So far, there is a scarcity of empirical studies on omni-channel retailing [13], and only a limited amount of studies gives advice regarding digital technologies and e-service touchpoints to integrate into the physical servicescape [e.g., 3, 14, 22, 24].

This article suggests *mirroring*—complementing a traditional BaM retail channel with e-service touchpoints that have been adapted from proven designs in other channels. The lens of the dominant design theory provides us with a starting point for the investigation. The theory argues that a product category establishes a representative set of functions over time, which is then seen as standard [32]. The lens has previously been applied to technological milestones such as microprocessor designs, PC operating systems, and television systems [32, 33]. The dominance of a technology can be investigated on different levels of analysis. One level is the consideration of "technological artifacts as composed of subsystems that are linked together [...] through specific interfaces" [33, p.274]. In our context, these artifacts can comprise the whole omni-channel system or a particular digital channel such as an e-commerce solution. As e-commerce is a mature domain [3], it is fair to assume that leading e-commerce systems have set such a dominant design, which comprises a set of functions that represent the consolidated requirements of various types of users [32]. In the consequence, the e-service touchpoints offered by leading e-commerce systems should meet customers' requirements to a large extent and provide value for them. Hence, they also might be relevant for customers shopping in the physical BaM retail servicescape.

While the mirroring approach appears promising for BaM retailers, it remains unclear, if and to what extent customers are likely to use these mirrored touchpoints. Particularly, Suárez reminds us that "a dominant design is not always that design which has greatest technological sweetness" [32, p.417].

3 Mirroring E-service Touchpoints for Brick and Mortar Retail

3.1 Identification of Dominant E-service Touchpoints

We assessed leading e-commerce solutions to identify the e-service touchpoints commonly offered in e-commerce. This assessment covers both the propriety solutions of the three German e-commerce market leaders (*amazon.de, otto.de,* and *zalando.de*) [34] and the five leading commercial off-the-shelf e-commerce solutions in the German market (*Shopify, Magento, WooCommerce, XT:Commerce* and *Shopware*) [35]. As the latter solutions can be customized by the retailers to serve their needs, we selected concrete instances. To cater for potential variances resulting from national peculiarities, customizing, and different product categories offered, we sampled three major Western European e-commerce retailers for each solution, yielding a sample of 18 online shops.

We employed a qualitative web-content analysis approach [36], where two of the authors with backgrounds in retail and service science manually simulated typical customer journeys on the online shops. In an open coding process, we inductively derived a total of 35 different e-service touchpoints that guide, support or enable the customer during its customer journey. Since we focus on the dominant design, we only kept those touchpoints that were offered by at least four online shops. Further, logistics-related touchpoints, as well as ones that require an online shop (e.g., *Click & Collect* and *Click & Reserve*), have been eliminated, because they do not constitute an independent BaM e-service touchpoint. 19 unique e-service touchpoints remained.

Figure 1 shows the identified e-service touchpoints from e-commerce and maps them to their mirrored BaM e-service counterparts. Some e-service touchpoints were mirrored into more than one touchpoint, whereas other e-service touchpoints have been merged into a single mirrored touchpoint, yielding a total of 20 mirrored BaM e-service touchpoints. Based on the type of value proposition, we grouped the touchpoints into four distinct categories that occur along the customer journey, viz., search and navigation, product information, selection and checkout, and communication and support.

3.2 Mirrored E-Service Touchpoints

Search and Navigation Touchpoints are research-supporting shopping aids [37] that help customers in the pre-purchase phase of their journey [12] to find and locate relevant products and services from the retailer's offered portfolio. These touchpoints reduce the search time and potential information overload customers might experience.

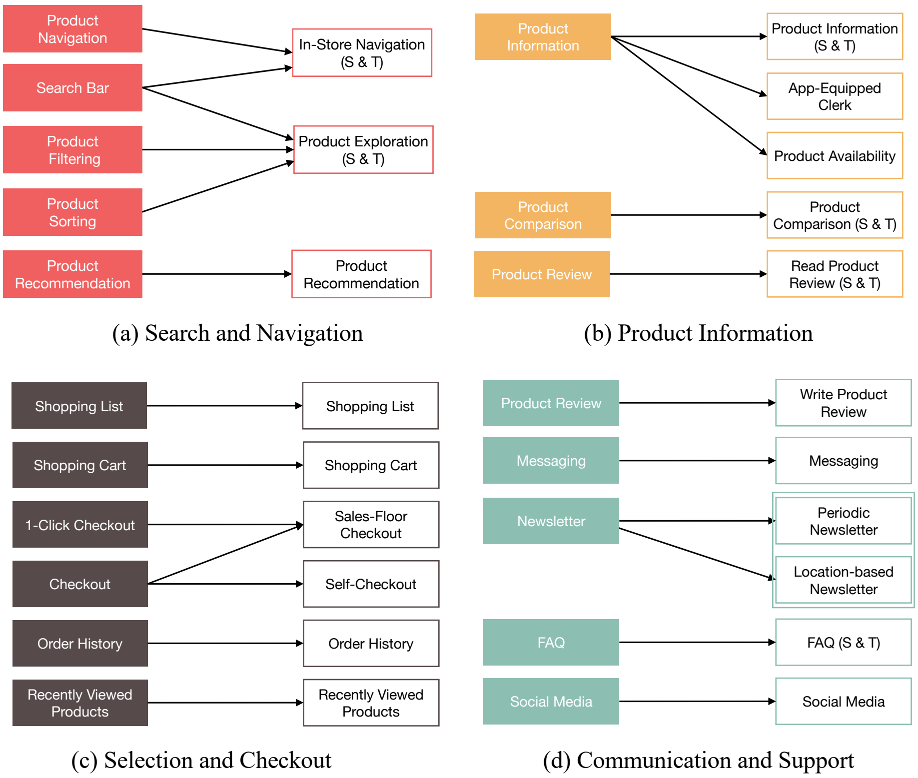

Figure 1. Mirroring of e-commerce touchpoints to BaM e-service touchpoints, grouped by touchpoint category (e-commerce touchpoint $\xrightarrow{\text{mirroring}}$ mirrored BaM e-service touchpoint)

In-Store Navigation Touchpoint: 83 % of the e-commerce solutions under consideration provide a global text search to directly track down desired products. This touchpoint is typically enhanced by auto-completion to assist with spelling and to provide first results before the search request is completed. Mirrored to the BaM context, this e-service touchpoint is particularly useful for large department stores and for customers unfamiliar with the store layout. It can support customers in locating a desired product and provides them with in-store directions. This touchpoint is feasible for both in-store terminals and smartphones. A smartphone-hosted app may use the tracking capabilities of the underlying device to provide real-time turn-by-turn navigation to a product.

Product Exploration Touchpoint: Due to their typically extensive product portfolios, online shops provide various means to browse and explore the portfolio. Sorting (e.g., lowest price or best reviews first) and filtering (e.g., product categories, brands) capabilities are provided to narrow down the product portfolio. Even though BaM stores fall short in terms of portfolio sizes when compared to online retailers [38], most retailers still offer a wide range of products. While e-commerce search touchpoints give direct product access, the portfolio might be harder to perceive in-store due to product presentation. In effect, potential BaM customers can experience issues in their orientation and selection process. Mirroring existing product exploration touchpoints to the BaM environment is facilitated by accessing the retailer's product data through terminals and smartphones, allowing the customer to apply the known filtering and sorting operations.

Product Recommendation Touchpoint: More than two-thirds of the considered e-commerce solutions feature a product recommendation engine. Based on behavioral customer data such as order history and recently viewed products, the e-service recommends products similar to previously considered items (content filtering) or ones that customers with similar taste have bought (collaborative filtering) [39]. By now, recommended products make up to 35 % of e-commerce purchases [40]. A mirrored product recommendation service takes into account behavioral customer data such as order history, shopping lists, or even their current in-store location. A smartphone app collects this information and, in turn, makes product recommendations.

Product Information Touchpoints assist the customer with retrieving of detailed information about considered products, and aid in the product selection process. As such, they primarily take place in the pre-purchase phase of the customer journey [12].

Extended Product Information Touchpoint: Urged by the inability of customers to physically experience products online, retailers responded by providing extensive textual and multi-media product presentations, which has led to online retailers giving more detailed information than their BaM counterparts. Customers can access a mirrored product information touchpoint by scanning product tags with their smartphones to receive detailed multi-media product information. Similarly, customers can carry products to an in-store terminal, scan their tags, and retrieve the information.

App-equipped Clerk Touchpoint: Some customers prefer personal service over e-service to get product information. Typically, store associates must have basic knowledge of all products in their responsible department. In case of detail questions, they might not be able to provide a correct answer. By providing store associates with a product information touchpoint (e.g., via a smart device), they can quickly look up the requested information for the customer.

Product Availability Touchpoint: Two in three analyzed online shops inform on product availability, i.e., whether a selected item is in stock, how many pieces are left, and send notifications when an out-of-stock product becomes available again. In a BaM store, product availability is visually apparent. However, even if a product is not on display, it might be available in the back room or a nearby warehouse. Through the introduction of a product availability touchpoint, which can be accessed by scanning a product's shelf label or manually searching a product, customers can access backstage warehouse availability information, trigger a refill or get a refill notification. As such, frustration from out-of-stock situations can be mitigated.

Product Comparison Touchpoint: As seen in the extended product information touchpoint, many online stores allow to compare the information linked to different products (e.g., size, price, and technical features) in a tabular fashion to improve the customer's selection process. Hence, a mirrored e-service touchpoint may allow scanning the tags of multiple products with a smartphone or in-store terminal app in order to obtain structured information for an efficient comparison.

Read Product Review Touchpoint: Product reviews, typically written by other customers, are one of the major information sources for online shoppers in their decision process [41]. The touchpoint can be mirrored as an extension to the product information service. In effect, the collective experience of the community in the form of ratings and reviews can be shown next to the retailer-provided product information.

Selection and Checkout Touchpoints support customers by helping them to plan future purchases, retaining control of the current purchase process, facilitating the checkout process, and keeping track of the past purchases [12].

Shopping List Touchpoint: E-commerce solutions frequently allow registered customers to create shopping lists or wish lists to save product references for later consideration. Interestingly, this touchpoint does not have its origins in the digital realm but was previously mirrored from traditional paper-based lists from the offline world. Now, the e-service implementation can be mirrored back to the physical realm. Customers can use a smartphone app to add selected products to a shopping list. Besides remembering relevant products, shopping lists allow for easy access to recurring purchases and to prepare store visits in advance.

Shopping Cart Touchpoint: Similar to shopping lists, shopping carts first had a physical representation before getting implemented in e-commerce. Digital shopping carts (or shopping bags) contain all selected products, display the subtotal and commonly allow to search and filter their contents. Mirrored back as an e-service for BaM, customers scan selected products before placing them into the physical shopping cart. Using their smartphones, customers can keep track of their projected spending and compare their selection to previously created shopping lists.

Sales-Floor Checkout Touchpoint: In e-commerce, customers do not have to wait in a queue or depend on a cashier to complete the checkout process, which renders it very efficient. One way to mirror a more efficient checkout to the physical realm lies in equipping store associates with smart devices to scan products and check out the customer on the sales floor. Hereby, the queue at the sales counter can be skipped.

Self-Checkout Touchpoint: Another way to digitally increase checkout efficiency is self-checkout. While these systems originally were introduced as a means for retailers to reduce labor cost [42], they can also facilitate efficiency gains for customers (e.g., skipping queues). In conjunction with the shopping cart touchpoint, a mobile self-checkout becomes feasible, where customers would only have to complete their purchase with electronic payment. This touchpoint satisfies shoppers' demand for "sofortness", similar to what they are used to from e-commerce.

Order History Touchpoint: In online shops, registered users usually can access prior orders to find out what has been bought. Mirrored to a smartphone app in the physical realm, a digital order history can help to keep an overview of what has recently been bought, and also to support recurring purchases such as groceries. The touchpoint also supports keeping track of the spending over time.

Recently Viewed Products Touchpoint: During online shopping, customers often interact with dozens if not hundreds of different products, which makes it hard to keep track of the items recently viewed. Respective touchpoints support customers by caching the accessed items. While BaM store portfolios are not as extensive as their online counterparts, they might still be sufficiently large to make it difficult for customers to keep track of all viewed products and retrieve the most desirable one (e.g., make a choice from different tried-on clothes). Again, customers can use their smartphone to scan the tags of considered products.

Communication and Support Touchpoints are used throughout the whole customer journey [12] to facilitate marketing, customer engagement, and customer care.

Write Product Review Touchpoint: Besides customers digitally consuming reviews, providing ratings and reviews themselves can also be mirrored by means of a smartphone app to the BaM context. By providing their opinion, customers support other shoppers and may also help retailers to adjust their product portfolio w.r.t. the customer reviews.

Messaging Touchpoint: Even though online retailers do not have the traditional shop-floor personnel, many of them provide customer service by means of a (video-)chat interface. Mirrored to a BaM store, an instant messaging touchpoint can ease interactions with store associates, especially when no associate is nearby.

Newsletter Touchpoint: Newsletters typically inform about a retailer's special offers or events. In contrast to conventional mass mailing such as catalogs, digital newsletters can be personalized. Personalized digital newsletters in a BaM environment can be viewed by the customer through a smartphone app. Further, a location-based newsletter touchpoint can exploit the smartphone's technological capabilities to enable location-based proactive newsletters that are sent out when a customer is passing by the store.

FAQ Touchpoint: Beyond product-related information, online retailers typically provide a list of answers to so-called "Frequently Asked Questions" (FAQ), which deal with topics such as warranty handling, delivery times, return policies or payment methods. Since FAQs are not customer-specific, this touchpoint can be mirrored both via smartphone and in-store terminal. An FAQ touchpoint helps to clarify time-consuming questions in advance that might otherwise be asked during consultations with store associated or at the checkout counter.

Social Media Touchpoint: At its beginnings, online shopping was a mere functional activity without a prevalent social component. With the rise of social media, the concept of "social commerce" emerged [43], where customers share their shopping experiences with others. While customers in BaM can directly interact with friends and other shoppers in-store, access to social media would enable interaction with a much larger group of acquaintances and strangers online. A retailer-provided social media touchpoint can, for example, facilitate discussions between customers or enable customers to showcase newly bought items.

4 Assessment of Mirrored E-Service Touchpoints

4.1 Survey Research Approach

Quantitative survey research [44] was employed to identify the shoppers' likeliness of use regarding the mirrored e-service touchpoints. We conducted a hypothetical thought experiment where participants were asked to imagine being in a fictitious "smart store", instead of presenting and surveying particular instances of the envisioned touchpoints. In an online survey, the participants were first introduced to the study context and the four categories of touchpoints that the fictional smart store will offer to complement traditional store operations (see Section 3). Afterward, each e-service was briefly introduced in one paragraph. Given the nature of the study where touchpoints were presented on a rather abstract level, we did not apply measures such as the Technology Acceptance Model [45], which are focused on well-specified particular instances of technology. Instead, for each touchpoint, we surveyed its likeliness of use by means of a single item five-point Likert-scale (e.g., "*how likely would it be for you to use such a product availability service?*"). When applicable, the question was asked twice—both for accessing the touchpoint in-store through a smartphone and through an in-store terminal. Finally, participants had to provide demographic information. In light of the overall relevance of BaM retail in society, we did not limit the survey to a particular audience. Instead, we recruited a diverse sample of more than 300 participants of at least 18 years of age from the Western world using *prolific.ac*. The recruiting platform aims at providing researchers with representative samples of users regarding age, gender, and educational level. An attention check question (adapted from [46]) was used to filter inattentive participants, which yielded 250 valid responses. The mean age of the respondents was 32.69 years (median 31 years, SD 9.96 years) and 53.60 % were female. Participants countries of origin were the United Kingdom (145), the United States (52), Canada (12), Portugal (9), the Netherlands (4) and sixteen other European countries (28). The average completion time for the survey was 9 minutes and 37 seconds. Participants were rewarded £1.15.

4.2 Survey Results

Figure 2 provides the distribution of the likelihood of use of the mirrored e-service touchpoints. The touchpoints are grouped by the four categories, and within each category, the e-service touchpoints are sorted in descending order by their average rating. The global average rating is 3.58 points. The social media service ranked worst with an average of 2.23 points, while the self-checkout service ranked best with an average of 4.35 points. An inter-group comparison revealed that respondents are most likely to use selection and checkout touchpoints (Ø 3.92 points). Product information touchpoints (Ø 3.79 points) and search and navigation touchpoints (Ø 3.73 points) ranked similarly, whereas respondents are much less likely to use communication and support touchpoints (Ø 2.94 points). The social media ($\sigma^2 = 1.71$; $\sigma = 1.31$), periodical newsletter ($\sigma^2 = 1.64$; $\sigma = 1.28$), location-based newsletter ($\sigma^2 = 1.60$; $\sigma = 1.27$), and messaging touchpoints ($\sigma^2 = 1.48$; $\sigma = 1.22$) were also the most controversial ones.

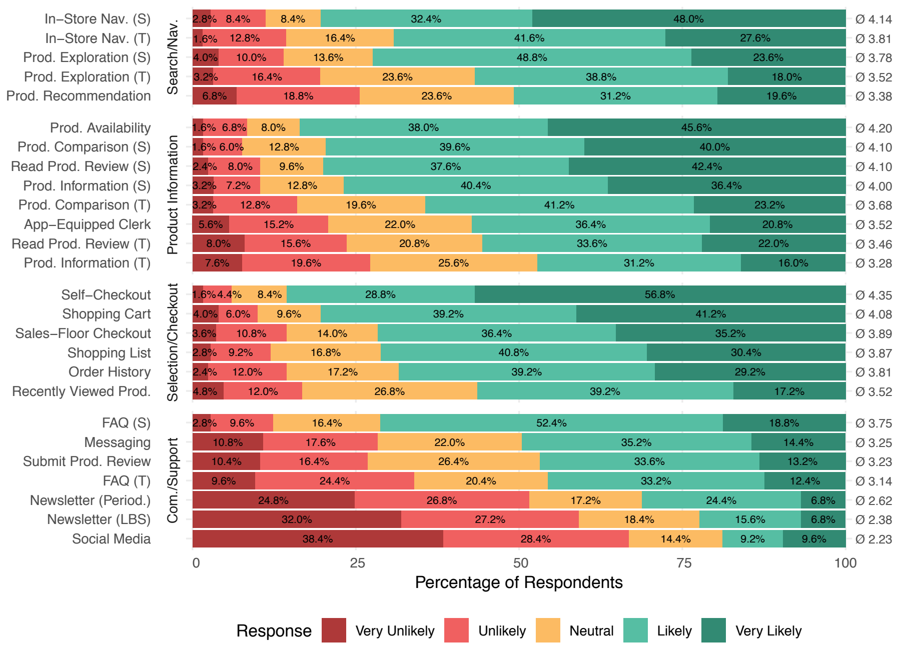

Figure 2. Distribution of likelihood of use per e-service touchpoint (grouped by touchpoint categories; within groups ordered descending by average score)

Pairwise Spearman's rank coefficients ρ between each e-service and the respondents' age indicated no significant relationships for most touchpoints, except for product comparison via in-store terminal ($\rho = .48$; $p < .001$), reading product reviews via in-store terminal ($\rho = .45$; $p < .01$), and accessing FAQs on an in-store terminal ($\rho = .39$; $p < .01$), which all show a positive relationship to increased age. On the contrary, the social media service ($\rho = -.43$; $p < .01$) has a negative relationship to increased age. Regarding relationships between the respondents' gender and their answers, Kendall's τ_b did not indicate significant relationships, except for a weak positive relationship between female respondents and the messaging service ($\tau_b = .16$; $p < .01$). However, women on average voted .08 points higher than men. Although not statistically significant, women, in particular, had a higher likeliness to use a smartphone (.31 points) or an in-store terminal (.38 points) to read product reviews compared to male respondents.

Six e-service touchpoints were surveyed regarding the two service interfaces smartphone (denoted (S) in Figure 2) and in-store terminal (denoted (T) in Figure 2). Results show that respondents prefer smartphones over terminals by an average of .50 points, and every e-service was ranked higher when accessed via a smartphone app. Differences were lowest for the product exploration service (.26 points) and highest for the extended product information service (.71 points). No unfamiliarity effects regarding mobile devices and e-commerce were evident, which could have influenced participants' responses. 99.20 % of respondents report owning a smartphone and 182 participants (72.80 %) report using their smartphone or tablet in-store. All but one respondent (99.60 %) have purchased goods and services online at least once. Nine participants (3.60 %) use e-commerce on a daily basis; 105 participants (42.00 %) report weekly e-commerce activities; whereas every second participant roughly shops online once a month. Ten participants use e-commerce as infrequently as once a year.

5 Discussion, Limitations, and Future Research

We mirrored e-service touchpoints for their application in BaM, and assessed shoppers' likeliness to use them to complement traditional service. Our findings offer several implications for academia and practice.

First, an overall positive response towards complementary e-service touchpoints provides support for channel complementary theory in the BaM retail domain [29] and supports the assumption that customers have a positive sentiment towards e-service in BaM retail. The results show that customers are likely to use e-service touchpoints in the physical retail servicescape to complement and improve their customer journey. In particular, selection and checkout touchpoints have a very positive response. It is fair to assume that most customers are used to the well-rated self-checkout touchpoint [47] and a mere-exposure effect might have occurred, i.e., respondents rated the touchpoint well just because of familiarity [48]. Nevertheless, most well-rated touchpoints comprise research-supporting and solution-oriented shopping aids [37], which increase customers' shopping effectiveness (find the right products) [22] and efficiency (fast service with high quality) [31, 49].

Next, the customers' age has a positive impact on the likeliness to use in-store terminals instead of smartphone apps. Also, it has a negative impact on the use of social media. These findings support prior studies on the use and adoption of self-service technology [42, 47, 49]. According to these studies, technology anxiety and effort expectancy have been found to determine the intention to use self-service technology. In-store terminals closely resemble other well-established self-service technologies such as ATMs or ticket machines that are common for a few decades. Consequently, also older customers are familiar with these types of technology and might be more confident in using them [47]. The proliferation of smartphones, on the contrary, has just started in the last decade, which implies comparably less experience with this technology [42] and potentially higher technology anxiety [49]. Nevertheless, customers overall prefer smartphone apps to access e-service touchpoints. While location-independence, the degree of customer-retailer connectivity, and perceived control over the shopping process are known influences on the use of smartphone apps in retail [21], future research is needed to clarify the determinants of in-store smartphone app usage. Lastly and in line with Yoo and Gretzel [50], female customers are more motivated to provide product reviews (e.g., to help other customers).

As with any research, our work comes with some limitations. Inherent to the survey research method are potential negative side effects or biases. Considering the rather "demanding" responses from the survey, some respondents might suffer from a "good-subject effect" where participants try to guess the purpose of a survey to give pleasing answers [51]. Additionally, we did not survey participants' prior experiences with the non-mirrored touchpoints, which will likely have influenced individual responses. This leaves room for further research on the influence of prior experiences in one channel on other complementary channels. As regards the unit of analysis of our study, we assessed the likeliness of use regarding the mirrored e-service touchpoints, without providing concrete touchpoint implementations and contextual factors. The relevance of e-service touchpoints is likely to differ, among others, based on the categories of goods sold and the size of the store. For example, an in-store navigation service might be more useful in a large fashion store that sells a plethora of different articles, than in a small delicatessen store where customers can find products easily without digital support. Also, the relevance of product information touchpoints might also be related to the complexity of the product, i.e., customers might require less information on a broom than on a robot vacuum cleaner. Nevertheless, our assessment provides a foundation and justification for BaM retailers to conduct individual, detailed analyses of e-service touchpoints that are feasible and economically viable for them.

Omni-channelling and e-service touchpoints in BaM are still emerging and developing at a fast pace [14, 24], leaving ample room for further research. First, retailers require instruments for decision support regarding the introduction of e-service touchpoints, as there is a variety of opportunities that can be considered by BaM retailers. In particular, SME retailers with limited financial resources require support, as high the upfront cost is known as a strong inhibitor for the adoption of digital channels [7]. This raises the question of whether the introduction of novel e-service touchpoints is feasible for SME BaM retailers. Further empirical work is required to investigate retailer-sided adoption and customer acceptance of e-service touchpoints in BaM retail with special consideration on the categories of goods sold, the size of the store, and the retailer's competitive strategy (e.g., individualization vs. cost optimization) [22]. Such research could result in a decision calculus that embeds impact, adoption, and success factors. Second, besides in-store terminals and smartphone apps, there are other digital technologies that enable the implementation of e-service touchpoints in the physical servicescape [14, 22, 24]. Further research could compare and contrast these partly complementary technologies w.r.t. the e-service touchpoints provided and effects on the customers observed. Third, in the long run, a set of common e-service touchpoints in the physical servicescape might eventually prevail. Using the multiple case study method, research can then identify a dominant design [32] of BaM e-service touchpoints to further support touchpoint management in BaM retail. However, even with such a dominant design, ongoing research is needed due to the continuous nature of the digital transformation [1]. As illustrated in our discussion of the different e-services in Section 3, e-commerce and BaM retail mutually stimulate each other in terms of digital innovation. First, e-commerce tried to introduce touchpoints similar to those known from BaM (e.g. social components). Now, e-service touchpoints get introduced to the physical servicescape. This interplay provides an interesting area for ongoing investigations.

6 Conclusion

Given that many traditional BaM retailers struggle to keep up with the digital transformation and the induced competitive disadvantage, this paper offers two primary contributions to research and practice: First, we applied dominant design theory to identify major e-service touchpoints that are commonly implemented in leading e-commerce software solutions, grouped them according to their value proposition, and mirrored them to complement the physical servicescape of BaM. Second, we assessed these touchpoints by means of an online survey. In support of channel complimentary theory, results showed that customers are likely to use e-service touchpoints in-store. Customers preferred touchpoints that aid in product search, information, and selection as well as facilitate an efficient customer journey. Communication, social and support services, on the contrary, were surprisingly undesirable. In line with related studies, in-store terminals have been identified as the preferred choice of the older generation, while smartphones are the overall favorable method to access e-service. Future research can build upon these insights to design and implement pilots for the most promising e-service touchpoints together with retail organizations. Subsequent empirical studies can then shed light on the advantages provided by, and customer acceptance and use of these mirrored e-service touchpoints.

Abstract. Digital platforms—technical core artefacts augmented by peripheral third-party derivatives—afford organizations to integrate resources in networked business ecosystems. Although digital platforms widely differ in their configurations, digital platforms' *dimensions* and *characteristics* to disentangle different digital platform configurations are under-researched. To bridge this void, we employ Nickerson et al.'s method for taxonomy development to systematically derive a taxonomy of digital platforms. Specifically, we embrace a platform architecture perspective to capture the configuration of digital platform's components. The resultant taxonomy facilitates a more pronounced understanding and grouping of digital platforms as configurations of certain *dimensions* and *characteristics*. Our findings suggest that digital platforms exhibit characteristics on at least four dimensions—namely, *infrastructure*, *core*, *ecosystem*, and *service* dimensions. Second, through instantiating the taxonomy, we find that digital platforms that exhibit *similar* characteristics share identical architectural profiles and, therefore, belong to one of three digital platform archetypes—namely, *orchestration*, *amalgamation*, and *innovation* platforms.

Keywords: Digital Platforms, Taxonomy, Platform Architecture, Platform Ecosystems, Archetypes.

1 Introduction

This study investigates *digital platforms*—sets of stable technical core artefacts augmented by peripheral third-party derivatives, and associated organizational arrangements [1]. A digital platform facilitates the integration of resources in business ecosystems and becomes increasingly valuable when more third parties join the platform and add their complementary derivatives [2]. Omnipresent in today's industries, digital platforms differ in their configurations [2, 3]—as exemplified by social media (e.g., Facebook and LinkedIn), mobile operating system (e.g., Android and iOS), payment (e.g., PayPal and Apple Pay), and peer-to-peer (e.g., Uber and Airbnb) platforms.

Beyond the diversity of digital platforms in practice, our review of digital platform literature exposes a wide variety of digital platform conceptualizations [1, 4]. We are specifically concerned that IS and management discourses on digital platforms [4] do

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

not consider the specific characteristics of digitality [5]. Conversely, they treat all technological platforms as a homogeneous group in which classifications are merely based on organizational arrangements [1]. For example, for *digital* platforms, openness does not merely relate to organizational arrangements such as entrance and exit rules, but also to openness of technologies such as software development kits [1].

The abovementioned diversity in digital platforms' instances and conceptualizations calls for a digital platform taxonomy to disentangle different digital platform configurations [2]. Taxonomies play a vital role in research and practice because the classification of objects helps researchers and practitioners understand and analyze complex domains [6]. For digital platforms, a taxonomy would organize digital platforms' divers instances and conceptualizations into a coherent organizing structure. To this end, we first extract digital platforms' *dimensions* and *characteristics* from existing digital platform instances and studies. Relying on such dimensions and characteristics, we then develop a digital platform taxonomy and eventually instantiate the resultant taxonomy to derive digital platform archetypes. This research therefore seeks to answer the following research question: *Which dimensions and characteristics distinguish digital platforms through their architectural configuration?*

To answer the research question, we first follow Reuver et al.'s [1] recommendation to provide clear definitions for key concepts in the digital platform context. Subsequently, we follow Nickerson et al.'s step-by-step and well-structured method for taxonomy development [6]. In this process, we code digital platform articles to identify a sample of 34 digital platform instances. The resultant taxonomy postulates digital platforms' dimensions and characteristics. We instantiate this taxonomy with the 34 digital platform instances to derive digital platform archetypes that capture archetypical configurations of digital platform profiles with similar characteristics.

Thereunto, we promote the use of *platform architecture* as a focused perspective to effectively capture the configuration of a given digital platform's components. Platform architecture here refers to the fundamental organization of a digital platform, embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution [4, 7]. We opt for this perspective as it conceptualizes digital platforms as layered modular architectures that uniquely differ in their components' configurations. Relying on the platform architecture perspective, we supplement prior research with a taxonomy and archetypes of digital platforms both of which rest on digital platforms' architectural dimensions and characteristics.

2 Research Background

Since this study aims to develop a taxonomy of digital platforms, we first provide an overview of digital platform research. We then review the presence of taxonomies in IS (in general) and digital platform research (in particular) to motivate and position our study. Eventually, we introduce digital platform architecture as this study's specific perspective. In *briefly* sketching these streams to examine their underlying logic, our citations to these vast streams are merely illustrative; a thorough review of each would be a substantial and worthwhile project in its own right.

