In this research study, we therefore concentrated on factors driving justification of mass surveillance. We consider mass surveillance to be a political arrangement, and therefore to be a system in the sense of the system justification theory (SJT) [16]. To use SJT in our research study, we follow previous recommendations to adapt a general theory to a particular context [30], by adapting existing concepts and by adding new concepts from literature on mass surveillance [10, 11, 13, 28, 29]. After having evaluated our research model, we are able to answer our research question which is *what factors drive individuals to justify mass surveillance?*

Our results indicate that perceived security is the major concept increasing justification of mass surveillance. Hence, if individuals have the perception that through mass surveillance, security is about to increase, then they are more likely to justify it. Also, individuals who have nothing to hide have a higher probability to justify mass surveillance. In addition to these two concepts from research on mass surveillance, two factors from SJT are also drivers of justification of mass surveillance: Individuals, who have a higher need for order and stability as well as individuals who perceive the world to be dangerous, are more likely to justify mass surveillance. Besides, perceived loss of privacy control has no influence on justification of mass surveillance. That means, even if individuals have the perception that through mass surveillance, they have lost control over their privacy, it does not have an effect on their justification of mass surveillance. These results have implications for theory in the area of IS, and specifically in the privacy-related domain, as well as for practice.

6.1 Implications for Theory

Mass surveillance is a system in the sense of the SJT: SJT has been used in a variety of settings outside of the IS domain, predominantly in the area of political science [17, 18, 20]. With this research study, we bring SJT to the area of IS research, by conceptualizing mass surveillance to be a political arrangement, and thus a system in the sense of SJT. Scholars, researching on justification of mass surveillance, can therefore also rely on SJT in their future research studies. With this, they are able to rely on additional factors [19] that could be used with SJT, to gain a further understanding of justification of mass surveillance.

Individuals who have a need for order and stability consider mass surveillance to be the current status quo: Individuals who are having a higher need for order and stability want to maintain their current status quo [17]. Since these individuals are more likely to justify mass surveillance, we conclude that they consider mass surveillance to be the current status quo, which they want to maintain. Based on this implication, scholars could use other theories, such as status quo bias theory which has already been applied in IS research [48] or related factors such as right-wing authoritarianism or conservatism [34], to further understand justification of mass surveillance.

Mass surveillance does not have to be a bad thing for individuals: Previous research, including this study, has assumed that mass surveillance is perceived to be negative by individuals, due to privacy issues [e.g. 10]. However, our results indicate that individuals do not necessarily consider mass surveillance to be a bad thing. Individuals think that through mass surveillance, the world might become less dangerous, and perceived security might increase, which is why they justify it. Especially the latter is a factor, that has often been suggested by previous research [13, 26, 28, 29]. However, to the best of our knowledge, we are the first ones to explicitly demonstrate that impact on justification of mass surveillance. Hence, if scholars in the domain of IS, aim to take mass surveillance as something individuals perceive to be negative, or aim to use it to fear individuals [38], they should put caution on it. Researchers should rather check in how far individuals really consider mass surveillance to be a bad thing or if they do not more consider it to be positive.

Loss of privacy control has no impact on justification of mass surveillance: One explanation for that could be, that loss of privacy control does not adequately reflect powerlessness. Powerlessness might also refer to other concepts, e.g., when it comes to the question of who is able to examine information. The majority of individuals is producing information, yet, only a minority of individuals is powerful enough to examine that information. Also, other conceptualizations, such as political power, might better serve as the conceptualization of powerlessness. Another explanation for the non-supported hypothesis would assume, that loss of privacy control does correctly reflect powerlessness. However, powerlessness has no impact on justification in a system of mass surveillance. Previous research on SJT has shown that powerlessness does not always have to lead to more justification of the system [19]. Different reasons have been provided, e.g. when individuals are more ego-centered [18]. Scholars could go deeper into that issue, by applying SJT, and use explanations for the non-significant effects of powerlessness. Independent of that, the results imply for scholars in the domain of IS, that when researching on mass surveillance outside of SJT, a loss of privacy control could be left out in a research model.

Besides theoretical implications, this study also provides practical implications.

6.2 Implications for Practice

Two practical implications arise from this study:

1) Perceived security needs to be aligned with objective security. In case individuals want to change their positive attitude on justification of mass surveillance, they might want to ask themselves, in how far mass surveillance actually increases security. For example, so far, evidence on increased objective security through mass surveillance is rather scarce [49]. Therefore, we recommend individuals to check on, in how far their level of perceived security is aligned with the actual level of objective security through mass surveillance.

2) Individuals who have the need for order and stability consider mass surveillance to be current status quo. Changing the status quo will bring additional problems. Therefore, in case governmental organizations are focusing on individuals, who have a high need for order and stability, they could try to just let things going without changing anything. This is because individuals often try to keep the current status quo [48].

After having discussed the implications of this study, we will now focus on limitations and future research possibilities.

6.3 Limitations and Future Research

This research study uses prior disclosure as a variable to control for, in how far the amount of information disclosed, has an impact on justification of mass surveillance. The results indicate no impact, yet, future research could still concentrate on other demographic variables of the participants, such as the country they are living in, to find out in how far there are differences in the justification of mass surveillance. Furthermore, age as a control variable indicates that the older the individual the less likely she will be to justify mass surveillance. We did not hypothesize on that relationship, yet, future research might more elaborate on these thoughts. One reason could be that older individuals know more how life is without the Internet, and without online mass surveillance, and therefore value that more.

Besides, this research study has concentrated on factors, driving the justification of mass surveillance. If one wants to actually change the level of justification, one could focus on these factors. Future research could thus try to find out, what determines the level of these factors, to then present actual recommendations on how to influence the level of justification of mass surveillance. Furthermore, future research could also expand the definition of mass surveillance, to not only focus on governmental organizations but also include private companies which might also use mass surveillance technologies [e.g., 50]. This could also be done, by focusing on designated journals, which are outside the domain of IS, but which particularly focus on mass surveillance. Future research could on the other hand also focus on the term governmental organizations, by better specifying that term and digging deeper into what particular governmental organizations conduct mass surveillance. In addition, this study has focused on studies in the domain of IS. Future research could also elaborate on other sources outside this domain. Plus, this research study has analyzed the results using a PLS approach. However, other approaches such as the ordinary least squares approach (OLS), might also be suitable. Therefore, future research might also consider using other methodologies than PLS, such as OLS.

In sum, this study has researched on factors, driving justification of mass surveillance. Based on SJT and previous research on mass surveillance, several drivers of mass surveillance justification have been provided, alongside with implications for theory and practice.

Abstract. Research on the Privacy Calculus, which explains individuals' intention to disclose personal data, mostly focuses on dyadic disclosures in which individuals disclose data to a single firm. So far, little attention has been paid to understand the characteristics of data disclosures to a network of firms. We refer to data sharing of firms in a network as "Business Network Data Exchange" (BNDE). We explore risk perception for data disclosures in a BNDE context based on an exploratory survey. Our results indicate that risk perception for data disclosures in the BNDE context deviates from rational risk perception theory. In particular, individuals perceive the risk to disclose data to a network of two firms as lower than the maximum risk of the separate dyadic data disclosures. These results portend the need for an adapted and nuanced view on perceived risks in this context and have important practical implications for data-sharing among firms.

Keywords: Privacy Calculus, Risk Perception, Business Network Data Exchange

1 Introduction

Most research in the privacy context focuses on situations in which individuals disclose data only to a single firm (e.g., [1]). However, recently more and more firms started to depart from this dyadic consumer-firm relationship and began to share consumer data within a network of firms [2, 3]. In accordance with Bidler et al., we will refer to such procedures as Business Network Data Exchange (BNDE) [4]. An example for BNDE is the music streaming service Spotify: Consumers' data is shared among a network of artists, record labels, and further third parties [5]. Potential differences between dyadic data disclosures and data disclosures in the BNDE context have rarely been examined in the literature. One difference could be the complexity or non-transparency of BNDE situations, which could promote irrational behavior [4, 6–8]. However, the Privacy Calculus, as the dominant theory to explain individuals' intention to disclose personal data by weighing their benefits against their risks, assumes rational behavior [3, 9–11]. As perceived privacy risks are the main factor reducing individuals' intention to disclose in the Privacy Calculus [11–13], we will focus on perceived risks as a key factor in this first approach. We argue that in BNDE data disclosures individuals' risk perception

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

differ from dyadic data disclosures. As a starting point for future research in the BNDE context, we first focus on the question: *Is individuals' risk perception of a data disclosure to a BNDE firm network consisting of two firms higher or lower than the dyadic data disclosure to a single firm?*

2 Theoretical Background on Risks

Privacy risk comprises "the degree to which an individual believes that a high potential for loss is associated with the release of personal information to a firm" [3]. In traditional risk perception theory a rational evaluation is expected as the perceived risk of an outcome is defined as the probability of a certain unfavorable outcome multiplied by the severity of the respective outcome [14–16]. If a risk is constituted by different risk components they are often assumed to be additive [17]. The assumption of rational evaluation as well as the additivity of risks was challenged by the Prospect Theory [18, 19]. According to the Prospect Theory individuals transform benefits and risks into a simpler mental representation and use a function to assign a subjective value (perceived benefits and perceived risk) to them. For this value function, monotony as well as a diminishing marginal value is assumed [18, 19]. Since the main emphasis of our paper is on risks, this means particularly that each added potential loss should increase the perceived risk (monotony), but this effect diminishes the more potential losses already exist (diminishing marginal value). In this short paper we focus on the simplest possible BNDE network consisting of just two firms (see Table 1). According to traditional risk theory as well as Prospect Theory, we expect the risk of a data disclosure to a BNDE network with two firms should be perceived higher than the risk of each of the dyadic data disclosures due to the monotony assumption. The risk increase should be caused by the additional (second) firm which obtains the individuals' data. This leads to our proposition 1a.

On the other hand, mutual control in cooperations plays a major role for firms [20, 21], thus it is possible that individuals' perceived or assumed control distribution among the firms in the network could alter individuals' risk perception as well. Furthermore, cooperations among firms offer several benefits for consumers and firms. For instance, firms can complement each other [22, 23], e.g., with technical security know-how. Additionally, firms can improve their own internal processes due to knowledge transfer in a cooperation [22, 24–26], which could reduce individuals' perceived risk for BNDE data disclosures, e.g., through better standards of conduct. Both was also described by some participants in pre-test interviews. This leads to our proposition 1b.

Proposition 1a / 1b: *The perceived risk for the BNDE data disclosure is perceived higher (Proposition 1a) / lower (Proposition 1b) than the maximum perceived risk of the two respective dyadic data disclosures.*

3 Exploratory Survey

The survey data (61 subjects, 33 male) was collected from end of November 2017 until mid of December 2017 in cooperation with a panel provider. The subjects were over 18 years, live in Germany, and the age distribution of them reflects the age distribution of German Internet users. The within-subject designed survey contained two groups with three scenarios each and a fixed scenario order (see Table 1).

Table 1. Empirical Setup

	Scenario 1 (BNDE)	Scenario 2 (Dyadic)	Scenario 3 (Dyadic)
Group 1 (n=32)	→ High-Risk-Firm → Low-Risk-Firm	→ High-Risk-Firm	→ Low-Risk-Firm
Group 2 (n=29)	→ Low-Risk-Firm → High-Risk-Firm	→ High-Risk-Firm	→ Low-Risk-Firm

The first scenario was a BNDE data disclosure scenario with two existent firms: The subjects saw a screenshot of the respective firm's website and were asked to disclose some personal data (name, address, net-household income, expenses per week, supermarkets they regularly visit, number of persons in the household, phone number). In group 1 (n=32) the subjects disclosed their data to the High-Risk-Firm, which shares the exact same data subsequently not anonymized with the Low-Risk-Firm[1]. This data sharing procedure between the two firms was described in the scenario. In group 2 (n=29) the data was disclosed to the Low-Risk-Firm and then shared with the High-Risk-Firm. In both groups, both firms obtain the same data. The benefit in all three scenarios was identical (20 Euro coupon which could be redeemed in both firms). Two groups were used to control for firm order effects.

After reading the respective scenarios the subjects had to assess their perceived privacy risk (PR) on a seven-point Likert Scale with one being "strongly disagree" and 7 being "strongly agree" based on a scale of Dinev et al. [27] (PR1: It is very risky in this situation to disclose personal information. PR2: There would be high potential for privacy loss associated with data disclosure in this situation. PR3: Personal information could be inappropriately used in this situation. PR4: Providing personal information in this situation would involve many unexpected problems; The average of the items was used as perceived risk). For the High-Risk-Firm a well-known search engine firm and for the Low-Risk-Firm a well-known grocery store were selected. Existing firms were used to make the whole scenario easier to imagine and comprehend. After assessing the risk for the BNDE disclosure (scenario 1) the subjects had to imagine and assess their privacy risk for the two respective dyadic data disclosures without any data sharing to further firms (i.e., scenario 2: disclosure only to the High-Risk-Firm and scenario 3: disclosure only to the Low-Risk-Firm). These two dyadic scenarios were the same in both groups.

4 Results, Discussion, and Outlook

As expected, the risk for the dyadic scenario 2 ($PR_{High\text{-}Risk\text{-}Firm}$) is perceived in both groups significantly higher than the risk for the dyadic scenario 3 ($PR_{Low\text{-}Risk\text{-}Firm}$), thus $PR_{High\text{-}Risk\text{-}Firm}$ is the maximum perceived risk of the two dyadic data disclosures. We used "R" with "EnvStats" for a one-sided paired randomization test for location [28–32] with 100k iterations to test each group separately as well as both groups together (see Table 2, Δ means test statistic). $PR_{BNDE\text{-}DD}$, the perceived risk for scenario 1, was significantly smaller ($\Delta = 40$, $p = 0.001$) than the maximum perceived risk out of the dyadic data disclosures ($PR_{High\text{-}Risk\text{-}Firm}$), thus we reject proposition 1a and accept 1b.

1 We conducted interviews as a pre-test (14 subjects, 11 male, age between 21 and 71) to ensure that the risk level is perceived as different between the two dyadic data disclosures.

Table 2. Preliminary Results

Group \ Scenario	Mean Perceived Risk (Standard Deviation)			One-Sided Paired Randomization Test for	
	PR_{BNDE} Scenario 1	$PR_{High\text{-}Risk\text{-}Firm}$ Scenario 2	$PR_{Low\text{-}Risk\text{-}Firm}$ Scenario 3	$PR_{Low\text{-}Risk\text{-}Firm} < PR_{High\text{-}Risk\text{-}Firm}$	$PR_{BNDE} < PR_{High\text{-}Risk\text{-}Firm}$
Group 1 (n=32)	4.25 (1.52)	5.11 (1.33)	3.52 (1.44)	$\Delta = 50.75$, $p = 0.000$	$\Delta = 27.50$, $p = 0.003$
Group 2 (n=29)	4.90 (1.52)	5.33 (1.33)	4.35 (1.44)	$\Delta = 28.25$, $p = 0.003$	$\Delta = 12.50$, $p = 0.074$
Both groups (n=61)	4.56 (1.61)	5.21 (1.52)	3.92 (1.63)	$\Delta = 79.00$, $p = 0.000$	$\boxed{\Delta = 40.00, p = 0.001}$

Contrary to the monotony assumption of the Prospect Theory, the perceived risk for data disclosures in a BNDE context with two firms is perceived as less risky than the maximum of the two respective dyadic data disclosures. These preliminary results indicate that we observe non-monotony behavior that could be explained by positive cooperation effects which reduce individuals' perceived risk due to individuals' assumption of positive changes in firms' data handling process. Future research could review the monotony assumption of the Prospect Theory in the BNDE context and extend the Privacy Calculus by considering positive cooperation effects. Future research should also investigate whether the changes in individuals' risk perception are an instance of irrational behavior in the context of the Privacy Calculus as suggested by Dinev et al. [9].