2.1 Digital Platforms

Originally viewed as facilitator of *bilateral* innovation activities (late 1990s) [e.g., 8], the platform concept increasingly captured networked, multi-lateral innovation activities (mid-2000s) [e.g., 9]. IS research then studied platforms as a *central* form of organizing technological innovation (2010s) [e.g., 10]. Today, the term *platform* is omnipresent in both IS and management research [1-4, 11], such as the *Information Systems Research* (ISR) special issues on *Platforms and Infrastructures in the Digital Age* [5]. Thomas et al. [4] organize platform research on a continuum from *firm-internal* to *firm-external* platforms. As digital platforms represent "layered modular technology architectures in business networks" [3, p. 186], they lie on the *firm-external* end of platform research that spotlights such business *networks* (e.g., *Android*'s mobile ecosystem). Within these networks, digital platforms mediate actor-to-actor interactions [2] and leverage innovation [12]. We thus view digital platforms as a *socio-technical* phenomenon rather than purely *technical* artefacts as they encompass both a technical core as well as business networks mediated by a technical core [1]. Table 1 synthesizes the key concepts that represent our understanding of digital platforms.

Table 1. Key Concepts in the Digital Platform Context

Concept	*Definition*
Platform Owner	Natural or legal entity that designs, implements, and maintains the digital platform [13]
Third Party	Natural or legal entity that augments the technical core with complementary derivatives (e.g., software extensions, services, and sales channels) [14]
End User	Natural or legal entity that uses the resources available on the digital platform [2]
Digital Ecosystem	Complex network of platform-mediated actor-to-actor interactions, turning increasingly accessible to end users through third parties' platform derivatives [13].
Service	Specialized competences (knowledge and skills) exchanged among different actors in the digital ecosystem through deeds, processes, and performances [15]
Technical Core	Extensible codebase serving as a building block upon which third parties devise platform-augmenting derivatives [16]
Digital Infrastructure	The computing and network resources that allow distributed actors to facilitate their resource exchange across spatial, temporal, and organizational boundaries [5]

2.2 The Role of Taxonomies in IS and Digital Platform Research

Intuitively, taxonomies[1] serve as sorting schemes to systematically organize objects in a domain of interest (e.g., digital platforms), a fundamental problem in many research disciplines [17, 18]. Technically, Nickerson et al. define a taxonomy T as a set of n dimensions, with each dimension consisting of at least two mutually exclusive and collectively exhaustive characteristics such that each object under consideration instanti-

[1] Prior literature often uses the different terms classification, framework, typology, and taxonomy equivalently [5]. As we employ Nickerson et al.'s method for *taxonomy* development [5], and as *taxonomy* is also the most common term across research disciplines, we opt for common recognition and consistency and use taxonomy *exclusively*.

ates one and only one characteristic for each dimension [6, p. 440]. The role of taxonomies—organizing IS domains through classifying objects of interest within these domains—is well recognized in the IS literature. Glass and Vessey [19] note that taxonomies provide an organizing structure to the IS body of knowledge. Fiedler et al. emphasize that taxonomies have been important in research "since Aristotelian applications over 2000 years ago" [20, pp. 11-12]. Similarly, Sabherwal and King argue that "taxonomies also help us understand divergence in previous research findings" [21, p. 180].

In the specific domain of digital platforms, prior digital platform research calls for using taxonomies for distinguishing digital platforms to ultimately specify different digital platform configurations [1, 3, 5]. However, only few theoretical accounts postulate *fragmented* dimensions and characteristics of digital platforms. For instance, while Kazan et al. [3, p. 187] conceptualize "two strategic architectural dimensions" of digital platforms—that is, (1) *core platform* and (2) *infrastructure* dimensions—, their research objective is not to classify digital platforms. Similarly, Williams et al. [22] focus on digital platforms' *digital service* dimension in deriving a taxonomy for platform-mediated digital services. Karhu et al. [23] promote *platform openness* as a dimension of platform architecture—differentiating *access openness* and *resource openness* (characteristics). However, their phenomenon of interest is platform forking in which a hostile firm (i.e., a forker) exploits a digital platform's shared resources, core and complements, to create a competing platform business. Overall, as there are fragmented discussions on classifying digital platforms, we reconcile a set of digital platform articles in the organizing structure of dimensions and characteristics to systematically derive a taxonomy of digital platforms for a specified use and purpose—that is, distinguishing digital platforms based on their architectural configuration.

2.3 Digital Platform Architecture

As the use of proper research perspectives guides IS scholars in both theory building and theory testing [24], in this study we promote the use of platform architecture as a purposeful research perspective to study configurations of digital platforms' components [7]. The targeted taxonomy's purpose is to distinguish digital platforms based on common *characteristics* within architectural *dimensions*. Our perspective effectively serves this purpose as follows. First, through viewing digital platforms as "layered modular technology architectures in business networks" [3, p. 186], this perspective accounts for the socio-technical and complex nature of digital platforms [1]. Second, its conception of digital platforms as layered modular technology architecture allows us to derive standalone but differentiating digital platform dimensions. Third, the platform architecture perspective describes a digital platform's architectural configuration to reflect the unique combination of a digital platform's components. Ultimately, this perspective facilitates the identification of digital platform archetypes as digital platforms exhibiting *similar* architectural configurations belong to the same archetype. Beyond these reasons, prior research also motivates the significance of using a platform architecture perspective for distinguishing digital platforms [1, 3, 5, 7].

3 Research Method

In this section, we outline the applied steps in our taxonomy development. We then instantiate the resultant taxonomy to derive digital platform archetypes.

Digital Platform Taxonomy. We adopt Nickerson et al.'s step-by-step and well-structured method for taxonomy development method [6] (see Table 2). This method has been frequently used in IS research [e.g., 17, 18]. As an input for Nickerson et al.'s ***empirical-to-conceptual*** (E2C) and ***conceptual-to-empirical*** (C2E) approaches, we review digital platform literature relying on [25][2] to not only derive dimensions and characteristics from extant research (C2E), but also to scrutinize digital platform instances studied in previous research to inform our taxonomy (E2C). These two approaches rest on our coding of 46 selected digital platform articles supported by *ATLAS.ti 8* as a technique in qualitative research to reduce data complexity [26].

Table 2. The Applied Steps of Nickerson et al.'s Method [6] in Our Taxonomy Development

Stage	*Stage's Application in Our Taxonomy Development*
1. Meta-characteristic: The meta-characteristic reflects the taxonomy's purpose that should rely on the taxonomy's expected use.	*Expected Use*: Digital platform designers, managers, and scholars seeking to classify digital platforms *Purpose*: Distinguish digital platforms based on their *high-level architectural configuration* (meta-characteristic)
2. Ending Conditions: Subjective and objective ending conditions determine when to terminate the method. Different ending conditions may generate different taxonomies.	*Objective Conditions*: The taxonomy consists of dimensions, each with mutually exclusive and collectively exhaustive characteristics. *Subjective Conditions*: The taxonomy must be concise, robust, comprehensive, extendible, and explanatory [6, p. 344].
3. Empirical-to-conceptual Approach: Reviewing a set of empirical instances (random, systematic, or convenience sample), the researcher tries to inductively group these instances' common characteristics into dimensions *without* considering existing conceptualizations.	*Sampling of Objects* (3.1): Coding of 46 selected papers yielding in a sample of 34 digital platform instances *Grouping of Objects* (3.2): Grouping of 34 digital platforms into 5 inductive, discriminate characteristics (*exchange*, *design* orientations; *direct*, *indirect*, *open* accesses) *Grouping of Characteristics* (3.3): Grouping of 5 characteristics into 2 inductive dimensions (*service* and *infrastructure* dimensions)
4. Conceptual-to-empirical Approach: Reviewing the previous taxonomy, the researcher tries to deductively conceptualize additional dimensions and characteristics that might not have been previously identified.	*Conceptualization* (4.1): Literature-based theorization of 2 additional deductive dimensions (*ecosystem* and *core* dimensions) *Examination of Objects* (4.2): Specification of 2 dimensions through 2 characteristics each (*private*, *federated* network; *access*, *resource* openness) after reviewing the sample of 34 digital platforms *Taxonomy Revision* (4.3): Revising final taxonomy (4 dimensions, 9 characteristics) to meet the ending conditions

[2] We search the *AIS Senior Scholars' Basket of Journals* in the *Business Source Premier* database employing the *EBSCOhost* search engine without time restriction. As digital platforms are an emergent modern concept, we also search the 2016/17 proceedings of ICIS and ECIS in the *AIS Electronic Library (AISeL)*. We select 16 journal papers, 10 ICIS papers, and 5 ECIS papers all of which have the phrase *"digital platform*"* in their abstract. The ISR special issue on digital platforms [14] is fully covered. A backward search adds another 15 papers.

First, we adopt the **E2C** approach in that we code the selected 46 papers to identify a sample of 34 digital platform instances that are studied in these 46 papers[3]. In the 1st iteration of the E2C approach, we randomly analyze 10 of the 34 instances (another 10 instances in the 2nd iteration; another 14 instances in the 3rd iteration). This resulted in extracting 5 inductive, distinct characteristics (*exchange*, *design* orientations; *direct*, *indirect*, *open* accesses). We group these 5 characteristics into 2 inductive dimensions (*service* and *infrastructure* dimensions) (see Table 2).

Second, we adopt the **C2E** approach in that we code the selected 46 papers to identify *existing* conceptions of digital platform characteristics. Therefore, we divide the 46 papers into 5 sets of 9, 9, 9, 9, and 10 papers, respectively. We thus embrace 5 iterations of the C2E approach in that we code 1 of the 5 sets of papers per iteration. We thereby identify 2 additional deductive dimensions (*ecosystem* and *core* dimensions). These 2 dimensions are specifically theorized in [3, 23]. In reviewing the sample of 34 digital platform instances, we further specify the *ecosystem* and *core* dimensions through 2 characteristics (*private*, *federated* network for the *ecosystem* dimension; *access*, *resource* openness for the *core* dimension). Rationalizing the overall 8 iterations in our taxonomy development, Table 2 synthesizes our methodological adoption of [6].

Digital Platform Archetypes. The next step is set out as the identification of digital platform archetypes. Therefore, we instantiate the taxonomy with the 34 digital platform instances to capture emergent archetypical configurations of digital platform profiles. Hence, we use architectural characteristics in each dimension as differentiating features of digital platforms to identify emerging dominant patterns that consistently reoccur. This is because digital platforms exhibiting *similar* characteristics along their dimensions should share identical architectural profiles, and belong to the same digital platform archetype [27]. We derive three dominant patterns of digital platform configuration as archetypes in this process. These archetypes are labeled as *orchestration*, *amalgamation*, and *innovation platforms* to reflect their main theoretical emphasis.

4 Taxonomy of Digital Platforms

Our findings suggest that digital platforms exhibit characteristics on at least four layered dimensions—namely, *infrastructure*, *core*, *ecosystem*, and *service* dimensions [e.g., 3, 23]. Afforded by the adopted platform architecture perspective, these dimensions reflect the socio-technical and complex architecture of digital platforms [1]. While the core dimension appreciates a set of stable technical core artefacts, the infrastructure, ecosystem, and service dimensions capture the dynamic periphery of platform components. Figure 2 sketches the identified *dimensions* that rest on the taxonomy's meta-characteristic to distinguish digital platforms from a platform architecture perspective. Figure 1 synthesizes each dimension's *characteristics* in a taxonomy of digital platforms in relation to Nickerson et al.'s *empirical-to-conceptual* (E2C) and *conceptual-to-empirical* (C2E) approaches (see Table 2).

[3] We list the 46 articles and the 34 digital platform instances in this database.

Architectural Dimension	Characteristic 1	Characteristic 2	Characteristic 3	E2C	C2E
Service	Exchange Orientation	Design Orientation	-	X	
Ecosystem	Private Network	Federated Network	-		X
Core	Access Openness	Resource Openness	-		X
Infrastructure	Direct Access	Indirect Access	Open Access	X	

Figure 1. Taxonomy of Digital Platforms

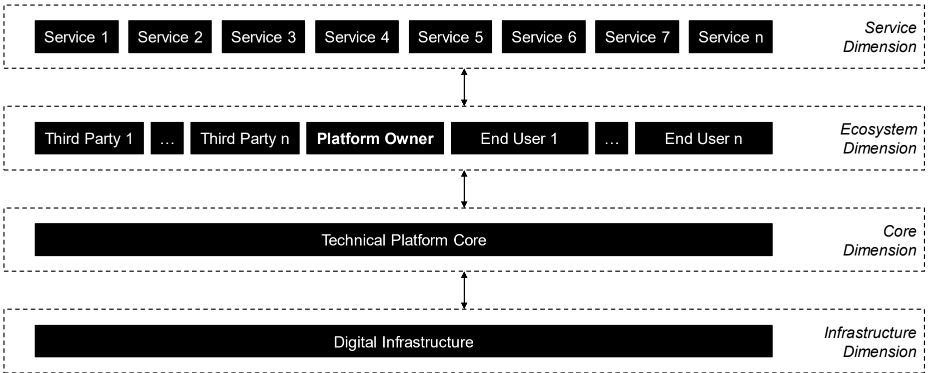

Figure 2. Digital Platforms' Dimensions from a Platform Architecture Perspective

4.1 Digital Platform's *Infrastructure Dimension*

Digital platforms are created and cultivated on top of **digital infrastructures**—here defined as *computing and network resources that allow distributed actors to facilitate their resource exchange* [5]. Examples of digital infrastructures include the Internet, data centers, open standards (e.g., IEEE 802.11 and USB), and consumer devices (e.g., smartphones and tablets). Digital infrastructures, therefore, are distinct from other types of infrastructures because of their ability to collect, store, and make digital data

Table 3. The Characteristics of Digital Platforms' *Infrastructure Dimension* [e.g., 5, 28]

Characteristic	*Definition*	*Rationale*
Direct Access [e.g., 28, 29]	Unobstructed access permission to an established digital infrastructure through the infrastructure owner that allows for guaranteed and instantaneous access	While reinforcing a platform's direct access rights through its enhanced status and market position, direct access infrastructures require costly access fees and extensive coordination between platform and infrastructure owners.
Indirect Access [e.g., 5, 28]	Obstructed access permission to an established digital infrastructure through intermediary, third-party access providers	Platforms with indirect access aim for hard-to-replicate partnerships with multiple intermediaries, allowing a plug-and-play strategy in selecting interchangeable intermediaries for cost reductions.
Open Access [e.g., 3, 29]	Unobstructed access to a new digital infrastructure devoid of permissions	Emulating direct access rights in a cost-effective fashion, open access infrastructures (e.g., blockchain) have lower market reach without comprehensive testing.

available across several systems and devices [28]. Relying on the E2C approach of our taxonomy development, we find that digital platforms access digital infrastructures in three ways—namely, *direct*, *indirect*, and *open* access. Table 3 outlines the *infrastructure dimension*'s three characteristics along with exemplary support from the literature.

4.2 Digital Platforms' *Core Dimension*

Digital platforms rely on a set of stable **technical core artefacts** of software and hardware. This set acts as technological foundation for a family of value-added platform derivatives [2]. These technical core artefacts denote an *extensible codebase serving as a building block upon which third parties devise platform-augmenting derivatives* (e.g., products, technologies, channels, and services) [16]. Relying on the C2E approach of our taxonomy development, we follow Karhu et al.'s [23] distinction of how core artefacts can interface with its periphery in two ways—namely, *access openness* and *resource openness* [23, pp. 3-6]—to promote third-party, platform-augmenting derivatives. Table 4 outlines these two characteristics of digital platforms' *core dimension*.

Table 4. The Characteristics of Digital Platforms' *Core Dimension* [e.g., 2, 16]

Characteristic	*Definition*	*Rationale*
Access Openness [e.g., 23, 30]	Granting of access to otherwise protected core artefacts to third parties by providing them with dedicated boundary resources to interact with the technical core artefact.	The rationale for *access openness* is to spark innovation within the platform ecosystem and induce third parties to use the core artefacts to create platform-augmenting derivatives that invoke positive network effects.
Resource Openness [e.g., 1, 23]	Opening the core artefacts' valuable resources by forfeiting their related intellectual property right (IPR)	The rationale for *resource openness* is that the technical core artefacts' owner sees it as advantageous to open the core resources by forfeiting related IPR.

4.3 Digital Platforms' *Ecosystem Dimension*

Digital platforms rely on a dynamic **platform ecosystem** here defined as *complex network of platform-mediated actor-to-actor interactions, turning increasingly accessible to end users through third parties' platform derivatives* [13]. Digital platforms are contingent on the availability and contribution of a critical mass of third parties within each of the relevant actor roles of the respective ecosystem. Prime examples for such actor roles are platform owner, partner, end user, and subcontractor [2, 31, 32]. Each of these actor roles offer complementary resources to the respective ecosystem to serve a wide range of end users and to satisfy various requirements [13]. For instance, Google generates most of its revenues within the Android ecosystem from advertisements powered through the use of its search engine, YouTube, and other Google services [23]. Relying on the conceptual-to-empirical approach of our taxonomy development, we follow Kazan et al.'s [3] distinction of two focal platform ecosystem characteristics—namely, *private network* and *federated network*. Table 5 outlines these two characteristics.

Table 5. The Characteristics of Digital Platforms' *Ecosystem Dimension* [e.g., 2, 13]

Characteristic	*Definition*	*Rationale*
Private Network [e.g., 1, 31]	Inward-looking, vertically integrated, and closed-loop ecosystem comprising an exclusive selection of private actors that shield their services from unauthorized actors	Private networks enact closed-loop systems to efficiently settle resource exchanges *within* their own boundaries. While the latter is virtually free, instantaneous, and guaranteed, resource exchanges *beyond* the closed-loop system demand fees, time, and risk from the private actors.
Federated Network [e.g., 1, 32]	Outward-looking, vertically disintegrated, and open-loop ecosystem mobilizing varied platform-augmenting third-party actors	Federated networks enact open-loop systems in which value creation and appropriation is distributed among federated third-party actors. These actors intentionally co-innovate with other external third-party actors to extend the capabilities and market reach of their mutual digital platform.

4.4 Digital Platforms' *Service Dimension*

With digital service being *the* value output of digital platforms [3], digital platforms eventually aim for and contribute to a gigantic shift from a product-based economy to one based on services, specifically *digital* services [22]. Digital service here refers to *an activity or benefit that at least one party can give to another, that is, predominantly provided through a platform-mediated digital transaction* [22, p. 507]. Notably, in contrast to classical bilateral owner-user relationships, platform-mediated digital service comprises a networked service *system* to integrate various organizational and technological resources to meet a given end user's needs. While the *giving* service offeror is the digital platform owner in cooperation with at least one platform partner, the *receiving* service beneficiary is the digital service user. Moreover, while a *single* transaction is sufficient to provide a digital service, often these transactions are provided *continuously* [33] and within actor-to-actor networks that configure the platform owner, at least one third party, and the end user in a unique manner [2]. Platform-mediated digital services are characterized by two distinct orientations—namely, *exchange* or *design* orientations. Table 6 outlines these two characteristics digital platforms' service dimension along with studies that support this dimension and its characteristics.

Table 6. The Characteristics of Digital Platforms' *Service Dimension* [e.g., 22, 33]

Characteristic	*Definition*	*Rationale*
Exchange Orientation [e.g., 34, 35]	Digital service aimed at reducing transaction costs in direct actor-to-actor exchanges	Exchange-oriented digital service (e.g., Facebook, PayPal, Uber, Airbnb) realize one-to-one matches between service offerors and beneficiaries and facilitate their subsequent direct exchange efficiently
Design Orientation [e.g., 1, 23]	Digital service aimed at enabling third parties to design platform derivatives and to disseminate them to a large audience	Design-oriented digital service (e.g., iOS, Android, Windows, Amazon Web Services, Linux) realize one-to-many matches between one third-party platform derivative designer and many derivative users

5 Archetypes of Digital Platforms

Our findings further suggest that digital platforms that exhibit *similar* characteristics belong to one of the three digital platform archetypes—namely, *orchestration*, *amalgamation*, and *innovation* platforms.

5.1 Orchestration Platform

Digital platforms that assemble federated networks—outward-looking, vertically disintegrated, and open-loop ecosystems—of platform-augmenting third parties through co-opetitive and inclusive platform profiles adhere to what we label as the *orchestration platform* archetype (see Figure 3). Orchestration platforms rely on high openness—both access or resource openness—to be highly integratable with existing third-party derivatives. These platforms' challenge is to derive a governance structure that *aligns* the business and technology interests among the platform owner and its many third parties. Orchestration platforms are highly dependent on established digital infrastructures (1) to connect third parties and end users; and (2) to attain elevated levels of joint market reach. However, each transaction on preexisting digital infrastructures negatively contributes to platform participants' costs as participants pay for access.

The expository case of *Android* [23] represents a prime example of orchestration platforms. The *Google*-sponsored open-source project (*access openness*) orchestrates a massive community of independent third-party developers (*federated network*) yielding in, depending on the estimate, a dominant 80%–90% share of the mobile phone market. Relying on *indirect access* to existing digital infrastructures (i.e., the Internet and mobile telecommunication infrastructures), its app store features over 3 million apps (*design orientation*) that generate more than 100 billion downloads per year [5].

Architectural Dimension	Characteristic 1	Characteristic 2	Characteristic 3	Digital Platform Archetype
Service	Exchange Orientation	***Design Orientation***	-	***ORCHESTRATION PLATFORM***: Co-opetitive and inclusive platform profiles
Ecosystem	Private Network	***Federated Network***	-	
Core	***Access Openness***	***Resource Openness***	-	
Infrastructure	***(Direct Access)***	***Indirect Access***	Open Access	

Figure 3. The *Orchestration Platform* Archetype

5.2 Amalgamation Platform

Digital platforms that assemble *private networks*—inward-looking, vertically integrated, and closed-loop ecosystems—comprising an exclusive selection of few private actors through monopolistic and assimilative platform profiles adhere to what we label as the *amalgamation platform* archetype (see Figure 4). Such platforms allow organizations to cultivate and grow private businesses without intervention from platform-augmenting third parties. In this sense, platform-mediated interactions are tightly controlled and directed inward to reinforce an insular digital platform. Amalgamation platforms are contingent on specific resources and capabilities to implement self-sustaining platforms by shielding their architectural dimensions from third parties. Moreover, such platforms are highly efficient, independent, and flexible in channeling their digital services through preexisting digital infrastructures. However, they face the challenge to maintain agility by avoiding the enactment of strategic linkages with third parties that are likely to introduce long-term legacy systems or platform derivatives. Such platforms rely on access to digital infrastructures to process digital services, while at the same time, seek to minimize resource outflows from its private network.

The expository case of *Pingit* [3] represents a prime example of amalgamation platforms. Launched by *Barclays* in 2012, this vertically integrated mobile payment platform captures value without third parties (*private network*). *Pingit* is designed to be a person-to-person (P2P) mobile payment exchange service (*exchange orientation*). Turning into a stand-alone application, however, it in turn incentivizes businesses to adopt *Pingit*. It is a proprietary mobile payment service as its development is fully internalized (restricted *access openness*). *Pingit* benefits from its direct access to *Faster Payments*, an existing digital infrastructure for mobile payments (*direct access*), to reach out to end users at rival banking institutions in a cost-efficient manner.

Architectural Dimension	Characteristic 1	Characteristic 2	Characteristic 3	Digital Platform Archetype
Service	***Exchange Orientation***	Design Orientation	-	***AMALGAMATION PLATFORM***: Monopolistic and assimilative platform profiles
Ecosystem	***Private Network***	Federated Network	-	
Core	***(Access Openness)***	Resource Openness	-	
Infrastructure	***Direct Access***	***(Indirect Access)***	Open Access	

Figure 4. The *Amalgamation Platform* Archetype

5.3 Innovation Platform

Digital platforms that assemble unobstructed access to a *novel* digital infrastructure devoid of permissions reverberate with our *innovation platform* archetype (see Figure 5). Such platforms embrace process innovation to deliver digital service through differentiated and cost-effective arrangements that are distinctively different from (and are seeking to transform) an industry's dominant process logic. This is realized through establishing—or forging strategic linkages with—*novel* digital infrastructures (e.g., blockchain). In this regard, affiliated stakeholders can circumvent the dominance of preexisting digital infrastructures—even though novel digital infrastructures that allow for open access may fail to become a dominant standard in facilitating digital services.

Architectural Dimension	Characteristic 1	Characteristic 2	Characteristic 3	Digital Platform Archetype
Service	***Exchange Orientation***	Design Orientation	-	***INNOVATION PLATFORM***: Hybrid and open platform profiles
Ecosystem	***(Private Network)***	***Federated Network***	-	
Core	***Access Openness***	***Resource Openness***	-	
Infrastructure	Direct Access	Indirect Access	***Open Access***	

Figure 5. The *Innovation Platform* Archetype

The expository case of *Blockchain.com* [3] leverages on third parties and subsidizing its digital services (i.e., payment, bitcoin wallets, exchange rates, JSON queries for blockchain data) for end users (*exchange orientation*). *Blockchain.info* thereby derives value from the bitcoin community by being integratable into various agnostic third-party services (*federated network*). Opening its core artefacts by forfeiting related IPR (*resource openness*), *Blockchain.info* operates on top of the *Bitcoin Blockchain*, an open digital infrastructure without access constraints (*open access*), to deliver bitcoins.

6 Discussion and Conclusions

Mediating various networked actors, digital platforms have become a pivotal means to shape digital ecosystems. We start with the premise that understanding and classifying digital platforms relies on a dedicated theoretical account on their *dimensions* and *characteristics* to postulate different configurations of digital platforms. Embracing the lens of platform architecture [7], we follow Nickerson et al.'s method for taxonomy development. The resultant taxonomy distinguishes digital platform instances through characteristics on their *infrastructure*, *core*, *ecosystem*, and *service* dimensions. We further disentangle *orchestration*, *amalgamation*, and *innovation* platform archetypes as a function of digital platforms' integral characteristics. We next discuss this study's theoretical and practical implications, limitations, and avenues for future research.

6.1 Implications for Theory and Practice

Theoretical Implications. *First*, we contribute to mitigating the outlined challenges of diversity in digital platforms' instances and conceptualizations. The 4 *dimensions*, 7 *characteristics*, and 3 *archetypes* serve as prospective theoretical means to more effectively guide and organize future theorization on digital platforms. That is, these means (1) seek to partially unify the variety of digital platform conceptions; and (2) classify digital platform instances. Thereby, through holding clearer definitions of *digital* platforms' dimensions and characteristics, the taxonomy considers the specific characteristics of digitality as an integral aspect of digital platform research in contrast to platform research in general [4]. We, thereby, hope to increase the comparability between digital platform instances and studies [5].

Second, we also contribute to mitigating the challenges of *vertically* and *horizontally* scoping digital platforms [1, p. 129]. *Vertical scoping* issues relate to choosing the appropriate level of the architecture for studying platforms. For instance, while mobile operating systems (e.g., Android) and associated app stores (e.g., Google Play) are often studied as the focal platform, new digital platforms are currently emerging *on top* of the mobile operating system (e.g., Facebook's Android app). To this end, our taxonomy contributes to disentangling the vertical scope of digital platform research through promoting four vertical architectural layers (see Figure 2). *Horizontal scoping* issues, in turn, refer to the variety of application domains (e.g., payment, health, banking, or mobile). Little research reflects the studied digital platform's application domain. The resultant lack of *contextualized* digital platform theory inhibits our understanding of how domain-specific digital platforms affect contextual outcomes. Characterizing digital platforms' context, the taxonomy facilitates more contextualized platform theory.

Practical Implications. This study contributes to the analysis of digital platforms [36] and is not prescriptive in nature. However, it has important implications for practice. *First*, without a well-developed taxonomy, it is difficult for managers and policymakers to differentiate diverse instances of digital platforms in their industries. Our taxonomy alerts these practitioners that not all digital platforms are equal, and it enables them to differentiate them regarding their characteristics, purposes, as well as required design decisions and institutional arrangements.

Second, this taxonomy becomes especially valuable when its characteristics and their distribution across digital platform instances are quantified. Specifically, practitioners can precisely measure various platform characteristics (e.g., types, frequencies, and durations of digital platforms' accesses to their underlying digital infrastructures) to link these measurements of diverse characteristics to digital platforms' differential impacts on platform outcomes (e.g., survival, performance).

Third, the paper identifies and differentiates three digital platform archetypes. These archetypes and their illustrative examples inform practitioners in making design decisions, as the archetypes represent ideal-typical configurations that have proven effective for platform survival and performance.

Fourth, the employed platform architecture perspective highlights the importance of developing the *architectural* approach to designing and maintaining digital platforms. Through embracing an architectural view on digital platforms, practitioners account for the socio-technical and complex nature of digital platforms [1]. Moreover, as the platform architecture perspective describes a digital platform's architectural configuration, practitioners are equipped to reflect the unique combination of their digital platform's components, respectively.

Fifth, policymakers can rely on the taxonomy in ensuring fair and efficient market regulations for digital platforms' constituent actors, which is in the interests of all platform participants, particularly in the light of lock-in and winner-takes-all effects. As such, the outlined dimensions and characteristics in the taxonomy inform policymakers in drafting legislative frameworks. Such taxonomy-informed frameworks would foster and regulate innovation effectively as the taxonomy allow policymakers to account for and balance multiple relevant dimensions of digital platforms. In turn, platform managers are provided with an organizing logic to more clearly define the specific aspects required in realizing *thriving* digital platforms. This may be especially useful for early design decisions that affect digital platforms' evolution trajectories. Managers might anticipate pivotal areas of concern and take appropriate measures.

6.2 Limitations and Future Research

While the taxonomy descriptively investigates digital platforms' dimensions, characteristics, and archetypes, it does not prescribe how to effectively configure digital platforms. Prospective research may thus investigate how different configurations translate into which outcomes (e.g., performance, survival, growth, flexibility, innovation). Further, we provide no statistical insights on what digital platform characteristics occur in which frequency. Future research may thus instantiate a *larger* sample of digital platforms to empirically learn more about the statistical distribution of characteristics.

Moreover, our taxonomy results from a restricted sample of 46 studies and 34 digital platform instances. Replicating our study with more digital platform instances in further contexts to validate and refine our taxonomy is thus pivotal. Moreover, our results are limited to the focused perspective of platform architecture. Alternative perspectives are likely to result in a different taxonomy and, therefore, in alternative archetypes. Therefore, due to opting for a specific perspective (i.e., platform architecture view), we neither claim exhaustiveness of the three derived archetypes, nor the comprehensiveness of the taxonomy in capturing all possible dimensions and characteristics.

Abstract. International professional football has become a billion dollar market worldwide. Up to half of the world's inhabitants watch major events such as the FIFA World Cup or the UEFA Champions League Final. Central players and elements in this global advertising market are the clubs' teams and the players themselves. Social media platforms today allow professional footballers to reach millions of people through private marketing as individuals, thereby creating their own brand. The brand and reach of each player is also a valuable resource for clubs in terms of player value and transfer activity. The outlined results in the following article show indicate a positive correlation between the social media value of professional players and the transfer activities of football clubs. Consequently, the impact of digitization on professional football can be shown by a relationship which has not been investigated in research to date.