Additionally, our preliminary results have important practical implications: When the risk for a BNDE data disclosure is perceived as less risky than one of the separate dyadic disclosures, joint data collections are more effective in total and specifically for firms associated with high risk. Since the perceived risk for BNDE data disclosures is nevertheless expected to be the same or higher than the minimum of the separate dyadic data disclosures, it might be beneficial to investigate redistribution mechanisms among firms to balance their cooperation benefits.

The presented preliminary results should be viewed in the light of their limitations: The sample size is small and the within-design without scenario order randomization could distort the results. Also, our results could hold only for BNDE networks consisting of just two firms. To rule out these possible error sources a new survey with bigger sample size, hypothetical firms, varying network size, and a between-subject design is in work.

In sum, we showed that data disclosures in a BNDE context are an interesting and unexplored field that requires further research. Thus, we aim for a deeper understanding in which BNDE constellations (e.g., firm combinations, network characteristics, etc.,) individuals assume positive changes in the data handling process of the network firms and perceive less risk for the BNDE data disclosure. For this, our exploratory study with the focus on risk perception shall serve as a starting point.

Abstract. Am Kapitalmarkt steigt der Bedarf einer Stakeholder-orientierten Nachhaltigkeitskommunikation von Unternehmen. Informationssysteme können Unternehmen in einer Stakeholder-orientierten und effizienten Nachhaltigkeitskommunikation unterstützen. Mithilfe einer fachlich deskriptiven Prozessmodellierung in BPMN 2.0 wird der Status quo der informationstechnisch verstandenen Nachhaltigkeitskommunikation beschrieben. Dies erfolgt auf Basis von Fachliteratur durch Abstraktion und Partitionierung. Es wird deutlich, dass Investoren vorrangig auf Primär- und Sekundärinformationen von Intermediären zurückgreifen und weniger auf Primärinformationen direkt von Unternehmen. Das entwickelte Ist-Modell eignet sich als Forschungsgrundlage in der Wirtschaftsinformatik, um beispielsweise die Nachhaltigkeitskommunikation mit einer Plattform zielgruppengerecht zu fördern. Es eröffnet sich ein grundlegendes Forschungs- und Anwendungsgebiet am Kapitalmarkt.

Keywords: Nachhaltigkeitsberichterstattung, SRI, nachhaltige Kapitalanlage, ESG-Research, Nachhaltigkeitsrating

1 Einleitung

Der Markt für nachhaltige Kapitalanlagen wächst und umfasst aktuell weltweit über ein Viertel der professionell verwalteten Kapitalanlagen [1]. Häufig wird die Finanzwirtschaft als Katalysator für die weltpolitisch beabsichtigte nachhaltige Entwicklung bezeichnet. Gemeint ist, dass die Finanzwirtschaft eine ökologisch und ethisch verantwortliche Transformation von Unternehmen beschleunigt [2]. Kapitalanlagen spielen in diesem Zusammenhang eine wichtige Rolle. Am Markt für nachhaltige Kapitalanlagen ist die Nachhaltigkeitskommunikation wesentlich, weil dort Investoren Nachhaltigkeit in ihrer Risikoabschätzungen berücksichtigen. Weiterhin ist die klassische Kapitalmarktkommunikation von Unternehmen mit wachsender Heterogenität der Investoren und mit der Digitalisierung in der Finanzwirtschaft konfrontiert [3]. Es stellt sich die Frage, ob die Nachhaltigkeitskommunikation von Unternehmen mit Blick auf den Kapitalmarkt verbessert werden kann, bspw. unter Einbezug von IT-Systemen.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Der vorliegende Beitrag beschreibt das aktuelle ökonomische Phänomen der Nachhaltigkeitskommunikation börsennotierter Großunternehmen am Kapitalmarkt. Ausgangspunkt ist der theoretische Kommunikationsbegriff aus Nachrichten-Perspektive. Definiert wird Nachhaltigkeitskommunikation somit als Austausch von Nachhaltigkeitsinformationen am Kapitalmarkt. Deutlich wird dabei, dass die Fäden der Nachhaltigkeitskommunikation zwischen Unternehmen und Investoren aktuell vorrangig über Intermediäre laufen. Letztere werden im Beitrag als Nadelöhr bezeichnet.

2 Perspektiven auf den Kommunikationsbegriff

Grundlage der Untersuchung bildet der theoretische Kommunikationsbegriff aus Nachrichten-Perspektive. Zur Diskussion der Ergebnisse wird punktuell der Kommunikationsbegriff aus der Perspektive der Sprechakt-Theorie hinzugezogen.

Die Nachrichten-Perspektive stammt aus der Informatik und betrachtet die Daten- und Informationsübertragung zwischen Sender und Empfänger gemäß dem Kanalmodell von Shannon und Weaver. Demnach entsteht zielführende Kommunikation dann, wenn Nachrichten gleichartig kodiert und dekodiert sowie störungsfrei übertragen werden [4, 5]. Schnittstellen mit der realen Welt sind hierbei Dateneingaben, -zugänge und Berichte [6]. Die Nachrichten-Perspektive versteht Kommunikation lediglich als das Übermitteln von Informationen und Daten. Informationen haben stets einen Zweckbezug und können sowohl maschinell als auch nicht-maschinell verarbeitet sein; Daten hingegen sind maschinell verarbeitet, ein Zweckbezug ist nicht notwendig [5].

Die Perspektive der Sprechakt-Theorie (Sprechakt-Perspektive), die der komplexen Lebenswelt zugewandt ist, definiert Kommunikation als Interaktion, die auf einen Konsens zu Geltungsansprüchen basiert. In den Sozialwissenschaften meint Kommunikation vor allem einen zwischenmenschlichen Prozess. Kommunikation kann sich demnach entwickeln aus einem „wechselseitig aufeinander bezogen (interaktiven) und absichtsvollen (doppelte Intention) kommunikativen Handeln“ [4] und basiert auf Sprachen mit Syntax und Semantik. Die Sprechakt-Theorie nach Austin und Searle, sowie die daran anknüpfende Theorie des Kommunikativen Handelns nach Habermas gehen davon aus, dass sprachliche Äußerungen Handlung sind und Sprache folglich erst Interaktion ermöglicht. Sprechhandlungen setzen jedoch voraus, dass die Inhalte verstanden werden. Die Theorie des Kommunikativen Handelns geht von universalen Bedingungen der Verständigung aus: Verständlichkeit, Wahrheit, Wahrhaftigkeit und Richtigkeit. Diese Geltungsansprüche bieten Ansatz zur Analyse von Verständigungsproblemen [7]. Unter Realbedingungen werden Beteiligte diese Geltungsansprüche nicht jederzeit vollständig anerkennen. Vielmehr werden diese durch soziale Diskurse thematisiert und fortwährend verändert, um schließlich das kommunikative Handeln weiterzuführen [7]. An dieses Kommunikationsverständnis der Sprechakt-Theorie knüpfen Winograd [8] und Flores et al. [6] für ihr auf Interaktion basierendes Systemdesign an. Damit grenzen sie sich von der Nachrichten-Perspektive der Datenübertragung ab, die dem herkömmlichen Entwicklungsansatz technischer Systeme zugrunde liegt [6].

3 Grundlagen und Forschungsstand

3.1 Investoren und nachhaltige Kapitalanlagen

Investoren zeigen zunehmend Interesse an unternehmensrelevanten Nachhaltigkeitsinformationen und nachhaltigen Kapitalanlagen. In den letzten Jahrzehnten ist der Nischenmarkt für Kapitalanlagen gewachsen, die nach ethischen und ökologischen Kriterien investiert werden [9]. Zunehmend nutzen auch Mainstream-Investoren Nachhaltigkeitsdatenbanken [10], bekennen sich mit der Initiative PRI (Principles for Responsible Investment) zu Grundsätzen des verantwortlichen Investierens [11] und unterstützen öffentlich die Abfrage umweltrelevanter Daten bei Unternehmen durch das CDP (Carbon Disclosure Project) [12]. Am Kapitalmarkt gewinnt deshalb bei Investitionsentscheidungen neben den klassisch wirtschaftlichen Anlagezielen (Rentabilität, Sicherheit, Liquidität) ein viertes Anlageziel an Bedeutung – die Nachhaltigkeit [13]. Der Markt für nachhaltige Kapitalanlagen – auch als Markt für Socially Responsible Investment (SRI) bekannt – hat sich aus der Nische heraus zusätzlich, mit unterschiedlichen Ausprägungen, in den Mainstream entwickelt.

Mit dem Anlageziel der Nachhaltigkeit kann eine nachhaltige Entwicklung von Unternehmen gezielt unterstützt werden [2]. Dieser Logik folgend haben Investoren den Anreiz, neben ökonomischer Rendite auch einen immateriellen Mehrwert durch ihre Kapitalanlage zu erzielen. Gleichzeitig setzt dieses Anlageverhalten bei Unternehmen einen Anreiz zur Umsetzung einer nachhaltigen Wertschöpfung, um ihren Marktwert zu maximieren [14]. In einer aktuellen Metastudie von Friede et al. [15] mit über 2000 Einzelstudien wurde ein positiver Zusammenhang von Nachhaltigkeit und finanzieller Performance bestätigt. Zusätzlich zu dieser extrinsischen ökonomischen Motivation ist es auch denkbar, dass Unternehmen intrinsisch motiviert eine nachhaltige Wertschöpfung umsetzen.

Investoren sind heterogen, mit verschieden ausgeprägtem Informationsbedürfnis und unterschiedlichen Investitionsentscheidungen. Es gibt private und institutionelle Investoren. Zu letzteren gehören Pensionsfonds, Versicherungen, Beteiligungs- und Investmentgesellschaften. Für Entscheidungen benötigen Investoren differenzierte Informationen aufgrund unterschiedlicher Ausrichtungen und Zwecke. [3, 16]

Nachhaltigkeit wird am Kapitalmarkt i. d. R. mit dem Akronym ESG zusammengefasst [17]. Diese Abkürzung steht für die Kategorien Ökologie, Soziales und Unternehmensführung. Nach diesen Kategorien bewerten Investoren das Risiko von Kapitalanlagen. Über eine genaue Definition von ESG gibt es jedoch keinen Konsens, da die inhaltliche Ausprägung je nach Nachhaltigkeitsverständnis verschieden ausfällt.

Mit Blick auf das Nachhaltigkeitsverständnis bilden Autoren und Institutionen häufig Abstufungen [9, 18-21]. Der vorliegende Beitrag orientiert sich an dem weitgefassten inklusiven Verständnis der Global Sustainable Investment Alliance [1] und bezeichnet das gesamte Spektrum vereinfachend als nachhaltige Kapitalanlagen. Wird diese erweiterte Definition für nachhaltige Kapitalanlagen verwendet, so sind derzeit weltweit 26% der gesamten verwalteten Kapitalanlagen nachhaltig investiert.

3.2 Praxis der Nachhaltigkeitsberichterstattung und -kommunikation von Unternehmen und Intermediären

Nachhaltigkeitskommunikation im Unternehmenskontext wird in der Praxis aus der Nachrichten-Perspektive gesehen und auch als Nachhaltigkeitsberichterstattung oder -reporting bezeichnet. Gemeint ist der Austausch von nachhaltigkeitsrelevanten Unternehmensinformationen. Seit einiger Zeit stellen Unternehmen Nachhaltigkeitsinformationen für ihre Stakeholder (Anspruchsgruppen) bereit, um ihre Nachhaltigkeitsperformance offenzulegen. Im Zusammenhang mit der Nachhaltigkeit von Unternehmen fällt häufig der Begriff Corporate Social Responsibility (CR, CSR), der das nachhaltige Verhalten und die Verantwortung von Unternehmen umfasst. In der Praxis der Unternehmenskommunikation ist der Nachhaltigkeitsbericht das Hauptmedium und es überwiegt die einseitige Nachhaltigkeitsberichterstattung von Unternehmen mit Multi-Stakeholderansatz. Für die Nachhaltigkeitsberichterstattung gibt es eine Vielzahl an Rahmenwerken und Standards [22], bspw. Global Reporting Initiative (GRI), Global Compact, AA1000 und ISO14001. Nur wenige dieser Rahmenwerke sind speziell auf die Stakeholdergruppe der Investoren ausgerichtet [18, 23-25]. Die weltweit am meisten genutzten Rahmenwerke sind die der GRI [26]. Zunehmend wichtig wird die Orientierung auf Stakeholder in der unternehmerischen Nachhaltigkeitskommunikation, da Stakeholder dieser mit unterschiedlichen Erwartungen entgegentreten [27]. Daher führen Unternehmen Stakeholder-Dialoge zu Nachhaltigkeitsthemen durch, um ihre Berichterstattung mit den Sichtweisen der Stakeholder abzugleichen [28].

Es gibt mehrere Gründe, die Unternehmen zur Kommunikation von unternehmensrelevanten Nachhaltigkeitsinformationen veranlassen. Die Publikation nicht-finanzieller Informationen ist für Großunternehmen durch das deutsche CSR-Richtlinie-Umsetzungsgesetz (CSR-RUG) seit dem Berichtsjahr 2017 zur Pflicht geworden (in Kraft seit 18.4.2017, setzt EU-Richtlinie um). Aus Investorensicht sind besonders die Nachhaltigkeitsinformationen von börsennotierten Großunternehmen interessant, deren Anteile in Streubesitz sind [16, 18]. Weitere Motive von Unternehmen sind nicht-materiell, wie bspw. Glaubwürdigkeit, Vertrauen und Image [29].

In der Nachhaltigkeitskommunikation mit der Stakeholdergruppe der Investoren fungieren häufig Intermediäre als Brücke, um zuverlässige unternehmensrelevante Nachhaltigkeitsinformationen an die Investoren heranzutragen. Zu diesem Zweck erheben Intermediäre – meist unaufgefordert oder seltener mit Beauftragung [18-19] – Informationen über Unternehmen. Zudem verfügen sie über Fachwissen und Erfahrung zur Bewertung der Nachhaltigkeitsperformance. Diese Definition der Intermediäre schließt alle heterogenen Eigenschaften ein, bspw. Unterschiede in Nachhaltigkeitsverständnis, Relevanz, Informationsgrundlage und Produktangebot. Viele Unternehmen teilen die Auffassung, dass ein positives Abschneiden in Nachhaltigkeits-Ratings die immateriellen Vermögenswerte positiv beeinflusst [29].

Es gibt unterschiedliche Typen von Intermediären, die auch Nachhaltigkeits-Research- oder -Rating-Agenturen, ESG-Research oder Responsible Investment Research (RIR) Groups genannt werden. Spezialisierte Anbieter sind z. B. CDP, RobecoSAM, MSCI und ISS-Oekom [30-32]. Dies sind meist profitorientierte Unternehmen. Eine Sonderrolle hat die Nichtregierungsorganisation CDP. Mittlerweile haben auch klassische Finanz-Research-Agenturen Nachhaltigkeitsinformationen in ihr Portfolio aufgenommen. Intermediäre können selbstständige Organisationen sein oder als interner Teilbereich von Finanz-Intermediären auftreten, die ein Portfolio nachhaltiger Kapitalanlagen managen [29, 33].