Keywords: social media, transfer market, digital strategy, football, star marketing

1 Introduction

Football is the world´s most popular sport and is no longer perceived solely as a game but also as a battle for financial success [1]. The Fédération Internationale de Football Association (FIFA) alone generated sales of USD 734 million in 2017 [2]. The development and growth of the industry reflects the immense interest of the sport spectators [3]. Half of the entire human population is enthusiastic about football; 3.2 billion people alone watched the 2014 FIFA World Cup [4]. No other industry in the world has such a level of attention and awareness.

Due to this level of attention, it would seem natural that the best clubs and players themselves create strong brands. Nowadays, the most important information systems for these actors are social media (SM) platforms like Twitter, Instagram, and Facebook [5]. Football companies and the players have a unique advantage over all other companies when it comes to SM. Fans are intrinsically motivated to consume the content provided by clubs, while traditional companies must actively contact customers to attract their attention [6]. The only challenge for the sport’s clubs is to attract fans from other clubs. An effective method is obvious: star marketing [7]. Fans are interested in clubs on the one hand, and in the players themselves on the other. A logical

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

conclusion would be to oblige all players to enhance their reputation among fans and thus be valuable for the club's SM appearance. However, to what extent the clubs have acted in this way has not been investigated in any field of research to date.

A lot of work was done on the use and value of SM for sports clubs [1,7,8]. However, to date, there is a research gap relating to the way and extent the SM value of players shape clubs' SM reach and how this is taken into a club's consideration regarding actual player transfer activities.

Consequently, in this paper the relationship between the SM value of players and related transfer activities will be examined. It is assumed that the purchase of a player on the one hand is driven by his value as a football player, and on the other hand also by his brand value. Consequently, transfer activities might be impacted by the SM value of the players, as SM is the predominantly used information system for brand development in the market. We provide a model to investigate this relationship. Concretely, the following research question should be answered:

Is there a correlation between SM parameters and transfer activities, and could professional clubs take this into consideration?

To answer this research question, this article is structured as follows: In the following section the theoretical foundations and relevant work of success criteria and brand management in sports are discussed. In the next section we apply the chosen research method to the field. Subsequently, we present the results and discuss the main findings. Finally, a conclusion is provided containing limitations, implications and future research.

2 Theoretical Background

2.1 Success Factor Player

First of all, in terms of market theory, the difference in a sporting and an economic competition between football clubs has to be remarked upon [9,10]. Sporting competition is characterized by sporting success as the defined market outcome. In relation to one's opponents, those who achieve better placings in competitions are successful in sport [11]. With respect to sporting outcome, the acquired player talent is the most influential determinant in football clubs' production functions [12-14]. The distribution of player talent therefore shapes the sporting competition and determines sporting success in team sports. The success in sport competitions, in turn, is of central importance for the economic success of clubs, defined as the greatest possible outcome on product markets and thus generation of revenue streams (e.g. tickets, media rights, merchandise items) [15]. In a simplified scheme, sporting success causes higher demand and results in more trophy money [16]. Team sports contain attributes of a positional good where marginal changes in sporting success cause huge differences in revenues [17-19]. However, players' talent or sporting success is only one determinant for the revenues generated on product markets. In addition, an impact is made by market size, consumer purchasing power, substitution possibilities, club history, fan culture, uncertainty of outcome or the team quality, including "superstar effects" [16,20].

However, sporting success not only influences economic success, but is also in turn highly affected by the economic potential the other way around. Economists describe this intertwining by the concepts of derived demand and marginal revenue product [21-23]. In simple terms, the marginal revenue product (MRP) is referred to as the marginal productivity of the player's labour effort in relation to the revenue the club can generate from that marginal product [24-26]. The higher the club´s revenue streams or the player`s ability to increase revenue streams, the higher the player´s MRP. Consequently, a higher MRP implies a higher demand for this player leading, ceteris paribus, to higher wages and transfer fees. In sum, the MRP is determined by club-related economic criteria as well as player-related characteristics. Big market clubs manage to generate more money regardless of the acquired playing talent. Consequently, these clubs are willing to pay higher wages and transfer fees caused by a generally higher revenue and MRP level.

Turning to the players' side, MRP relevant factors can be distinguished in two aspects [27]. The first part describes the players' contribution to sporting success and related revenue, including trophy money. Furthermore, and besides actual on-pitch performance, a player-related revenue could be generated because of his image and brand value. Hence, the MRP in a single period can be specified as [27] :

$$MRP = (PWC \times MWR) + PBV \tag{1}$$

PWC stands for player win contribution or, in other words, the marginal gain in sporting team success. MWR is the marginal win revenue the club can generate out of this marginal gain in sporting success. PBV means player brand value and represents the brand-related revenues which can be made out of the additional media and spectator attraction.

The effect of generating additional and often disproportionate revenues solely due to the image or brand of a player is often referred to superstar effects [28,29].

As sporting competition is mainly driven by player talent, and, as seen above, talent demand is strongly connected to economic demand, it appears that economic competition would seem to highly correlate with sporting competition [30]. Obviously, from both an economic and a sporting point of view, players are the clubs' most important investment [31].

The transfer markets are the central platform to invest in players and to process player transfers. Transfers are often based on different MRPs indicating different demand curves between buying and selling clubs. Greater MRP differences due to greater revenue divergences trigger player transfers and are clearly among the main reasons for expanding player migration in global football, although if a player is to change clubs before the end of his contract, this contract must be terminated. The buying club pays the selling club a transfer fee so that the seller is willing to terminate the current contract with the player [32]. In relation to the Union des Associations Européennes de Football (UEFA), the market value of a professional athlete represents the monetary amount the club is willing to pay in order to contractually bind this athlete [33]. The market value of all players in a club results in a total team market value [34]. As seen above, the market value of players expresses the sum of the discounted MRPs over the length of the player`s contract [27]. On the premise that clubs act with economic rationality, transfer fees should not exceed the MRPs and should reflect the market value.

2.2 Social Media Brand Value

Advertising and transmission fees represent the largest sources of income for clubs [35]. The strategy of owning a brand strong enough to generate sufficient revenue from merchandise, ticket sales and international transmission is therefore a key objective in team sports economic competition [11]. A brand is the focus of all expectations and opinions of customers, employees and other stakeholders about an organization and its products and services. According to Brand Finance, a brand's technical implementation comprises the components contribution, strength and value [36].

Television has changed sports brand marketing and the sports information industry. Similarly, SM also triggered a great change [7], which brings with it the digital transformation of sports companies [37]. A strategic orientation towards SM is necessary for the successful brand management of football clubs [37]. One reason for this is that, more than ever, brands are required to find new ways to communicate with young consumers who spend less time on television, print and other traditional media, and are more likely to be addressed by digital marketing communication [38]. SM is increasingly seen in this context as an additional marketing channel through which companies can communicate and interact with their consumers or potential customers [39]. SM marketing is therefore primarily about listening to the users of SM and responding appropriately [40]. These dialogues have a direct positive effect on the advertisers' results by driving the fans' behavior towards the consumption of the advertised services and products [41]. Professional sport associations are trying to address and monetize this potential use of SM marketing [8]. This is currently done via SM communication [8] and Web 2.0 technologies [40].

The SM presence is subject to a complex composition, though. The presence refers to all engagements [8] which are implemented with club-own or player-own profiles in social networks. In addition, it is important to implement a purposeful approach to the player's brand, in order to distinguish him as an independent brand from the mass of professional football players. As part of sports marketing, this refers to star marketing and could be of great importance for the brand of a club, because the combination of different SM profiles has a positive effect on the interaction of each individual page [7]. Digital reaches are created by the profiles of the clubs on SM channels [8] and are reinforced by profiles of the players, because each player represents the image of the club [42].

The overall aim of this paper is to disclose player transfer effects and the inherent player SM activities on the clubs' SM appearance and to interpret the influence of SM on the transfer activities itself.

3 Research approach

3.1 Model Assumptions

To design the relationship, the complex reality is broken down into a simplified model. The following axioms therefore apply to the further procedure, which are intended to illustrate complex real interrelationships in a simplified manner:

1. A search query of an individual (fan) to the search engine Google implies interest of this individual (fan) in the object (transfer or club) or subject (player) searched for.
2. The interest of an individual in an object (transfer) or subject (player) lies in the expected change of his state (transfer of player).
3. The interest of an individual (fan) in the expected change of state of a subject (player) justifies the willingness to use information channels (SM channels of the clubs).

Football fans exist as supporters of clubs and as supporters of individual players. Only negative associations can arise, therefore, when players leave. Although there are cases in which player changes among local rival clubs lead to a negative mood among fans, these are neglected in the present analysis. On the one hand, no profound rivalries between the old club and the new club could be found in any of the transfers levied. On the other hand, only new players are considered. From this follows the continuing formulation of two further axioms:

4. A change in the state (change of players) of a subject (player) can only positively influence the information channels (SM channels of the clubs) of an object (club).
5. The regularity of exceptional events confirms their dependence on a regularly recurring variable.

Based on these assumptions, the procedure is further divided into three steps. The first section deals with the study of the existence of a stochastic dependence of the growth of the clubs' SM reach in the season, particularly the transfer period (Section 3.2). The second step aims to identify and describe the direct influence of a player transfer on the SM accounts of the clubs (Section 3.3). Lastly, the final step is to categorize transfers to obtain an assessment of club activities (Section 3.4).

3.2 Stochastic Dependence

If fans have a special interest in player changes, that interest will affect the search hits and therefore affect the clubs´ SM reach regarding to the above-mentioned axioms 1 & 2. The effect we are looking for lies in the distribution of clubs´ SM reach growth peaks. Players can only be transferred during those periods and hence a fans´ action on interest in player changes appears during transfer periods. Related to this constraint, growth peaks of clubs´ SM must depend on the transfer periods. To prove this, we investigate the stochastic dependence of both quantities. Stochastic independence from events means that they do not influence each other or are influenced jointly by other events. This relationship makes it possible to determine the direction of an existing stochastic dependence from the assumed causal relationship. The existence of stochastic independence is confirmed if formula 2 is fulfilled.

$$P(S \cap T) = P(S) \times P(T) \tag{2}$$

The existence of stochastic dependence is therefore confirmed in the event of inequality between the two terms. The variables S or T stand for event one or event two. Event one (S) represents the absolute count of growth peaks. Event two (T) therefore outlines the absolute count of data points within the transfer period. The data collected are available in the form of absolute daily growth. Each data point consists of both the index T whether it is inside the transfer period or not, and the index S whether it is a growth peak or not. Growth peaks S are extracted using boxplot diagrams. Then the distribution of the outliers over four intervals was measured.

3.3 Interest in Players Analysis

The aim of this paper is to investigate the possible impact of SM on the transfer activities of professional sports clubs. With this in mind a special focus lies in asking to what extent player changes and therefore the interest of fans on players can influence the SM reach of sport clubs. If an effect of a transfer on the clubs´ SM channels can be shown, a new dimension of players´ value will be identified. This digital transformation-driven value might open up new types of transfer fee amortization and income.

To analyze this influence, we focused on the growth behavior of the SM reach of the clubs during the weeks of the year in which transferred players received the highest media interest. Doing so allows us to extract the periods in which the player was of special interest among fans because they looked for information about him. Corresponding to the above-mentioned axioms 2-4, the fans´ interest causes SM engagement with the clubs´ channels. In contrast to the method used in Section 3.2, which was used to identify the link of SM growth and the transfer periods, the approach described in this chapter quantifies the direct influence (E_{dir}) of transfers on the SM channels and therefore the willingness to pay for players with regard to their digital value.

The analysis tool Google Trends is highly valuable in recognizing fans' interest. Using this tool allows us to identify the search relevance per week of a player on the search engine Google over the last 12 months [31]. Again, regarding axiom 3, this exposed interest can be related to the willingness of the searcher to get information about a player and therefore encourages the usage of information channels about the player. Consequently, an increase in hits to players´ and clubs´ SM channels is predicted. The method used in this chapter is meant to show a direct influence (E_{dir}) which would prove the mentioned relation between fans´ interest and an increase in SM channels´ followers.

$$E_{dir} = Z_{middle,week} - Z_{middle,period} \tag{3}$$

The variable $Z_{middle,week}$ characterizes the mean daily SM follower growth during the week within the considered period in which the search volume of an individual was of highest interest on Google´s search engine. In contrast, $Z_{middle,period}$ stands for the mean follower growth of the individual´s channels over the entire survey period. The difference between the average daily increase within the week in question and the average daily increase over the survey period represents the direct effect E_{dir} of the player transfer on the clubs' platforms. The search peak of the new player and not the date of the change of player was selected as the period to be examined. This made it possible to include the reaction speed of the interested individual. The premise was that a fan can only become active on search engines and social channels as soon as he or she learns of at least one rumor about a possible transfer or the execution of the transfer itself.

3.4 Transfer Classification

After examining the direct influence of the transfers on the channels of the clubs, the individual player changes were categorized. For this we took into consideration four basic characteristics: (1) new player improves the starting line-up, (2) new player uses SM, (3) new player causes a recognizable effect (E_{dir}) on clubs´ SM channels´ followers, and (4) new player evinces SM potential. All of the characteristics have been regarded as dummy variables. The changes were hierarchically assigned to the classes: supplementary player, SM reach applied player, balanced player, sporting improvement player, SM star player and star player.

Previous research took various factors such as fitness, minutes played, and duel strength into account to compare sporting analysis units [15,31]. For this study, however, the sporting performance of a player was limited to the achieved point average per game and the average minutes played per game. A player who plays for a team that has a high average score and is therefore successful shows a high sporting quality simply through his status as a team member. The inclusion of the average minutes played per game additionally specifies the qualitative classification of the player. The importance of the player in the team is derived from this, since better players are usually used more frequently [31].

To measure the sporting performance, a new variable F was implemented. As mentioned above, F consists of the average minutes played and the achieved point average during the season 2016/17 ($PPS_{16/17}$). Formula 4 shows that the average minutes played per match were calculated by dividing the absolute minutes played by the player during the 2016/17 season ($M_{16/17}$) by the total number of matches played by the team the player represented during the 2016/2017 season ($G_{16/17}$).

$$F = M_{16/17} * (G_{16/17})\text{-}1 * PPS_{16/17} \quad (4)$$

If a player has a better score than his worst position-related competitor, this transfer was considered a sporting improvement. Not all players of the squad were used as a yardstick: only the players of the starting line-up. The starting line-up is based on a 4-4-2 system as standard. A midfielder was therefore a sporting improvement if at least one of the four best midfielders has had a worse factor than the player in question.

The attributes 'uses SM' and 'effect recognizable' reflect the ability of the player to gain a digital advantage for the buying team. The former attribute includes the player's own digital commitment. A positive manifestation exists as soon as the player in question operates one or more official SM channels. The latter feature, on the other hand, is based on the findings of the above-mentioned interest in player analysis. This attribute is available as soon as a positive effect has been recorded ($E_{dir}>0$).

The SM-sports weight ratio (WR_{SMS}) ultimately provided information about the transfer motive.

$$WR_{SMS} = (\text{SM reach}) * (F)^{-1} \quad (5)$$

As a quotient of the SM reach and the player's sporting performance factor, the WR_{SMS} stands for the SM potential of the player. An above- or below-average ratio indicates a large (small) or small (large) digital (sporting) potential. All above-average digital potentials that could be identified as outliers via a boxplot diagram were classified as exceptionally strong. A weak potential is automatically present if the player in question does not have a SM channel. It is important to note that we did not investigate where the player's followers came from, for which reason they became followers, or who manages the profile.

The classification was executed using a Bayes Classifier. Therefore, we provided the above-mentioned characteristics to a sample data set. We then applied a Bayes learner as shown in Figure 1. The sample data used represented all combinations of states that the variables could assume.

The learner then predicted the algorithm learned from the sample data for the Bayes Classifier which we executed on the main data set of 124 player changes. As a result, every transfer was matched to one of the five classes described in the following: A balanced player may use SM and possibly might have a direct effect, but the sporting factor must be weighted more strongly in relation to its digital reach. Therefore, this player is neither an enormous sporting improvement nor an outstanding digital improvement. A sports-related transfer is therefore every player who represents an improvement in sports and whose weighting tends to be in addition to the sporting value. If there was a sporting improvement together with a strong or extraordinarily strong SM potential, this player would represent a star transfer. Conversely, SM stars have an exceptionally strong SM potential but cannot remarkably improve the squad in sporting terms. A player with a higher weighting on the reach, who either cannot have a direct effect or does not represent a sporting improvement, is assigned to the reach class. Finally, all players who do not fulfill any of the attributes are additional players.

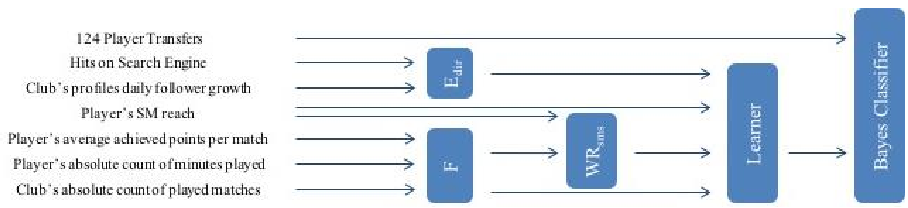

Figure 1. Statistical Approach

3.5 Data Collection

The analysis focuses on the 20 clubs with the highest income in football worldwide [35]. Müller et al. [31] point out that in professional football, the channels YouTube, Facebook, Twitter and Instagram are the most important. YouTube is a video portal and primarily serves to support the sporting event [40]. For this reason, it is assumed that growing reach in this medium is based more on sporting highlights than on transfer effects. The analysis used daily followers growth from all official channels of the clubs on Twitter and Instagram platforms. Channels which obviously had no relevance for the men's football team (youth, women's division, handball, etc.) were ignored. A total of 43 official Twitter and 20 official Instagram channels were identified. The historical data was collected by the online platform SocialBlade, which resulted in a dependence on the platform in terms of data quality and completeness. The study took place from November to December 2017. The increases were considered in the period from May 1, 2014, to October 31, 2017. Missing data entries were added using linear interpolation.

In addition, data on transfer transactions were used. Due to the lack of coverage of historical data on Twitter profiles, the individual consideration of the transfers had to be limited to the summer change period of the 2017/18 season. The Transfermarkt.de platform, which is characterized by high data quality and domain-related relevance [31], collected all new transfer entries for the aforementioned change period of all 20 clubs considered. All returns on loan that had already been purchased and subsequently borrowed in previous periods were excluded. Also disregarded were former youth players who transferred from the youth team to the men's team of the same club. The survey yielded 124 hits. For the all the relevant transfers found, the existing SM reaches of the players on Instagram and Twitter channels were collected on May 30, 2017. The SM reach represents the sum of the followers on both channels. The weekly time period for each transfer in which the search volume of the player concerned was highest was then collected with the help of Google Trends. The period in which the maximum number of search queries was determined was twelve months retroactively from December 31, 2017. From a total of 37,868 data points, 1,904 profile-related outliers could be identified as growth peaks S. As expected, 30.79% of all data points were within the transfer period due to the seasonal distribution. 73.58% of the growth peaks were in the period of one transfer period.

4 Findings

The application of formula 1 to the values resulted in an inequality. This result confirms the existence of a stochastic dependence of the variable peak growth and transfer period. As stochastic dependence indicates only the existence of a correlation and not the cause of it; the direction of this dependency cannot be determined from the numerical values. Nevertheless, 73.58% of all growth peaks were in the transfer period interval and 70.97% of the considered transferred players experienced the largest search volume in at least one week which intersects the transfer period.

For the purposes of this review, a positive effect of a transfer for a club has been defined as an impact on its SM commitment. In this model, this effect was assigned to the growth of the follower numbers. From the connection of the week of the search peak and the increase of the SM channels, the key figure of the direct effect could be calculated. Table 1 shows the effects of the summer transfer period 2017/18 and the transfer sums for each player.

91 out of 124 newcomers use SM. At the same time, 72.53% of these were able to gain a direct effect of an average of about 4.5 thousand new followers. The medium SM reach of these players thus exceeded the medium reach of players without effect by about 2.8 million followers. The average transfer fee for players with an SM appearance was about twice as high as for those players who do not maintain a presence in social networks.

Table 1. Transfers and SM usage

Influence	Descriptive statistics	Uses SM	Doesn't use SM	Total
$E_{dir} > 0$	Number	66	19	85
	Share (within vertical category)	72.53%	57.58%	
	Share (within horizontal category)	77.65%	22.35%	
	Share (of the whole)	53.22%	15.32%	
	Average transfer fee (€)	25,093,878.79	10,036,842.11	
	Mean positive effect (adjusted for mean growth)	4,472.83	3,859.21	
	Average follower number	3,498,609.42	-	
	Correlation follower and E_{dir}	0.2988	-	
$E_{dir} \leq 0$	Number	25	14	39
	Share (within vertical category)	27.47%	42.42%	
	Share (within horizontal category	64.10%	35.90%	
	Share (of the whole)	20.16%	11.29%	
	Average transfer fee (€)	13,623,800.00	6,230,769.23	
	Average follower number	726,469.12	-	
Total		91	33	124

The data also show that 57.58% of the transferred players without a SM appearance also have direct positive effects. The transfer sum for those players without SM channels is also approaching at least the transfer sum for players with a SM presence. The average transfer fee paid for players without SM and with effect was closer to the average amount paid for players with SM and without effect than for players without SM and without effect.

Finally, Table 2 presents the classification of individual transfers for the 2017 summer change period. 6.45% of the transferred players were purchased for an average of 5.75 million euros. Balanced players make up a share of 29.84% with an average transfer fee of 11.8 million euros. With 33.87%, the sports class represents the largest share of transfers. The average transfer fee is 17 million euros above the average for additional players, but below the sums paid for the individual classes with SM motives. The three categories that indicate a SM motive (reach, SM star, star) account for a total of 29.83%. Consequently, almost every third transfer could at least be associated with SM strategic motives.

Table 2. Classification

Class	Number	Share	Average transfer fee (€)
Additional player	8	6.45%	5,750,000.00
Balanced player	37	29.84%	11,841,756.76
Sport improvement	42	33.87%	17,084,047.00
SM reach improvement	10	8.06%	18,615,000.00
SM star	10	8.06%	19,310,000.00
Star player	17	13.71%	41,382,352.94

5 Interpretation

The results show that the development of the SM reach of clubs is not a coincidence. As seen in the findings, the greatest growth spurts result from events that occur within the transfer window, hence a concrete connection between the SM growth and the annual transfer period was confirmed. Due to the given assumptions, this indicates that transfers have an impact. Being able to achieve a SM effect through a transfer therefore should influence the transfer decision itself. This explains SM's influence on the transfer decision and thus on the transfer market, because clubs try to use SM as a strategic means to ensure long-term success [8,11].

However, there were also growth peaks outside the transfer period. These peaks can be explained either by sporting events, i.e. particularly sensational events, or speculations in the run-up to an imminent transfer [5]. However, since these are the minority, the question of a connection between the appearance of players and clubs on social networks and the transfer market can be answered affirmatively.

Regarding transfers in the context of this paper, the SM motive and therefore the influence of SM on the transfer market is associated with an additional reach, which is transferred to the sphere of influence of the club in the form of the reach of the new player. This might influence the willingness of clubs to pay for players, as the higher transfer sums indicate. This expresses the potential benefit via the indirect digital expansion through followers of the player profiles. The potential can be explained by the fact that fans and followers of the player can identify more strongly with a club if the favored player is under contract with the club. The media interest of the fans in the club increases through the interest in the player.

An unexpected direct effect was caused by players who do not have a SM profile. A possible explanation for this unexpected finding is once again the interest of fans in re-accessing the game. However, this creates a conflict, as consumers have no direct access to the player due to the player's lack of digital presence. Clubs can integrate these players into the generated content as part of the star marketing effort [7].

Due to the greater transfer sums, it can be assumed within the framework of the assumptions made that the clubs are aware of the digital potential from transfer transactions. Nevertheless, the values indicate a lack of knowledge in dealing with the digital potential of the players. The potential benefit consists of the components ‘direct effect’ and ‘additional reach’ through player profiles. The results suggest that the clubs are only aware of the players who have SM profiles on their own. The average fee paid for players who don´t have SM but could impact a direct effect are lower than the fee paid for players who have SM but could not impact a direct influence. Therefore, if clubs would have been aware of those hidden players they would have been transferred with higher fees, especially when recognizing the average follower count of the players that do have SM but could not cause a direct effect being about 700,000. That volume of followers seems not to justify paying a higher fee.

Lastly, the differentiation between the six classes reflects the significance of the SM component in the transfer market. It was to be expected that star newcomers would require the highest transfer fees. However, it is noticeable that both SM stars and purchases for the reach are generally more expensive than for sporting improvements. This means that a player who only offers added value in the digital field is of greater value for sports clubs than a player who only contributes on the field. Against the background of any commercialization and globalization of sport, it can be confirmed within the framework of the assumptions made that it is no longer athletics but brand value that is in the foreground.

6 Conclusion, Limitation and Further Research

The model and the analysis steps depict reality in a highly simplified manner. Although it was suitable for identifying anomalies, the model does not manage to explain these anomalies in their complexity of real circumstances. This requires a much more specific and precise consideration. Both the categorization of transfers into classes and the comparative classification of club strategies offer a good approach for further refining the transfer analysis and still providing more sustainable models for the analysis of modern football than are available today [15]. Moreover, a more detailed analysis on individual players (e.g., good players in worse clubs) should be added to strengthen the model and analysis. Nevertheless, it is necessary to extend the transfer parameter set in subsequent analyses in order to take club and sporting MRP components into account. In addition, the sustainability of the analysis should be strengthened by extending an analysis to other SM platforms. Müller et al. [31] and Buhler et al. [40] cite as examples platforms which are of the greatest importance in professional association football. A local analysis is another component that should be added to the model developed in order to identify the strategic actions of clubs. Finally, it is recommended to extend the analysis to a randomized sample in order to cover the entire global professional association football.

This study should be seen as a first step in the field. The authors tried to operationalize the underlying assumptions. As the results show, there is a relationship between the SM value of players and the transfer activities of clubs. Further research should develop the model to a more theory-driven basis and incorporate more parameters and a greater sample size.

As professional sports and SM do have a huge impact on social life, both academia and practice should increase the research in this field. Furthermore, professional Football Clubs should take this topic more seriously. As could be seen in the data, there are informational gaps about the potential value a player can add to the club by using SM. The teams should strengthen their knowledge in identifying those players and their potential values in a digitalized society, especially those players without SM profiles on their own.

Abstract. Competitors and customers put Local Owner-Operated Retail Outlets (LOOROs) under digitalization pressure. Local Shopping Platforms (LSP), acting as intermediaries between LOOROs and their customers, explicitly make use of the locational strength of LOOROs and seem to be a promising vehicle to help LOOROs overcome their manifold digitalization difficulties. In this study, with the help of a structured content analysis of 27 LSPs in Germany, Switzerland, and the U.S., we analyze LSPs as local descendants of e-marketplaces and derive a functionality-based typology. Furthermore, we scrutinize how LSPs harness LOOROs locational advantages. Despite their visible role as inter-organizational service-hubs and a low-level entry option to e-commerce for LOOROs, our results show that LSPs currently unduly focus on location-enabled services that support the online channel, while neglecting the potential of location-based services and the local stores as a Point of Sale (PoS).

Keywords: Local Shopping Platforms, LOOROs, Location-dependent Services, Retail.

1 Introduction

In an otherwise positively developing market environment, Local Owner-Operated Retail Outlets (LOORO) face an intense business and market transformation. The market share of LOOROs has already declined from 26% in 2003 to 17.9% in 2015 in Germany [1]. Several independent studies predict a further decline in revenue for LOOROs in Germany of 30% within the next four years [2], [3] and of about 50% within the next ten years [4]. Big box retail outlets, chain stores and online retailers on

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

the one side, as well as changing customer shopping habits and a decline in shopper frequency in the high streets on the other side, are threatening the very existence of LOOROs [5], [6]. Further, studies show that LOOROs, like other small- and medium-sized enterprises (SME), still hesitate to adopt e-commerce channels (e.g. by starting their own online shops) [7], [8] as well as to participate in electronic marketplaces (e.g. selling on eBay or Amazon) [9]. Existing research has explained this phenomenon of reluctant digital transformation with an extensive set of internal (e.g. financial constraints, lack of knowledge, lack of infrastructures, fear of global competition, etc.) and external (e.g. lack of standards, lack of understanding of SME needs, etc.) influence factors acting as adoption barriers [10-13].

Currently, Local Shopping Platforms (LSPs) as intermediaries and inter-organizational service hubs between LOOROs and their customers are spreading in German cities [14]. For instance, Atalanda.com is a local shopping platform provider that offers LSPs in now thirteen German cities. Atalanda enables small and medium sized stationary retailers to sell their products online via local Atalanda marketplaces (e.g. “OnlineCity Wuppertal” or “Einkaufen in Attendorn”).

The advent of LSPs has many ties to the long tradition of e-marketplaces and e-intermediaries with one clear distinction: On large e-marketplaces, like Amazon or eBay, the boundaries between Business-to-Business (B2B) and Business-to-Consumer (B2C) as well as regional or national restrictions blur [15], [16]. With the advent of LSPs, we see a counter-development of platforms that implement location-dependent self-restrictions into their business models. It is either a limitation to the cooperation with retailers from a certain area, the limitation of just doing business with customers from a certain area, or both. LSPs use these location-dependent self-restrictions as their unique selling proposition. They sell the existing offer of merchandise of LOOROs via their platform and try to reach time advantages in delivery and service by using the connected local shops as decentralized storages in direct neighborhood to the households of the local customers [17].

On the one hand, this LSP approach seems to be promising for LOOROs, as it helps them in their digital transformation and to overcome the e-commerce adoption barriers by outsourcing the digitalization challenge to the platforms [18], [9]. The LSPs serve as digital service providers and relieve LOOROs from the burden of building up their own digital infrastructures and hiring specially educated staff [19]. Furthermore, LSPs enable cooperation and shared services among competitors, allowing for synergy effects for the digital transformation of all participating retailers in the city centers. For example, LSPs can spread the development cost of the platform’s infrastructure (IT, logistics) across the connected shops, avoiding the need for individual high investments [20].

On the other hand, local shopping platforms seem to be problematic for LOOROs, as these seem to step into a self-reinforcing spiral of ubiquitous online price competition with significantly declining (online) sales prices when joining the platforms [16]. Furthermore, it remains unclear whether customers will (in the long-term) accept electronic marketplaces that are limited to offers from only local vendors, or whether they will prefer global marketplaces with nearly unlimited offers like eBay and Amazon [21]. Today, the business model of LSPs still lacks proof of concept and is therefore an uncertain bet as a sustainable backbone for the digital transformation of LOOROs.

Against this background, LSPs seem to be a premature approach, but the integration of location advantages and physical infrastructures into their service strategy could lead to competitive advantages for LOOROs. It could help them win back market shares and revenue from the big online and offline competitors and to catch up in the ongoing digital transformation of the retail sector.