3.3 IT-Systeme zur Stakeholder-orientierten Nachhaltigkeitskommunikation

IT-Systeme unterstützen Unternehmen in einer zielgerechten und effizienten Nachhaltigkeitskommunikation aus Nachrichten-Perspektive. Existierende Nachhaltigkeitsmanagement-Software für Unternehmen verfügt teilweise über Reporting-Module, die die Daten nach verbreiteten Standards ausgeben, bspw. SAP SuPM (SAP), SoFi (thinkstep) und Enablon publisher (Enablon). Mehrere Autoren heben das Potenzial des Internets für die Nachhaltigkeitskommunikation von Unternehmen hervor. So werden zielgruppenspezifisch Tiefe und Umfang von Informationen variiert [34]. Haßler [35] beschreibt Chancen und Herausforderungen für Intermediäre, die durch Nachhaltigkeitsberichterstattung im Internet entstehen. Aus Sicht von Kommunikationsagenturen betonen Behrens und Winter [34] die Möglichkeit für den Dialog mit Stakeholdern. Isenmann, Marx Gómez und Süpke [36-37] zeigen das Potenzial von individualisierter, zielgruppengerechter und automatisierter Nachhaltigkeitsberichterstattung mit Hilfe eines Software-Werkzeugs. Auch Solsbach et al. [38] untersuchen serviceorientierte und maßgeschneiderte Nachhaltigkeitsberichterstattung und den Dialog in einem betrieblichen Umweltinformationssystem. Solche IT-Systeme unterstützen den Abschied von der einseitigen und Stakeholder-übergreifenden Kommunikation. Allerdings werden sie bisher in der Praxis nicht weiterverfolgt. Speziell für die Zielgruppe der Investoren birgt die individualisierte Ausgabe von Nachhaltigkeitsinformationen großes Potenzial, weil Investoren ein heterogenes Informationsbedürfnis haben. Als Austauschformat eignet sich dafür XBRL, da es bereits in der digitalen Finanzberichterstattung verbreitet ist [39] und für die Nachhaltigkeitsberichterstattung nach GRI vorliegt [40]. Für die ökologische Dimension der Nachhaltigkeit untersucht eine aktuelle Forschungskooperation der Universität Oldenburg und der Volkswagen AG die prototypische Realisierung einer Unternehmensplattform: „Environmental Communication Data Platform for the Financial Community“ (eco4fin).

4 Forschungsdesign

4.1 Herleitung der Forschungsfrage

Immer mehr Investoren legen ihr Kapital nachhaltig an und nutzen Nachhaltigkeitsinformationen über Unternehmen für die Risikoabschätzung ihrer Investitionsentscheidungen. Diese Nachhaltigkeitsinformationen gelangen über Kommunikationswege zur Stakeholdergruppe der Investoren. So stellen Unternehmen in der Praxis etwa relevante Nachhaltigkeitsinformationen gebündelt für die Stakeholder bereit. Darüber hinaus haben sich Intermediäre etabliert, die die Kommunikation zwischen Unternehmen und Investoren vermitteln. Aus Nachrichten-Perspektive bergen IT-Systeme das Potential, die Nachhaltigkeitskommunikation weiterzuentwickeln, indem sie Stakeholder-orientiert und effizient maßgeschneiderte Informationen ausgeben. Im Vorfeld der Entwicklung solcher IT-Systeme bedarf es der Kenntnis, wie die Nachhaltigkeitskommunikation am Kapitalmarkt aktuell gestaltet ist.

4.2 Methodisches Vorgehen

Die vorliegende Untersuchung analysiert literaturbasiert den Status quo der Nachhaltigkeitskommunikation am Kapitalmarkt. Zunächst wird mit Hilfe einer Literaturarbeit das Phänomen der Nachhaltigkeitskommunikation am Kapitalmarkt beschrieben. So werden Strukturen herausgearbeitet, die in ein strategisches Prozessmodell einfließen. Dieses Modell dient dem Überblick über die Interaktion der beteiligten Akteure und stellt Formate ihrer Interaktion heraus. Damit dient das Modell einer fachlich groben Erklärung des Prozesses. Der strategisch beschreibende Charakter des Modells erfordert eine fachlich exakte Darstellung mit übersichtlichem Detaillierungsgrad. Auf die Modellierung eventueller Ausnahmen und Restriktionen wird verzichtet. Das Modell bildet mit dem Geltungsanspruch eines Ist-Modells die Nachhaltigkeitskommunikation am Kapitalmarkt als gesamten Prozess im Überblick ab. Die Komplexität des Prozesses wird durch starke Abstraktion reduziert. Schwerpunkte werden durch Zerlegung verdeutlicht und teilweise zusätzlich als Teilprozesse abgebildet. Es wird die Organisationssicht gewählt, weil das Erkenntnisinteresse im Verständnis der Rollen im Nachhaltigkeitskommunikationsprozess am Kapitalmarkt liegt. Die wesentlichen Prozessbeteiligten werden als Pools dargestellt: Investor, Intermediär und Unternehmen. Auf eine weitere Untergliederung wird verzichtet, da die Darstellung einen allgemeinen Überblick geben soll und in der Praxis die Beteiligten innerhalb der Pools variieren. Die fachliche Prozessmodellierung der vorliegenden Arbeit nutzt Business Process Modell and Notification Version 2.0 (BPMN 2.0) des Standardisierungsgremiums Object Management Group [41-42]. Die Spezifikationssprache ist ein weltweit führender De-facto-Standard für Geschäftsprozesse [43]. BPMN 2.0 ist in Wissenschaft, Informatik und im praktischen Geschäftsleben etabliert und ermöglicht die Einbindung von Artefakten, Objekten und Datenspeichern.

5 Ergebnisse

5.1 Literaturarbeit

Mit der Situation der Nachhaltigkeitskommunikation befassen sich in den Wirtschaftswissenschaften unterschiedliche Modelle. Diese behandeln die Kommunikation und Interaktion der Akteure am Markt für nachhaltige Kapitalanlagen [18, 29, 44]. Ein häufig zitiertes Modell der Akteure stammt von Schönheit [44] und zeigt neben dem Wertfluss auch den Informationsfluss [29, 33]. Der Informationsfluss verläuft einerseits direkt an Investoren und andererseits über Nachhaltigkeits-Research-Agenturen und Finanz-Intermediäre. Neuere Modelle zeichnen den Kommunikationsfluss der Unternehmen an Investoren allein über die Intermediäre. So reduzieren Schäfer et al. [18] ihr

Modell auf den Informationsbedarf und stellen Nachhaltigkeits-Research-Agenturen als Informations-Intermediäre dar. Diese versorgen die Investoren entweder direkt mit angefragten Informationen oder stellen wahlweise Zusatzinformationen über Informationsprodukte zur Verfügung [18]. Auch Arnold [29] betont den Zwei-Stufen-Fluss der Kommunikation am SRI-Markt zwischen Unternehmen und Investoren. Auf der mittleren Kommunikationsstufe schließt er neben Nachhaltigkeits-Research-Agenturen auch Finanz-Intermediäre ein. Die vorgestellten Modelle zeigen teilweise begriffliche und inhaltliche Unterschiede, die sich mit unterschiedlichen Forschungsschwerpunkten begründen lassen. Auffällig ist, dass die direkte Kommunikation zwischen Unternehmen und Investoren in den neueren Modellen wegfällt, und so die zentrale Rolle der Intermediäre betont wird.

Hinsichtlich der Nachhaltigkeitskommunikation beschreibt die Fachliteratur ein Kommunikationsproblem zwischen Unternehmen und Investoren. Denn aus Nachrichten-Perspektive greifen Investoren bei der Recherche von Nachhaltigkeitsinformationen weniger auf Primärinformationen zurück, die ihnen Unternehmen direkt zur Verfügung stellen [16, 45, 46]. Häufig verfolgen Unternehmen bei der Informationsverarbeitung und -bereitstellung einen Multi-Stakeholder-Ansatz. Das gilt sowohl für die Zustellungsformen (Nachhaltigkeitsbericht) als auch für die am häufigsten zugrundeliegenden Rahmenwerke wie die der GRI [26]. Speziell auf Investoren ausgerichtet ist bspw. das neu erarbeitete Rahmenwerk für klimarelevante Berichterstattung der Task Force on Climate-related Financial Disclosure (TCFD) [23]. Ältere weitergefasste Rahmenwerke und Standards mit speziellem Investorenbezug finden sich bei Schäfer et al. [18] und Bassen & Senkl [24]. Kapitalmarktorientiert und europaweit bekannt ist der freiwillige Standard für Schlüsselkriterien (ESG-KPI), der von der Deutschen Vereinigung für Finanzanalyse und Asset Management (DVFA) erarbeitet und von der europäischen Dachvereinigung EFFAS übernommen wurde [25]. Trotz der vielen Rahmenwerke und Standards ist die direkte Nachhaltigkeitskommunikation zwischen Unternehmen und Investoren nur ansatzweise vorhanden. Insb. greifen Investoren auf folgendes Material zurück, das sie relativ mühelos für direkte Analysen abrufen können: Nachhaltigkeitsbericht, Informationen vom Internetauftritt des Unternehmens, Lagebericht im Rahmen des Geschäftsberichts und Berichterstattung an investorenunterstützte Initiativen [16]. Dadurch entgehen den Investoren unternehmensrelevante Nachhaltigkeitsinformationen, die an anderen Orten bereitstehen, bspw. in Broschüren oder in einzeln veröffentlichten Umwelterklärungen. Für die Investitionsentscheidung schließlich nutzen Investoren die von Unternehmen bereitgestellten Nachhaltigkeitsinformationen lediglich eingeschränkt bis gar nicht, und kritisieren deren Nachhaltigkeitsberichterstattung [16, 45]. Für diese mangelnde Nutzung von Informationen finden sich in der Literatur mehrere Gründe auf Seiten der Unternehmen und des Kapitalmarkts [16, 46]. Die zugrundeliegenden Ursachen dafür liegen meist im mangelnden Verständnis der jeweils anderen Interessen und Grenzen [16]. Beheben könnte dies ein verbesserter Dialog zu Nachhaltigkeitsthemen [45]. Bspw. initiieren Investor-Relations-Abteilungen der Unternehmen proaktiv Investoren-Veranstaltungen (sog. Roadshows), Telefonkonferenzen und Einzelgespräche [18].

Bisher haben Intermediäre eine Brückenfunktion eingenommen. Sie prägen die Nachhaltigkeitskommunikation sowohl technisch als auch inhaltlich, denn Investoren nutzen vorrangig Primär- und Sekundärinformationen, die Intermediäre bereitstellen [16, 30-31, 45]. Auf der einen Seite sammeln Intermediäre in vorgefertigten Fragebögen Primärinformationen und stellen diese unbewertet den Investoren bereit (z. B. CDP, RobecoSAM). Auf der anderen Seite tragen sie die Informationen in einer eigenen Datenbasis zusammen. Auf der Grundlage dieser Informationsbasis generieren sie durch Analysieren und Bewerten Sekundärinformationen als eigene Produkte, die sie – individualisiert oder standardisiert – an Investoren weitergeben. Die Produkte der Intermediäre reichen von unbewerteten Informationsprofilen bis hin zu abgeschlossenen Bewertungen der Nachhaltigkeitsperformance des betrachteten Unternehmens. Bspw. veröffentlichen viele Intermediäre Nachhaltigkeits-Rating-Produkte. Dazu zählen Nachhaltigkeits-Indizes, -Rankings und -Ratings [32], wie etwa der Dow Jones Sustainability Index (DJSI). Es existieren viele unterschiedliche Research-Agenturen und Rating-Produkte [31-32]. In den letzten Jahren wurden jedoch Tendenzen der Konsolidierung in der Nachhaltigkeits-Rating-Industrie erkennbar [30].

Intermediäre sind auf Nachhaltigkeitsinformationen von Unternehmen angewiesen, um zuverlässige Ergebnisse zu liefern [19]. Informationsgrundlage und -analyse können auf frei verfügbaren Unternehmensinformationen oder auf zusätzlich beschafften Informationen basieren. Letztere stammen aus Ad-hoc-Abfragen bei Unternehmen oder aus Informationsdatenbanken Dritter [16, 33]. Insb. Informationen über börsennotierte Großunternehmen führen Intermediäre gern im Portfolio, weil Investoren diese häufig nachfragen [16, 18]. Informationen werden von Analysten ausgewertet, die über das notwendige Fachwissen verfügen. Häufig fordert die Fachliteratur eine bessere Qualität und Verfügbarkeit von Informationen für Intermediäre. Schritte in diese Richtung sind erkennbar. So etwa, weil Unternehmen davon ausgehen, dass sie durch zielgruppengerechte Kommunikation und Informationsbereitstellung Ratingergebnisse beeinflussen können [29].

Ohne den Blick auf Intermediäre finden sich in der Literatur unterschiedliche Ansätze, um das Kommunikationsproblem zwischen Unternehmen und Investoren zu lösen. Laut Schäfer et al. [18] bedarf es dazu keiner neuen Rahmenwerke und Standards. Stattdessen schlagen sie ein kapitalmarktorientiertes Leistungsindikatorsystem auf Grundlage bestehender Richtlinien vor. Sullivan [16] hingegen argumentiert, dass sowohl Indikatorsysteme als auch bessere Standards das Kommunikationsproblem nicht lösen könnten, weil Investoren bestrebt seien, sich voneinander abzuheben. Auch weist er darauf hin, dass Unternehmen nur begrenzte Ressourcen hätten, um die von Investoren gewünschten Informationen bereitzustellen [16]. Eine solche Bereitstellung haben Unternehmen jedoch i. d. R. nicht etabliert. Für eine bessere direkte Ansprache von Investoren können Unternehmen ihre Nachhaltigkeitskommunikation im Hinblick auf deren Nutzen anpassen [10, 16, 18]. Arnold [29] schlägt eine eigene zielgerichtete Nachhaltigkeitskommunikation für den Kapitalmarkt vor. Dazu werden aber die inhaltlichen und technischen Anforderungen von Investoren in der Literatur nur indirekt angesprochen [45-46] und nicht strukturiert erhoben. Einige Forschungsarbeiten schlagen einen maßgeschneiderten, dialog- und internetbasierten Kommunikationsansatz vor [18, 40, 38, 47, 48]. Dies entspricht einem Wechsel von der einseitigen (Push-) zur zweiseitigen (Pull-) Kommunikation [49]. Auch wird das Zusammenlegen der Finanz- und Nachhaltigkeitsberichterstattung diskutiert [46], was in der Praxis teilweise schon umgesetzt wird. Bisher lassen sich jedoch keine überzeugenden Hinweise auf eine Verbesserung des beschriebenen Kommunikationsproblems in der Praxis finden. In dieser Situation soll das Handbuch von Sullivan [16] Investoren im Umgang mit dem derzeit verfügbaren Datenmaterial der Unternehmen unterstützen.

5.2 Prozessmodell aus Nachrichten-Perspektive

Abbildung 1 zeigt das Ist-Modell der Nachhaltigkeitskommunikation zwischen den Kapitelmarkt-Akteuren im Überblick. Zwei Ausschnitten stellen die aufgegliederten Subprozesse dar: Abbildung 2 zeigt die Informationsbeschaffung des Intermediärs, Abbildung 3 den Informationsaustausch zwischen Investor und Intermediär.