However, also reknown pure players, like esp. Amazon, have already started to enter the stationary retail sector (e.g., Amazon Books Stores, Amazon Go Stores, Amazon Now and Whole Foods). These examples of online-to-offline ventures experiment with ambitious retail concepts (e.g., the use of sensors and other technology to identify and automatically charge customers). Therefore, the stakes are high and LOOROs are facing tough competition. As LSPs are a rather new approach, we still do not know enough about their service offers and about how they facilitate the locational advantages of LOOROs in the digital realm. It is not yet to say, if LSPs will actually be able to help LOOROs transform their business models and survive in the highly competitive digital future [19]. Therefore, with regard to the ongoing transformation process of LOOROs and the according role of LSPs, in this paper we aim to answer the following research questions:

RQ1) *What kind of local shopping platform approaches exist?*

RQ2) *Which local services do these local shopping platforms offer in order to utilize the locational advantages of LOOROs?*

The paper is structured as follows: In section 2, we discuss the theoretical background needed for the analysis. We then introduce the methodological foundation of the structural content analysis in section 3. In section 4, we discuss the results of the content analysis. Finally, in section 5, we conclude, point out limitations and discuss future research opportunities.

2 Theoretical Background

2.1 Functionality and Categories of Local Shopping Platforms

Local Shopping Platforms represent e-marketplaces with a local focus. Like traditional e-marketplaces, they serve three main functions: 1) they match (local) buyers and sellers, 2) they enable the exchange of information, and 3) they facilitate transaction and fulfillment services [22], [15].

As with e-marketplaces, also the services provided by local shopping platforms are not standardized and strongly differ [23]. The service landscapes provided range from simple externalized management of the online front-end (e.g., online shop, marketplace) to the outsourced management of complex sales and marketing processes, including pricing, invoicing, data processing, and logistics [23], [24]. According to Peterson et al. (2007) [25], this diverse service landscape enables a typological differentiation (categorization) of LSPs based on the typical e-marketplace functionalities (see Table 1).

Following this approach, we derived five types of local shopping platforms: The first e-marketplace function (match of buyers and sellers) allows for the differentiation of two categories of local shopping platforms, *Store Locator Platforms* and *Product Catalog Platforms*. *Store Locator Platforms* offer only contact and store location information. They do not provide any information on products or any online shop functionalities to enable the core buying process. In addition to this contact and store location information, *Product Catalog Platforms* as the second category of LSPs provide an overview of the products available in the connected stores. As *Store Locator Platforms*, also *Product Catalog Platforms* do not provide any online shop functionalities. Considering the e-marketplace function (exchange of information), we derived an additional platform category named *Product Enquiry Platforms.* These platforms enable customers to request product availability information, while still not providing online shop functionality. Regarding the e-marketplace function (transaction and fulfillment), two more types can be differentiated. *Affiliate Transaction Platforms* allow the purchase of products, but customers complete the transaction process on an external website with the help of an affiliate shop. Finally, *Full Transaction Platforms* offer the full e-marketplace service range, including payment and logistics. Table 1 summarizes the typology.

Table 1: Local Shopping Platform categories with regards to the main e-marketplace functionalities, derived from Peterson et al. (2007)

	Information	**Communication**	**Transaction & Fulfillment**
Platform Categories	Store Locator Platforms	Product Enquiry Platforms	Affiliate Transaction Platforms
	Product Catalog Platforms		Full Transaction Platforms

2.2 Location Theory & Location-Dependent Services

“Location! Location! Location!” has long been a mantra for the stationary retail sector and its service providers. In the pre-e-commerce era, it was widely believed that the choice of a location is the single most important decision for retailers [26]. In fact it has been even argued that poor location may be an insurmountable obstacle for even the best retailers [27]. In the advent of e-commerce, location seemed to have lost its importance [28]. Many pure players built big warehouses outside the cities to enable the efficient implementation of the fulfillment promises they made to their customers [29]. However, with the rising service competition between pure e-commerce players and stationary retailers (Big Box Retail Outlets and LOOROs), including services like e.g. same day delivery or even same hour delivery, the importance of location for the retail sector and the interest in location theory is increasing again [30], [31]. For example, Kim et al. (2017) [32] point out that the impact of distance in the e-commerce age “is not dead”, and in their study they highlight the negative effects of growing transportation costs on online sales prices and customer demand. Furthermore, in their study they show that location-dependent services, like logistics services and especially express delivery services are positively correlated with repurchases and the loyalty of customers. Further, research showed that even in an environment with near zero trade cost, physical distance matters [33] and that especially location-dependent service are essential to attract and retain customers in multi-channel retail environments [34], [35].

To make use of locational advantages, location theory suggests the facilitation of location-dependent services for multi-channel retailers and e-marketplaces. In fact, there are two types of services to look at. First, location-enabled services: these services are possible if the location of the store is close to the households of the customers and thus enables short distance services with low transportation costs [36], [37]. Second, location-based services: These services aim to utilize foot-traffic at popular places like main streets, parks, etc. using location-awareness information systems and devices, like smartphones and wearables [38-41].

Table 2: Differentiation Location-independent and Location-dependent Services

Location-independent Services	**Location-dependent Services**	
Standard Web-Services	Location-enabled Services	Location-based Services
All Services provided on e-marketplaces and not related to location.	Services that are feasible if the location of the retailer is close to the households of the customers.	Services that are feasible if the customers are close to the store location.

3 Analysis

3.1 Methodology

To analyze the different types of existing LSPs and their offered services, we conducted an extensive content analysis [42-44] and followed the procedure suggested by Krippendorff (1980, 2004) [45], [46] and Mayring (2010) [47]. Accordingly, after defining the research scope and questions, in a first step we identified the existing LSPs through an explorative web search. In the second step, we conducted a pre-test, categorizing 30% of the identified LSPs and their services. This pre-test was followed by a revision procedure to improve the categorization and to streamline the coding agenda.

Subsequently, in a fourth step, three individual coders conducted the full content analysis (100%). Finally, in the last step, an expert panel of senior researchers discussed and resolved discrepancies in the coding results (see Figure 1). All mentioned research steps will be discussed in detail in the following.

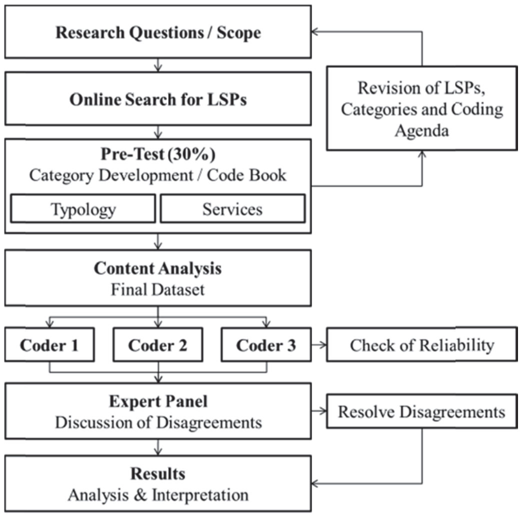

Figure 1: Research Procedure (based on Kripppendorff 2004 and Mayring 2010)

3.2 Sample

For the identification of the LSPs we conducted an online search process in June and July 2016, using the following keyword combinations in English and in German: "Local" + ("E-Marketplace", Shopping Platforms", "Shops Online", "Vendors Online", "Marketplace", "Products Online", "Retail", "Online shop"). The online search process was limited to the first ten result pages on Google per search iteration (first 100 results). To get as unbiased results as possible, the search engine settings where switched to "Do not use private results".

The search process resulted in a first set of 52 candidates for local shopping platforms. A second level selection and screening process to improve the quality of the findings reduced this set to 27 LSPs (selection criterion: local self-restriction to either cooperation with retailers from a certain area, the limitation of just doing business with customers from a certain area, or both) from three countries. 21 platforms were from Germany, four platforms from the U.S. and two platforms from Switzerland (see Table 6). Despite the bilingual keyword combinations and the disabled private results setting, there were distortions in favor of German platforms. The reason for this bias could be default settings of the Google.de search engine.

3.3 Pre-Test, Coding, and Full Content Analysis

After the pre-test (30%) and the revision procedure, the coders together categorized the identified local shopping platforms and their services (100%) in a joint effort to achieve a consistent coding. They screened each platform for 74 possible items: 5

typological items and 69 service items (see Table 5 and 6). Each item was considered with 1 point in the Code Book (Yes / Available = 1, No / Not Available = 0), resulting in two scores: (1) a Typological Score, ranging from 0 to 5, and (2) a Service Score, ranging from 0 to 69 (see Table 3 and 4).

Table 3: Code Book: Platform Typologies

Items / Functions	Definition	Coding Rule
Store location	Shows locations and contact information of local retail stores	Available = 1 Not available = 0
Product Description and Pictures	Shows products and descriptions of products of local retail stores	Available = 1 Not available = 0
Product enquiry	Offers the functionality to write a product enquiry to a local retail store	Available = 1 Not available = 0
Affiliate links	Shows products and prices from local with affiliate link to an external online shop	Available = 1 Not available = 0
Full transaction handling	Offers full transaction handling for local retail stores on the platform	Available = 1 Not available = 0

Table 4: Code Book: Services

Type	Categories	Definition	Items	Coding Rule
Location-Dependent Services	Location-Enabled Services	Services based on the proximity to the customers	16	Available = 1 Not available = 0
	Location-Based Services	Services based on the location of the customer	13	Available = 1 Not available = 0
Location-Independent Services	Information & Recommendation Services	Services offering basic information and / or recommendations	12	Available = 1 Not available = 0
	Communication & Support Services	Services offering a communication channel	14	Available = 1 Not available = 0
	Payment & Billing Services	Services enabling the payment process	8	Available = 1 Not available = 0
	Fulfillment Services	Services for delivery and / or pick-up	6	Available = 1 Not available = 0

3.4 Intercoder Reliability

The verification of the Intercoder Reliability followed the guidelines of Raupp and Vogelsang (2009) [48] and Tinsley & Weiss (1975, 2000) [49], [50]. For this, the Holsti's Coefficient of Reliability $r_{H,}$ and Krippendorffs α were calculated. Concerning the platform typologies, there were 5 items and 27 platforms, so that each coder had to judge 135 different items in total. In sum, complete agreement was achieved ($r_{H,}$=1; see Table 5).

Table 5: Holsti´s Coefficient of the typological items

Coder Pair	**C1 + C2**	**C1+C3**	**C2+C3**
coder's consensus	135	135	135
percentage agreement	1.00	1.00	1.00
r_H	1.00		

Regarding the services, each coder had to examine 27 platforms for 69 services (1,863 items). The Holsti´s reliability coefficient of $r_H = 0.916$ shows an almost complete agreement [51]. The Krippendorff's α coefficient marginally missed the threshold for very good (0.9) but is still good with α = 0.895 [46], [52] (see Table 6).

Table 6: Krippendorffs α and Holsti´s Coefficient of Reliablility r_H

Coder Pair	**C1 + C2**	**C1+C3**	**C2+C3**
Agreement / Coder Pair	1719	1698	1705
Correlation Coefficient / Coder Pair	0.923	0.911	0.915
Holsti´s Coefficient of Reliablility r_H	0.916		
Krippendorff's α	0.895		

3.5 Expert Panel

To overcome and harmonize uncertainties (the coders agreed on 1668 out of 1863 items), an expert panel of four senior researchers with high expertise in the field of e-marketplaces and e-commerce discussed all remaining discrepancies (195 items) and made final decisions. Furthermore, the expert panel reviewed and discussed all platforms and confirmed the coding results.

4 Results

The platform types derived from literature in section 2 could be confirmed in practice. Of the 27 platforms identified, 21 are located in Germany, two in Switzerland, and four in the U.S. Only two platforms represent *Store Locator Platforms* and two others *Product Catalog Platforms*. Six platforms provide the functionalities of *Product Enquiry Platforms*. Four platforms can be considered *Affiliate Transaction Platforms,* and thirteen platforms offer the full range of online shopping transaction and fulfillment services as *Full Transaction Platforms* (see Figure 2). These results clearly indicate that the majority of the platform providers strive to offer complete shopping experiences on their platforms.

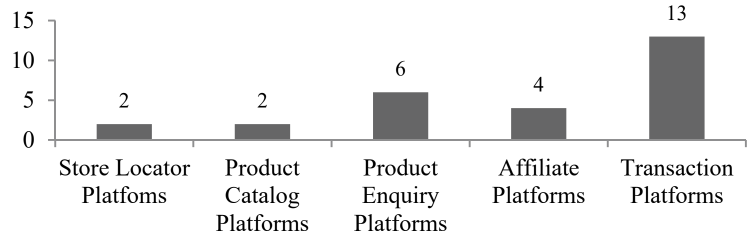

Figure 2: Distribution of types of local shopping platforms in the data sample

Table 7: Identified Location-Dependent Services on LSPs

No.	Location-Enabled Services	#	No.	Location-Based Services	#
	Information Services			**Information Services**	
1.	Map with store locations	16	1.	Location-based product consultation	0
2.	Information about local news	1	2.	Barcode scanner	2
3.	Information about local events	3	3.	Location-based map with store locations	8
4.	Information about product availability (In-Store)	12	4.	Location-based map with closest product location	3
5.	Information about store opening hours	19		**Communication & Support Services**	
6.	Information about store contact data	22	5.	Location-based support	0
	Communication & Support Services		6.	Location-based advertisement	1
7.	Support at home	9	7.	Location-based loyalty program	0
8.	Face to face support	1	8.	Location-based price-draws	0
9.	Local loyalty card	7	9.	Location-based discounts	0
10.	Customer integration (Customer feed-back on store services)	13	10.	In-Store navigation	0
11.	Community integration	10			
	Navigation Services		11.	Outdoor navigation	0
	-		12.	Location-based shopping tour	0
	Payment and Billing Services			**Payment and Billing Services**	
	-		13.	Self-Checkout	0
	Fulfillment Services			**Fulfillment Services**	
12.	Same day delivery	2		-	
13.	Same hour delivery	6			
14.	Click & Return	3			
15.	Click & Collect	0			
16.	Reserve & Collect	6			

Altogether, the 27 platforms provide a range of 67 different services. These services support the different functions of e-marketplaces and can therefore be categorized as follows [15], [22]:

(1) Information & Recommendation Services
(2) Communication & Support Services
(3) Payment & Fulfillment Services

Table 8: Amount of services offered of Location-Dependent and Location-Independent Services on Local Shopping Platforms (July 2016) – Sorted by typology

	Local Shopping Platform			Location-Dependent Services									Location-Independent Services			
				Location-Enabled Services				Location-Based Services

26.	Yategolocal	1	7	**3**	3	0	0	**0**	0	0	0	0	2	2	0	0
27.	Kaufnah BETA	3	3	**0**	0	0	0	**0**	0	0	0	0	0	3	0	0

From the 67 different services, 40 services are location-independent and 29 are location-dependent services. Thirteen services of the latter group are Location-Based Services, while 16 are Location-Enabled Services (see Table 7). Among the location-dependent services, information services are dominating, while among the location-independent services communication services are in the majority.

The extent to which LSPs provide location-dependent services differs quite strong. On average, LSPs offer 23% of all identified services, ranging from a min. of 4% to a max. of 41% of the services. Between 0% and 56% of the identified Location-Enabled

Services (average 30%) and between 0% and 31% of the identified Location-Based Services (average 5%) are provided by the platforms. For comparison, concerning location-independent services, 0%-50% of the information & recommendation services (average 20%), 7%-64% of the communication & support services (average 41%), 0%-75% of the payment & billing services (average 28%), and 0%-50% of the logistics services (average 15%) are provided by the LSPs (see Table 8).

A deeper look on location-enabled services shows that local shopping platforms provide between 0%-83% of the identified information services (average 45%) and 0%-80% of the identified communication & support services (average 13%) as well as of the logistics services (average 30%). As location-based services, only two categories are used: information (0%-75%, average 12%) and navigation services (0%-67%, average 6%).

Logistics services are one of the major advantages that LSPs can offer to customers. Regarding Affiliate and Full Transaction Platforms, which both support the complete shopping process, further interesting findings are that: (1) only seven full transaction platforms offer same day delivery, (2) ten full and two affiliate transaction platforms offer click and collect, (3) five full and one affiliate transaction platform offer click and return, (4) and three full and four affiliate transaction platforms offer reserve and collect.

Regarding the typology, platforms of higher categories tend to use more services than platforms of lower categories. However, this cannot be generalized, as some platforms of category 1 are ranging in the midfield while categories of 5 and 4 can also be found in the lower field.

5 Conclusion

5.1 Discussion

In total, 23 shopping platforms that focus on local retailers and local customers were identified, out of which four are from the U.S. and 23 are from German and / or Switzerland.

Concerning the services provided, there is much room for improvement on local shopping platforms. In average, the examined platforms offer only 16 of the identified 69 services, including only eleven out of 40 location-independent services (27.5%), 4.8 out of 16 location-enabled services (30%), and 0.7 out of 13 location-based services (5%). Thus, although local shopping platforms strive to make use of the locational proximity between shops and customers, they fall short in providing appropriate services. A closer look at location-dependent services reveals that mostly general information regarding shop addresses, contact details, opening hours, and product availability are provided. Most platforms do not offer advanced services that really make use of the position of the customers around or in the local stores connected to the platforms, neglecting the local stores as a PoS. The very few location-based services offered underpin this finding. It almost seems that LSPs are not interested in strengthening the locational position of the connected LOOROs, but only try to benefit from them by focusing on services that foster online sales, like support or payment and billing services.

5.2 Practical implications

For LOOROs: It is questionable if LSPs can help LOOROs with their digital transformation in a sustainable manner. So far, the service offers of LSPs are focusing solely on the online PoS of the platforms itself, while neglecting the digital opportunities of local physical stores. In today's omnichannel retail world with merging sales and communication channels, such a single channel service strategy needs to be considered outdated [21]. Furthermore, big retail chains started to revolutionize the stationary retail sector with innovative store concepts; LSPs seem to be ignoring this upcoming challenge so far [53] (see Table 8).

Despite these critical aspects, LSPs also carry opportunities for LOOROs. The small retailers could make use of the strength of LSPs to get a low barrier entrance to the realm of e-commerce and use the digital environment to learn for their own digital transformation. Accordingly, LOOROs should utilize LSPs as digital service hubs. Furthermore, to improve their role in the relationship with the platforms, LOOROs should demand location-based services from the LSPs to support their physical stores and help to attract more foot-traffic. At the same time, satisfied offline customers have the opportunity to buy 24/7 at their preferred LOOROs via the local platforms. This offers loyal customers an online channel, preventing them from switching to other online shops [35].

For LSPs: With their current business and service strategy, LSPs miss a great opportunity. Instead of solely installing a sales platform that restricts itself and its market to local customers, LSPs should focus more on the locational advantages of LOOROs and foster location-based and enabled services as unique selling proposition [28], [34]. This would strengthen the position of the connected LOOROs in the city centers and help them attract more customers. Such effects are important also for the LSPs, as only strong local retail partners are able to provide a sustainable base for a long-term cooperation, securing the very existence of LSPs. Without support structures that strengthen the local retailers in their ongoing digital transformation, LSPs run the risk of being only a temporal phenomenon.

5.3 Limitations and directions for future research

The results of this study should be interpreted in the context of several key limitations. First, we derived the sample for the analysis from an explorative web search on Google that might have missed additional types of LSPs hidden on the Web. Additionally, the search settings of Google's search algorithm are not fully transparent and therefore the study could suffer e.g. from a country-dependent search bias. Therefore, future studies should consider also other sources of information to identify platforms, like e.g. industry information websites or blogs, and they should work with different language and regional settings on Google. Furthermore, due to the coders' language proficiencies, the analysis was limited to German and English language platforms. Insights about digital platforms for local retailers from other countries would have been of interest, too. Regarding the services offered by LSPs, research is needed on the orchestration of Location-enabled and Location-based Services, and the list of Location Dependent Services in general. Finally, further research is necessary on if and how LSPs and Location Dependent Services can help LOOROs overcome informational disadvantages in comparison to online retailers (e.g. In-Store Analytics via Location-based Services).

Abstract. The ability to generate business-relevant information and its use for business process improvements is a key success factor for businesses today. Answering the call for further research on success-relevant practices and instruments for managing business analytics, we report on the results of a three-year action design research project at a global car manufacturer. Drawing on the socio-technical systems theory, we identify seven meta-requirements and specify four principles for the design of an instrument to manage Analytics-as-a-Service (Aaas) portfolios. Our results reinforce the importance of coordinating different socio-technical components in business analytics initiatives and demonstrate how concrete management instruments, such as the proposed portfolio management tool, contribute to socio-technical alignment. For practitioners, the documented design components may provide guidance on how to design and implement similar instruments that support the management of Aaas portfolios.

Keywords: analytics-as-a-service, action design research, big data analytics, business analytics, governance.

1 Introduction

The ability to generate business-relevant information and exploit it to improve business processes is a key success factor for businesses today in facing the digital transformation [1]. Even in industries with commodity products and highly standardized services, business analytics offers companies the opportunity to generate new competitive advantages [2]. The possibilities for use are diverse and range across the individual functional areas of a company (e.g., supply chain, pricing, marketing, product quality, research, and development) with companies such as Amazon or Google to established companies such as Wal-Mart or Novartis, who successfully use analytics to their advantage [2]. Although the trend towards leveraging data to improve decision-making is not entirely new, the technological pervasion through digital technologies such as sensors or personal digital devices (e.g., smartphones and tablets) and the ability to store and analyze data in real-time through innovative technologies led to the emergence of the phenomenon of big data analytics [1]. In order to leverage this disruptive potential and to bundle analytics competencies, larger companies increasingly adopt shared service models and offer Analytics-as-a-Service (AaaS) to

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

business units [3]. However, most traditional companies are unable to generate business value through analytics projects and AaaS offerings, because they fail to address the associated structural, skill-specific, technology-oriented, and business process-oriented challenges stemming from the socio-technical nature of business analytics [4–6]. More precisely, the process of value creation through analytics requires an active and collaborative sense-making process of organizational participants (e.g., analysts and business managers) within the boundaries of the organizational socio-technical work system [7, 8]. Consequently, the management of AaaS not only involves the management of business demands and service requirements but requires an active management of service prototypes and implementations. Such activities are typically handled by a portfolio management function supported by specific management tools or instruments (most particularly a portfolio management tool) [9, 10]. Despite the growing body of practitioner reports [1, 5] as well as of academic literature [11, 12], research on how to exploit analytics to the advantage of companies is still scarce [11, 13] . With our research we address the lack of academic knowledge on portfolio management for AaaS by identifying principles for the design of a portfolio management tool. Accordingly, we pose the following research question: *"How to design a portfolio management tool to support the systematic management of AaaS?"*

We report on the results of a three-year action design research project, which was started at the beginning of 2015. This project aimed at developing a single point of truth for all analytics services to manage analytics services according to the priorizations of the central analytics unit's customers of the organization *CarCo*. At the beginning of our project all services were managed and coordinated with manual documentation on a printed excel spread sheet. Due to the increasing complexities the central analytics unit faced the underlying manual tasks were not feasible anymore and slowed down the day to day work of the central analytics unit. During this project, we used several academic approaches to tackle our phenomenon of interest (e.g., focus group workshops, semi-structured interviews, and observations).

Our work provides two key contributions. First, this work specifies requirements and design propositions for designing an AaaS portfolio management tool and thus addresses the need to further consider "socio-technical and socio-material design considerations for algorithmic decision systems" [14]. Second, this paper contributes rich empirical insights on the (up to this date underexplored) success factors of managing AaaS and responds to calls for further research in this area [11, 14–16].

2 Theoretical Foundations

2.1 A Socio-Technical Systems Perspective on Business Analytics

The socio-technical systems (STS) theory offers a multivariate system perspective on information systems that consists of four interrelated system components and allows its analysis [17, 18]. The social subsystem comprises *structures* and *actors*, whereas the technical subsystem comprises the *technology* and a *task* component [17, 18]. Actors are, amongst others, characterized by employees' capabilities and qualifications as well as a shared culture, structures by project organizations and institutional arrangements, technology by tools and technological platforms, and tasks by the required processes to fulfill work or the delivery of services [17–19].

Following Chen et al. [12] and Holsapple et al. [20] we use business analytics as an umbrella term encompassing the term big data analytics. Business analytics can be understood as a socio-technical phenomenon affecting organizations in multiple ways [20, 21]. Accordingly, to conceptualize analytics from a STS-perspective, (1) the technical system and (2) the social system have to be differentiated. First, the implementation of analytics technology, such as Hadoop cluster and hive (*technology*) is required to provide the technological basis to improve e.g., decision-making processes, and to achieve product, and service innovation (*task*) [1, 22, 23]. Second, in regard to the social system, *actors* require applied skills in the areas and intersections of technology, analytics, and business, others a general knowledge about big data analytics to successfully lead, manage, and implement big data initiatives [24]. Further, an organization needs to transform its organizational *structures* such that they support and establish cross-departmental collaboration [2, 4]. Therefore, we regard analytics as a strategic capability to gain analytical insights from (big) data which equally resides in technological and organizational system components.

In IS research STS theory proved to be useful to elaborate IS induced changes in the organizational context by taking interrelationships between social and technical system components into account [19]. The interactions between the social and technical systems are inherently recursive, that is "users shape the technology structure that shapes their use" [25]. The recursive use of technology in the organizational context results in "enacted structures of technology use" and "while users can and do use technologies as they were designed, they also can and do circumvent inscribed ways of using the technologies" [25]. Thus, knowledge about the alignment of socio-technical components is of critical importance, because information systems are continuously challenged by incremental and punctuated changes to one or more of its system components [19].

This view has general implications for the development of a tool to manage and govern an AaaS portfolio: Before successfully exploiting a technology innovation such as analytics, a multitude of organizational transformations is necessary (e.g., cultural and structural change). Thus, when designing tool to manage and govern an AaaS portfolio the "enacted structures of technology use" [25], which might result from the recursive interaction with analytics services, need to be taken into account. Therefore, to realize the potential advantage of AaaS, organizations need to analyze and understand how they can use and manage data analytics and require associated management instruments. Following the call of Abbasi et al. [15] for further research on data analytics and big data, we use "action design research (ADR) to guide the development and harnessing of big data IT artifacts [in a real-world] organizational [setting]" [15]. In particular, we focus on designing and implementing an instrument to manage the AaaS portfolio at the central analytics unit of a leading car manufacturer using the socio-technical systems theory as reference theory.

2.2 Portfolio Management

In the following, we relate our study to portfolio management, in general, and to project portfolio and service portfolio management, in particular, as these adjacent research fields inform our design of the portfolio management tool for AaaS. The original concept of portfolio management was coined by Markowitz [26]. Portfolio management in its original sense targeted the financial domain to decide on investments portfolios. Over the years, portfolio management was used to manage new product development [27], new service development [28], project management [29–31], and IT service management [32–34]. Extant literature on portfolio management [27, 29, 31] outlines several key objectives of portfolio management: maximization of value (i.e., value maximization of the portfolio against business objectives), balance of the portfolio (i.e., managing the risk of the portfolio), and strategic alignment (i.e., alignment of the portfolio with the overall strategy). Literature on project portfolio management further details these objectives into "(1) defining goals and objectives, i.e., clearly articulating what the portfolio is expected to achieve, (2) understanding, accepting, and making trade-offs, (3) identifying, eliminating, minimizing and diversifying risk, (4) monitoring portfolio performance, i.e., understanding the progress that portfolio is making towards the achievement of the goals and objectives, and (5) establishing confidence in achieving a desired objective" [30]. In targeting the systematic portfolio management of AaaS, we understand service portfolio management "as a dynamic decision-making process that is dedicated to the continuous, strategically aligned revision of service portfolios" [33]. Thereby, several portfolio management models can be distinguished, e.g., financial models, scoring models and checklists, mapping approaches, or mathematical optimization procedures [27]. To achieve this, the portfolio management is widely supported by a dedicated portfolio management tool [28, 30]. Accordingly, the ultimate goal of this research endeavor is the provision of a corresponding portfolio management tool for AaaS.

In summary, the literature provides valuable insights into project and portfolio management related to the definition of projects and of goals, minimization of goals as well as the confidence in these goals [30]. However, due to the socio-technical nature of analytics the realization of the potential business value from analytics, socio-technical configurations, amongst others related to a data-oriented practices, structures, technologies, and analytical processes need to be taken into account when pursuing analytics projects and developing a portfolio management tool for AaaS [7, 8]. For this reason, previous approaches are not applicable in this context without adapting or extending these approaches.

3 Research Approach

We conduct action design research (ADR) with the goal to obtain relevant results by means of a rigorous yet pragmatic approach due to its suitability for addressing practice-inspired research problems [35, 36]. By drawing on the existing body of knowledge and by guiding the artifact building and evaluation phases, ADR supports the development of prescriptive design knowledge. ADR aims at generating solutions that apply not only to a problem instance but to a class of problems [36]. We embedded the 3-year ADR project in a collaborative practice-oriented research initiative [37] and followed Sein et al.'s [36] methodological guidelines (e.g., practice-inspired research, theory-ingrained artifact, and reciprocal shaping) (see Figure 1).

At the outset, we founded a collaborative research initiative with *CarCo*, a leading innovative original equipment manufacturer in the automotive industry who was on the edge of launching an AaaS initiative. *CarCo* is a multinational car manufacturer who targets customers in the premium segment and is known for their technological advancement and produces around 2 million cars a year making a profit of around €4 billion and employing around 90000 people world-wide. Particularly, we collaborated with several members of the central analytics unit at *CarCo* (among others the Head of Data Strategy and Analytics), who represent the targeted users of our artifact - in our case the portfolio management tool. We discussed and evaluated preliminary results in the build phase of the ADR project with practitioner experts. Thereafter, the prototype was iteratively built, evaluated, and refined with the targeted users, i.e., the Head of Data Strategy and Analytics, and stakeholders, i.e., the Head of Analytics Services.

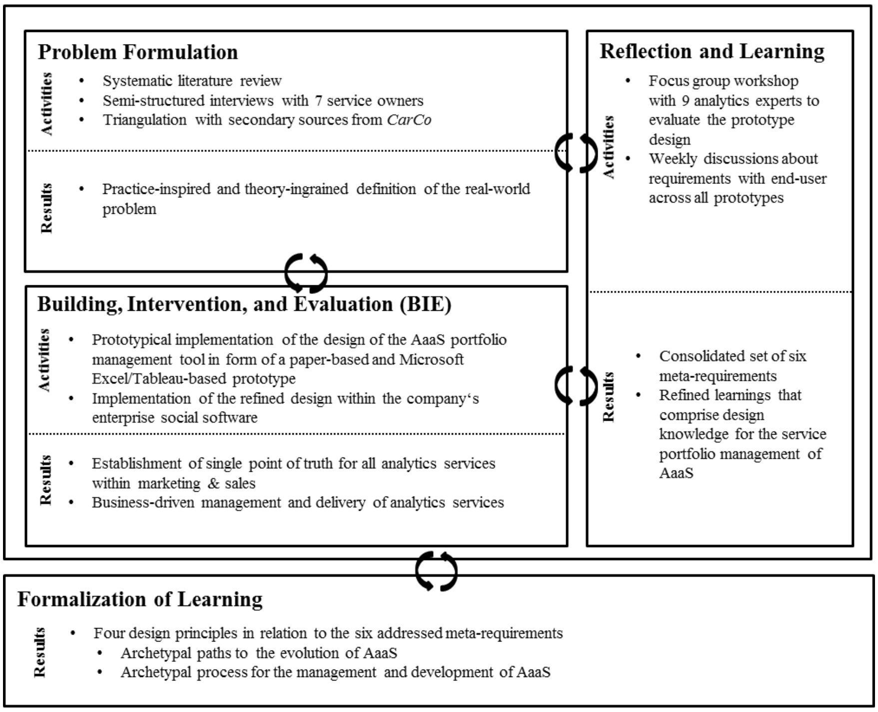

Figure 1. Overview of ADR stages with Key Activities and Results [36]

Following the ADR methodology and particularly Sein et al.'s [36] principle of 'guided emergence', meta-requirements (MR) emerged from the reflection on and learning from the problem formulation phase. In the subsequent building, intervention and evaluation phases, a solution design was iteratively refined in a three-cycle design process. The concurrent reflection on the design in our real-life application context resulted in learnings that comprise generalized design knowledge for the service portfolio management of AaaS to address not only a problem instance but also a class of problems [38]. Thus, we elicit MRs that apply to the problem class that the ADR project aims to address (i.e. AaaS portfolio management). To do so, we follow the two key principles of Sein et al. [36]: (1) practice-inspired research and (2) theory-ingrained artifact. To elicit MRs, we use triangulation and rely on rich data from both (1) a systematic literature review and (2) data obtained from a focus group workshop with domain experts, and multiple bilateral interviews with targeted end-users (i.e., Head of Data Analytics & Strategy). Finally, these learnings were formalized as generic design principles (DP) addressing the identified MRs to generate prescriptive design knowledge.

Problem Formulation. First, to identify potentially relevant related work, we conducted a literature search following the guidelines of Webster and Watson [39]. We were interested in identifying prior business analytics portfolio management approaches, following Sein et al.'s [36] principle of drawing on prior theory ("Principle 2: Theory-Ingrained Artifact"). We broadly searched the literature base for articles addressing the management of business analytics and analytics services. As keywords, we used the terms: "business intelligence" and "analytics" in combination with the more general terms "service" and "portfolio management" to query the databases "EBSCO Host Business Source Complete", "ProQuest", and "AIS library" resulting in 22 hits for "analytics" and 9 hits for "business intelligence".

We, initially, screened all articles in detail to sort out irrelevant articles. However, we were not able to identify reusable concepts for our phenomenon of interest (i.e., the management of an AaaS portfolio) in the current body of literature. As a consequence, we turned to more general theories on business analytics, its antecedents and contextual factors and portfolio management in general. In particular, we turned to IT service management [32–34], project portfolio management [29–31], and product portfolio management [27]. Since business analytics represents a socio-technical phenomenon that affects organizations in multiple dimensions (e.g., in regard to culture, organizational structures, work processes, capabilities, or, ultimately, business models) [1, 21, 23, 40] and to follow the principle of a "theory-ingrained artifact" [36], our research is informed by the socio-technical systems (STS) theory. In doing so, we are able to increase rigor within the problem formulation phase of our action design research project. Drawing on these foundations we conducted interviews with seven service owners, which were responsible for the management and development of seven analytics services within the AaaS initiative. We collected meta-requirements in the four STS-dimensions and used Atlas.ti for analyzing and coding interview notes. Third, secondary data that had been provided either by the interviewees or the manager in charge of the AaaS initiative further augmented our empirical data. As a result of data triangulation, we derived MRs and refined them in a focus group workshop with nine experts on business analytics to pursue the process of ex-ante evaluation of our prescriptive design knowledge [41]. These experts were a Performance and Improvement Manager as well as a Product Manager Business Intelligence from the agriculture industry, a Head of Digital Market Intelligence from market research industry, a Product Manager Business Intelligence & Data Science as well as a Chief

Executive Officer of an analytics advisory from retail industry, a Head of Digital Marketing from lightning industry, a Product Manager Data Management as well as a Product Manager Business Intelligence from the fast moving consumer goods industry, and a Professor for Digital Business. To do so, a paper-based prototype consisting of 15 data fields each corresponding to our initial set of MRs was explained to the participant of focus group workshop. In a next step, the participants gave formal feedback through a handout as well as informal feedback in case further explanations were needed.

Building, Intervention, and Evaluation (BIE). We performed an ex-post naturalistic evaluation drawing on interviews and observations as evaluation methods [41, 42]. To do so, the identified MRs were addressed in a first cycle by means of a prototypical paper-based implementation. We applied and refined at *CarCo's* analytics unit based on multiple user feedback cycles with the Head of Data Analytics & Strategy. In a second cycle a prototypical portfolio management tool was designed using Excel's functionality to not only store data but also to create user interfaces and manipulate data through its programming language Visual Basic for Applications and Tableau as visualization software to make the artifact tangible for the end-users (managers of the central analytics unit and the product management of the AaaS initiative) allowing the evaluation of its practical use [41]. Thus, after this initial implementation of the management tool, it was evaluated and validated with the Head of Analytics Services during a two-hour meeting and with the Program Manager for the AaaS initiative [36] during an additional two-hour meeting. This resulted in the consolidation of our initial set of 15 meta-requirements to 6 MRs for the following reasons. First, our initial set of MRs did consider the service instance on a fine granular level, which increased the effort to maintain the service portfolio. Second, due to the feedback of the focus group workshop rather redundant fields were eliminated (e.g., "business problem" as it was perceived as too detailed and too redundant to the existing field "business value"). Acknowledging the consolidated set of 6 MRs, the tool was finally in a third cycle integrated into *CarCo's* enterprise social software (ESS) as part of the AaaS Atlassian Confluence Space of the central analytics unit. During this implementation, we constantly evaluated in face-to-face meetings our artifact with the Head of Data Analytics & Strategy, the Head of Analytics Services, and, primarily, the product owner of the analytics-as-a-service initiative by ensuring the practical use and foremost feasibility to maintain and sustain the artifact after our action design research project.

Formalization of Learning. To provide prescriptive design knowledge we derived design principles through three additional interviews representing market participants (i.e., Head of Artificial Intelligence and Machine Learning at *VehicleCo*, Head of Data Analytics at Marketing and Sales at *VehicleCo*, Managing Consultant Development of Analytics Services at *PremCo*), as well as one interview with the program manager of the AaaS initiative drawing on our previous research steps. *VehicleCo* and *PremCo* can be seen as the most important competitors to *CarCo* targeting the same customer segment and producing cars in a similar engineering quality. As a result of analyzing this interview data and reflecting the project results, we were able to identify four design principles that reflect core characteristics of the proposed instrument for AaaS portfolio management. We acknowledged during these interviews that not only *CarCo* but also

VehicleCo and *PremCo* follow an archetypal path for the initial development of AaaS and sourcing decision. Moreover, in a similar fashion depending on their sophistication in regard to technology (i.e., technological readiness), analytical expertise and analytical capabilities (i.e., analytical readiness), and domain knowledge three archetypal paths dominated how analytics services are managed through their classes of services (i.e., descriptive, predictive, and prescriptive analytics services).

4 Results

4.1 Problem Design and Problem Solution

In the following, we elaborate on the six meta-requirements, which are based on our theoretical foundation (i.e., STS theory) and result from the reflection on the problem formulation phase (see Table 1):

Table 1. Overview of Identified Meta-Requirements

ID	Description	STS Domain
MR1	The service description must include a definition of the analytics service in order to achieve a common understanding of each service's functionality and outcome.	Task
MR2	The business value of each analytics service needs to be described.	Structure
MR3	The artifact should allow maintaining the feasibility and costs of the analytics service.	Structure
MR4	The artifact should allow to maintain the roll-out status and plan depending on the real-world context and the level of granularity.	Task
MR5	Service owners from both the business side as well as the analytics experts should be identified for each analytics service instance.	Actor
MR6	The description of each analytics service should include the analytical type (i.e., descriptive, predictive, and prescriptive) and the analytical method.	Technology

MR1. Following the need for a structured service description for service portfolio management [33] in general and in particular for analytics projects [7], we formulate MR1 based on our empirical findings as follows: "The service description must include a definition of the analytics service in order to achieve a common understanding of each service's functionality and outcome." Addressing MR1, the data fields service name, service definition, and comment are included to ensure a unified understanding of each service. The service definition describes the service functions in a business-oriented manner and thus refers to the task dimension of the socio-technical system.

MR2. To fulfill one of the main purposes of portfolio management (i.e., strategic alignment) [27, 30, 31, 33] – in our case to strategically align analytics services with the overall strategy - and grounded in our empirical insights, we introduce MR2: "The business value of each analytics service needs to be described". In addition, knowledge about the inherent value of analytics projects plays a crucial role to communicate service innovation possibilities [7, 8]. Addressing MR2, each generic service of the service portfolio is mapped to its corresponding value driver (i.e., business value) and business area (e.g., marketing & sales) enabling a prioritization of services. A strict value-orientation allows to govern analytics services in accordance with business strategy and thus affects the structure dimension of the socio-technical system.

MR3. To allocate a company's resources, align the portfolio with an organization's capacity, and to avoid losing sight of the costs [30, 31, 34] and drawing on our empirical evidences MR3 is theorized as "The artifact should allow maintaining the feasibility and costs of the analytics service." In particular, as analytics projects are evolutionary in nature the continuous control of costs is key for the management of AaaS. Addressing MR3, an initial estimate of the cost, as well as the complexity of the implementation of the analytics service, is provided by the management instrument. This supports communication and work flows in the governance dimension of the social-technical system. The ability to track and manage feasibility of the analytics service is particularly important for the end-user of this artifact as the provision of analytics services is charged to of internal business customers.

MR4. Due to the diverse customers of the AaaS initiatives (i.e., different target groups as part of CarCo or external, such as dealers and importers of CarCo) different granularity levels of services and their current status need to be taking into account [32–34]. In particular, CarCo's dealers and importers are distributed across the globe and do not form part of CarCo's organization. Therefore, they also might use services from external partner more easily. In result, the marketing of the analytics services based on the conducted implementation activities and the rollout status is highly important. Therefore, MR4 is phrased as "the artifact should allow to maintain the roll-out status and plan depending on the real-world context and the level of granularity." Answering to MR4, the rollout status of each service instance is documented within the service inventory table. The rollout status describes conducted implementation activities and thus relates to the task dimension in the socio-technical system.

MR5. To align business and IT, to assure a clear allocation of responsibilities, and to achieve confidence in the service [30, 32, 33] as well as due to the cross-disciplinary nature of analytics [4] MR5 is theorized as "Service owners from both the business side as well as the analytics experts should be identified for each analytics service instance." In response to MR5, each service instance has one service owner from the business department at the demand-side (i.e., a business owner) and one service owner stemming from the analytics experts at the provider-side (i.e., analytics owner). The specification of service owners relates to the actor dimension in the socio-technical system.

MR6. Allowing the prioritization and management of services depending on their current class of service [32, 33] MR6 is phrased as follows: "The description of each analytics service should include the analytical type (i.e., descriptive, predictive, and prescriptive) and the analytical method." Guided by MR6, each service is mapped to the analytics type (i.e., descriptive, predictive, and prescriptive) and the analytics model (e.g., decision-tree). These descriptions of the technological underpinnings relate to the technology dimension in the socio-technical system.

Instantiation of the Problem Solution. The artifact itself comprises a service portfolio management tool aiming at representing the single point of truth for all analytics services within marketing and sales. For instance, the AaaS offering includes a service to analyze depending on CarCo's data the demographic distribution of potential leads to increase the lead conversion as well as to potentially achieve up-selling – in the case of CarCo to transfer a customer from one car model to a superior car model. As such it follows a similar goal as project portfolio management. Namely, a centralized view of all projects – in our case analytics services - in an organization. Following Cooper et al. [27] the service portfolio management tool is a portfolio management tool to map current analytics services according to their strategic prioritization and to index analytics services according to their current status. As a result, analytics services are maintained by the analytics unit in the service portfolio management tool and a customer-orientated delivery of analytics services to internal business customers can be achieved.

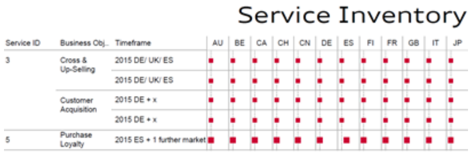

Figure 2. Extract of the Prototype (only non-confidential information visible)

The derived meta-requirements (see Table 1) are met through specific data fields, which are needed to describe an analytical service on a detailed level. Being initially implemented with a Tableau dashboard and an Excel spreadsheet using VBA for data entry (see Figure 2) the artifact was finally implemented within the space of the central analytics unit's enterprise social software (see Figure 3). In doing, so the final artifact was accessible for all relevant personnel, namely the product owners of each service. They were tasked with maintaining the key information of the artifact and were updated to any changes made regarding their services due the clear assignment through the field "responsible" leveraging the notification system of Atlassian Confluence.

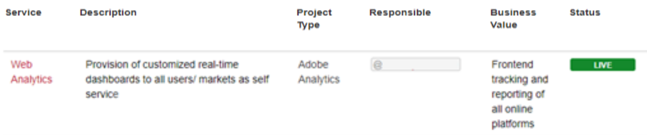

Figure 3. Extract Service Overview of the Live Version (only non-critical information visible)

4.2 Formalization of Learning

Contributing to the scientific body of knowledge on service portfolio management tools for AaaS, the design knowledge obtained within the ADR project is formalized in general design principles. These design principles represent learnings and generalized knowledge of the solution that was built within the course of the ADR project [36]. Table 2 provides an overview of the derived design principles and relates them to the addressed meta-requirements. They are further discussed in the following.

Table 2. Overview of Identified Design Principles [36]

ID	Design Principle	Addressed MRs	STS Domain
DP1	Maintain a taxonomy that guides the specification of business objectives of an AaaS offering in the portfolio management instrument.	MR1 MR2	Structure, Task
DP2	The demand-side business owner of an AaaS instance must be documented within the portfolio management instrument. Further, this business owner must be accepted by the supply-side.	MR3 MR5	Structure, Actors
DP3	For portfolio management to identify implementation status and to guarantee service quality, the portfolio management instrument must allow to assess how the implementation of each AaaS complies with a standardized archetypical development process.	MR3 MR4 MR6	Actor, Task
DP4	To ensure the successful implementation of AaaS, portfolio management instrument must allow the consideration of the trinity of technological readiness, analytical readiness, and business acumen.	MR3 MR5	Actor, Technology

DP1. The first design principle ensures sufficient visibility and budget for the development of AaaS offerings. Since in early project phases it is often non-trivial to define feasible and realistic business objectives, the maintaining of a taxonomy of AaaS business objectives and examples supports the specification of business objectives related to a planned or realized AaaS offering:

"You need the business case, you need the customer. Just to take data, to analyze it and to show the results is not enough. This approach often failed in the past because the business units just have no interest." Product Owner Analytics Services #1, CarCo, 2016

DP2. The second design principle targets a close collaboration of both the analytics experts (possibly part of business departments or IT department) and the requesting business units. A demand-side owner of the service instance should be specified for portfolio management. Further, this business owner should be accepted by the supply-side as a respected and qualified counterpart:

"The projects are always strong when a strong business unit is on board and that is something, we learn little by little in the projects. That means those topics that we started in a data-driven manner, and about which we had information only based on our available data, mostly did not make it far. But if we have someone from the demand-side, who is excited about the topic, and a business owner, who is familiar with the business problem, and combine this with analytical expertise, then it works." Head of Data Analytics & Strategy, CarCo, 2016

DP3. Relating to the third design principle**,** an archetypical process for the development of AaaS supports portfolio management in specifying implementation stage and in guaranteeing service quality: Triggered by a crisp and clear project idea in mind, the phase of exploration starts. Within this phase, the strategic relevance of the corresponding idea is assessed together with the internal feasibility (i.e., it is assessed if it can be implemented as AaaS internally). In this regard, an initial assessment of the technological readiness (i.e., data sourcing, access, integration, and delivery), the available or potential analytical expertise and analytical capabilities (i.e., analytical readiness) is conducted. If the project idea is assessed as strategically relevant and feasible, then, an internal implementation is pursued as far as possible. Non-strategic topics, however, are outsourced due to their minor business relevance. This principle highlights the critical importance of how well the business department understands the business value they want to achieve (i.e., business acumen and understanding).

"We particularly select the cases with a high strategic impact and a high complexity in regard to the analytical method necessary. In doing so, we encourage and challenge our employees to make sure we develop the best people" Head of Artificial Intelligence & Machine Learning, VehicleCo, 2017

DP4. When pursuing AaaS, an organization has to develop corresponding knowledge and capabilities. This includes: (1) data sourcing, access, integration, and delivery as well as connected data sources and continuous data streams (i.e., technological readiness), (2) analytical expertise and analytical capabilities (i.e., analytical readiness), and (3) domain knowledge to understand what is hidden behind the company's data (i.e., business understanding and acumen). Portfolio management must assess these capabilities since they determine implementation costs and the evolution paths of business analytics services. For instance, as *CarCo*, *VehicleCo*, and *PremCo* matured with respect to these three dimensions, three archetypical paths became evident in the empirical data. These pathways characterize how an analytics service can be further developed depending on an organization's maturity on technological readiness, analytical readiness, business acumen and understanding (due to page limitations these pathways are not illustrated in detail). For instance, to acknowledge these pathways the portfolio management tool references to and documents the underlying technological infrastructure (e.g., data source systems and streams) to consider the technological readiness. Further, the responsible data scientists and developers are documented to ensure the consideration of the analytical readiness. Finally, the business uses cases, their responsible employee, as well as a product owner from the analytics unit to consider aspects of business understanding form part of the portfolio management tool's data fields.

5 Conclusion

Although business analytics receives considerable attention in practitioner and academic literature, little research is providing empirical evidence on value realization and utilization so far [16]. Building upon the holistic enterprise perspective of the socio-technical systems theory, we report on the results of a 3-year ADR project, in the course of which we designed and implemented a database that supports the management of an AaaS portfolio. In this article, we illustrate our problem design and solution and present the accumulated knowledge, which results from the formalization of learnings. There are three key limitations in the light of which our research results have to be interpreted. First, our research was conducted in form of a collaborative research initiative. Since ADR projects may suffer from a bias related to the subjectivity of the involved researchers, we included researchers from outside of the project in our team and involved multiple researchers in the coding of our qualitative data. Second, since this

ADR project was exclusively conducted at a single company, our results may suffer from limited generalizability. To ensure that our proposed solution applies to a class of problems (and not only to the specific problem instance at CarCo), we involved external experts in multiple phases of the research project (e.g., focus group workshop with 9 analytics experts and three additional interviews with *VehicleCo* and *PremCo*). Third, guided by the extant body of knowledge as well as the project-based approach of *CarCo* to the management of AaaS our results bear similarities to the existing body of knowledge (e.g., requirement of a detailed service description). With our meta-requirements and design principles for the design of a service portfolio management tool for AaaS, we contribute a nascent design theory [43] to the emerging literature on AaaS [44, 45]. In particular, we address a lack of research on instruments and practices for the management of business analytics to realize the business value [11, 13]. Given the important role of portfolio management for the development of successful service offerings [9, 10], we develop a prescriptive instrument for the management of AaaS portfolios informed by STS theory. Ignoring the socio-technical complexity of implementing analytics services is a main reason for project failures [5, 6], our holistic approach covers all components of a socio-technical system. Particularly, the meta-requirements focus on the individual STS components (see Table 2). The design principles target the alignment and interrelationship of individual STS components (see Table 3). For example, conjunctively nominating demand-side business owners (DP2) leads to an alignment of governance instruments (i.e., the structure component) and involved actors. Similarly, assessing the technological readiness leads to an alignment of the actor's technology capabilities (i.e., the actor component) with the applied analytical instruments (i.e., the technology component). The results of our ADR projects reinforce the importance of coordinating the different socio-technical components in business analytics initiatives. Our contribution to practice lies in providing actionable guidance on how to implement a database that supports the management of an AaaS portfolio.

Characterizing Approaches to Digital Transformation: Development of a Taxonomy of Digital Units

Christoph Fuchs[1], Philipp Barthel[1], Ina Herberg[1], Matthias Berger[1], and Thomas Hess[1]

Abstract. Confronted with the imperatives of an increasingly digital world, organizations are challenged to maintain the exploitation of existing revenue sources while simultaneously exploring novel paths for a digital future. One option to manage this organizational ambidexterity and to foster innovation activities within the companies is to implement digital units. However, although the introduction of digital units has increasingly become common practice for organizations, a high uncertainty about the nature of such units remains. Therefore, we develop a taxonomy to characterize digital units by building on pertinent literature in the fields of digital transformation, organizational ambidexterity, and organizational design. In combination with employing a qualitative-empirical research approach, we contribute to existing literature by offering an initial characterization of digital units and a first empirical application of our taxonomy. We also provide descriptive findings on digital units in practice and offer insights for companies that consider to implement such specific units.

Keywords: Digital Transformation, Digital Units, Organizational Ambidexterity, Taxonomy Development, Qualitative Case Studies.

1 Introduction

Emerging advancements in information technology (IT) continuously facilitate the development of new digital products, services, and business models [1], [2]. Digital technologies impact markets by increasing their transparency, thus resulting in lowered markets' entry barriers and enhanced competition [3]. Consequently, in such a *digital world*, so far successful business models are threatened to be disrupted by new market entrants, forcing incumbent companies to rethink how business value is created [3], [4].

To remain competitive in such a volatile business environment, companies are urged to continuously renew themselves. Besides other aspects, a constant organizational progress includes the adoption of new technological achievements for the development of digital innovations [5-7]. Thereby, a digital innovation can be understood "as the creation of (and consequent change in) market offerings, business processes, or models that result from the use of digital technology" [8, p. 224]. To enable innovation activities and explore paths for a digital future (e.g., trends such as agile methods [7]),

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

companies increasingly create specific units, so-called *digital units* [9]. Digital units enable companies to realize organizational ambidexterity. While core organizations focus on operating the traditional business and leveraging existing revenue sources (i.e., *exploitation*), digital units focus on innovation and exploration activities in their search for new revenue sources (i.e., *exploration*). Consequently, digital units represent one vital option for managing companies' digital transformation [5], [9].

Existing scientific literature sparsely touched the specific topic of digital units, but addressed essential aspects of the research field. For instance, literature investigates the influence of digital technologies on the nature of innovations and the innovation process itself [2], [8]. Digital units can also be part of digital transformation strategies (DTSs) that aim to govern the digital transformation of companies from a strategic perspective [10], [11]. Additionally, research addresses the question whether companies need to establish the specific role of a Chief Digital Officer (CDO) [12], [13]. However, current literature lacks research on how to engage and anchor the digital transformation in organizations – besides the introduction of a single management position such as the CDO. With digital units representing one option to structurally embed the digital transformation within companies, the emerging organizational designs appear to be an interesting and current research topic from a scientific as well as practical perspective.

A related research field where the necessity for ambidextrous approaches is already addressed is literature on the restructuration of companies' IT functions. Such *bimodal IT organizations* typically encompass a *traditional IT function*, which is responsible for the operation of companies' core IT systems, and a *digital* or a*gile IT function*, which focuses on digital innovation activities [14], [15]. Whereas Horlach et al. [14] clarify the concept of bimodal IT, Jöhnk et al. [15] develop a taxonomy for agile IT design options. Although this research is akin to the approach of implementing digital units, the topic of bimodal IT and agile IT setups has a distinct perspective focusing on the organizational IT function. However, such an IT-focused lens may miss out on some of the diverse forms of digital units realized in practice (e.g., innovation labs, incubators) [9], [16]. In contrast to this focus on the IT function and the related IT ambidexterity, we aim to employ a broader lens that captures the digital innovation activities in light of the entire company and considers approaches to realize organizational ambidexterity.

Although scientific literature discusses important aspects of the fields of digital transformation and bimodal IT, empirical research focusing on the specific issue of digital units and their establishment in companies is still sparse. Therefore, we aim to contribute by developing an initial understanding of what digital units are and how they can be characterized. It appears fruitful to start with a descriptive approach and build initial knowledge in a novel research field [15]. Consequently, we can provide a theoretical basis for future research that examines digital units through an explanatory lens. We derive as a guiding research question: *How can digital units be characterized?*

To answer this question, we aim to develop a taxonomy of digital units. This taxonomy shall reflect pertinent organizational design options of digital units as they are realized in practice. The taxonomy's frame is initially derived from literature by deducing relevant categories. These are then revised and broken down into dimensions and corresponding characteristics based on observations of real-world digital units. To examine these units, we employ a qualitative approach by compiling five case studies.

2 Underlying Research Foundations

2.1 Impact of the Digital Transformation

Specific environments require specific *organizational designs*, for example in times of rapid technological change [17]. The implications of an ongoing digital transformation for markets and companies (e.g., products, business models, operations) reach beyond resource digitization and process automation by means of IT [1], [5]. Consequently, the digital transformation resembles an *IT-enabled organizational business transformation* [18], [19] that can be interpreted as a specific environment which necessitates a unique organizational design such as the implementation of digital units.

It may also be of interest to examine whether the implementation of a digital unit in an organization is part of a holistic DTS [11]. This refers to the origin of digital units and represents a specification whether the units' implementation results from a top-down plan or emerges bottom-up from individual initiatives [20].

2.2 Digital Transformation and Organizational Ambidexterity

Organizational ambidexterity describes the ability of companies to be successful in competing in mature markets while at the same time exploring new markets with flexibility and experimentation [21], [22]. These challenges of ambidexterity can also be transferred to the digital transformation context. Companies need to, for instance, invest in the development of innovative digital business models (i.e., exploration), while at the same time operating their (mostly) non-digital core business (i.e., exploitation) [23]. A prominent approach to achieve organizational ambidexterity is the alteration of the companies' *organizational design* by means of creating separate units for exploration and exploitation [24]. These units are not only structurally separated, but also differ with regard to, for instance, competencies and processes [22], [24]. Exploratory units, such as digital units, typically show higher degrees of freedom and autonomy from the core organization and allow companies to escape the inertia of existing business operations and organizational structures [24], [25]. Accordingly, the creation of separate units in the context of the digital transformation can be observed in practice and sparks organizational units such as innovation labs and incubators [12].

2.3 Understanding the Organizational Design of Digital Units

To examine how digital units can be characterized, we consider design parameters that determine organizational units. As a result, we assume that organizational units require 1) an *objective*, 2) *resources*, and 3) a *structure* to exist within companies [26], [27]. The objective describes the purpose for which the units are created and represents the central determinant for the overall design. This is especially true for units that are designed for a specific purpose, such as in the case of digital units [27]. Subsequently, units require resources to be capable of operating. Besides the financial resources, organizational units also need access to human resources, since the personnel's skills, knowledge and experience are a critical determinant of the effectiveness of units [26], [28]. Additionally, there is also a need for structure, both in the internal (inside the organization) and external (outside the company) function of organizational units [28].

2.4 Practical Approaches to Digital Units

Practitioners have made initial efforts to characterize digital units. For instance, the consulting company etventure offers a differentiation into four types: innovation labs, company builders, incubators, and digital units [16]. The main differences are whether the innovation activities happen within (e.g., innovation lab) or outside of the core organization (e.g., incubator). A similar categorization is offered by Ramus and Velten [29] referring to innovation labs, company builders, accelerators, and incubators. There also exist more fine-grained categorizations that use several layers to define various types of digital units. For instance, Sindemann and von Buttlar [9] separate between digital innovation units (e.g., innovation labs, accelerators) and special forms (e.g., customer co-creation labs, digital venture capitalists). Although these contributions by practitioners are relevant, the proposed characterizations are neither consistent nor theoretically sound. Therefore, we explore the characterization of digital units on a general level without specifying types and thus refer to the general term of *digital units*.

2.5 Initial Grasp of Digital Units

To summarize, the specific organizational design of exploratory units, here digital units, represents one approach to address the digital transformation of companies. Based on the discussed research foundations, we derive an initial understanding of such digital units that guides our study and our qualitative-empirical research approach. Consequently, we comprehend digital units as organizational units that 1) primarily focus on *innovation* and *exploration activities* to pave the companies' paths for a digital future, 2) have *secured access* to financial as well as personnel resources, and 3) possess high degrees of freedom within the respective companies to operate *autonomously*.

3 Research Method

3.1 Taxonomy Development Approach

We develop a taxonomy for the characterization of digital units, because this research approach enables us to offer initial theoretical and empirical insights in an area that is currently predominantly shaped by consulting articles (e.g., [9], [29]).

In our approach, we followed the taxonomy development method proposed by Nickerson et al. [30]. In a first step, it is essential to determine the meta-characteristic of the taxonomy which should "reflect the purpose of the taxonomy" [30, p. 343]. Consequently, reflecting our research question, we defined as our meta-characteristic: *Characteristics of digital units*. Additionally, we assumed that *dimensions* exist that contain a spectrum of coherent characteristics. With the taxonomy development approach being of iterative nature, it is crucial to define *ending conditions* – distinguished into *objective* and *subjective* – that determine a stop to the iteration cycles. We defined the following objective ending conditions: a) No new characteristics were added in the last iteration, b) no characteristics were merged or split in the last iteration, and c) every characteristic is unique and not repeated. In accordance with prior research [15], we did not follow the objective ending condition that characteristics need to be mutually exclusive. Otherwise, combinations of characteristics would need to be included by means of individual characteristics what contradicts the prerequisite of taxonomies to be comprehensive and parsimonious [30]. Therefore, we allowed for combinations of characteristics within one dimension to portray the nature of digital units. Regarding the subjective ending conditions we built on the suggested conditions of Nickerson et al. [30] (i.e., taxonomy is concise, robust, comprehensive, extendible, and explanatory) and formulated a holistic subjective ending condition. This end was represented by the point where all observed real-world cases could be classified in the taxonomy and where we did not have to implement further alteration in the taxonomy.

Since little data about the phenomenon is available, we followed the recommendation of Nickerson et al. [30] and began with a *conceptual-to-empirical* iteration. Here, we reviewed general literature on organizational ambidexterity (e.g., [22], [23], [25]) and organizational design (e.g., [17], [28]), as well as specific articles on digital transformation (e.g., [11]), and practical contributions on digital units (e.g., [9], [29]) to define a frame for the taxonomy. We searched the literature for elements commonly considered as relevant for characterizing organizational designs in general (e.g., objective of organizational units) and digital units in specific (e.g., possible origin from DTSs). Next, we clustered these elements according to their *thematic fit*, resulting in superordinate *categories*. These categories were then extended and refined in the subsequent *empirical-to-conceptual* iteration by identifying coherent dimensions and corresponding characteristics of digital units.