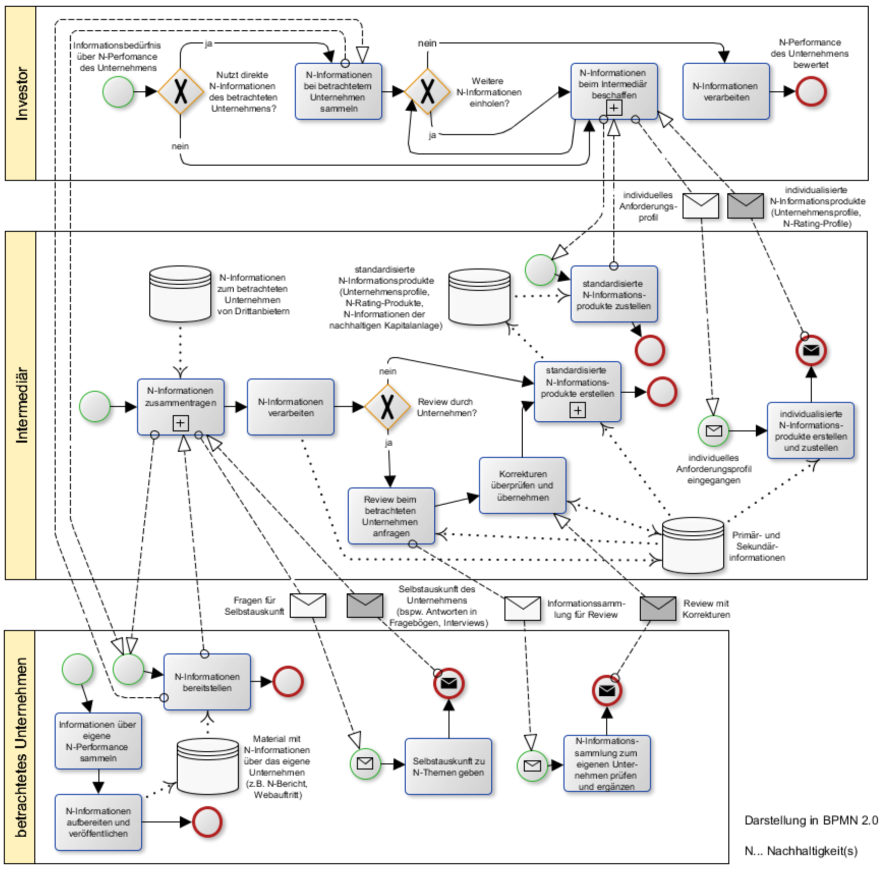

Abbildung 1. Nachhaltigkeitskommunikation am Kapitalmarkt

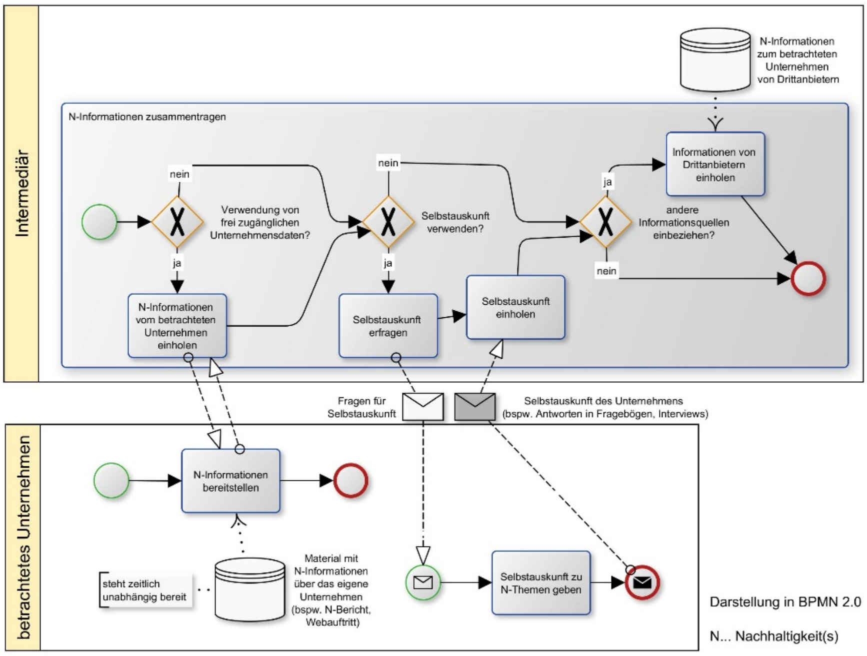

Abbildung 2. Informationsbeschaffung des Intermediär

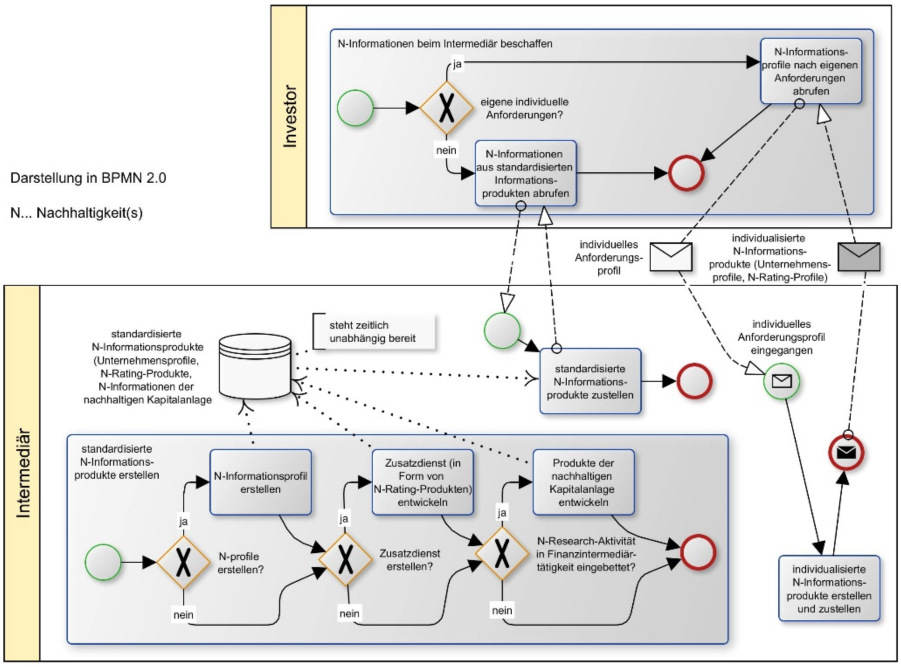

Abbildung 3. Informationsaustausch zwischen Investor und Intermediär

Initiiert wird der Prozess der Nachhaltigkeitskommunikation – mit Blick auf den Kapitalmarkt – durch das Informationsbedürfnis des Investors. Dieser möchte die Nachhaltigkeitsperformance des Unternehmens bewerten. Gegebenenfalls sammelt er zu diesem Zweck Informationen direkt vom Unternehmen. Zusätzlich kann er sich weitere Informationen von einem oder mehreren Intermediären beschaffen (Subprozess: *N-Informationen beim Intermediär beschaffen*). Die gesammelten Informationen verarbeitet der Investor und bewertet die Nachhaltigkeitsperformance.

Ausgelöst vom Informationsbedürfnis des Investors sammelt ein Unternehmen intern Informationen über die eigene Nachhaltigkeitsperformance und bereitet diese auf. Schließlich veröffentlicht es diese, bspw. als Nachhaltigkeitsbericht oder in Form eines Webauftritts. Unternehmensseitig stehen damit Nachhaltigkeitsinformationen in aufbereiteter Form öffentlich zur Verfügung.

Der Intermediär trägt Nachhaltigkeitsinformationen zum betrachteten Unternehmen zusammen (Subprozess: *N-Informationen zusammentragen*), verarbeitet diese und sammelt sie. Räumt der Intermediär dem Unternehmen anschließend die Möglichkeit zum Review ein, so erhält er auf Anfrage vom Unternehmen eine Überprüfung und Ergänzung seiner Informationssammlung. Nach Überprüfung übernimmt der Intermediär die Korrekturen. Auf dieser Basis kann er standardisierte Nachhaltigkeitsinformationsprodukte erstellen (Subprozess: *standardisierte N-Informationsprodukte erstellen*). Hierbei bereitet der Intermediär seine Informationssammlung zum standardisierten Abruf vor. Zusätzlich hat er die Möglichkeit, diese Sammlung für individualisierte Nachhaltigkeitsinformationsprodukte zu nutzen, die er auf Anfrage eines Investors erstellt.

Abbildung 2 zeigt die Informationsbeschaffung des Intermediärs detaillierter als in der Übersicht. Der Intermediär hat unterschiedliche und miteinander kombinierbare Möglichkeiten, Nachhaltigkeitsinformationen über das betrachtete Unternehmen zu sammeln. Der Intermediär kann dabei, ebenso wie der Investor, auf frei zugängliches Informationsmaterial des Unternehmens zurückgreifen. Weiterhin kann er auf Anfrage eine Selbstauskunft vom Unternehmen erhalten. Zusätzlich können Nachhaltigkeitsinformationen von Dritten hinzugezogen werden, die i. d. R. nicht frei zugänglich sind.

Die Übersichtsdarstellung in Abbildung 1 verdeutlicht den direkten Kontakt von Intermediär und Unternehmen im Prozess der Nachhaltigkeitskommunikation. Der Intermediär kann den Kontakt herstellen, indem er das Unternehmen zu einer Selbstauskunft auffordert, welche i. d. R. einen Fragebogen oder ein Interview umfasst. Darüber hinaus kann der Intermediär dem Unternehmen ein Review anbieten, das die gesammelten Nachhaltigkeitsinformationen über dieses Unternehmen beinhaltet. Das Unternehmen gibt das Review mit Korrekturen und Ergänzungen zurück.

Abbildung 3 veranschaulicht den Informationsaustausch zwischen Investor und Intermediär über standardisierte und individuelle Informationsprodukte. Für den Investor zeigt Abbildung 3 den aufgegliederten Subprozess *N-Informationen beim Intermediär beschaffen*. Zur Auswahl stehen mehrere standardisierte Produkte. Entscheidet sich der Investor für individualisierte Produkte, so ist dafür im Vorfeld die Übermittlung eines individuellen Anforderungsprofils an den Intermediär notwendig.

Für den Intermediär veranschaulicht Abbildung 3 den aufgegliederten Subprozess *standardisierte N-Informationsprodukte erstellen*. Daneben ist die Erstellung individualisierter Informationsprodukte abgebildet, die der Intermediär gemäß den Anforderungen des Investors realisiert. Individualisierte Produkte sind bspw. Unternehmensprofile und Nachhaltigkeitsratingprofile. Standardisierte Produkte kann der Intermediär bereits im Vorfeld einer Investoren-Anfrage, auf Grundlage seiner Nachhaltigkeitsinformationssammlung, erstellen. Dabei bieten sich dem Intermediär mehrere Möglichkeiten: (1) Er kann ein standardisiertes Informationsprofil über das betrachtete Unternehmen erstellen oder (2) er kann Zusatzdienste wie standardisierte Nachhaltigkeitsratingprodukte (Indizes, Rankings, Ratings) anbieten. (3) Er kann – sofern er Teil eines Finanz-Intermediärs ist – die Nachhaltigkeitsinformationen ergänzend zur internen Finanzanalyse nutzen und Produkte zur nachhaltigen Kapitalanlage entwickeln. Die Informationen aus diesen Anlageprodukten werden ebenfalls als standardisierte Informationsprodukte eingeordnet.

6 Diskussion, Fazit und Ausblick

Mit der Modellierung ist eine aktuelle Übersicht gelungen, die die Möglichkeiten der Nachhaltigkeitskommunikation am Kapitalmarkt zwischen den Akteuren darstellt. Das Modell zeigt, dass Investoren auf die Dienste von Intermediären zugreifen – entweder als alleinige Informationsgrundlage oder als Ergänzung zu selbst recherchierten Unternehmensinformationen. Allerdings ist aus der Forschung bekannt, dass viele Investoren die von Unternehmen bereitgestellten Nachhaltigkeitsinformationen nicht für ihre Investitionsentscheidungen verwenden. Daraus und aus der Tatsache, dass viele Investoren dennoch nachhaltige Kapitalanlagen tätigen, wird auf die zentrale Position der Intermediäre geschlossen. Bildhaft kann dieses Phänomen als Nadelöhr im Informationsfluss bezeichnet werden.

Folgende Limitationen liegen vor. Zum einen basiert das Modell auf einer Literaturrecherche und wurde nicht empirisch validiert, sodass Lücken oder Verzerrungen im Vergleich zur Diskurswelt möglich sind. Zum anderen führen methodische Grenzen der Prozessmodellierung dazu, dass das Modell keine Aussage über die praktische Relevanz der aufgezeigten Möglichkeiten geben kann. Außerdem macht das Modell keine Aussagen über Inhalte und Formate der Nachhaltigkeitskommunikation. Auch die Heterogenität und Relevanz von Investoren und Intermediären wird vernachlässigt. Jedoch deuten die Artefakte auf individuell verschiedene Anforderungen hin. Darüber hinaus vernachlässigt das Modell die Verständigung, die aus Sprechakt-Perspektive Voraussetzung für eine erfolgreiche Kommunikation auf Nachrichtenebene ist. Insb. zum Geltungsanspruch der Wahrhaftigkeit ist möglicherweise ein Diskurs notwendig, da nicht per se davon auszugehen ist, dass die Intentionen der Akteure wechselseitig anerkannt sind; d. h. die Glaubwürdigkeit von Unternehmen (z. B. Greenwashing), Investoren (z. B. ehrliches Interesse) und Intermediären (z. B. Intransparenz).

Aktuell nutzen vor allem Intermediäre in ihrer Rolle als Nadelöhr die Möglichkeit, den Faden der Nachhaltigkeitskommunikation am Kapitalmarkt zu führen. Dies kann zur Konzentration der Deutungshoheit führen. Dem entgegen steht der Wettbewerb unter den Intermediären, die sich durch unterschiedliches Nachhaltigkeitsverständnis und Deutungspluralität auszeichnen. Ein Lösungsansatz besteht in der

Dezentralisierung der Informationsbereitstellung. Das meint aus Nachrichten-Perspektive eine Stakeholder-orientierte Bereitstellung von Primärinformationen von Unternehmen direkt an Investoren. Jedoch trägt eine neue Infrastruktur nicht dazu bei, ein möglicherweise bestehendes Verständigungsproblem im Kommunikationsprozess zu lösen. Daher unterstützt aus Sprechakt-Perspektive der Diskurs über bestehende Verständigungsprobleme (z. B. Glaubwürdigkeit der Akteure) die Weiterentwicklung einer zielführenden Nachhaltigkeitskommunikation. Durch eine aus diesen beiden Kommunikationsperspektiven verbesserte Nachhaltigkeitskommunikation entsteht eine solide Grundlage, die Investoren und Intermediäre größere Sicherheit bei der Bewertung der Nachhaltigkeitsperformance von Unternehmen verleihen kann. Ebenso entstehen dadurch für Unternehmen Vorteile, wie Effizienz durch Automatisierung und Ableiten von Abfrage-Bedarfsanalysen. Die zentrale Rolle der Intermediäre könnte durch die Umsetzung von alternativen Strukturen der Informationsbereitstellung aus Nachrichten-Perspektive entfallen. Aus der Sprechakt-Perspektive wird jedoch zusätzlich deutlich, dass eine zentrale Rolle der Intermediäre unter Umständen weiterbesteht, da diese zur Verständigung (Geltungsanspruch Verständlichkeit) beitragen. Denn nur ein Teil der Investoren hat das Fachwissen zur Bewertung der Informationen. Der andere Teil bleibt auf die Expertise von Intermediären angewiesen.