3.2 Case Study Research Approach

For this second, *empirical-to-conceptual*, iteration, we selected an explorative, qualitative-empirical research approach by conducting five case studies on organizations that implemented digital units. Case studies are especially suitable for recent phenomena that should be studied within their real-life context such as the phenomenon of digital units [31]. To increase the study's robustness and enable cross-case analysis, a multiple-case design was selected [31]. We followed a theoretical replication logic to generate contrasting results by choosing diverse cases, thereby enhancing the external validity of the study [31]. Our case selection process was primarily guided by our initial understanding of digital units (see 2.5). We employed a criterion sampling logic and searched for companies that implemented digital units as part of their organizational digital transformation. Additionally, we looked for organizations where the operations of the digital units reached beyond their conceptualization [31]. We identified the manufacturing industry as especially relevant. Respective companies are usually slow to react to the implications of the digital transformation since the mostly non-digital business models are not yet threatened [32].

Our sample consists of five cases that stem from the manufacturing industry, but have distinct areas of operations. Although all companies have a business-to-business focus, they differ in size, experience with and approaches to the digital transformation and their digital units. An overview is shown in Table 1.

Our data collection took place January 2018 – March 2018. We conducted between one and three semi-structured interviews per case. For each case, we aimed to capture the insights of a position responsible for the digital unit (e.g., CDO, head of digital unit) and (if possible) one permanent employee (PE) of the unit. Interviews ranged 45 – 60 minutes and were conducted face-to-face or via telephone. The interviews followed a guide with open-ended questions comprising sections about the digital transformation of the companies, the implementation history of the digital units, and the units' work processes. All interviews were recorded and transcribed verbatim [33]. We triangulated our primary data by secondary data (e.g., firm websites, press releases) to increase the validity of the study [33]. ATLAS.ti was utilized to pool and analyze our gathered data.

Considering the data analysis approach, we followed a two-step approach. First, two researchers independently evaluated the interviews and jointly condensed the collected data to cases. Secondly, we analyzed the cases in terms of the taxonomy development. Hereby, we followed a descriptive coding approach with codes deduced from the categories (i.e., result of the conceptual-to-empirical iteration). During this second step, codes for the derivation of dimensions and characteristics were inductively added. This step was performed by three researchers independently, whereas significant differences in code application were discussed collectively and resolved consensually [33].

Finally, the resulting taxonomy was employed to classify the digital units of the five case studies. To consistently match statements from our data to the dimensions and characteristics, we defined coding guidelines which we refined in the coding process. All classifications were again carried out by three researchers independently, whereas varying assessments of the units' characteristics were discussed and resolved collectively. To complement this empirical-to-conceptual iteration, we reached out to our interview partners and presented them the results of our taxonomy development and the characterization of their digital unit. The subsequent discussions only sparked minor alterations in terms of, for instance, wording of dimensions or characteristics.

Table 1. Overview of the sample

	Case A	**Case B**	**Case C**	**Case D**	**Case E**
Focus within Manufacturing Industry	Steel Processing	Machines for Food Industry	Specialty Chemicals	Investment Holding	Tools
Revenue (2017)	≈ 41 bn. €	≈ 3.7 bn. €	≈ 14 bn. €	≈ 3.6 bn. €	≈ 1 bn. €
Employees (2017)	≈ 160,000	≈ 15,000	≈ 36,500	≈ 17,700	≈ 3,000
Foundation Year DU*	2016	2016	2017	2016	2017
Employees DU*	3	≈ 8	30	8	≈ 20
Number/Dates of Interviews	2/01.2018	1/02.2018	2/01.2018	2/03.2018	3/01.2018
Interviewees by Position *DU is short for Digital Unit	· Head of DU · Project Member (Core Org.)	· Head of DU	· CEO of DU · PE	· Project Lead · PE	· Head of DU · Project Lead · PE

4 First Iteration Cycle: Foundation for the Taxonomy

Reflecting the conceptual-to-empirical iteration cycle, we derived an initial set of categories as foundation for our taxonomy. In this section, we discuss the identified categories against their literature background and in light of digital units.

Objective & Scope. As we are concerned with exploratory units, we set a special focus on the digital units' scope in the innovation process [34]. In addition, the orientation of the units' innovation activities – whether they are directed to external markets or to internal organizational improvements – needs to be specified. Owing to the specificity of the digital transformation, organizations with primarily externally directed digital units may also face the decision whether the focus of innovation activities lies on exploring solutions for existing business areas, discovering new markets, or a combination of these two alternatives [4], [5]. Besides innovation activities, there can be further objectives such as the renewal and expansion of existing core competences and the exploration of current management trends [7].

Staffing & Collaboration. Staffing of digital units and respective projects is expected to be critical. Deploying employees from the core organization may provide company-specific knowledge and an intra-organizational social network, which can be valuable for integrative activities. Delegated employees of the core organization can also acquire novel digital capabilities and transfer them back to the organization. However, often, not all knowledge and capabilities required for exploratory activities can be found within the company. Therefore, external collaborations may be important and a combination of internal and external personnel appears fruitful [24], [25], [35].

Funding. As digital units' projects affect companies as a whole, a logical choice is to offer central funding from the core organization. Digital units would then be cost centers like other support functions, whereas the units' budget is regularly reviewed and the units' heads have to justify spending [25]. A decentralized alternative would be to make different departments provide a share of their budget to the digital units. A third option is that if the units' projects include the commercialization of innovations and thus generate external revenues, it is possible to set them up as profit centers [24].

Governance & Structure. The concept of organizational ambidexterity builds on the assumption that exploratory and exploitative units should be separated to be successful [25], [35]. Both objectives can thus be pursued simultaneously in appropriate settings spanning distinct management concepts, organizational structures and even organizational cultures [23]. However, the approaches to achieve this separation and the degrees of freedom the exploratory units have can vary. Therefore, diverse modes for structurally embedding digital units are possible, ranging from their integration in the core organization to spinning them out as separate legal entities [24], [35]. Exploratory units can also be dissolved or re-integrated after a certain time-span [23]. Besides an organizational separation of units, the physical separation of exploratory units (e.g., distinct location from the core organization) has been considered as a relevant measure to shield innovation activities from the constraints and routines of the core organizations [36]. Additionally, the degrees of freedom of digital units are majorly related to the decision-making power of the digital units' management teams (e.g., power over project topics, applied management concepts, or resource use) [25].

Origins. DTSs are supposed to coordinate, prioritize, implement, and govern a company's digital transformation. Next to the changes in value creation, use of technology, and financial aspects, one important element of DTSs is the aspect of structural changes within the organizations. These changes can, for instance, comprise the implementation of a digital unit. Therefore, we consider companies' DTSs as prevalent origins of digital units, reflecting top-down decisions. Digital units can also emerge from bottom-up initiatives that are later incorporated into a DTS [10], [11].

5 Second Iteration Cycle: Refinement and Application of the Taxonomy

In the following, we present the results of the empirical-to-conceptual iteration cycle and thus the developed taxonomy (see Table 2) as well as its application on our cases. This includes the individual description of all five cases as well as a cross-case analysis.

Table 2. Taxonomy of digital unit's characterization

Category	Dimension	Characteristic				
Objective & Scope	Main Objectives	Digital Innovation	Cultural Change	Development of Digital Expertise		
	Innovation Orientation	Purely Internal	Primarily Internal	Balanced	Primarily External	Purely External
	Market Focus of Innovation	Existing Business Areas	Novel Business Areas

Origins	Origin from DTS	Yes	No			
	Formation	Top-Down	Bottom-Up			

Case A. The digital unit of case A focuses on the development and implementation of digital, digitally enriched and non-digital innovations to explore novel business areas. The unit also aims at accelerating the core organization's cultural change and at building up and transferring digital expertise to the rest of the company. However, no specific activities are undertaken to achieve these additional goals. The projects of the digital unit are initialized and funded by the core organization's higher-level managers. Due to this sponsorship model, the digital unit's degrees of freedom are limited, for instance, the unit does not decide on its project portfolio. Instead, only projects that are sponsored by the core organization's managers are undertaken. Every six months, the sponsors decide on the follow-up financing of projects based on their market chances. The projects of the digital unit are carried out by employees of the core organization who work part-time in the unit's projects. Thereby, the project teams are guided by the digital unit's managing team. The work on the innovation projects takes place in the premises of the core organization and in the co-working space of the digital unit, which is located offsite. The digital unit of case A is not a separate entity, but is a virtual organization[1] located within the company's internal training unit. Consequently, every six months, the continuation of the digital unit's program depends on the availability of core organization managers who are willing to fund projects. The idea to establish a digital unit was launched bottom-up by two members of the core organization and the decision to implement the digital unit was not taken by the executive management.

Case B. The innovation activities of case B's digital unit are limited to the early stages of the innovation development process (i.e., idea generation, selection and prototype development) and focus on existing business fields and the customer side. Additional objectives of the unit include the acceleration of the core organization's cultural change and the acquisition as well as transfer of digital expertise to the core organization. While the former is pursued by conducting workshops, the latter is not pursued by any dedicated activities. Projects to develop innovations are carried out by PEs of the digital unit and employees of the core organization, which are involved part-time in the unit's projects. A central committee consisting of members of the core organization decides on the undertaken projects in the unit. The digital unit is not provided with a budget to carry out projects independently, but instead only approved projects (by the committee) are funded centrally. From an organizational point of view, the digital unit of case B is embedded in the core organization's research and development department, but is physically located offsite in an entrepreneurship center together with other companies. The decision to set up a digital unit was taken at a strategy conference by the organization's board of directors.

Case C. The digital unit of firm C engages in a variety of innovation activities. Among these are the development and implementation of novel digital products and services for new markets, the ideation and testing of corresponding new business models, the leveraging of existing business fields by enriching the respective products and services digitally, the acquisition of pertinent start-ups, as well as the investment in digital pioneers. With its work, especially with projects that take place in cooperation with employees of the core organization, the digital unit aims to transfer digital expertise to the core organization. The acceleration of the core organization's cultural change is excluded from the digital unit's objectives, since it is considered as a task of the digital unit's Chief Executive Officer (CEO) in his role as the core organization's CDO. The unit, which is established as a Limited Liability Company (LLC), is provided with an overall budget from central funds, but also has a profit responsibility and thus generates revenue that it can reinvest in its own projects. The digital unit manages its

[1] In this case, it is an intra-organizational virtual organization that arises due to the task-oriented networking of employees of different business departments.

own project portfolio. Additionally, the unit has co-working spaces in the vicinity of the corporate headquarters and near a branch in China. The digital unit was founded to help the realization of the previously devised DTS of company C. Establishing the digital unit in its existing form was a top-down decision by the executive management.

Case D. Company D's digital unit aims to improve internal business operations, advance existing business fields, and explore new markets. Its primary focus thereby is on the development and implementation of new business models. By involving employees of the core organization in the unit's work, the digital unit aims to accelerate the cultural change of and transfer digital expertise to the core organization. In the course of an innovation's development, the responsibility for it is gradually transferred from the unit to the respective business area in the core organization. Consequently, the projects are staffed with members of the digital unit (e.g., project leads), employees of the core organization (part-time), and external partners. The latter serve the purpose of relieving the digital unit's employees of their work and thus enable several parallel projects within the unit. Additionally, the external partners contribute required skills that are not available in the company. Projects are selected by managers of the core organization and digital unit members jointly. With company D being an investment holding, its digital unit is funded like a business department whereas the core organization provides the financial resources for each project. The work space of the digital unit is designed as a co-working space and is located offsite. The digital unit of company D is an LLC. The board of directors initiated the digital unit at the same time as the organization's DTS has been developed and the unit was integrated into the DTS.

Case E. Company E's digital unit aims to develop novel digital products and services, enrich existing offerings digitally, and establish new digital business models that are related to the organization's core business. Besides this customer centric focus, further activities target internal process improvements. Affecting the company's cultural change and fostering know-how transfer are defined as additional objectives and the digital unit's employees pursue these goals with dedicated activities such as conducting workshops and trainings. The unit engages in the entire innovation process from idea generation to go-to-market strategies and thus is also responsible for the operation of new digital products and services. As a separate unit with responsibilities for its developed products and services, the digital unit operates on a revenue-based model where the core organization provides fixed budgets and treats the digital unit as a profit center. The projects are mostly staffed with PEs of the digital unit and only a small portion of core organization employees. External support is mostly included for missing skills in the project teams. The digital unit of case E is located at the company's headquarter. The unit acts with relatively high degrees of freedom since it determines the products to develop as well as the corresponding development plans autonomously. The decision to establish the digital unit was part of the organization's DTS.

Cross-case Analysis. By comparing our cases, it can be seen that the primary *objective* of all five digital units is the development of digital innovations. Here, the cases vary accordingly whether these innovations are solely externally directed at the targeted markets (i.e., cases A-C) or include the improvement of internal business operations (i.e., cases D and E). The market focus of the case companies differs. Whereas company A solely aims at innovations in novel business fields and organizations B and E focus on their existing business fields, the companies C and D emphasize innovation activities in both business areas. Almost all observed companies aim to employ their digital units as vehicle to accelerate the organizational cultural change and to foster digital expertise in the core organization. Only company C excludes the cultural change as topic for the digital unit, however, this goal is addressed in the core organization by the CDO. While companies B and E use workshops to foster organizational change, all companies rely on interdisciplinary projects with PEs of the digital unit and members of the core organization to transfer knowledge and digital expertise. In the cases A, B, and D the respective digital units gradually hand over the responsibility of the digital innovations to the core organization and do not participate in the actual operation of the products and services. Only in the case of company E, the digital unit takes responsibility in the commercialization of innovations by developing respective strategies and operating products and services. Owing to its diverse activities, the digital unit of company C also covers the commercialization step of the innovation process by means of acquiring and integrating start-ups and the respective products in the portfolio of the organization.

For *staffing and collaboration* of the digital units' projects, all case companies rely on interdisciplinary project teams consisting of PEs of the digital unit, the core organization, and external partners. Owing to the sponsorship model in case A, the projects are performed by core organization members but guided by the digital unit.

This *funding* model of company A is unique, since most digital units' projects are centrally funded by their companies (i.e., cases B, C, E). Owing to the nature of company D as an investment holding, the implementation of the digital unit as a business department enables agency within the diverse structures of the company.

Considering the *governance and structures* of the digital units, all digital units with the exception of the ones of company A and E are exclusively located outside the organizations' headquarters and are designed as co-working spaces. Owing to six-months funding cycles of case A's digital unit, it has to be interpreted as the only non-permanent option. Besides the virtual organization of the digital unit at company A, we found diverse structural embedding of digital units across the cases. Whereas the digital unit of organization B is integrated in the research and development department, the units of companies C and D represent separate legal entities manifested in their status as LLCs. The digital unit at company E is also a separate department, however still legally integrated in the core organization. Albeit these diverse structural embedding options, we cannot derive a direct link between the structures and the degrees of freedom that the units possess. For instance, the integrated digital unit at company B does not possess significantly less autonomy than the two LLCs. Since both digital units at company C and E operate as profit centers and generate own revenues by means of the commercialization of their innovations, these units enjoy higher degrees of freedom, for instance by independently deciding on their project portfolios.

In four of five cases the digital units are part of a *DTS* and were installed on basis of a *top-down decision*. Only the digital unit of company A is not part of the company's DTS. Although other companies (i.e., case D) integrated the already existing digital units in their DTS, the digital unit of case A still lacks a board-level decision which also reflects its bottom-up nature. An overview of our findings can be seen in Table 3.

Table 3. Overview of the cross-case analysis

6 Implications, Limitations, and Future Research

We contribute to literature by providing a theoretically sound and empirically derived taxonomy for the characterization of digital units. Referring to our research question – *How can digital units be characterized?* – we initially characterized digital units as organizational units that 1) primarily focus on *innovation* and *exploration activities*, 2) have *secured access* to financial and personnel resources, and 3) possess high degrees of freedom within the respective companies to operate *autonomously* (see 2.5).

Referring to characteristic 1), we found that digital units can also have the purpose to support the cultural change of the core organizations and to build up and transfer digital expertise. However, their main focus is on developing and implementing digital innovations for customer markets. These activities can aim to expand existing business fields or explore novel business areas. In light of characteristic 2), all but one observed digital unit (i.e., case A) have secured financial funding for their projects and a stable embedding in the structures of the core organizations. We found that the digital units' projects are typically interdisciplinary staffed with members from the unit and from the core organization. The importance of external partners varied widely across the cases, allowing no general statement. Considering characteristic 3), we found empirical evidence that puts the originally derived high degrees of freedom into perspective. Although most observed digital units were located offsite, only two units (i.e., cases C and E) can, for instance, autonomously direct their project portfolios, whereas the projects of the remaining digital units are either entirely determined by (i.e., cases A and B) or jointly with the core organizations (i.e., case C). This can be attributed to the observation that almost all digital units result from top-down decision and are integrated in organization-wide DTSs. Therefore, it is appropriate to state that digital units operate autonomously *within* the organizational scope that is given by the companies.

Consequently, we define digital units as organizational units with the goal to foster the organizational digital transformation by 1) performing innovation and exploration activities in existing and/or novel business areas. Digital units 2) possess a structured organizational embedding and a secured access to financial resources, 3) conduct projects together with the core organization, 4) act autonomously within the given scope, and 5) are part of company-wide strategies addressing the digital transformation.

Considering practical implications, on basis of our taxonomy, managers can observe the possible design options for establishing digital units within their organizations. Our data shows that there are diverse setups enacted in practice and we could not identify an overall best practice to establish a digital unit. Instead, responsible managers need to purposefully evaluate their companies' specific requirements and implement digital units accordingly. Thereby, it is important to note that our derived dimensions and thus the respective characteristics are not entirely independent from each other. For instance, an interdisciplinary staffing with members of the digital unit, core organization's members and external partners can foster the development and transfer of digital expertise. Additionally, the selected funding option of the digital unit's projects has implications for its degrees of freedom. A sponsorship model, for instance, limits the opportunity for the digital unit to manage its own project portfolio. However, the implementation of a digital unit as a profit center seems only expedient if the unit can, for instance, decide on undertaken projects and has the opportunity to commercialize its innovations. Also, central funding can lead to conflicts between executive management's rather short-term goals to the digital unit's mid- to long-run profitability.

Our findings are not without limitations. Although we followed the guidelines for the development of a taxonomy rigorously [30] and refined our insights on basis of qualitative data, we cannot guarantee that we captured all categories, dimensions, and characteristics to define digital units. In addition, our empirical findings are derived from large companies located in the manufacturing industry with a business-to-business focus, thus limiting the overall generalizability of our results. Therefore, capturing small and medium-sized companies as well as organizations from different industries and with diverse business focuses may spark further insights for the taxonomy. However, as demanded by literature [30], our taxonomy is extendible in regard to further categories, dimensions, and characteristics. Additionally, although we refer to possible connections of various dimensions and respective characteristics, we do not thoroughly investigate the relationships between certain dimensions and characteristics. Therefore, this appears as a fruitful approach for future empirical research on digital units' characterization. Also, in contrast to existing consulting articles (e.g., [9], [29]), we do not derive archetypes of digital units that follow a specific categorization in terms of our developed taxonomy. The development of such a typology requires additional empirical data applied on our taxonomy. Such archetypes of digital units may also potentially be used as blueprints for establishing digital units.

Expectations vs. Reality – Benefits of Smart Services in the Field of Tension between Industry and Science

Simon Hagen[1] and Oliver Thomas[1]

[1] University of Osnabrueck, Chair of Information Management and Information Systems
Katharinenstr. 3, 49074 Osnabrueck, Germany
{simon.hagen,oliver.thomas}@uni-osnabrueck.de

Abstract. The term "Smart Service" gains increased interest in science and practice since it promises to significantly improve a company's value offering. However, its publicity might lead to overdrawn expectations, especially between practitioners and scientists working in this field. Therefore, we conduct a mixed-method study comparing the expected benefits of Smart Services in science and industry to help identify and close occurring gaps. The study consists of a literature review for the scientific point of view and a survey among practitioners to capture the benefits of Smart Services in both groups. The results predominantly reveal the same vision of both groups for Smart Services, but indicate slight but fundamental differences.

Keywords: Smart Service, Benefits, Literature Review, Survey, Industry

1 Introduction

Increasing digitalization of products and services resulted in "today's service world" [1] and the advent of Smart Services [2], which promise to significantly improve a company's service offerings and enable customized service features for customers through information and communication technology (ICT) [1]. Smart Services "raised high expectations on their potentials" [3] and are widely used to describe a company's innovativeness. In contrast, the research domain of Smart Services is still in its initial phase and after first strategies for its exploration were proposed [e.g. 1], it currently seeks for a foundational knowledge base [4]. In addition, a comprehensive insight of customer perceptions is required [1], but "only little is known about the level of user awareness and usage of smart services" [5].

Naturally, the lack of a theoretical foundation of Smart Services as well as missing methods and models for their implementation imposes challenges on both research and practice. On one hand, companies are aware of the topic, but on the other hand they just partly start implementing Smart Services and often fail or hesitate [6] due to their complexity. This results, amongst others, from the number of disciplines which have to be involved in their development and application [4] and leads to "limited empirical evidence […] about how the new markets for these novel services are created" [7]. In addition, different perceptions of Smart Services in science and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

practice in terms of their capabilities and benefits lead to gaps in expectations and thus weaken the joint work on the topic and an industry-wide introduction of Smart Services. Therefore, some scientific papers propose descriptions and structures for the topic [e.g. 8] or analyse barriers for an industry-wide adoption [9], but no common knowledge base in terms of definitions has been established so far. Thus, no structured development methods for such systems are present in practice and the systems cannot be classified accordingly. This can sometimes lead to the misuse of the term, e.g. for a marketing purpose [10].

With this publication, we address the gap between practitioner's expectations and scientific reality by conducting two separate studies, which compare the expectations of practitioners with benefits of Smart Services proposed in scientific literature. Thereby, our research fits into the research agendas of Wünderlich et al. [1] and Larson [4] and answers the following research question: *What are the main perceived benefits and expectations of Smart Services in science and practice and where do they resemble or differ?* The results help understand each other's perspective and thus bring both fields closer together, which is vital for a narrow exchange of knowledge and for an in-depth development of the topic. A common understanding enables an integrated view on the topic and consequently allow a higher value proposition in a shorter period of time. Especially the field of Information Systems (IS) can play a key role, since it aims at design-oriented and integrated development of systems at the interface between different disciplines [11, 12].

Therefore, after defining the term Smart Service (chapter 2), we conducted a structured literature review according to Webster & Watson [13] and identified 32 sources which mention benefits that result from implementing Smart Services in companies (chapter 4.1). In a second step, we conducted a web-based survey among 76 employees of different sized companies and asked them for their expectations by offering or using Smart Services (chapter 4.2). In addition, we had the participants validate the benefits identified in the literature as well (chapter 4.3). Finally, we compare the findings of the literature and the survey in chapter 5 and discuss the results in chapter 6.

2 Smart Services

The term "Smart Service" was primarily introduced to a scientific context by Allmendinger and Lombreglia in 2005 [2], but it has become popular in recent years. In the literature the term is explained with many different characteristics, e.g. awareness and connectivity [14] or its pre-emptive nature which is based on a "hard field intelligence" [2]. According to Wünderlich et al. [1] all characteristics fit into three groups: technological, customer oriented and context-specific perceptions. This highlights the nature of Smart Services, which relies on the use of IT to generate customer value according to current or upcoming situations.

Paluch [15] defines Smart Services therefore as "digital services, that are delivered through an intelligent and networked IT-infrastructure and generate value in combination with physical objects/products by continuous data collection and analysis". In a more generic definition Acatech [16] states that Smart Services are "individually configured bundles of (physical) products and services via the internet". This generic definition highlights the close relationship to Product-Service Systems (PSS), which also aim at fulfilling the customer needs in a holistic view, but do not focus on the technology [6, 17]. Some even state that PSS and Smart Services are the same thing [e.g. 18].

To achieve this holistic solution, Smart Services have to incorporate many different disciplines like engineering, computer science, economics or social sciences for development and application of the system [4]. They influence the business relationship of the provider and customer of a service and "are enabled and influenced by information that different industrial devices and processes generate, store and transmit to enable efficient operation, optimization, analysis and integration of business functions" [9]. Thus, Beverungen et al. [8] argue that Smart Services are enabled *by Smart Products, which* can be defined through core properties like unique identification, connectivity, sensors or actuators. The combination of different entities within a Smart Service is summarized by the term *Service System*, which refers to the same concepts according to Edvardson [19]. Spohrer et al. [20] define Service Systems as "socio-technical configurations of people, technologies, organizations, and information designed to create value by fulfilling the needs of those participating in the system" and Larsson [4] emphasizes the key role of the humans in the system. The National Science Foundation [21] adds in terms of the 'smart' component that a Smart Service System "amplifies or augments human capabilities to identify, to learn, to adapt, to monitor and to make decisions. The system does so through self-detection, self-diagnosing, self-correcting, self-monitoring, self-organizing, self-replicating, or self-controlled functions".

It becomes obvious that many terms are used in the same or likewise context and refer to similar concepts, which makes it difficult to distinct them correctly. Their concept has been applied in diverse industries like science and education, production industry, health sector or for individuals, e.g. in smart homes. This implies yet again the vast opportunities but also the complexity and the manifold obstacles in understanding, defining and developing them.

3 Method

To gain insights on both the scientific and practical perceived benefits of Smart Services we conducted a triangulation approach according to the mixed-method research concepts of Greene et al. [22]. Therefore, each method aims at identifying beneficial factors of Smart Services for the receiver or provider of the offering but from different perspectives. The findings of both studies, an extensive literature review and a web-based survey, are aggregated and discussed in section 5 and 6.

For the literature review we followed the approach of Webster and Watson [13] and used the databases *AISeL*, *EBSCOHost*, *ISI Web of Knowledge* and *SpringerLink* with the search term "smart service" in addition with the words advantage, benefit, value, result and their German counterparts. No further limitations regarding year of publication etc. were made, which led to 1.515 hits in total. After removing duplicates we filtered for title and abstract, which left us with 57 publications for detailed analysis. Interestingly, even though title and abstract sounded promising, less than half of these publications (25) contained useful insights on the beneficial factors of Smart Services. To obtain these, we applied two rules while analysing the publications: First, we only used publications that themselves rely on the term Smart Service. We did not evaluate and classify whether the descriptions in the paper fit to the definition of Smart Service, since there is no common understanding of the topic yet (c.f. Introduction) and therefore it is not clear which concept the authors were relying on. Second, we only considered benefits for companies using Smart Services which were stated as such, no deduction from an open statement (like a characteristic) into a benefit was made. This process was performed according to Mayring's [23] three-step process of content analysis (paraphrasing, generalizing, reducing) and led to the identification of 18 individual benefits, which could be grouped into five categories.

On the other hand, to analyse the perceived benefits of practitioners, we conducted a web-based survey among employees of German enterprises of various sizes. The survey was divided into three parts: (1) demographic data, (2) general concepts and (3) beneficial factors of Smart Services. To obtain unbiased insights on the opinions of the participants, we first asked them about their opinion of beneficial factors in a free text field (in part 3 of the survey). To get additional insights on their thoughts on the results from the scientific perspective, we secondly asked them about the factors identified in the literature review. We used two questions for each superordinate group (c.f. Section 4.1) to keep the survey in an adequate length. The questions had a 5-point Likert-Scale and were aligned to the guidelines of [24]. We chose this order to avoid distorted or biased results. In total 76 people participated, of which 40 fully completed the survey (52%).

4 Results of the Studies

4.1 Beneficial Factors of Smart Services in the Literature

The different understandings and shapes of Smart Services in the literature lead to various practical examples and therefore beneficial factors. A distinct trend in the topic can be identified when plotting the years in which the papers were published (c.f. Figure 1). By far most papers are from 2017 and this years (2018) number of publications is already (late summer) almost as high as 2005-2016 in total. In addition, we analysed the type of customer relationships (B2B or B2C) of Smart Services that were named in the publications. We did this by evaluating the given examples and for which customer group they are relevant. For each paper we did not count more than one occurrence of B2B or B2C group. As one can see in Figure 2, the term is applied in a B2B context nearly twice as much (19) compared to the B2C sector (11). Interestingly, some papers do not limit their scope to one sector and describe benefits for both.

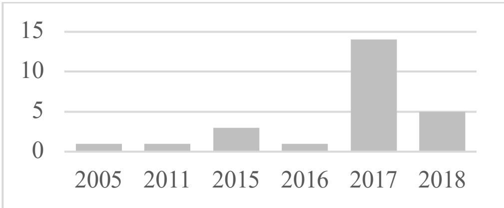

Figure 1. Publications per year in the literature review

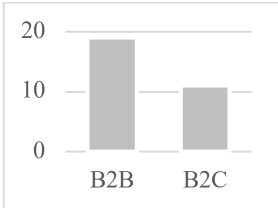

Figure 2. Mentioning's of customer segments

For the beneficial factors we identified 18 in total which we grouped into five segments (see Table 1 in the Appendix, chapter 8). In the following we will describe each group and the containing factors briefly. The whole matrix containing all publications and their concepts can be found in the appendix.

Group one includes benefits which in general describe effects of Smart Services in terms of **decreasing cost and time effort**. The costs are specified to 'traveling costs' (1 mention), since they are decreased due to opportunities of remote services, and 'search or transaction costs' (4 mentions), e.g. by using "fully automatic marketplaces" [16]. The majority (9 mentions) refers to 'reduced costs' in general, for instance through fewer downtime costs [25]. The 'reduction of time efforts' is usually explained as the receiver of a Smart Service has to spent less time in doing an action, since it is e.g. able to automate more tasks [26].

Group two summarizes benefits that in general **improve objects or conditions** through the application of Smart Services. In detail it specifies 'product' (5) and 'quality improvements' (6), 'increased performance' (12), 'higher flexibility' (7) and 'improved service provision' (2). While most of them are self-explanatory, the last one was described as enabling the customer of a Smart Service to benefit from a higher availability of the service providers offerings [1], which is in addition partly linked to flexibility, as the first enables the second.

Group three is named **customer related benefits**. Based on the definitions of Smart Services one could argue that they by nature add value to their customers, however some authors stated it explicitly. This group therefore focuses on the customer as a person or institution. It contains the factors 'relationship to the customer' (5), the 'customer experience' (5) which goes together with customer experience and a generic collection of 'values added for the customer' (12). Paluch [15] for example mentions the individual configurability, which implies an increased value for the customer. According to Allmendinger and Lombreglia [2] the relationship to a customer is "own[ed] […] as never before" by the offering company. The convenience that can accompany Smart Services can also lead to an increased customer experience [5]

Group four, **monitoring and maintenance**, is the second largest in terms of mentions (27 in sum), even though it contains only the two factors '(real time) monitoring' (17) and '(predictive) maintenance' (10). Monitoring is seen by some as a prerequisite [e.g. 27] and can be with regard to the machine itself, but also to observe the state of the object of interest, e.g. plants in agriculture [28]. In addition it not only enables maintenance, but for instance also adjusts the object (remotely) [8], which leads e.g. to increased performance (c.f. group two). Predictive maintenance enables providers e.g. to repair machines, which becomes especially valuable in production chains [6].