Die Ergebnisse schaffen eine Basis für weitere Forschung zur Nachhaltigkeitskommunikation am Kapitalmarkt im Bereich der Wirtschaftsinformatik. Forschungsaktivitäten sind zu betrieblichen umwelt- und nachhaltigkeitsbezogenen Informations- und Kommunikationssystemen denkbar. Praktikern bietet das Modell einen Ansatz für die gezielte Weiterentwicklung der Nachhaltigkeitskommunikation im eigenen Unternehmen. Der vorliegende Beitrag zeigt, dass IT-Systeme dazu beitragen können, die Nachhaltigkeitskommunikation von Unternehmen zielgerecht und effizient auf Investoren und Intermediäre auszurichten. An das aufgezeigte Spannungsfeld knüpft die Forschungskooperation „Environmental Communication Data Platform for the Financial Community“ (eco4fin) an. Das Projekt untersucht den Einsatz einer Plattform zur Umweltkommunikation von Großunternehmen mit Investoren und Intermediären.

Abstract. The article gives a description of the method of material flow cost accounting. Secondly general obstacles and capabilities are described. The gathering of the necessary data is a serious problem for applying companies. A series of software requirements, with the potential to reduce the problem, were determined through a usability study and are presented in the last part. The implementation of these requirements can help to diminish the obstacles and help with the diffusion of the method.

Keywords: Material Flow Cost Accounting, Software Requirements

1 Einführung

Die Materialflusskostenrechnung (engl. Material Flow Cost Accounting, kurz MFCA-Methode) zielt darauf ab, die Kosten, die aus Verlusten während der Erzeugung von Produkten in der Prozess- und Fertigungsindustrie entstehen, aufzudecken. Damit bilden die Ergebnisse eine Entscheidungsgrundlage für eine Reduzierung der Materialkosten. Ungewünschte Nebenprodukte im Produktionsprozess lassen sich lokalisieren und minimieren. Damit ist sie geeignet, eine Verringerung von schädlichen unternehmerischen Umweltwirkungen bei gleichzeitiger Erhöhung der ökonomischen Effizienz zu realisieren. Die klassische Kostenkalkulation eines Produktes basiert darauf, dass alle in die Produktion fließenden Rohstoffe letztlich im Produkt landen und in die Preisgestaltung einbezogen werden (Vgl. [1] S. 3-5, [2] S. 3-6). Dies ist insofern konsequent, dass das produzierende Unternehmen diese Kosten in der Produktion hatte und in den Endpreis des Produktes einpreisen muss, um keine Verluste zu machen. Andererseits verhindert es eine zielgerichtete Reduzierung von Ressourcenverschwendung und vermeidbarer Kosten. Die Menge an Rohstoffen, die als Abfall nicht im Produkt landen, wird dabei vernachlässigt. Jedoch macht nur die Kenntnis dieser Mengen und Kosten, eine Reduzierung des Abfalls möglich. Der

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Vorteil der Materialflusskostenrechnung gegenüber der Stoffstromanalyse liegt in der einfacheren Vergleichbarkeit, da das Ergebnis in einer einzelnen monetären Kennzahl (Kosten der Materialverluste) angegeben wird, während die Stoffstromanalyse in der Regel eine Ökobilanz mit der Aufstellung von Umweltwirkungen zum Ergebnis hat, die schwieriger zu vergleichen sind. Das Ziel des Beitrags ist es, die Methode besser nutzbar zu machen, indem diese durch eine anwenderfreundliche Software unterstützt wird.

Die Forschungsfragen des vorliegenden Beitrags sind:

- Welche Vorteile bietet die Methode?
- Welche Schwierigkeiten verhindern eine weitere Ausbreitung?
- Welche technischen Hilfsmittel können zu einer Reduzierung der Schwierigkeiten beitragen?
- Wie lassen sich die Ergebnisse einer Materialflusskostenrechnung nutzen, um damit Kosten und negative Umweltauswirkungen zu reduzieren?

Zunächst erfolgt eine grundlegende Beschreibung zum Verständnis der Methode, da dieses wichtig ist, um Softwareanforderungen zur Methodenumsetzung zu verstehen. Anschließend wird die bisherige Verbreitung der Methode dargestellt. Eine Reihe von Hindernissen, die eine stärkere Akzeptanz bisher verhindern, kommt im darauf folgenden Abschnitt zur Sprache. Die Hindernisse werden schließlich aufgegriffen, um eine Reihe von Anforderungen an eine Software zu definieren, die das Potential besitzen, die Hindernisse zu reduzieren. Den letzten Abschnitt bilden ein Fazit und ein Ausblick auf die weitere Entwicklung.

2 Vorgehen

Die Idee zu dem Beitrag entstand durch Beobachtungen bei Unternehmen, die sich für die Reduzierung der Materialverluste interessieren, sich jedoch, aufgrund bestehender Probleme, vor der Umsetzung der Methode scheuen. Die Befragung von Unternehmensvertretern ließ den Schluss zu, dass die Softwareunterstützung die Methode nicht wesentlich vereinfacht. Anschließend wurde mittels systematischer Literaturrecherche nach Quellen gesucht, die einen tieferen Einblick in die Methodik zulassen. Eine Betrachtung der bestehenden Softwarelösungen, führte dann zu einer Reihe von Fragen, die sich mittels einer Benutzerbefragung beantworten lassen. Aus diesem Grund wurde ein typisches Vorgehen bei der Methodenanwendung ausgearbeitet und Benutzer im Rahmen einer Usability-Studie mit der Bearbeitung beauftragt.

3 Methodenbeschreibung

Die Durchführung einer Materialflusskostenrechnung setzt zunächst die Festlegung eines Untersuchungsobjekts voraus (z.B. das gesamte Unternehmen oder ein bestimmtes Produkt (Vgl. [3], S. 30)). Für das gewählte Betrachtungsobjekt, werden die generellen Stoffströme sowie die darin enthaltenen Materialverluste quantitativ erfasst. Zu diesen gehören alle Stoffe und Energien, die nicht direkt ins Endprodukt fließen, z.B.:

- Ungewünschte Nebenprodukte (z.B. Späne, Schnittreste, Stanzstreifen, Rückstände) (Vgl. [4], S. 87)
- Verpackungsabfälle von Vorprodukten, Roh-, Hilfs- und Betriebsstoffen
- Abfälle durch unsachgemäße Lagerung (z.B. durch Verderb, Verfall) (Vgl. [4], S. 87)
- ungenutzte Materialien (z.B. Körnerverluste bei der Getreideernte)
- aussortierte Fehlprodukte, beschädigte und verunreinigte Produkte (Vgl. [4], S. 87)
- aussortierte Produkte, für die keine Nachfrage existiert, z.B. durch veränderte Modetrends in der Textilindustrie
- Testprodukte und Muster
- Betriebsstoffe (z.B. Schmiermittel, Druckluft, Wärmemittel, Kühlmittel, Energieträger, Reinigungsmittel zur Anlagen Vor- und Nachbereitung) (Vgl. [4], S. 87)

Nicht enthalten sind weitere vermeidbare Verluste, die jedoch im Endprodukt enthalten sind und somit nicht als Materialverluste klassifiziert werden können, wie Materialien die bspw. durch überdimensionierte Produktabmessungen verbraucht werden oder ineffizient ins Produkt integrierte Materialien und Energien. Somit fokussiert die Methode auf das Verhältnis zwischen Inputs, die in den Produktionsprozess fließen und Outputs, die im Endprodukt landen. Demnach sind alle Stoffe, die nicht im Endprodukt verwendet werden, Materialverluste. Nach der Erfassung der Mengen an tatsächlich ins Produkt geflossenen Input-Materialien und der nicht ins Produkt geflossenen Materialverluste, erfolgt die Umrechnung der physischen Mengen mittels monetärer Einheiten in die Kosten der Materialverluste. Dazu werden zunächst die Beschaffungskosten der als Materialverluste klassifizierten Produktionsmittel mit den Kosten für die Entsorgung der Materialverluste summiert. Außerdem werden bestimmte Gemeinkosten anteilig hinzugerechnet. Somit enthalten bspw. die Materialverlustkosten für Schnittreste die Kosten für die Rohstoffbeschaffung, die Energiekosten für den Betrieb der Produktionsanlagen bei der Erzeugung des Verschnitts, die Abfallmanagementkosten, wie auch die Personalkosten für die Erzeugung und die anteiligen Wertverluste der Produktionsanlagen (Abschreibungen) und anderer versteckter Kosten (Vgl. [5], S. 234-235). Wenn eine Maschine in 5% der Betriebszeit Fehlteile produziert, so werden die Kosten für die Wartung der Maschine mit gleichem Anteil den Kosten der Materialverluste hinzugerechnet.

Abb. 1. Exemplarische Darstellung von Materialverlusten über den gesamten Herstellungszyklus eines Produkts

Die Stoffe und Energien werden entlang des gesamten Produktionszyklus über sog. Mengenstellen verfolgt. Eine Mengenstelle kann entweder ein Produktionsprozess oder ein Ort, an dem Bestandsveränderungen durchgeführt werden (z.B. ein Zwischenlager), sein. Damit können sowohl für jede Mengenstelle die Materialverlustkosten einzeln berechnet, als auch eine Summierung der gesamten Materialverlustkosten über den gesamten Produktionsprozess vorgenommen werden.

Sobald die Materialverluste erfasst sind, können mittels der Ergebnisse zielgerichtete Maßnahmen geplant und umgesetzt werden, die dazu führen, dass die kostenintensivsten Verluste vermieden oder zumindest minimiert werden. Mögliche Maßnahmen sind, bspw.:

- Die Nutzung von mathematischen Planungsverfahren zur Verschnittminimierung,
- Die Optimierung der Anlagenumrüstung bzw. von Werkzeugwechseln zur Reduzierung des Betriebsstoffverbrauchs, bspw. durch Total Productive Maintenance (TPM) (Vgl. [4]),
- Die Instandhaltung und Wartung von Maschinen zur Verringerung von Fehlproduktionen,
- Die Optimierung der (Produktions-)Anlagenkonfiguration hinsichtlich eines möglichst effizienten Materialverbrauchs,
- Die Überarbeitung des Produktdesigns im Hinblick auf eine möglichst verlustfreie Herstellbarkeit (Vgl. [4], S. 78),
- Die Verwendung von Produktionsanlagen mit einer hohen Energieeffizienz zur Reduzierung des Energieverbrauchs bei der Produktion von nicht vermeidbaren Materialverlusten,
- Die Nutzung von effektiven Verfahren zur Nachfrageprognose (z.B: Qualitative Prognosen, Zeitreihenprognosen), um möglichst keine Produkte herzustellen, für die keine Nachfrage besteht,
- Die Minimierung von Lager- und Transportvorgängen,
- Die effiziente Nutzung von Verpackungs- und Transportmaterialien,

- Die Verstärkung der Zusammenarbeit mit vor- und nachgelagerten Akteuren in der Produktionskette im Hinblick auf Datenaustausch und die Kosten durch Materialverluste.

Lassen sich die Materialverluste nicht vermeiden oder minimieren, kommt auch noch eine Wiederverwendung in Betracht, bspw. durch das Einschmelzen und Recyceln von Metallspänen. Diese führt ebenfalls zu einer Senkung der Kosten, die aus den Materialverlusten resultieren. Allerdings ist die Wiederverwendung in der Regel signifikant nachteilig gegenüber der Vermeidung von Materialverlusten (Vgl. [4], S. 86-87). Das Recycling führt dazu, dass die Materialien den vorherigen vermeidbaren Arbeits- und Energieaufwand in der Stoffbilanz weiter tragen. Deshalb ist es besser, Produktionsprozesse so anzupassen, dass der Materialverlust und damit der gesamte Materialbedarf des Produktionsprozesses minimiert wird, anstatt Fehlprodukte oder Verschnitt in einem nachgelagerten Prozess erneut zu verwerten (Vgl. [3], S. 24). Das Idealziel der MFCA ist es, die Materialverlustkosten auf null zu senken (Vgl. [2], S. 16). Hierbei gilt die Einschränkung der Wirtschaftlichkeit. Somit sollten die Kosten für die Reduzierungsmaßnahmen die daraus resultierenden Kostenpotentiale nicht übersteigen.

MFCA kann von Beginn an als integrativer Produktionsprozessbestandteil systematisch implementiert werden. Jedoch besteht auch allgemein die Gefahr, dass das Verhältnis zwischen dem Aufwand und dem Nutzen negativ wird, wenn die gesamten Implementierungskosten (also die Kosten der Datenerfassung, Modellierung, Analyse und Maßnahmenumsetzung) die späteren Reduzierungspotentiale übersteigen. Im Regelfall dürfte das vor allem bei weniger materialintensiven Industrien und kleinen Stückzahlen der Fall sein. Da die Anwendung der Methode vor allem bei einem positiven Verhältnis zwischen Aufwand und Nutzen vorteilhaft ist, schlägt die maßgebliche ISO-Norm 14051 zunächst eine Pilotanwendung bei einer Produktionslinie vor, die als besonders ressourcenintensiv gilt (Vgl. [3], S. 30), da dort auch die größten Einsparpotentiale für Materialverluste zu erwarten sind. Nach der erfolgreichen Durchführung, kann mit Hilfe der gewonnenen Erkenntnisse entschieden werden, auf welche anderen Produktionsbereiche sie angewandt wird und ob eine systematische Einbindung in das Produktionsmanagement erfolgt.

4 Ausbreitung und Potential der MFCA-Methode

Obwohl die MFCA-Methode bereits seit den 1980er Jahren existiert und seit 2011 ISO normiert ist, ist die Ausbreitung bisher eher schleppend verlaufen (Vgl. [6], S. 2-6). Recherchen zum Stichwort Materialflusskostenrechnung fördern aktuell hauptsächlich Veröffentlichungen von Wissenschaftlern, Wirtschaftsverbänden (bspw. International Federation of Accountants), Regierungsvertretern und NGOs (UN) zutage. Unternehmensreferenzen gibt es mit Ausnahme einer Studie des japanischen Ministeriums für Wirtschaft, Handel und Industrie (METI) [4] bisher nur in geringer Anzahl. Die Ausbreitung befindet sich momentan in der Diffusionsphase der „Early Adopters" (Initialphase) (Vgl. [6], S. 2-4). Die Methode wird somit noch nicht von einem breiten Anwenderkreis getragen. Ein wesentlicher Grund dafür liegt in der Komplexität der Methode (Vgl. [6], S.5-8). Die Geschwindigkeit, mit der eine Innovation in Unternehmen integriert wird, sinkt mit einer höheren Komplexität und bei einer zunehmenden Voraussetzung von Kenntnissen und Fähigkeiten (ebd.). Für die potentiellen Nutzer ist zunächst nicht erkenntlich, wann der Aufwand für die Einführung der Methode sich durch Kosteneinsparungen amortisieren wird, da vorher nicht erfasst wurde, wieviel Prozent eines bestimmten Inputs nicht im Endprodukt landen, weil sie etwa als Teil von Fehlprodukten von der Qualitätssicherung aussortiert werden. Der Schlüssel zu einer umfassenderen Ausbreitung liegt darin, dass die Methode in den Unternehmen, in denen sie prototypisch angewandt wird, ein positives Kosten-Nutzen-Verhältnis erzeugt und somit einen Wettbewerbsvorteil bewirkt (Vgl. [7], S. 17-29). Die Wettbewerber sind dann aus Wirtschaftlichkeitserwägungen gezwungen, ebenfalls die Methode anzuwenden.