Table 1. Beneficial factors of Smart Services from the literature
(G=Group, M=Mentions, R=Relative Mentions, S=Sum of Mentions/Group)

G	*Benefit*	*M*	*R*	*S*
1) Cost/Time Reduction	Cost Reduction	9	7,63%	20
	Time Reduction	6	5,08%	
	Search/Transaction Cost Reduction	4	3,39%	
	Reduced Travel Cost	1	0,85%	
4) Monit. & maintenance	(Real time) Monitoring	17	14,41%	27
	(Predictive) Maintenance	10	8,47%	
3) Customer rel. benefits	Customer Value	12	10,17%	22
	Customer Relationship	5	4,24%	
	Consumer Experience	5	4,24%	

G	*Benefit*	*M*	*R*	*S*
2) Improvements	Increased Performance	12	10,17%	32
	Increased Flexibility	7	5,93%	
	Quality Improvement	6	5,08%	
	Product Improvement	5	4,24%	
	Increased Service Provision	2	1,69%	
5) Miscellaneous	Safety	5	4,24%	17
	Information Provision	5	4,24%	
	Environmental Benefits	5	4,24%	
	Partnerships	2	1,69%	

Group five, **miscellaneous**, holds beneficial factors that do not relate to any other group mentioned so far. It has the least mentions (17) of all groups and contains the factors ‘safety’ (5), ‘information provision’ (5), ‘environmental benefits’ (5) and ‘partnerships’ (2). Safety can be achieved in different contexts, e.g. in the industry [16], mobility [29] or in the health sector [30] by recognizing events and acting autonomously to prevent or decrease the harm. Through Smart Services information can e.g. be provided context-aware [31] or customized to the user [32]. Environmental benefits, e.g. fewer waste of scarce resources, can also be achieved through Smart Services [33]. Petrie et al. [34] argue that through more standardized services companies can partner in an easier and more efficient way.

4.2 Practitioners’ Expectations of Smart Services from a Web-Based Survey

In our web-based survey, we asked the participants in an open text field about their expectations and experiences with the benefits of Smart Services in their daily business. 76 practitioners participated of whom 40 finished the survey entirely. Most of the participants work at SMEs: 35% in companies with 101-200 employees, 17,5% have 11-100 colleagues and 10% work in very small firms (<10 employees). 37,5% are employed at big firms (<250 employees). They compete, amongst others, in industries like service (12,5%), mechanical engineering (10%) or forest and woodworking industry (17,5%). Of the 40 participants who completed the survey, 11 are female and 29 male. The majority (75%) is between 20 and 30 years old, the remaining 25% are older. 29 participants (72,5%) stated a job description that suggests intangible primary or supporting activities like clerk, marketing, sales or project manager. The remaining 20% work in jobs closely related to production or the products themselves, the remaining 7,5% cannot be classified (e.g. “student”).

The answers of the experts from the survey were clustered as well, which resulted in five groups: Alleviation of work, customer satisfaction, time/cost reduction, monitoring and maintenance and miscellaneous (see Table 2). As one can see, they in general go along with the clusters identified in the literature.

Table 2. Groups of beneficial factors of Smart Services from the web-based survey

#	*Group*	*No. of Coding’s (%)*	*Matching group from Literature*
1	Monitoring & Maintenance	31,0 %	4 - Predictive maintenance 23%
2	Assistance, Alleviation and Reduced Workload	21,4 %	2 - Improvements (partly) 27% 3 - Customer rel. benefits (partly)18
3	Customer Satisfaction	16,7 %	3 - Customer rel. benefits (partly)18
4	Reduction of Time and Cost	16,7 %	1 - Cost/Time Reduction 17%
5	Miscellaneous	16,7 %	None

The group with most mentions, **monitoring and maintenance**, compares to group four of the literature, which is the second most common there. In this context statements like “capture machine history”, “better/more precise monitoring” and even “predictive maintenance” were made, which are benefits for companies according to the interviewees. This is often linked to benefits resulting from them, e.g. “increased efficiency” of a machine or facility. In some cases also concrete data metrics were named which are valuable for the companies, for instance the feed speed of a machine, its ‘internal’ status or GPS coordinates. Interestingly only few remarks were made on the maintenance, the monitoring and capturing of data was mostly in the foreground.

Another major cluster deals with **assistance, alleviation and reduced workload** for the employees. Participants for example stated that they expect or experienced “simplified processes”, “improved information (flow)”, “less paperwork”, “decision support” and a “seamless production” by using Smart Services. This cluster closely relates to group three of the literature (customer related benefits) and shows that advantages do not only arise from an economic point of view.

Approximately the same amount of statements fit to the cluster **customer satisfaction**, which can be improved significantly by adapting Smart Services according to the participants. It partly also refers to group three of the literature (customer related benefits) and contains improvements for the customers like “better customer relationship” and “better customer satisfaction”, it enables them to provide “offers tailored more specific to customer needs” and to “optimize the services”.

The fourth group summarizing statements that indicate **reduction of time and cost** needed is also the fourth rarest mentioned one in the literature. The participants stated benefits such as “less downtime”, the “optimization of workflows” or an “increased efficiency”.

Lastly, remaining statements were grouped into **miscellaneous**. Despite sharing the same name with group 5 of the literature, in general no common statements were made. Benefits stated primarily refer to “fewer mistakes”, “more efficient machine utilization”, “improved customer acquisition” and “new business areas”.

4.3 Validation of Literature Findings from Practitioners in Web-Based Survey

In order to validate the findings of the literature we had the participants of the survey validate each group identified in the literature (c.f. Section 4.1). To prevent biasing their answers of their own expectations the validation took place at the end of the survey. In addition, to keep the survey short and prevent the participants from interrupting, we had two questions per group summarizing the findings of the literature. Each questions was answered on a 5-point Likert-Scale, asking for the consent (1:“Strongly Agree”) or refusal (5: “Strongly disagree”) of the statement. We left out group five (miscellaneous), since it cannot be summarized accordingly.

The following table shows the average of all given answers and the standard deviation for both questions.

Table 3. Results of the evaluation of benefits of Smart Services from the literature review (c.f. Section 4.1)

		Group 1	Group 2	Group 3	Group 4
Question 1	**Avg.**	2,25	2,13	2,18	2,15
	Std. Dev.	0,86	0,98	0,63	0,88
Question 2	**Avg.**	2,73	2,23	1,98	1,93
	Std. Dev.	1,30	0,88	0,72	0,75

5 Intersections of Expectations and Benefits

In general, the clusters from the literature review and the survey are quite similar in terms of the underlying concepts. However, the answers of practitioners are more specific or concrete and less abstract, probably since they have own experiences or ideas how Smart Services can benefit their company. This infers that both groups are on a similar track regarding their ideas of Smart Services, but on different levels of abstraction.

One topic that stands out is “predictive maintenance”. It ranks second in terms of mentioning’s in the literature and in the survey the group “monitoring & maintenance” is the most mentioned one. This implies that the connection to a physical product seems to be a core element of Smart Services, since it allows an in-depth observation of the object itself or other elements of interest in their surroundings. Besides real-time information this enables forecasting’s or improvements based on statistics and thus becomes essential for the whole system.

The cluster “assistance, alleviation and reduced work” from the survey (second most mentions) refers to the topics mentioned in groups two (improvements) and three (customer related benefits) from the literature. This is probably due to the different points of view, since the practitioners experience the effects of Smart Services as alleviations and in the literature they are described objectively. However, the "customer satisfaction" was mentioned as a single group in the survey as well, but only matches some of the "customer related benefits" from the literature.

The "reduction of time and costs" was mentioned similarly in the literature and from the practitioners, but only ranks in the lower third in terms of relative number of mentioning's. This group is the only exception to the above mentioned differentiating levels of abstractions between literature and practice. The statements by the practitioners, which otherwise are concrete and contain specific expectations, are more generic in this group. This infers, that the factor is assumed to be prevalent and not a core benefit to practitioners, even though it is a crucial aspect for a widespread dissemination of Smart Services.

The last group, miscellaneous, cannot be compared in a reasonable way, since the containing topics are too different. Also, each domain stated benefits that were not mentioned by the other at all, e.g. 'safety' or 'environmental benefits'. Those were listed in the literature, but not mentioned by the practitioners. Probably due to their increased relevance in the current phase of Smart Service dissemination and adoption.

The validation of the benefits from the literature in the survey (c.f. Section 4.3) mostly confirms these findings and the similarities, since each question (except Group 1, Question 2) scores a value about 2, which refers to "agree" on a 5-point Likert-Scale. The groups with the best scores in average are "monitoring & maintenance" (4) and "time and cost reduction" (3), which exactly matches the results described above. The evaluations of "alleviation of work" (1) and "customer satisfaction" (2) also point out their relevance, but are not that important.

6 Discussion, Limitations and Outlook

The term "Smart Service" gains increased interest in science (c.f. Figure 1) and in practice many companies acknowledge the benefits that arise from implementing them. However, the expectations and possibilities from both domains seem to differ and no methods for concrete adoption are present. That is why companies hesitate to implement them in full regard. Thus, we compared the benefits of Smart Services stated in science and practice, which originate from an extensive literature review and a web-based survey with experts from companies. This enabled us to answer our research question in a two step process: The first part of the question ("What are the main perceived benefits and expectations of Smart Services in science and practice […]") is answered in sections 4.1 and 4.2 and allows the comparisons of the findings ("[…] and where do they resemble or differ?") in section 5. In this section we discuss the results in the context of IS-research and derive steps for future research to overcome the identified gaps and to build upon common ideas and experiences.

The findings described in the previous sections, the consensus for benefits of Smart Services between science and practice, appear to be obvious in a first instance. This does not seem to be unexpected, since the term "Smart Service" is attracting increased interest and the ideas are exchanged between the domains. The differences are predominantly on the different levels of abstraction. For companies the concrete implementation of a Smart Service is most important, thus they derive benefits from the offerings they can supply so far or know about. In a scientific context however the scope is, due to the more generic approach, broader and thus more widespread ideas arise, e.g. the opportunities of a positive impact on ecologic sustainability. However, the practitioners also mention several ideas that have not yet been mentioned in a scientific context. Those ideas are assorted in group 5 five (miscellaneous) and do not match any group or even concrete statement from the literature. This implies that there are still topics that remain uncovered by one of the groups evaluated (science and practice) and leaves room to exchange experiences and ideas in both directions.

Both domains agree that Smart Services have the potential to fundamentally improve or change the way companies generate value for their customers, that's probably the reason why this is the largest group in terms of mentioning's in the literature (32 in total, group two). It is interesting that one of the core elements in both literature and practice is the strong connection to physical products, expressed e.g. by the expected functionalities and benefits of predictive maintenance. Even though only a few participants of the survey are from the machinery industry and no focus or hint on this topic was given in the survey, it is the most mentioned aspect. This supports one of the current streams in IS research, which proposes such strong connection between the physical and intangible components [e.g. 8]. However, substantial adoptions are scarce, which seems to be similar to the adoption of PSS after their introduction in a scientific context. The concepts and benefits of PSS are widely agreed on in science and practice, but practical methods for their development are still not prevalent. In addition, many benefits named by the practitioners, except predictive maintenance, could also be realized by applying "regular PSS" without a "smart component". This verifies the unclear separation of PSS and Smart Services in both domains but at the same time confirms their strong interconnectedness (c.f. Section 2). To simplify adoption in practice it seems to be helpful to highlight the relations and point out the underlying concepts in order to build upon existing knowledge and implementation initiatives. The analysis of the progression from PSS to Smart Services and the development of Smart Services themselves through various scientific iterations can support the adoption in practice as well, by enabling companies to adept the steps of development from science.

Another interesting result is that there is no distinct separation of benefits from participants of the survey working in "intangible" or "tangible" jobs (c.f. Section 4.2). Both groups share the same ideas in terms of product, service or business related features. The same applies for examining the answers across different industries. The participants seem to have rather comprehensive ideas of Smart Services and their concepts and benefits and are not limited to their own perspective. However, we do not find a correlation between the groups. Scientists can build upon this broad view to analyse the often complex structures of Smart Service (Systems) [20]. This goes along with the finding that practitioners from many different disciplines propose beneficial factors of Smart Services despite their relation to information or engineering research. Therefore, from an IS-research perspective, it seems to be valuable to cooperate with other research disciplines in this field, e.g. product or production engineering [4]. This would also accommodate to the strong relationship of the physical and intangible parts. In addition, a common concept or technology for an in-depth integration of the various disciplines seems to be valuable.

To foster the cooperation of science and practice and to allow sharing of knowledge between the disciplines, we can derive the following future research approaches. Practitioners gave many examples of Smart Service applications, but only few mentioned their importance on generating valuable business model. Scientists can support this change in mind-set by developing frameworks to structure and implement sustainable value offerings. Also, our results reveal benefits which are not common yet, e.g. a building relationships between companies through Smart Service or an improved environmental impact. Research can focus on these benefits to extend the scope of Smart Services beyond the smart product and service perspective solely. The investigation of Smart Service in the pure service sector, e.g. banking, is another topic that needs further consideration in order to prove if the value of Smart Services only realizable in combination with physical products or how the concepts can be transformed and adopted. This matches with the possibilities of substituting the physical and service components in the system and the question, how this affects the conceptualization of Smart Services from a research perspective and the value offering for companies.

This contribution serves as a starting point for future studies of Smart Services and therefore has some minor limitations. The survey does not allow empirical evaluations, since it has not enough participants to guarantee for statistical evidence and practitioners from more industry sectors would improve the results. Participants from “intangible” jobs, which might bias the findings, also dominate the present group. In addition, the validation of the clusters found in the literature with only two questions each is just small indication for its validity. Like every other content analysis (literature and survey), the coding of the benefits and grouping them is a partly subjective task, particularly when the benefits often determine and result in each other. Finally, another data source for insights on practice, like white papers, could have been used.

In conclusion, many streams of Smart Services are similar in science and practice and, even though they are often on different levels of abstraction, they proceed in similar directions. For many research topics stated in prior scientific publications proposals for further investigation were already made, however they need to incorporate the concrete requirements and ideas from practice, to prevent divergence of the perspectives.

7 Acknowledgements

This research is partly funded by the European Regional Development Fund and the State of Lower Saxony (NBank) in the scope of the research project SmartHybrid – Service Engineering (ID: 6-85003236). We would like to thank them for their support.

Innovation Networks and Digital Innovation: How Organizations Use Innovation Networks in a Digitized Environment

Axel Hund[1,2], Heinz-Theo Wagner[2]

Abstract. The digital transformation dramatically lowered the costs for communication and coordination, thus, enabling new forms of cooperation. Companies seize this opportunity by creating new types of innovation networks. Until now, we know little about which types of innovation networks are currently prevalent and why organizations use them. In this paper, we build upon a recent study dealing with categorization of innovation networks and present the results of an exploratory series of case studies conducted with 27 high-level executives from 11 organizations in various industries. Our results indicate that companies are maintaining high-levels of centralized control over the innovation network, which is contrary to what the literature suggests. Furthermore, there is a strong trend towards more heterogeneous knowledge within a network. Additionally, we identify mechanisms that help companies to transition from one type of innovation network to another one and investigate why organizations use certain innovation networks.

Keywords: innovation network, digital innovation, digital transformation, case study research

1 Introduction

'Two heads are better than one' is a common proverb and the increasing reliance on innovation networks - instead of individual innovators - appears to confirm this assumption (e.g., [1],[2]). Innovation networks can be understood and defined as "a set of actors connected by a set of ties. The actors […] can be persons, teams, organizations, concepts, etc." [3]. For this paper, we have a focus on socio-technical networks formed between various actors and their respective tools in an increasingly digitized environment as described by Lyytinen et al. [1].

The increasing reliance on different forms of digitally enabled innovation networks is reflected in widespread practices such as open innovation [4], user innovation [5] and crowdsourcing [6]. These practices are enabled by the progressive digitization of our environment (e.g., [7],[8]) with costs for communication and computation at an unprecedented low level [9], which, enables companies to easily access knowledge from

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

beyond their organizational boundaries [10], [11]. Hence, innovation networks are poised to become the backbone of successful innovation efforts in a digitized environment [1], [2], [12]. Accordingly, recent research addresses the topic of innovation networks. For example, striving for conceptual clarity Lyytinen et al. [1] built upon extant literature on innovation networks and put forward a framework to distinguish between different forms of innovation networks by categorizing them along the dimensions of (1) control over resources and (2) degree of heterogeneity.

However, even though we can observe the rise of innovation networks over single innovators (e.g., [4], [5], [10]), and know that different types of innovation networks lead to either incremental or radical innovation outcomes [1], we do not know which types of innovation networks are actually prevalent among incumbent companies since digitization became nearly ubiquitous. Furthermore, we do not know how companies can fluidly transition between different types of innovation networks. Moreover, we do not know why organizations decide to use a certain innovation network. Thus, as pointed out by Nambisan et al. [12] we cannot comprehend "how firms are able to successfully and fluidly mix, match, and integrate internal and external parties and various diverse communities in digital innovation". As innovation is the ultimate raison d'être for companies [13] it is paramount to further examine how the pervasive digitization of entire industries influences innovation networks and why organizations use specific network types. Thus, this paper investigates two research questions:

RQ1: Which types of innovation networks are currently prevalent and why do organizations use them?

RQ2: How can companies fluidly transition between different types of networks?

Striving to answer these questions, we conducted 27 interviews with high-level managers from 11 different companies in different industries and inquired about their approaches to organizing and innovating in a digitized environment. Theoretically, we rely on the framework by Lyytinen et al. [1] to clearly delineate and categorize different forms of innovation networks. This allows us to distinguish between common forms of innovation networks, categorize them within the framework and examine which types of innovation networks are currently prevalent and why companies use them. Additionally, it allows us to identify mechanisms that companies use to transition from one type of innovation network to another. In the following sections, we will review the literature on the influence of digitization on innovation networks and describe how we analyzed the case studies. Furthermore, we present our findings, discuss the implications of our findings and highlight potential limitations and promising avenues for future research.

2 Related Literature

New types of innovation networks are emerging as traditional approaches struggle to efficiently coordinate the increasing amount of connected actors and integrate the vastly heterogeneous knowledge available [1]. There are entire literature strands that take a more granular look on different types of innovation networks such as network-centric innovation [2], open innovation [4], [14], distributed innovation [15], user innovation [5], [16] and crowdsourcing [6], [17]. All of those literature strands have in common that they accentuate an external focus for innovation. This makes perfect sense when considering that "[…] in any given sphere of activity most of the pertinent knowledge will reside outside the boundaries of any one organization, and the central challenge for those charged with the innovation mission is to find ways to access that knowledge" [15]. Thus, organizations experience an increasing blurring of their external boundaries and leverage digital technology to enable new cooperation's [12]. All of the beforehand mentioned articles focus on different aspects of external cooperation. For example, user innovation focuses on the involvement of the user in the development process to better understand user needs [5]. Crowdsourcing on the other hand is about outsourcing tasks to an undefined crowd through tournament-style or collaboration-style open calls [6]. In addition, digital technology also plays a vital role for more traditional approaches such as merger and acquisitions (M&A), as digital technology-related M&As can make or break the efforts of a company to master the digital transformation [18], [19]. In general, research on networks has grown exponentially and can be categorized on basis of the respective focal point such as for example social capital, embeddedness or organizational networks [3]. Another typology put forward by Mentzas et al. [20] delineates inter-organizational knowledge networks along the nature of exchange (sharing / trading) and the nature of community (closed / open). However, since our research focuses on *innovation* networks in a digitized environment, we chose to build upon the theoretical framework put forward by Lyytinen et al. [1] as it was designed to do exactly that. The framework helps delineate between different types of innovation networks along two dimensions. These two dimensions embody the effect of ubiquitous digital technology, which leads to:

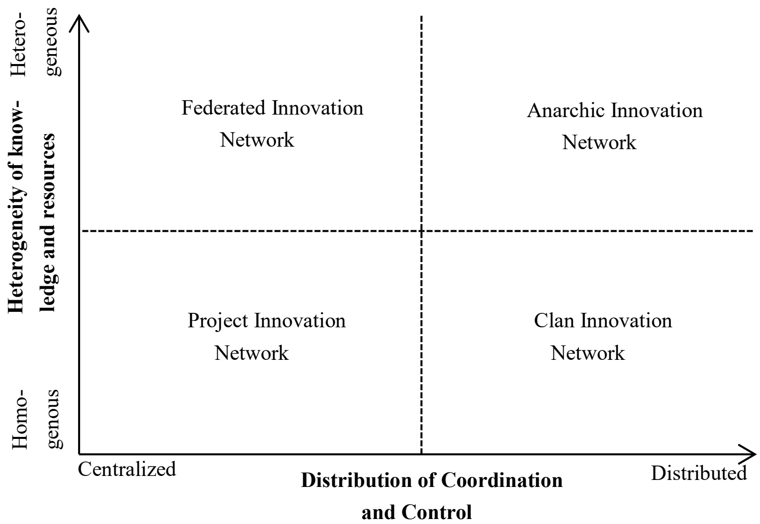
(1) **Distribution of coordination and control:** Vanishing costs for communication allow connecting, coordinating and controlling innovation network contributors and resources independently of time and location. In the past, business models and innovation networks were limited by the high cost of communicating and processing information [21]. However, with the rise of ubiquitous digitization these costs have diminished to the brink of almost vanishing [9]. Plummeting costs for communication make it possible to connect and coordinate previously unconnected actors and, thus, enabled the creation of new types of innovation networks (e.g., [4], [6]).

(2) **Heterogeneity of knowledge and resources:** Combining the expertise of previously separated knowledge communities increases the heterogeneity of resources and knowledge within the innovation network. When a formerly static product or process is digitized it is endowed with an unprecedented level of flexibility and openness [8], [22]. Increased openness and flexibility enables previously separated knowledge communities to combine their distinct areas of expertise as demonstrated in the "quadruple-play" – the combination of phone functionalities with TV-services, broadband internet and mobile internet apps [1], [8]. The convergence of heterogeneous knowledge enabled the creation of a groundbreaking digital innovation - the smartphone [1], [8]. As different knowledge communities are more interconnected and form innovation networks, the heterogeneity of knowledge available within these innovation network increases [1]. Moreover, due to the higher flexibility, contributors can frequently enter and exit the innovation network when the focus of an innovation network changes or

requires different forms of knowledge [23]. This dynamism increases the heterogeneity even further as the contributors in innovation network constantly change [12].

Lyytinen et al. [1] conceptualize along those two dimensions four canonical archetypes of innovation networks which can be intra-organizational or inter-organizational. The first archetype is *project innovation networks* which is characterized by homogenous contributors coming from the same discipline and, therefore, have the same knowledge background. Project innovation networks rely (mostly) on hierarchically integrated structures as given within an organization, thus, allowing for tight control of resources and the goal of the innovation efforts [1]. The second archetype is *clan innovation networks,* which also comprises a homogenous group of contributors that have the same – or at least very similar – knowledge background. However, in a clan innovation network the contributors are not controlled by a hierarchical structure and can freely determine which innovation outcome they pursue. A typical example of a clan innovation networks are open-source communities [1]. The third archetype is *federated innovation networks,* which are characterized by contributors from different disciplines and heterogeneous knowledge. Even though they come from different backgrounds, resources and the eventual innovation outcome are tightly controlled by hierarchically integrating the contributors. Classic examples of a federated innovation network are automotive manufacturers, which rely on numerous knowledge communities ranging from logistics over engineering to design. Contributors from different departments or even different companies work together beyond the classic company or discipline-boundaries. Nonetheless, the final outcome of innovation efforts is tightly controlled by the manufacturer [1], [24]. Lastly, there are *anarchic innovation networks,* which are characterized by contributors from different disciplines with heterogeneous knowledge backgrounds and no hierarchical control. Hence, anarchic innovation networks introduce an unprecedented level of complexity and dynamism as vastly heterogeneous knowledge communities' work together in absence of any formalized form of control over the innovation outcome, the innovation process or even the structure of the network. An example for an anarchic innovation network was the Gehry project in Bilbao in which numerous independent companies from diverse backgrounds took part [25]. Figure 1. depicts the four types of innovation networks along two dimensions:

Figure 1. Four Types of Innovation Networks



3 Method

“Case studies are the preferred strategy when "how" or "why" questions are being posed, when the investigator has little control over events, and when the focus is on a contemporary phenomenon within some real-life context” [26]. Due to the nature of our research, we neither have control over the events nor the context, and are fundamentally guided by “how” and “why” research questions. Thus, case study research is a perfect match [26]. For the sampling procedure, we focused on companies that currently conduct digitalization projects and aimed a minimum of three senior managers per company to ensure multi-facetted insights into the project. However, depending on company size, sometimes one person was in charge of every critical area of interest. In total, we interviewed 27 senior managers from 11 different companies in various industries as listed in table 1:

Table 1. Case Study Overview: Industry, ID, Interviewee Position and Length

Case	Industry	ID	Interviewee Position	Length

The interviewed senior managers held positions in various departments such as IT, innovation, and R&D. Most interviews were conducted during 2016 and onsite and were guided by the following guidelines: First, we asked the interviewees to briefly summarize their background and to describe their position in the company. Subsequently, we asked how they personally define digitization and whether they could talk about a recent digital initiative. Following up, we asked in detail about the company's internal structures and decision hierarchies. Furthermore, we asked about innovation processes, innovation co-operations and resource allocations. Additionally, we included questions concerning the personal opinions of the interviewed senior managers to gain a better understanding of critical success factors. The interviews were recorded and subsequently transcribed. The qualitative data analysis was conducted deductively following the guidelines of Mayring and Fenzl [27]. We started by defining clear research questions and, henceforth, selected and prepared the appropriate material as described above. We then searched the literature for frameworks that help determine categories which are firmly grounded in theory – in our case Lyytinen et al. [1] provided an ideal place to start as the framework specifically focuses on innovation networks in a digitized environment. Subsequently, guided by existing best practices in the literature (e.g., [27], [28]) we deductively coded the interviews in accordance with our established coding guideline as depicted in table 2:

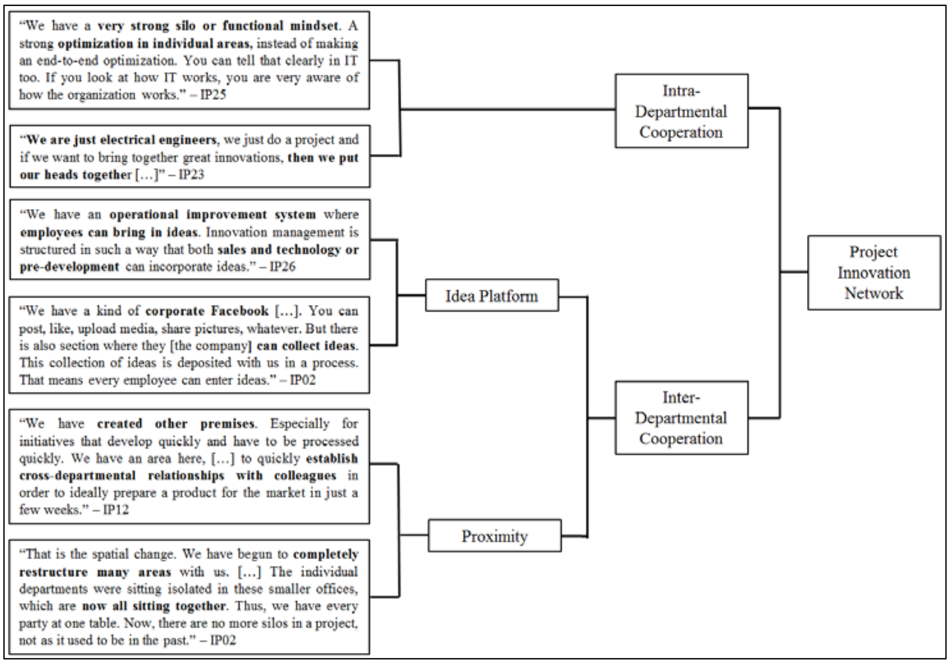
Table 2. Coding Guidelines based on Lyytinen et al. [1]

Type	Network Characteristics	Coding Rules
Project	**I.** Homogeneous actors / tools, readily identified and mobilized **II.** Hierarchically integrated control, mostly within a single company	There are clearly identifiable control structures for resources and outcomes. Actors within the network must have homogeneous knowledge and are easily identifiable.
Clan	**I.** Homogeneous pool of dynamic actors driven by common interest and well-defined set of tools; readily identified & mobilized **II.** No centralized hierarchical control	No clearly identifiable control structure. Outcome control is not existent or distributed. Actors within the network must be easily identifiable and have homogeneous knowledge.
Federated	**I.** Heterogeneous pool of actors, that need to be identified **II.** Hierarchically integrated control structure, within and beyond company boundaries	There must be a clearly identifiable control structure, which controls resources as well as the outcome. Actors within the network come from different knowledge communities; knowledge is heterogeneous.
Anarchic	**I.** Heterogeneous & dynamic pool of actors / tools, that need to be dynamically identified & mobilized **II.** No centralized hierarchical control	No identifiable control structure. Outcome control is not existent. Actors within the network come from different knowledge communities; highly heterogeneous knowledge.

For the process of coding and displaying the results, we used MaxQDA Plus 12 and built upon on the recommendations of Mayring and Fenzl [27] to organize the statements made in the interview within the established framework.

In the next step, we carefully went through each established category and searched for emerging subcategories, which would point us towards trends within each type of innovation network. This helped distinguish between different forms of, for example, project innovation networks, thus, further structuring the results. An example of the process is depicted in figure 2:

Figure 2. Exemplary Process of Subcategory Coding



4 Results

In the following section, we present the results of the deductive qualitative analysis. During the analysis, a general, overarching theme emerged that underscored the importance of better understanding how pervasive digitization changes the way organizations cooperate and innovate. As IP 12 put it: "[Digitization] is already changing the world and is changing our world […]. Until now, we relied on creating value ourselves. This will not stay the case with digitization because we already believe that we cannot do it alone. But the question is: "Where do you differentiate yourself, where do you work together and where do you have the differentiation potential in the future?"

In the following subsections, we put the subcategories that emerged during the coding process in bold font at the beginning of each paragraph.

4.1 Project Innovation Network.

Overall, 16 out of 27 interview partners (IP) mentioned forms of cooperation that fit the established characteristics of project innovation networks. In the following, we list the subcategories we identified during analysis as depicted in figure 2.

Intra-departmental co-operation. Surprisingly, only 2 out of 16 interviewees (IP23, IP25) mentioned pure forms of project innovation networks in which all actors come from a specialized subdivision within the same company. It is characterized by a very homogeneous group of actors, which are working and specializing within one department, while avoiding external input. Furthermore, within the setting of an organization there is a clearly identifiable, high level of hierarchical control over resources and the expected outcome. For example, IP 25 stated: "We have a very strong silo or functional mindset - a strong optimization in individual areas, instead of making an end-to-end optimization."