In Japan kennen, begünstigt durch eine Initiative des Ministeriums für Wirtschaft, Handel und Industrie (METI), 80 % der Unternehmen die Methode, es setzen sie aber nur 6,5% ein (Vgl. [8], S. 332). Das lässt darauf schließen, dass die Methode nicht aufgrund von Unkenntnis nicht über die Phase der Early Adopters hinaus gekommen ist, sondern aufgrund von Schwierigkeiten bei der Umsetzung. Das Ministerium hat eine Fallstudie erstellt, in der die Implementierung der Methode von 23 japanischen Unternehmen vorgestellt werden. Davon haben 12 Unternehmen quantitative Angaben zu den Ergebnissen gemacht. Mit einem durchschnittlichen Anteil von 25,9% Materialverlusten an den Gesamtkosten, ist ein bedeutendes Optimierungspotential vorhanden (Vgl. [4], S. 8-84). Von den 23 aufgezeigten Beispielen, finden sich auch fünf Unternehmen, die nicht selbst produzieren, sondern im Dienstleistungsbereich zu verorten sind. Die Beispiele zeigen, dass die Methode zwar generell eher für die Industrieproduktion geeignet ist, aber auch darüber hinaus zu einem Prozessverständnis und zu Effizienzgewinnen führen kann (sog. Awareness). Für die Datenerhebung wird zwar die Expertise von Ingenieuren, Produktionsplanern sowie Buchhaltern gleichermaßen benötigt, die Methode an sich wird aber auch schnell von Nicht-Spezialisten verstanden (Vgl. [6], S. 5). Für die Anwendung der Methode bietet es sich deshalb an, interdisziplinäre Teams zu bilden.

Zwar ist die MFCA prinzipiell eher gut für produzierende Industrien geeignet, jedoch zeigt die Studie des METI [4] in fünf verschiedenen Fallstudien Möglichkeiten auf, die Methode bei Dienstleistungsunternehmen einzusetzen. Dabei werden alle Ressourcen, die bei der Erbringung der Dienstleistung notwendig sind und während des Dienstleistungsprozesses verloren gehen oder unnötig aufgewendet werden, als Materialverluste gewertet, wie bspw. defektes Büroinventar oder nicht verwendete Essensreste in einem Restaurant. Die Methode ist nicht geeignet, die externen Kosten der Materialverluste (z.B. Umweltbelastungen, die aus der Abfallentsorgung resultieren) abzuschätzen und somit die ökologischen Folgen die sich durch die Ineffizienzen ergeben, zu beziffern. Dadurch ist es möglich, dass die Ergebnisse finanzielle Einsparpotentiale aufzeigen, die durch Substitution eines Materialverlustes durch ein anderes Material möglich sind. Diese Substitution kann dann zwar ökonomisch sinnvoll, aber ökologisch nachteilig sein. Dies wäre bspw. der Fall, wenn ein Blei-Säure-Energiespeichersystem aufgrund niedrigerer Kosten durch ein Speichersystem auf Lithium-Eisenphosphat-Basis ersetzt würde, das eine schlechtere Ökobilanz aufweist (Vgl. [9], S. 74 ff.).

Selbst wenn keine signifikanten Einsparungen erzielt werden, bringt die Methode den Vorteil, dass das generelle Verständnis der Produktion erhöht wird und eine grundlegende Transparenz in der Lieferkette erzeugt wird.

5 Herausforderungen bei der Implementierung einer Materialflusskostenrechnung

Vergleichsweise wenige Unternehmen erheben die für eine MFCA erforderlichen Daten systematisch, bezogen auf Materialien, Produkte oder Prozesse, sodass die Methode nicht ad hoc am Schreibtisch angewandt werden kann (Vgl. [8], S. 26-32). Die generelle Berechnung der Kosten, die über die Verkettung von Mengenstellen für Materialverluste anfallen, ist dabei nicht die größte Herausforderung, sondern die Erfassung von bisher unbekannten Mengendaten bzw. das Zusammentragen der Daten aus verschiedenen Quellen. Im Prinzip wäre die Erfassung der relevanten Daten trivial, wenn man zunächst alle Materialien, die als Input in die Produktion fließen, wiegen würde und nach der Produktion die Anteile am Endprodukt erneut wiegen könnte, da die Differenz zwischen beiden Werten die physischen Materialverluste darstellen. Da jedoch während der Produktion Stoffe Verbindungen eingehen und genaue Anteile einzelner Materialien im Endprodukt im Regelfall nicht ohne weiteres zu bestimmen sind, müssen als Materialverluste die Mengen bestimmt werden, die nicht ins Endprodukt geflossen sind. Eine Ausnahme davon bilden Prozesse, bei denen lediglich ein einzelnes Material als Input verwendet wird.

Bei der Datenerfassung wird bisher häufig auf eine maßgeschneiderte Softwareunterstützung verzichtet, stattdessen wird auf allgemeine Tabellenkalkulationsprogramme zurückgegriffen oder mit Zettel und Stift gearbeitet (Vgl. [4], S. 8-84). Prinzipiell kann die Methode auch ohne Softwareunterstützung angewandt werden, da als Ergebnis die Materialkosten in tabellarischer Form dargestellt werden. Die bevorzugte Darstellungsform ist eine nach ISO 14051 normierte Kostenmatrix (siehe Abb. 2).

	Materialkosten	Energiekosten	Systemkosten	Entsorgungskosten	Gesamtkosten
Endprodukt	15.000	1.000	17.000	-	33.000
	38,7%	2,6%	43,8%	-	85%
Materialverluste	3.000	300	2.000	-	5.300
	7,7%	0,8%	5,2%	-	14%
Abfall / Recycling	-	-	-	500	500
	-	-	-		1%

Abb. 2. Materialflusskostenmatrix als Ergebnis der MFCA-Analyse

In der Praxis führt die Methodendurchführung ohne spezialisierte Hilfsmittel aber zu einer Reihe von Umsetzungsschwierigkeiten. Vor allem bei großen Datenmengen und einer dauerhaften Implementierung der Methode wird eine systematische Herangehensweise erforderlich, die vor allem mit Hilfe von Softwareunterstützung erreicht werden kann (Vgl. [4], S. 64.). Die Mengen werden in der Regel über einen vorbestimmten Zeitraum durch Zählung, Wiegung oder andere Messverfahren exemplarisch erfasst. Aus diesen Beispieldaten müssen die Werte für den Betrachtungszeitraum der MFCA-Analyse extrapoliert werden, da eine exaktere Bestimmung häufig nicht möglich ist. Materialverluste können teilweise sehr unregelmäßig auftreten und es fehlt an einfachen Messmethoden, da die Materialverluste nicht automatisch durch die Produktionsanlagen erfasst werden. Durch benutzerfreundliche Softwareanwendungen lässt sich die Komplexität bei der Datenerfassung jedoch senken (Vgl. [10], S. 1-10). In Problemfällen können Hilfestellungen zur Verfügung gestellt werden. So kann eine Anwendung bspw. darauf hinweisen, dass es sinnvoller sein kann mit Referenz- oder Schätzwerten zu arbeiten, anstatt über einen langen Zeitraum exakte Daten zu erfassen und die Methodenanwendung so unrentabel werden zu lassen. Materialien, bei denen geringe finanzielle und ökologische Auswirkungen erwartet werden, können bei der Datenerfassung ausgeklammert werden (Vgl. [2], S. 9). Jedoch nimmt damit auch die Qualität und damit die Aussagekraft der Ergebnisse ab. Es ist also das richtige Maß zu finden zwischen einer kostspieligen und aufwendigen Erhebung exakter Messwerte einerseits und der wirtschaftlichen Implementierung der Methode mittels weniger genauer Messwerte andererseits. Generell lassen sich diese Schwierigkeiten aber verringern, so dass das Potential für eine schnelle Ausbreitung gegeben ist (Vgl. [6], S. 8).

Ein zuvor veröffentlichter Beitrag von Hemke und Wohlgemuth [11] stellt eine Auswahl bestehender Softwareanwendungen zur Durchführung einer MFCA vor. Dazu gehören Umberto Efficiency+ [12] und bw!MFCA [13] der ifu Hamburg GmbH, der Materialflusskostenrechner des VDI Zentrum Ressourceneffizienz [14] sowie Excel-Kalkulatoren, die jedoch in japanischer Sprache verfasst sind [15]. Die Software-Lösungen sind jedoch noch nicht auf dem Entwicklungsstand, der die genannten Herausforderungen für Unternehmen senkt und eine systematische Umsetzung begünstigt. Einige der Kritikpunkte sind:

- Die fehlende Unterstützung bei der Datenerfassung,
- geringfügige Unterstützung zum Verständnis der Methode,
- unzureichende grafische Auswertungsmöglichkeiten,
- die Vernachlässigung der Vorgaben der ISO 14051,
- fehlende Verknüpfung mit anderen Datenbeständen mittels Schnittstellen,
- ein, über die MFCA hinaus gehender, Funktionsumfang und damit verbundene unnötige Anschaffungskosten, sowie
- eine fehlende Unterstützung verschiedener Einsatzszenarien (z.B. Pilotstudie).

Gleichwohl treffen diese Kritikpunkte nicht generell auf alle genannten Anwendungen zu.

6 Softwareanforderungen zur systematischen Umsetzung der MFCA-Methode

Eine Reihe von Anforderungen, deren Umsetzung mittels Software zu einer Vereinfachung der Datenerfassung und Modellbildung förderlich ist, wird im folgenden Abschnitt zusammenfassend beschrieben. Zur Ermittlung wurde von den Autoren eine Usability-Studie durchgeführt, bei der sechs Testpersonen typische Aufgaben im Rahmen einer Materialflusskostenrechnung erledigt haben. Die Testpersonen setzten sich aus Firmenvertretern und Masterstudenten der Umweltinformatik zusammen, bei denen eine Affinität zu dem Thema gegeben ist. Ziel war es, Hinweise zu erarbeiten, wie die Methode effektiv, effizient und zufriedenstellend umgesetzt werden kann. Die sechs teilnehmenden Testpersonen verfügten bereits Vorkenntnisse aus dem Bereich der Umweltinformatik. Der Ablauf und weitere Ergebnisse werden von Hemke und Wohlgemuth [11] vorgestellt. Weitere Anforderungen wurden mittels einer Anforderungsanalyse ermittelt.

6.1 Datenerfassung

Zunächst sollte die noch zu entwickelnde Anwendung den Spagat bewältigen, den die Empfehlung der ISO 14051 nahelegt, nämlich die Methode zunächst testweise in einer kleinen Pilotphase einzusetzen und mit den gewonnenen Erkenntnissen diese dann in weiteren Unternehmensteilen bis hin zum gesamten Unternehmen zu implementieren. Dadurch sollte sie es ermöglichen, sowohl kleine Ketten von Mengenstellen übersichtlich zu modellieren, als auch große Eingabemasken für die Darstellung von globalen Produktionsketten zur Verfügung stellen. Sobald das Modell größere Ketten von Mengenstellen abbildet, muss eine Skalierung der Benutzungsoberfläche dafür sorgen, dass die Übersichtlichkeit nicht verloren geht (bspw. mittels Responsive Design). Sind die Mengenstellen für das Untersuchungsobjekt vollständig erfasst, müssen zu diesen Mengenstellen jeweils die genutzten Materialtypen der Input-Stoffe, deren Mengen und Kosten gesammelt werden. Bei der Angabe von Materialtypen können Materialdatenbanken eine Hilfestellung geben (wie z.B. MatWeb [16]). Anschließend muss der Anteil der Input-Materialien bestimmt werden, der nicht ins

Endprodukt fließt und damit als Materialverlust zu werten ist. Die Erfassung dieser Mengen ist in der Regel der Knackpunkt bei der MFCA-Analyse, da Unternehmen vorher noch nicht über alle notwendigen Daten und Erfahrungen verfügen und es mitunter zu Schwierigkeiten oder Fragen kommt, etwa:

- Wieviel Kilogramm wiegt ein 7 m³ Container in dem sich Verschnitt befindet?
- Ist die aktuell gemessene Menge an Fehlteilen repräsentativ für den Betrachtungszeitraum?
- Wieviel Strom hat die Anlage zur Herstellung von einem Produkt verbraucht?
- Welche Menge von Hilfsstoff X wird exakt für die Herstellung eines Produkts benötigt?
- Wie werden Materialmengen, die in unterschiedlichen Einheiten gemessen werden, auf eine gemeinsame Einheit umgerechnet (z.B. von Liter in Kilogramm)?

Der Aufwand zur Datenerfassung wird sich nicht gänzlich durch eine Software beheben lassen, aber er kann gesenkt werden, in dem die Anwendung eine möglichst große Bandbreite an Hilfestellungen für diesen sensiblen Punkt in der Materialflussanalyse bereitstellt. Hierzu gehören etwa Durchschnittswerte für die Umrechnung von Volumen zu Masse, die softwareseitige Unterstützung zur Datenintegration von mobilen Messsensoren (digitale Wagen, Smart Meter etc.) und Datenschnittstellen zu bestehenden Datenbanken und ERP-Systemen. Die Ergebnisse bei der Nutzung von Durchschnittswerten und Näherungswerten entsprechen zwar nicht immer exakt der Realität, sie sind jedoch der Alternative, keine Daten zu erheben und damit auch keine Materialflusskostenrechnung durchzuführen, überlegen. Auch begründete Schätzwerte können ein wichtiger Baustein sein, um sonst nicht überbrückbare Lücken in der Datenerfassung auszugleichen (Vgl. [17], S. 20-31). Die Materialien müssen in unterschiedlichen Einheiten angegeben werden können, so dass eine interne Umrechnung stattfindet. Gleiches gilt für die Währung, in denen die Materialien bezogen wurden.

Eine besondere Hürde besteht außerdem im Ausgleich der Bilanz zwischen Input-Mengen und Output-Mengen einer Mengenstelle. So muss die Gesamtmasse der Materialien, die in der Produktion eingesetzt werden, genau so groß sein, wie die Gesamtmasse des Endprodukts und der Materialverluste. In der Praxis kommt es hierbei häufig zu Problemen, da es zu Rundungsfehlern kommen kann oder Materialien, von denen nur geringe Mengen genutzt werden, vergessen werden. Für diese Hürde ist eine Hilfestellung zu konzipieren, etwa indem die Anwendung selbst ermittelt, in welcher Mengenstelle es zum Konflikt gekommen ist, wie groß die Abweichung ist und wie sie zu beheben ist.

Zusätzlich zu den direkten Kosten, die die Beschaffung der Input-Materialien verursacht hat, müssen allgemeine Systemkosten bzw. Prozesskosten erfassbar sein. Zu diesen zählen etwa Energiekosten, die Abfallmanagementkosten und andere Kosten (etwa Abschreibungen auf Anlagen, Personalkosten, Instandhaltungskosten etc.). Diese

Systemkosten, werden anteilig den Materialverlusten hinzugerechnet, so dass die Kosten der Materialverluste bspw. zuletzt auch den Anteil der Personalkosten enthalten, der für die Produktion von Fehlprodukten aufgewendet wurde. Vorteilhaft ist an diesem Punkt, eine Eingabemöglichkeit sowohl von absoluten, als auch von prozentualen Anteilen (Vgl. [14]).

Projektteams, die mit der Umsetzung betraut werden, sollten einen Querschnitt des Unternehmens abbilden, bestehend aus der Unternehmensleitung, der Buchhaltung, der Produktionsplanung, der Umweltabteilung und Produktionsmitarbeitern, die mit dem genauen Ablauf der Produktion vertraut sind und die Änderungen im Produktionsprozess umsetzen müssen (Vgl. [2], S. 12). Insofern muss die Anwendung für Benutzer mit unterschiedlichen Sichtweisen und Kenntnisständen gleichermaßen konzipiert sein.

6.2 Datenauswertung

Die Darstellung der Ergebnisse erfolgt generell in Form der MFCA-Kostenmatrix nach ISO 14051 (siehe Abb. 2), diese sollte daher auch den Kern der Datenauswertung darstellen. Zusätzlich sind jedoch weitere Auswertungsfunktionen denkbar, die die Aussagekraft der Ergebnisse steigern können bzw. bei großen Analysen bestimmte Ausschnitte leichter ersichtlich machen. Eine Aufschlüsselung der Materialverlustkosten je Mengenstelle kann dabei eben so viel beitragen wie eine Nachvollziehbarkeit der Verluste eines spezifischen Materials über mehrere Mengenstellen hinweg. Zur grafischen Veranschaulichung des Mengenstellenmodells bietet sich ein Materialflussmodell an, das die Mengenstellen und deren Zusammenhänge darstellt. Die Kostenströme können durch Sankey-Diagramme visualisiert werden, die die Kosten durch größenproportionale Pfeilen darstellen. Die Ergebnisse einer MFCA sind wichtige Kommunikationsmittel bei der Managementunterstützung wie auch in der Außendarstellung (Vgl. [3], S. 16). Demzufolge bieten Möglichkeiten zur grafischen Aufbereitung und Verdichtung der Ergebnisse (z.B. mittels Kennzahlen) einen wichtigen Vorteil bei der Nutzung der Methode. Die Auswertungsmöglichkeiten müssen dem Ziel der Methode, nämlich unnötige Materialverluste aufzudecken, angepasst werden.

6.3 Weitere Anforderungen

Neben der Darstellung der Ergebnisse, sollte die Anwendung Hilfestellungen zur Ergebnisinterpretation geben und den Benutzern somit einen Einstieg in die Reduzierung der Materialverluste geben (z.B. in Form von Best Practices oder Vergleichsstudien). Das größte Potential zur Reduzierung bringen in der Regel die Mengenstellen mit den höchsten Kosten durch Materialverluste. Hierbei sollten dem Benutzer aber Hilfestellungen zur Ergebnisinterpretation und zum Verständnis der Methode bereitgestellt werden. Für Materialverluste, die sich nicht beseitigen lassen, sollte die Anwendung Möglichkeiten zum Recycling vorschlagen. So könnte bspw. eine Vermittlung von mehreren Unternehmen hin zu einer Industriesymbiose erfolgen, so dass die Abwärme eines Unternehmens von einem anderen Unternehmen als Prozessinput verwendet wird (Vgl. [18]). Um eine parallele Datenhaltung zu vermeiden und die erhobenen Daten auch in anderen Kontexten nutzen zu können (bspw. Carbon Footprinting), sollte die Anwendung eine Funktionalität zum Daten Import und Export enthalten. Weitere administrative Anforderungen, wie das Festlegen von Rollen und Zuständigkeiten, das Festlegen der Systemgrenzen und die Erfassung von Erfahrungswerten (Lessons Learned) werden von der Asian Productivity Organization [2], S. 17-25 genannt. Sinnvoll ist zu diesem Zweck eine Sammlung von Best Practices in Form eines Repository.

7 Zusammenfassung und Ausblick

Die aktuelle Situation bei der Ausbreitung der Materialflusskostenrechnung kann als ambivalent eingeschätzt werden. Einerseits bietet die Methode ein großes Potential, die unternehmerische Effizienz zu erhöhen und damit die Kosten bei gleichbleibendem Sinken der negativen Umweltauswirkungen zu reduzieren. Eine ausführliche Pilotstudie in Japan, die auf einer Initiative des METI basiert, zeigt die großen Einsparpotentiale auf (Vgl. [19], S.401-407). Abgesehen davon bleibt die Ausbreitung bisher aber hinter den Erwartungen zurück. Als wichtiger Grund dafür ist die Notwendigkeit der Erfassung von Daten, die bisher in der erforderlichen Form selten vorliegen. Der Aufwand lässt sich schwer gegen einen vermuteten Nutzen abwägen, zumal eine Befragung ergeben hat, dass Unternehmen häufig der trügerischen Überzeugung sind, dass bei ihnen keine unnötige Verschwendung stattfindet (Vgl. [4], S. 91), Fallstudien jedoch das Gegenteil zeigen (Vgl. [20], S. 7-8).

Da bei der Datenerhebung, je nach Komplexität der Produktion, sehr große Datenmengen zu managen sind, ist ein systematischer Ansatz bei der Erfassung sowie der MFCA Berechnung notwendig (Vgl. [4], S. 64), der durch eine zielgerichtete Softwareunterstützung sicher gestellt werden kann. Die beschriebenen Schwierigkeiten bei der Datenerfassung sollten im Fokus der Anwendung stehen, da hier die größten Potentiale bestehen, die Methodenanwendung zu vereinfachen. Der vorliegende Beitrag hat in einer ersten Studie eine Vielzahl von Softwareanforderungen ermittelt, die jedoch noch keine abschließende Auflistung darstellen. Die bestehenden Anwendungen decken schon Teile der Anforderungen ab, liefern aber keine zufriedenstellende Gesamtlösung. Sie sind jeweils nur auf bestimmte Anwendungsfälle fokussiert. Außerdem bieten die zur Verfügung stehenden Softwarelösungen an neuralgischen Punkten, wie der Datenerfassung, wichtige Hilfestellungen nicht an, so dass die Benutzer auf externe Hilfsmittel angewiesen sind, oder unnötigen Mehraufwand in Kauf nehmen müssen. Eine Softwarelösung zur Durchführung der MFCA, die an den Bedürfnissen der Benutzer ausgerichtet ist und damit über eine gute Usability verfügt, kann die Kosten der Methodenumsetzung deutlich reduzieren und damit die Vorteile der Methode besser nutzbar machen.

In folgenden Studien, ist geplant, mittels Interviews und Marktforschung mit Beratern, die bereits Erfahrung bei der Einführung der Methodik und der ISO-Norm besitzen, da hier das größte Potential besteht, die Anforderungen an Hilfestellungen bei der Implementierung der Methodik zu ermitteln und Einblick in die Akzeptanz im Managementbereich zu erlangen (Vgl. [6], S. 8). Welche Treiber und Hindernisse sind bei der Implementierung festzustellen? Wie können die Treiber der Methode durch eine benutzerfreundliche Anwendung zur Geltung gebracht und die Hindernisse abgeschwächt werden? Zur Bearbeitung dieser Fragen werden zukünftig weitere Untersuchungen folgen. Angedacht sind Interviews und Umfragen unter Unternehmensvertretern, die in die Förderung und Anwendung der MFCA-Methode involviert sind. Diese Untersuchungen werden vor allem dann verwertbare Informationen liefern, wenn die Methode in Zukunft weitere Ausbreitung und Bekanntheit erlangt.

Computing Incentives for User-Based Relocation in Carsharing

Abstract. Carsharing offers an environmentally friendly alternative to private car ownership. However, carsharing providers face the challenging task of matching shifting vehicle supply with fluctuating customer demand to prevent related operational inefficiencies and ensure customer satisfaction. To date, researchers have improved existing relocation strategies and developed new concepts with the use of information technology tools. Still, current literature lacks research on optimization and implementation of user-based relocation solutions. The most urgent need currently lies in the development of algorithms to compute and implement effective incentives for user-based relocation.
We address these needs by utilizing a design science research approach to develop an automated machine learning-based incentive computation solution for incentivizing user-based relocation. We use a survey of 274 participants resulting in 1370 individual data points to train an incentive computation model, which is then applied within a small-scale field test. Results suggest that the algorithm computes appropriate incentives.

Keywords: Design Science Research, Carsharing, User-based Relocation, Incentive Computation, Green IS

1 Introduction

The demand for new sustainable mobility options as substitutes to private vehicles has increased in recent years. However, to be considered a valid alternative, new mobility options should not only be sustainable but also be flexible enough to meet dynamic customer and environmental needs. In this context, the use of alternate mobility services can be a possible solution, with carsharing as a prime example [1–3].

Current research in the area of carsharing views balancing vehicle supply and demand as one of the key enablers for this to happen [4–6]. Carsharing providers face the challenge of a shifting vehicle supply and demand, leading to insufficient vehicle supply at some locations. Consequently, some customers may request a vehicle, but may have their rental request rejected [7–9]. This situation reduces revenue and leads customers to view carsharing as inflexible and inferior to a privately owned vehicle [5].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Hence, there is a need for carsharing providers to take countermeasures to sustain a sufficient vehicle distribution. The common counter-measure is to relocate vehicles in advance by operator-based relocation [6, 10], a process in which employees move vehicles between stations or areas to comply with local demands [3, 5, 6]. However, this procedure has high costs (e.g. personnel and fuel) associated with it, while lowering these operating costs remains a key success factor for carsharing [3, 9, 11].

Therefore, to provide an alternative researchers have developed a new concept called user-based relocation. The idea of user-based relocation is to motivate users to return currently rented vehicles to locations with high vehicle-demand [4, 12]. This relocation approach is deemed to be less expensive [3, 12], but is yet to be implemented within a real-world commercial carsharing system. Inducing user-motivation to perform relocation using the right mechanisms, e.g. offering monetary incentives, is a major obstacle in this process, as methods to compute sufficient incentives are still lacking [3, 4, 13]. Current carsharing research often uses a simplified function to compute incentive costs for their scenarios [4, 12] without real-world application. However, the incentive must be derived from various factors, such as weather, distance or time. To close this research gap, we aim in this paper to answer the following question:

RQ: How can a cost-efficient incentive be computed for user-based relocation?

2 Related Research

Carsharing systems can be distinguished into three forms [6]:
(1) **Station-based two-way carsharing:** Vehicles can be rented by customers from any station and the vehicles have to be returned to the same station.
(2) **Station-based one-way carsharing:** Vehicles can be rented from any station but can also be returned at any available station.
(3) **Free-floating carsharing:** Unlike station-based carsharing, free-floating carsharing allows cars to be rented and returned anywhere within the operation area of the carsharing provider.

The flexibility of station-based, one-way, and free-floating carsharing possesses a drawback in the form of the vehicle relocation problem – vehicle distribution is altered by rentals, leading to an under-supply of vehicles at some stations or in some areas. Hence, carsharing providers have to manage vehicle distribution by vehicle relocation to achieve a more balanced system [14].

Currently, vehicle supply and demand management measures can be distinguished into three forms:
(1) **Operator-based relocation:** Staff members rearrange the vehicles by driving, towing or ride-sharing them to the desired location [15].
(2) **User-based relocation:** Selected users are motivated by the carsharing provider during a rental to return their currently rented vehicle at a station with a high vehicle demand, when their initial destination has sufficient vehicle supply [12].
(3) **Prevention-based:** Through territorial pricing strategies and other price incentives, attempts are being made to proactively encourage users to use certain vehicles and park

them at selected locations in order to maintain a balanced supply-demand ratio with regard to vehicle locations [16, 17].

We conducted a literature review [18] to evaluate the current status quo of user-based vehicle relocation research and identify relevant research gaps. For this, we conducted a tailored keyword search to ensure that the results fit the carsharing domain and user-based concept within the following databases: ScienceDirect, EbscoHost, JSTOR, and AIS electronic library. Variations of the following search query were used:

((“car sharing” OR “carsharing”) AND (“relocation” OR “rebalancing” OR “allocation”) AND (“user-based” OR “user based” OR “userbased”))

After filtering, the search resulted in 13 separate publications. Next, we did a forward and backward search, identifying 10 additional publications. All together, we gathered 23 publications on the topic of user-based relocation (see Table 1). In the following, we will present the incentive computation methods for user-based relocation that we found through our research.

Brendel et al. [12] presented a function of time for relocation to compute the incentive. They derived the function from a survey of 26 participants. However, the sample is relatively smaller and lacks an evaluation. Furthermore, only using time for relocation simplifies the problem significantly.

Wagner et al. [4] developed an incentive concept based on the idle time reduction a relocation grants. The user is offered free-minutes in relation to the idle time reduction. However, they do not specify a method to determine the amount of time required to motivate users to relocate.

Angelopoulos et al. [17] call their approach user-based but it does not fit the common definition of user-based relocation. Their approach refers to a dynamic allocation of vehicles to users, based on incentive systems that use reservations to manage mismatches between supply and demand, to create price incentives for rewarding users when they agree to fetch their vehicle from an oversupplied station and/or hand it over to an undersupplied station. On that account, it is a preventive vehicle supply and demand management approach. The other articles found are mainly concerned with providing technical (e.g. algorithmic) support for future implementations of user-based relocations.

X ≙ covers topic completely; (X) ≙ addresses topic partially

For instance, Wagner et al. [4] develop a support system for user-based relocation within free-floating carsharing, which detects imbalances in vehicle distribution based on idle time patterns. Discounted alternative stations are simulated. Bianchessi et al [21] present the “Feedback Dynamic Pricing” approach, which is based on modelling a vehicle sharing system as a dynamic system, aiming to control fleet balancing by varying the price of the service in real time. For this purpose, a simulator was developed. Both articles stand exemplary for the current focus of user-based relocation research. Novel and sophisticated algorithms for detecting and counteracting vehicle imbalances are developed, while necessary incentives are often a comparative side note and not investigated as profoundly.

In summary, current research has not engaged with the topic of incentive prediction from a practical standpoint. The approach of Brendel et al. [12] comes closest to a practical application. However, their study focuses on estimating the potential costs of user-based relocation and is not intended for practical application. Thus, it is visible that developing a practice-ready incentive computation method for user-based relocation is still an evident research gap.

3 Research Approach

We followed a combination of the frameworks by Hevner et al. [35] and Hevner [36]. The DSR setting and its interrelated cycles are depicted in Figure 1. The relevance cycle connects the design activities of the design cycle with the artifact's intended environment. By this, it enables researchers to assemble real-world requirements to describe and later solve the subsequent real-world problems. Furthermore, artifacts are introduced to the environment as part of a relevance cycle. The rigor cycle relates the design activities to the existing body of knowledge. Thus, existing knowledge can be integrated into design activities and research results can later extend the knowledge base. The central part of a DSR process is the design cycle. It represents the design and evaluation activities of the researcher.

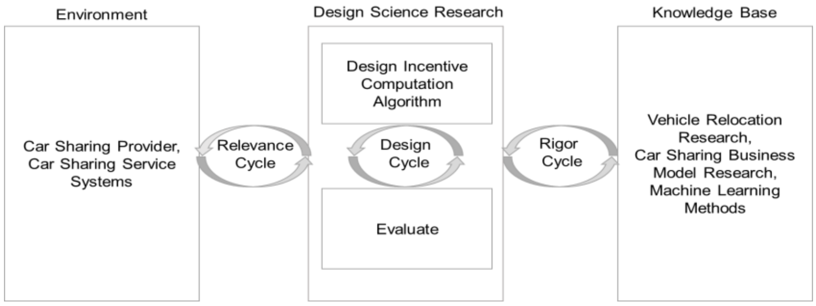

Figure 1. Design Science Research Setting (following [32])

Additionally, during the research process, we also applied a theorizing process similar to heuristic theorizing [37] as described by Brendel, Brennecke, et al. [16] for the development of a design theory. The development of a six component design theory [38] is achieved by implementing the following steps after each research activity:
(1) Review the current design theory and evaluate the need for refinement of each of the six components.
(2) If refinement is needed, iteratively add new components and/or adjust existing components until all new knowledge is incorporated.