Inter-departmental co-operation. Most interviewees (12 out of 16) pointed towards less clear-cut forms of project innovation networks as they involved inter-departmental cooperation. The networks still consist of actors from the same organization but cooperate beyond the boundaries of their respective department. Hence, the knowledge available in these inter-departmental settings is – while still being similar - less homogeneous than in the case of a silo mindset. IP06 described this trend by stating: "Departments used to be very well organized side by side – now everything is somehow dissolved a bit. It also produces much greater transparency. For better or worse." This trend of cooperating beyond the respective department boundaries manifests itself in the creation of idea platforms (IP02, IP26), increased proximity (IP03, IP04, IP12) and the formation of inter-departmental teams (IP01, IP02, IP05, IP11, IP16, IP20, IP21).

Idea platforms help generate new ideas and facilitate exchange between different departments and often take the form of corporate social media platforms. IP02 stated that: "We have a kind of corporate Facebook […]. You can post, like, upload media, share pictures, whatever. But there is also section where they [the company] can collect ideas […]. That means every employee can enter ideas". Furthermore, companies not only create virtual platforms to foster cooperation but also change the workspaces itself to increase the physical proximity between formerly separated departments. IP12 elaborated that: "We have created other premises. Especially, for initiatives that […] have to be processed quickly. We have an area here, […] to quickly establish cross-departmental relationships with colleagues in order to ideally prepare a product for the market in just a few weeks." The most common mechanism is the formation of inter-departmental project teams that pursue several goals such as entering new markets (IP01), quickly solving unexpected problems (IP11), strategy planning (IP16) and establishing new work processes (IP20). In order for such endeavors to be successful, numerous success factors were mentioned such as a good-will commitment of the executive board (IP01), the ability to focus 100% on the new task (IP01) and an open culture between different departments (IP05).

4.2 Federated Innovation Networks

During our conversations, federated innovation networks emerged as the most prevalent type of innovation network overall. Here, organizations strive to engage with highly heterogeneous knowledge (mainly) from outside the company and even from other markets while still maintaining a high level of control over resources and expected outcomes. In total, 26 out of 27 interviewees explicitly mentioned some or multiple forms of federated innovation networks. The most prominently mentioned ones are: Partnerships and cooperation (IP05, IP11, IP12, IP20-IP22, IP26), cooperation with startups and fintechs (IP02, IP05, IP08, IP10, IP20, IP25, IP26), customer panels (IP02, IP07, IP11, IP12, IP20, IP21), outsourcing (IP09, IP11, IP12, IP15), creation of platforms (IP01, IP11, IP15, IP24), external consultants (IP05, IP13, IP16, IP17), spin-offs (IP01, IP08, IP15). The most important ones, which were mentioned by at least five different interviewees, are explained in more detail below:

Partnerships and Co-operation were mentioned by 7 of the 26 different interviewees. As products and services are becoming increasingly complex [25], companies rely on an increasing number of co-operations to access external, heterogeneous knowledge and skills to solve problems that are out of their area of expertise. Control over the outcome and scope of such partnerships is typically ensured through contracts and agreements. IP20 stated: "I need other disciplines, other specialized [areas of] knowledge, which do not necessarily exist in our classical background of the company. In turn ... I said it before, I have to invest much more than I am used to in partnerships." Oftentimes companies collaborate with other companies that have expertise in fields such as the development of new IT solutions (IP13) or design choices (IP10, IP22). These co-operations aim at increasing customer value (IP11), extending research capabilities (IP20) and acquiring additional knowledge (IP26). The interviewees named an open-mindset on both sides (IP07), accepting failures in order to be able to try new things (IP21) and the development of strong networks (IP22) as important factors for success.

Startups and Fintechs. Even though co-operations with startups and fintechs could also be listed under the subcategory "partnerships and co-operations", 7 out of 26 interviewees specifically highlighted them as a special case of co-operation. startups were mentioned 6 times (IP02, IP05, IP08, IP10, IP25, IP27) and fintechs 3 times (IP02, IP10, IP20). The startup and fintech co-operations have the purpose of creating new ideas (IP05) and generally to increase value for customers (IP20, IP25). Furthermore, such co-operations are viewed as "a kind of research and development extension from outside [the company]. Of course, we only engage with ideas which we do not have to get out of our way." Furthermore, while they are perceived as an easy way to expand one's network and engage with new ideas, several interviewees pointed out common pitfalls such as that startup cooperation are great to learn but oftentimes do not end up profitable (IP05). Furthermore, startups and fintechs frequently compete for direct customer contact, which could transform incumbents into mere suppliers (IP20).

Customer Panels were mentioned by 6 out of 26 interviewees. Organizations try to closely align their offerings with what the customers want by directly acquiring feedback from their customers. To achieve this, companies create platforms on which customers can share suggestions for improvements or general feedback (IP03) or they even create an advisory board of specific customers to test products and quickly acquire feedback (IP03, IP07). The aim here is always to acquire customer feedback. However, it is crucial to build up the necessary processing capacity as it is easy to be overwhelmed by the amount of suggestions. IP03 stated for example: “The problem is, we have 1200 employees and 2 million customers. And 500 employees in the customer interface. They also get a lot of ideas from the customer and carry them there. So there are umpteen suggestions a day. They have to be evaluated. There must be someone who has time to look at his day-to-day business.”

4.3 Clan and Anarchic Innovation Networks

Interestingly, there were no statements that fulfilled the requirements for being classified as clan or anarchic innovation network. We will elaborate on this insight in the discussion section.

4.4 Mixed Forms of Project and Federated Innovation Networks

During the analysis, an additional mixed type of innovation network emerged. Such a mixed type of innovation network appears to help companies moving from one type of innovation network to another. Within this mixed innovation network type we distinguish between two subcategories: (1) transition mechanisms and (2) integration mechanisms.

Transition mechanisms are mechanisms that companies rely on to transition towards the north (more heterogeneous knowledge) or east (more distributed control). In total, we found 7 interviewees mentioning different examples such as: Creating new internal departments which become spin-offs (IP01, IP05), focusing on inter-departmental cooperation but involving some external actors (IP04, IP15, IP20, IP24, IP26) and creating internal startups (IP05). All of them are examples for the transition from project to federated innovation networks (i.e., north) or from project innovation networks towards a clan network (i.e., east).

An example for an east-transition is provided by IP01 who describes how the company went from full hierarchical control to a more distributed form of control by spinning off a project team and turning it into a more independent company: “It was a project team within Department 1 that […] has pushed this project forward […]. Until at some point – along with the market entry - the time was right to spin-off the project team into an independent sales GmbH. An independent business unit, which is one of our more successful business units to this day, because they have since made a very beautiful growth story.” Whereas it is questionable that this already qualifies as a full-fledged clan or anarchic innovation network, it certainly is a step towards this direction.

In general, the interviewees stated that such mixed forms are used to experiment with new business models or markets (IP01, IP05), quickly acquiring expertise from outside the company and speeding up the process of innovation (IP24) and for transformation projects (IP24).

Integration mechanisms are mechanisms that help integrate external actors, over which a company has little or no control. Thus, integration mechanisms help to move innovation networks towards the west (i.e., more centralized control) or south (i.e., more homogenous knowledge). Altogether, six interviewees mentioned integration mechanisms. Examples are acquisition (IP05), permanently integrating freelancers into work processes and decision-making (IP15) and classic hiring of valuable individuals (IP02, IP03, IP05, IP13). For example, IP 15 described how freelancers are completely integrated in decision making processes and feel as part of the team: "I also do not make the decision myself […], but I say: "The external and internal guys have decided on the design". There too, no separation. Freelancers already integrated internally. They also feel like internals. Connect with the company. Which is important - otherwise they cannot work the same as an internal one if they do not feel that it is their baby as well." Over time, the integrated freelancers develop a shared knowledge base with the company, thus, leading to a more homogenous knowledge base. Such a development signifies a slow move towards a project rather than a federated innovation network. Generally, these mechanisms were mentioned to help acquire new expertise (IP03, IP05, IP08, IP13) and to foster "out-of-the-box-thinking" (IP02).

5 Discussion

Theoretical Implications. This paper set out to answer two research questions. The first question is: *Which types of innovation networks are currently prevalent and why do organizations use them?* The main insight is that incumbent companies appear to rely only on project and federated innovation networks but not on clan and anarchic innovation networks, thereby, always maintaining control over resources and the eventual outcome. Furthermore, we found that organizations use project and federated innovation networks for different purposes. Project innovation networks are mainly used to facilitate idea generation, and to allow for fast problem solving and experimentation. Federated innovation networks on the other side are mainly used to gain access to external expertise, and to increase customer knowledge and thus customer value. Investigating which types of innovation networks are currently prevalent and why organizations use them addresses the "need to examine to what extent organizations simultaneously engage in multiple different types of networks, and how the intensity and proportion of these engagements affects the level and nature of their innovation work" [1].

The second question is: *How can companies fluidly transition between different types of networks?* We found that companies gradually transition between project and federated innovation networks by using mixed forms of innovation networks, which we categorized as either transition or integration mechanism. These identified mixed forms help address the fact that the two dimensions of control and heterogeneity are not as clear-cut in reality as they are theoretically [1]. By recognizing and categorizing mixed forms between different types of innovation network, we are able to take a more granular look and position the identified forms of innovation networks more precisely within the framework. Thereby, contributing to extant literature.

In the following, we discuss the highlights of our results and point out avenues for future research. When we started to analyze the data, we expected to find examples for distributed forms of control over the innovation network, the actors and the eventual outcome. This would be in line with the prediction of Lyytinen et al. [1] which stated that due to the ever more prevalent digitization there would be a trend towards more distributed forms of coordination and control. However, as stated above, our results do not support the prediction that there is a trend towards more distributed forms of control. For future research, it would be a worthwhile endeavor to investigate why organizations currently choose not to use clan and anarchic networks. A possible explanation is that while products become increasingly complex [8], [22], incumbents must engage their entire supply chain in order to successfully innovate (e.g., [29]). Thus, certain actors within a network of suppliers specialize for specific components which are then assembled into the final product by the manufacturer [24]. For such a modular design to be successful, manufacturers on top of a supply chain must maintain tight, centralized control over the innovation network and ensure that the individual components are modular and fit together [24]. Nonetheless, as Lyytinen et al. [1] stated, we can already observe examples of distributed control such as in open-source communities (e.g., [16], [30]). Projects such as Linux prove that the creation and development of highly complex products is feasible without any formal hierarchy [1], [24]. Thus, even though the incumbents in our case studies are currently not experimenting with more distributed forms of control, this may only be due to the tried-and-tested ways traditional companies always conducted their business. Path dependence, i.e. continuing to do things the traditional way, has implications for any renewal or restructuring process (e.g., [31]). Henceforth, after the successful emergence of open-source networks in highly digitized industries such as software and electronics, we expect "other industries [to follow] this trend as they embrace digitization in their products and services – for example, through implementing Internet of Things, digital product libraries, 3D printing and big data" [1, p.69]. Future research is needed to fully understand the factors that favor or hinder distributed forms of control and the decision of organizations to not use certain innovation networks.

Our results do support the prediction of Lyytinen et al. [1] that there is a strong trend towards more heterogeneous types of innovation networks. This is displayed in two different ways. First, 16 out of 27 interviewees mentioned project innovation networks. However, intra-departmental co-operation (co-operation within the same department; very homogenous setup) was only mentioned twice, whereas the overwhelming majority (12 of 16) referred to inter-departmental cooperation (co-operation across various departments; less homogenous as different fields of expertise within the company are involved). Thus, even within project innovation networks appears to be a strong trend towards the north. Second, multiple forms of federated innovation networks were mentioned by 26 of 27 interviewees, hence, providing a strong indication that the involvement of more heterogeneous knowledge is becoming increasingly important. This development provides many opportunities for further investigation as each form of cooperation has different advantages and disadvantages. Quantitative research might be able to further analyze these factors and relate them to innovation success or failure.

Limitations and Practical Implications. As for every research endeavor, it is important to understand and point out possible limitations. The chosen form of research design cannot claim to produce generalizable results but rather aims at conceptual clarity and identifying valuable areas of further inquiry. Furthermore, our sample of 27 interviews has a strong focus on the financial and manufacturing industry, which may results in biases. Furthermore, our case studies were conducted by exclusively interviewing high-level executives in incumbent companies. Thus, it would be interesting to contrast our findings with insights in upcoming, less established companies that might or might not rely on very different innovation networks including distributed forms of control. Hence, we welcome future studies to supplement our results with insights derived from qualitative or quantitative research.

The results of our research offer numerous implications for practitioners. First, our results indicate that different types of innovation networks are used for different purposes. Practitioners are well advised to focus on inter-departmental project innovation networks to facilitate idea generation, rapid experimenting and problem-solving if the knowledge necessary to address such issues already exists within the company. If there is the need to acquire additional expertise that does not exist within the company, practitioners can use several forms of federated innovation networks. Federated innovation networks were pointed out to be especially powerful to access external expertise. Furthermore, federated innovation networks can be utilized to directly get in touch with the customer and acquire real-time feedback, thus, providing ample opportunity to increase eventual customer value.

Second, even though there are successful examples of distributed control in some industries, the incumbents in our case studies appear to not actively experiment with distributed forms of control. Hence, here might lay new opportunities for innovative forms of collaboration and new business models.

Third, companies trying to slowly increase the heterogeneity of their resources and knowledge without disrupting their current processes can experiment with transition mechanisms. If there is a need to increase control and streamline heterogeneous knowledge resources into a more consistent, homogenous knowledge base practitioners can rely on integration mechanisms.

In conclusion, this paper produced new insights into how companies can move from one type of innovation network to another and which innovation networks are currently prevalent among incumbents. Most importantly, our results produce novel insights about why different types of innovation networks are used and point towards fruitful avenues for future research on innovation networks.

Characterising Social Reading Platforms—
A Taxonomy-Based Approach to Structure the Field

Kristin Kutzner[1], Kristina Petzold[2], and Ralf Knackstedt[1]

Abstract. Due to digitalisation the way of discussing on books changes. Especially social reading platforms foster a more sociable and collaborative mentality. Manifold platforms exist that differ, for instance by enabling different formats to discuss on books, such as book club, forum or direct text work. As no consolidated overview of social reading platforms exists, this study aims at deriving a taxonomy of social reading platforms to structure the field. Based on (1) an initial literature review and (2) a collection of social reading platforms, we derived (3) the taxonomy that considers essential characteristics. Further, through (4) a cluster analysis, four types of platforms could be identified. Overall, based on the taxonomy researchers and practitioners can be informed within the variety of platforms, to compare, refine and develop further social reading platforms.

Keywords: Digital Transformation, Creative Industries, Digital Humanities, Social Reading Platforms, Taxonomy.

1 Introduction

"*The digitalisation is likely to change written culture, and therefore, at the same time society, even more than the development of Gutenberg's book printing*."
(translation of Volker Oppmann, CEO of the social reading platform Mojoreads)

Digitalisation refers to changes in various fields and influences human life [1]. Due to digital transformation, the way of communication, collaboration and participation within the entire society is changing [2, 3]. Creative industries (e.g., art, music, film) including book industry, as Volker Oppmann already stated, are highly affected by digital transformation as new information technologies enable changed ways of discussion on cultural and aesthetic practices. A variety of social reading platforms—the wide range will still increase—fosters a more sociable and collaborative mentality, enabling different formats to discuss and share opinions on books in the community. Consequently, digitalisation will lead to changed reading attitudes, habits and practices, resulting in novel realities and discourses [4]. Further, a notable part of German book sales—about 18.8% of sales of the German book trade in 2017 [5]—takes part on the

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Internet. According to [5], the estimated sales of Internet book sellers in 2004 accounted for 506 Mio. €, and in 2017 for 1.710 Mio. €, which is an increase of about 3.4 times over 13 years. Especially social reading platforms become more important for sellers and publishers, as they offer new opportunities, to improve the visibility of books for sales and book recommendations [4] and to address trends, influencing future product developments. For instance, LovelyBooks records more than 1.5 Mio. users per month and 70% of the users regularly buy books which they discovered on LovelyBooks [6].

Although social reading platforms are of growing interest, these platforms are very heterogeneous. That is why it is difficult to maintain an overview of their characteristics. Prior studies provided an overview of existing social reading platforms [4, 7] or a first proposal to structure social reading spaces [8, 9], focussing on limited characteristics of social reading. Nevertheless, as there is a need for "a taxonomy to make sense of a range of behaviours all which fit within the current 'social reading' rubric" [8], to the best of our knowledge, no consolidated overview exists. In order to promote this evolving field, we aim to develop a taxonomy that structures the field of social reading. Accordingly, this study aims to answer the following research question:

What kind of characteristics are provided by social reading platforms and how can these characteristics be structured?

To answer this question, we aim to derive a taxonomy of social reading platforms. A taxonomy facilitates the characterisation and analysis of a certain domain and supports ordering the complexity and provides a foundation for IS research, potentially leading to future research directions [10]. Both for research and practice, the taxonomy can be used to derive implications for future social reading platforms. Researchers are, for example, supported to position and redesign their platforms or research results, and to identify gaps that need to be addressed by future endeavour. Practitioners (book sellers, publishers), for instance, can be informed within the wide range of social reading platforms, to compare, refine and develop further platforms. In addition, users (e.g., reviewers, authors) are supported to make an informed decision concerning the selection of a social reading platform as they receive an overview of platforms and their characteristics. For developing the taxonomy, we first outline the background of social reading and social reading platforms (Section 2). Following our research design (Section 3), we gathered initial literature, collected social reading platforms and applied a taxonomy-development approach to classify the platforms based on specified characteristics. Further, we identified types of social reading platforms by carrying out a cluster analysis (Section 4). Afterwards we discuss the limitations, results and implications (Section 5) and conclude with our main findings (Section 6).

2 Background

In this section, we introduce the concepts of social reading, social reading platform and attempts in research to structure social reading platforms.

Social reading platform. Traditionally, reading is associated to be done alone, underlining text passages and writing notes in the margins. However, readers have always communicated their impressions and evaluations about what they read, restricted to small communities (e.g., traditional book clubs) [4]. Thus, reading itself as it functions as a vehicle of human interaction by transferring thoughts and emotions between people can be defined as a social activity. According to various researchers, digitalisation changes the basic structures of communication before, during and after reading [11] and enables a changed form of socialisation of reading that encourages collaboration and exchange, resulting in a more and more social reading [4, 12, 13]. In addition, social reading can be described as a form of collective reading of digital texts and communication in reader-centred communities in digital networks [11]. An Internet platform or a specific software product is the meeting place for social reading in the above described sense. Taking part in such an application, users can communicate, exchange information and share opinions on books [14]. To do so, for instance, the platforms allow users to write reviews on books or participate in books clubs.

Structuring social reading platforms. Due to the increasing relevance of social reading platforms, some studies already attempt to structure and specify them. Nonetheless, by conducting a literature review[1], we found only a few articles that provide a first structure. Whereas Cordón-García et al. [4] and Boesken [7] provided an overview of existing social reading platforms, Stein [8] provided a taxonomy of social reading in order to make sense of behaviours that fit with the current social reading practices. However, he focuses on technology and considers online discussion used in social reading in a more general way. Moreover, Winget [9] provides an augmented taxonomy of social reading, reflecting background in commonplace books and annotation behaviour. Following, to the best of our knowledge, there is no research providing a consolidated structure of social reading platforms, and there still seems to be a need for a widely accepted overview. Accordingly, in this study we aim to close these gaps by providing a proper basis for further research in the field of social reading.

3 Research Design

In order to develop a taxonomy of social reading platforms, and therefore, to address our research question, we conducted a four-staged research design. As first steps, we carried out (Stage 1) an initial literature review and (Stage 2) collected social reading platforms. Following, based on the findings, we (Stage 3) iteratively built a taxonomy to structure the platforms obtained and performed (Stage 4) a cluster analysis to identify types of social reading platforms (Figure 1).

Stage 1: Initial literature review. As a first step for characterising social reading platforms, we conducted a literature review based on the rigorous procedure of vom Brocke et al. [15]. In March and April 2018, we searched for relevant literature in the scientific domain (that is book chapters, books, conference papers, working papers and journal publications) in both IS and literary studies. Based on our definition of social reading (Section 2), we used the following combinations of keywords in AISeL, Google

[1] We searched for existing research that structures social reading platforms. We used "Social Reading Platform" AND ("Classification" OR "Taxonomy") as search phrase in AISeL and Google Scholar (accessed on July 2018).

Scholar, BDSL and university library catalogue: *book, literature, social reading, platform, forum, community, book seller, online shop*. After reading title, abstract and keywords, we finally considered seven scientific sources (two books, three book chapters, one journal publication, and one working paper) to define potentially initial dimensions and characteristics of the taxonomy.

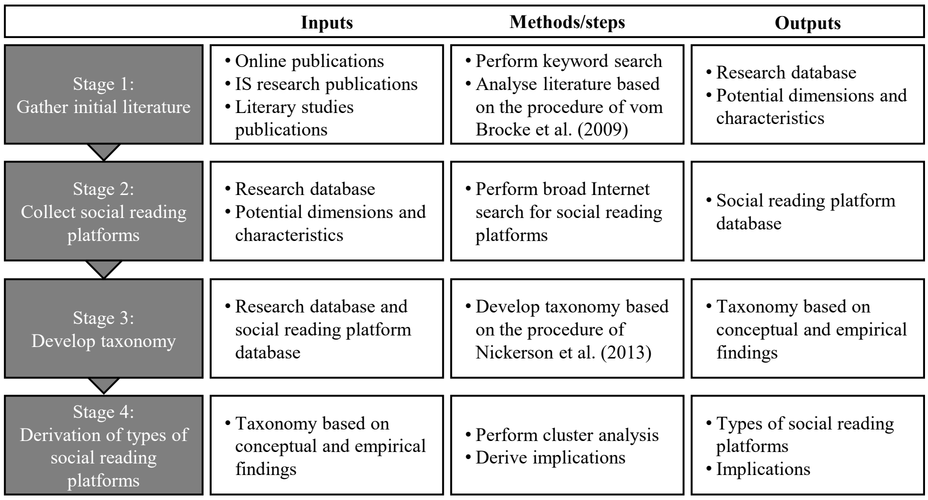

Figure 1. Research design

Stage 2: Collection of social reading platforms. Based on the results from the initial literature review and the researchers' expertise in the area of social reading platforms, in May and June 2018, we investigated a number of social readings platforms combined with a broad Internet based search for social reading platforms. To contribute to comparability, we included German platforms as Germany is one of the largest European markets in terms of publishers' turnover [16]. We excluded platforms that do not longer exist—although they are still listed in the Internet—or have less emphasis in the community (measured by small user numbers). As a result, we obtained ten social reading platforms.

Stage 3: Taxonomy development. The development of taxonomies has often been used to structure and analyse fields both in IS [17–19] as well as especially in creative industries [8, 20]. Moreover, taxonomies can be seen as a step towards developing analytic theories [21, 22]. In our study, we build a taxonomy in line with the rigorous procedure of Nickerson et al. [10]. Following, we define *meta-characteristics* as the components of social reading platforms. Moreover, Collaboration Virtualization Theory [23] provides significant factors (e.g., task, technology, team) which influence the success of collaboration technology. In line, as it provides potential factors that might affect the usage of social reading platforms, we adopted the framework and extended the meta-characteristics. Further, we adopted the *objective and subjective ending conditions* proposed by Nickerson et al. [10]. According to Nickerson et al. [10], the taxonomy development process is an iterative one within we may choose between *empirical-to-conceptual* and *conceptual-to-empirical approach*. In sum, we run through 13 iterations, whereby after six iterations no more changes occurred (Figure 2).

As a *1st iteration* (*conceptual-to-empirical*), we integrated the taxonomy dimensions and characteristics identified during the literature review (Stage 1). As an initial result, we introduced ten dimensions: *type of communication* [4, 7, 8, 11, 24], *realisation of subsequent communication* [7, 11, 24, 25], *off-topic communication* [7], *system-based roles* [7, 24], *identity customisation* [7, 11, 24, 26], *provided link to other communities* [4, 7, 11, 24], *registration for the platform* [7], *visibility of content* [7, 11, 25], *financing of the platform* [7, 11] and *reviewer gratification* [11, 24, 26]. Based on these conceptual findings, in the *second, third, fourth, fifth and sixth iteration* (*empirical-to-conceptual*), the social reading platforms that we collected were investigated and classified by two researchers independently to contribute to the robustness.[2] In a subsequent workshop (*iteration 7*) the results were consolidated and structured within the taxonomy, resulting in (i) new dimensions: *type of cultural artefact addressed by subsequent communication*, *assistance for subsequent communication*, *social media intelligence*, *transaction offerings*, *author gratification* as well as (ii) additional characteristics. After the sixth iteration the taxonomy led to the successful classification of all social reading platforms from the database (detailed descriptions see Section 4). In contrast to Nickerson et al. [10], the characteristics of each dimension are not mutually exclusive.

Stage 4: Derivation of types of social reading platforms. Finally, to identify types of social reading platforms we performed a cluster analysis. This type of analysis is a widespread used analytical tool in IS research for grouping objects and investigating correlations in differently-sized samples from small datasets (e.g., 15 items) to larger ones (e.g., 9025 items). Especially, for further analysis of derived taxonomies, a cluster analysis is often used in IS research [27]. In line, we used the selected social reading platforms as items and the set of characteristics on the basis of the taxonomy as clustering variables. Following, we applied the K-means algorithm that is one of the most common methods for such a clustering [28]. Following [18, 29], we applied a two-step approach to identify clusters of social reading platforms from our taxonomy by using python module *scikit-learn* that provides a wide range of machine learning algorithms, both unsupervised and supervised [30].

1. Step (Ward's method). The ward's method is a procedure to build hierarchical clusters of subsets on the basis of their similarity. The method combines two closest subsets into one cluster and repeats this procedure until all subsets are in one cluster [31]. The amount of identical characteristics along the taxonomy determined the similarity between two subsets [18]. To follow the sequence in which the subsets have

[2] After the initial literature review (1) for each iteration, we considered a new social reading platform that we identified and performed subsequent workshops in order to consolidate results: (2) LovelyBooks (www.lovelybooks.de), (3) BuecherTreff (www.buechertreff.de), (4) Amazon (www.amazon.de), (5) Lectory (www.lectory.io), (6) Mojoreads (www.mojoreads.com), (7) Workshop, (8) WasLiestDu? (www.wasliestdu.de), (9) Buechereule (www.buechereule.de), (10) Literaturforum (www.literaturforum.de), (11) Buecher.de (www.buecher.de), (12) Hugendubel (www.hugendubel.de), (13) Workshop. After the sixth iteration, no more changes occurred.

been united in relation to the distances, we plotted a dendrogram. Regarding the significant jumps in the distance of the joint clusters, we identified three or four clusters as useful numbers. To highlight more different cluster, we chose four.

2. Step (K-means method). Second, we applied K-means method that divides data into clusters, minimising the within-cluster sum of squares [32]. We chose initial cluster centres using 'k-means++' and the algorithm iterated 300 times. Within each iteration, the algorithm run with ten different centroid seeds to get the best results.

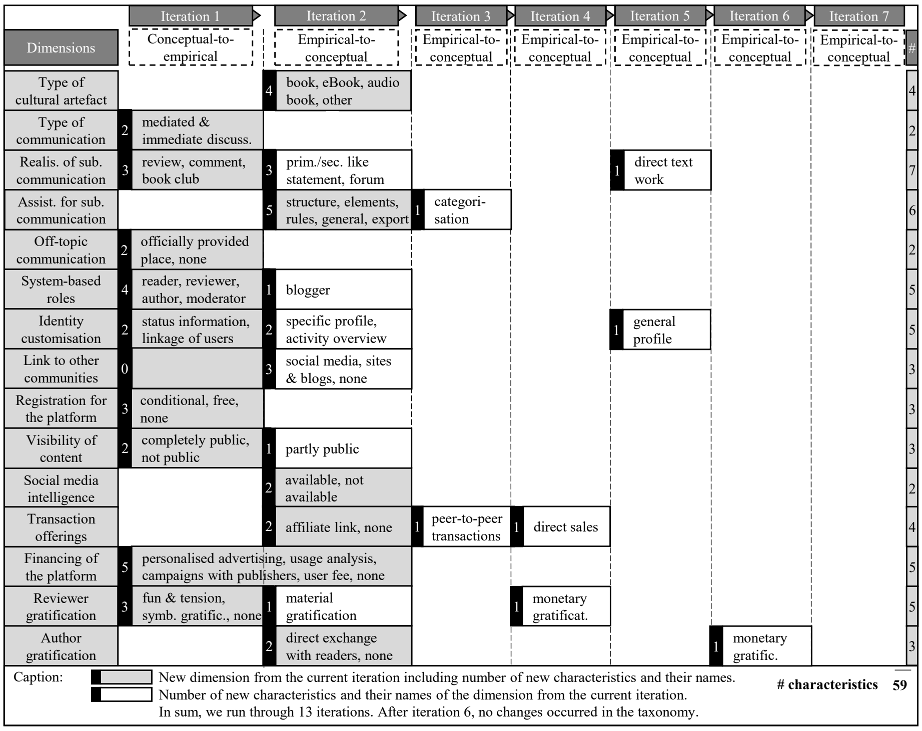

Figure 2. Development of dimensions and characteristics for the taxonomy

4 Characteristics of Social Reading Platforms

In this section, we present our main contribution, a taxonomy of social reading platforms and the derived types of social reading platforms.

4.1 A Proposed Taxonomy of Social Reading Platforms

The resulting taxonomy contains 15 dimensions, each with two to seven distinct characteristics (Figure 3). Each dimension and their corresponding characteristics are explained in the following. It is important to note that the taxonomy contains the most important dimensions along which the platforms differ. Consequently, components that are identical for all platforms (e.g., analysis of personal data, increasing publicity of books as gratification) are not listed here. Further, each dimension relate to one or more categories of Collaboration Virtualization Theory *task, community, technology* [23] that we extended with *business* as the taxonomy considers business issues as well.

Dimensions	Characteristics							
Type of cultural artefact addressed by subsequent communication (**TA**, B)	book	eBook	audio book	other				
Type of communication (**TA**, C, TE)	mediated discussion on a book (change of medium)	immediate discussion on a book (in the margins)						
Realisation of subsequent communication (**TA**, C, TE)	primary thematisation Writing a review	secondary thematisation Comment function	primary thematisation Like statement	secondary thematisation Like statement	book club: one type / diff. types	discussion forum	direct text work (visual marks)	
Assistance for subsequent communication (**TA**, C, TE)	prescribed structure of a review	proposed elements of a review	direct instructions	general instructions	writing rules & tone	general assistance	categorisation of reviews	export function
Off-topic communication (**TA**, C, TE)	officially provided place	none						
System-based roles (TA, **C**, TE)	reader	reviewer	author	moderator	blogger