For this, we abstracted and de-abstracted the requirements, the development process and the artifact to obtain context specific or meta-components [37].

The DSR process started with a relevance cycle (see Table 2), revealing a lack of implemented user-based relocation system and methods to compute incentives for user-based relocation (see the Literature Review section). To validate our findings, we discussed these results with two carsharing providers. During both the interviews with the managing directors, we presented and discussed the concept of user-based relocation and the related research gap. For this, we prepared the following open questions:
(1) What general limitations and restrictions come to your mind when you think about incentives and user-based relocation in general?
(2) What are the requirements to be considered for the development of an algorithm that can compute appropriate incentives for user-based relocation?

Our findings were confirmed, resulting in the identification of a practice relevant problem manifested as a lack thereof incentive prediction methods for user-based relocation. Furthermore, we gathered requirements for the algorithm design process.

As a second step, we performed a rigor cycle to draw from existing vehicle relocation publications. While seeking a starting point for the design process, we identified machine learning as the basis for our development. This decision was made based on the potential of machine learning [39] and its already successful application in the contexts of carsharing and vehicle relocation [6, 13]. Machine learning can identify patterns within given datasets and predict values based on them. Therefore, it can be considered a potential approach for developing an incentive computation algorithm.

Table 2. Overview of Performed Relevance, Design and Rigor Cycles

	Relevance Cycle	*Rigor Cycle*	*Design Cycle*
Inputs	• Publication databases	• Research database	• Machine learning literature
Methods	• Literature review • Expert Interviews	• Literature review	• Survey • Field study
Steps	• Gather publications from literature reviews • Analyze publications • Discuss findings with experts • Gather requirements	• Analyze publications • Identify input knowledge for design process	• Identify requirements • Design machine learning algorithm • Gather dataset • Train algorithm • Test algorithm in field study
Results	• Research database • Identification of a lack of incentive prediction methods for user-based relocation	• Identification of machine learning methods as a possible solution	• Machine learning algorithm for incentive computation

In the following design cycle, we developed an algorithm based on machine learning and evaluated it by training and testing it with a dataset. As datasets for incentives in the context of user-based relocation are currently not available and cannot be referenced, we had to gather a dataset via survey.

The survey included 1370 data points gathered from 274 survey participants (their characteristics are depicted in Table 3). They were questioned on the street, following a structured questionnaire. The questions were designed to mimic the setting of user-based relocation. In user-based relocation, users walk the extra distance from their new vehicle destination to their previously intended one. Hence, they had to evaluate their possible incentive by factoring distance, weather, weekday and time of the day. These factors were derived as an initial explorative step with the partner company and based on accessibility. Other potentially helpful data sources (such as user data from customers) were inaccessible to us.

Table 3. Characteristics of Survey Participants

Characteristics	*Property*				
Age	< 25 46.31%	26-35 33.22%	36-45 4.36%	46-55 9.73%	> 56 6.38%
Education	No Education 3.42%	(High) school 36.99%	Some college or profession 10.62%	College with degree 45.21%	Higher education or PhD 3.77%
Gender	Male: 58.19%			Female: 41.81%	

The partner carsharing company has mainly younger customer base and is located within a University student majority city. For this reason, it is conclusive that the sample is also relatively young, reflecting the actual average age of customer base. Furthermore, we would like to note that we had not specifically targeted nor filtered our questionnaire for younger participants.

Each participant was asked if they would accept a certain incentive to walk a given distance (between 800m and 1,500m) on a specific weekday. The incentive was presented to the participants in a sale by bidding format, starting from 0.50€ and going up to 6€ [12] in 0.50€ steps. Additionally, the participants were distributed with the weather conditions for the walk. The weather was characterized by: (1) temperature, and (2) weather condition (rainy, windy, snowing, cloudy etc.). In total, each participant was surveyed for five different combinations. The first one was the current time and place's weather conditions. In order to ensure a variety of different real-world weather conditions within our dataset, we conducted the survey in two time-windows: one week in April and one week in October 2016. For the other four, each parameter combination was generated randomly, while any sort of illogical combination (e.g. snowy and 30°C) was discarded. Further, each question was asked by corresponding researcher while the participants did not actively fill out the question themselves (preventing wrong inputs within the questionnaire).

We chose to apply a threshold for the maximum incentive and also to utilize the bidding mechanism based on a preceding pre-test. In a small pre-test (of 40 participants), we discovered that participants answered with either very high or low values, when not given a context in the form of a limit. For example, some participants stated that they would like to get an incentive of 50€ or more to walk 800m in good weather conditions. Hence, we limited the participants by putting a cap of 6€ on the incentive (assuming that users demanding an incentive of over 6€ would not participate in user-based relocation) and also by using a bidding style questionnaire. Furthermore, each participant had the option of answering with the statement that they were unwilling to walk the distance under the given circumstances for under 6€. This framework greatly improved the consistency of the gathered data.

The trained algorithm was then evaluated. Normally, machine learning algorithms are evaluated using error metrics. However, as the aim of the developed algorithm is not to predict a value, but rather to iteratively learn to compute incentives, we had to use a different approach. Firstly, the algorithm was trained using the survey data. Secondly, it was evaluated in a small field study. In the field study, 20 carsharing customers were asked to relocate their vehicle during an ongoing rental.

4 Results

4.1 Incentive Computation Algorithm

Building on current user-based vehicle relocation publications [4, 12] and the discussion with carsharing providers, it is evident that despite being an interesting option, implementation of user-based relocation is difficult in the fact that it has to be set within existing infrastructure. Nonetheless, focusing on incentives as key enablers of the concept, we identified the following requirements:

R1 Self-learning: The algorithm must be self-learning to avoid manual adjustments of the computation algorithm.

R2 Context sensitive: The algorithm must consider external factors (like weather), which influence the decision making of customers.

R3 Real time: The incentives must be computed in real-time to achieve a dynamically working user-based relocation system.

R4 Cost-efficient: The algorithm must avoid overpaying customers and paying more than the cost of operator-based relocation.

R5 Simple to implement: The algorithm must be easy to implement to ensure adaptation by other carsharing providers.

R6 Adaptive: The algorithm must be adaptable to different carsharing systems.

R1 addresses the need for an incentive computation algorithm to be self-learning. The customer base of a carsharing system changes over time and incentives must be context sensitive to address price elasticity. Additionally, short-term influences (such as weather) can change the needed incentive and therefore, should be considered during computation (R2). Similarly, an incentive computation algorithm must provide incentives in real-time (R3). User-based relocations must be communicated quickly to potential relocating users to ensure the immediate execution of the relocation. Otherwise, potential users could arrive at their destination to find no cars available or the vehicle distribution could change, leading to relocations that cannot be performed or are unnecessary or even counterproductive. R4 captures the main objective of relocation, as well as the perspective of the carsharing provider. Vehicle relocations must be cost efficient, meaning that the incentives for user-based relocation should be as low as possible, avoiding any overpayment. This allows full leverage of the cost-saving potential of user-based relocation [3, 12]. Due to the fact that carsharing providers are mainly concerned with the "physical" part of carsharing, the implementation of complex algorithms is outside the range of their core-competencies. To ensure a wide adoption of an incentive computation algorithm, it must be designed with an easy implementation in mind (R5), which can maintain an easy and efficient cohesion with the existing infrastructure. Lastly, R6 captures the primary intentions of DSR, which is to develop artificial solutions and to understand solution design on an abstract level, e.g. as design principles [37, 38, 40]. Therefore, the incentive computation algorithm must be applicable in different carsharing systems.

Building on the requirements and a search for relevant knowledge, we decided to use machine learning and apply a regression tree. Machine learning algorithms can find patterns within a given dataset (R1, R6). A regression tree is a well understood and commonly applied algorithm, which has been implemented in one of the most common machine learning programming libraries, e.g. scikit-learn [39], making it simple to implement (R5). It can incorporate different context inputs provided in the dataset (R2, R6) to quickly (R3) compute a numeric output. The cost-efficiency of the computed incentive depends on the provided input data set. If the algorithm can locate robust patterns within the given dataset, the computed incentive will be as cost-efficient as possible (R4). As we used Scikit-learn [39] for our implementation (R5), the Classification and Regression Tree (CART) was used.

In the following design cycle, the gathered requirements and the identified regression tree algorithm were combined to develop an incentive computation algorithm (see Figure 2).

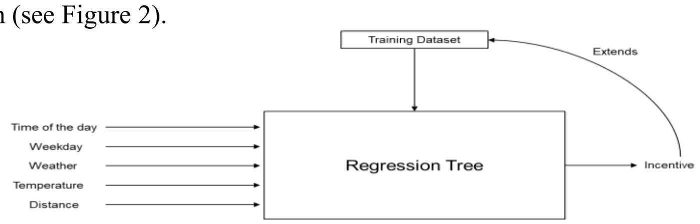

Figure 2. Incentive Computation Algorithm

In the center of the incentive computation algorithm, the regression tree machine learning model is displayed. It is trained via a training dataset (for further information see [41]) and computes incentives based on the time of the day, day of the week, weather, temperature and relocation distance. As a result of the algorithm requiring to adapt to the potentially shifting price sensitivity of the customer base, it likewise requires itself to be self-learning (R1). Hence, we designed the following process: (1) The computed incentive is presented to the users. (2a) If the user accepts – The incentive is decreased by a fixed factor and added to the training dataset along with its parameters. (2b) If the user declines – The incentive is increased by a fixed factor and added to the training dataset along with its parameters. (3) The regression tree is re-trained with the extended training dataset.

The incentives are altered before they are added to the dataset to induce a learning process. Accepted incentives can potentially be too high and the algorithm must learn to compute lower incentives. The same goes for declined incentives. In the circumstance when they are too low, the algorithm must learn to compute higher incentives. This will lead to a training dataset that can increasingly adapt to the application case (R6) and also to the machine learning algorithm.

To evaluate the performance of the algorithm and to study the real behavior of users and not just the intended one, we carried out a trial field study for one month (February 2017) in a carsharing system environment. 20 carsharing customers were asked to install a simple user-based relocation smartphone application.

During the field study, 11 users interacted with the various relocation requests. The relocation request within the application contained information regarding the desired relocation, e.g. the distance differences intended and relocation destination as well as the offered incentive, computed by the algorithm itself. During the field study, 20 relocations were requested, of which 11 were accepted and 9 rejected. The average accepted incentive was 2.75 Euro, while various weather conditions were represented.

The temperatures were around 9 degrees Celsius and the average relocation distance was 940m. Given that more than half of the participating users accepted the incentive calculated by the algorithm, it is positively affirmed that the developed algorithm potentially fulfills its original purpose.

4.2 Design Theory

Following Gregor and Hevner [40], each DSR process adds to practice and theory by developing new design theories and by explaining "how to do something". Correspondingly, we developed a design theory for an incentive computation approach for user-based relocation. The developed theory corresponds to the model proposed by Gregor and Jones [38].The design theory is summarized in Table 4.

Table 4. Design Theory of an Incentive Computation Approach for User-Based Relocation (following [38])

Component	*Description*
Purpose and Scope	The approach computes adequate incentives to motivate carsharing users to change their rental destination. Requirements: Self-learning, Context sensitive, Real-time, Cost-efficient, Simple to implement, Adaptive
Constructs	Demand, Supply, Vehicle, User, Relocation, Incentive, Accept, Decline, Destination, Location
Principle of Form and Function	Machine learning (e.g. Regression Tree) can be applied to compute incentives for user-based relocation (R1,R2,R4, R5). The value of declined incentives should be increased and added to the training process (R1, R2, R4). The value of accepted incentives should be decreased and added to the training process (R1, R2, R4). The initial training dataset can be gathered via survey, using weather and bidding as frames/anchors (R1, R2, R5, R6). The trainings parameter should include weather, weekday, temperature, distance, time of the day (R2, R6).
Artifact Mutability	The incentive computation algorithm can be adapted using a context-specific dataset. The input factors as well as the regression tree parameters can be changed.
Testable Propositions	The computed incentives motivate users to comply with user-based relocation. A good incentive remains below employee costs (6€) and motivates certain users (50%)
Justificatory Knowledge	Carsharing Literature, Machine Learning Literature

5 Discussion

The presented study contributes to carsharing literature by developing an incentive computation algorithm to be applied to user-based relocation within carsharing service systems. The computation of incentives to motivate users to relocate a rented vehicle is a fairly new research question [4, 12]. Thereupon, the presented algorithm marks a first step into this new problem domain, proving a valuable base for future research.

Ultimately, the findings of this study have implications for the field of sharing economy research. Carsharing is recognized as a prime example of the sharing economy [2]. However, more research is required to establish the ways in which IS can support carsharing service systems [2]. In this regard, the presented development process and artifacts unravel the contribution of IT and IS to providing sustainable sharing services and creating value with and for customers. To be specific, the focus is currently centralized on how IT and IS help increase the comfort and flexibility of carsharing by implementing user-based relocation. The developed algorithm becomes a key enabler for this concept. It is important to note that the algorithm could also be used for other fields of application e.g. enriching dynamic ride sharing. Passengers could be incentivized to walk to a pickup location by cheaper prices and at the same time drivers need to be incentivized by addition revenue to perform detours. Hence, having a good understanding of how to compute incentives would not only help to improve carsharing but also other mobility services [42–44]. The same reasoning would apply to crowdsource delivery. The algorithm could calculate incentives to motive drivers to perform a detour for a delivery or to walk a certain distance to drop off or pick up a parcel [45].

Additionally, as the presented research demonstrates the different ways in which machine learning methods can be used, it contributes to the research body of machine learning, by introducing it to the domain of carsharing. To the best of our knowledge, no previous study has applied and implemented machine learning models to compute the incentive of user-based relocation. Hence, the successful application and evaluation of the algorithm suggests that machine learning should be further researched in this context.

In context of DSR, this study contributes on several levels. Firstly, it serves as an example for the application of DSR in solving the specific problem of incentive computation in carsharing. Secondly, when positioning the developed artifact within the DSR knowledge contribution framework [40], we argue that the problem of incentive computation for user-based relocation participants is a rather new problem domain, constituted by the current state-of-the-art attention focused on user-based relocation algorithms, without engaging in its real-world applications. Hence, it constitutes a novel problem class. Similarly, the application of machine learning to compute incentives can be seen as a transfer of existing knowledge, classifying the solution maturity as high. Hence, the developed artifact constitutes an exaptation, characterized by a low problem domain maturity and a high solution maturity [40]. Furthermore, the contribution of this study is situated on two different levels of theoretical abstraction [40]. The developed framework and principles of form and function can be characterized as a nascent design theory (level 2), while the implemented and tested algorithm provides a tangible instantiation (level 1).

Besides the theoretical contributions, this study holds valuable implications for practitioners. Firstly, this study demonstrates how to develop and implement an incentive computation algorithm for user-based relocation. Combined with previous studies about the identification of necessary relocations [4, 12], it enables user-based relocation implementation and further practical research within the field. Consequently, carsharing providers are now enabled to substitute operator-based with user-based relocation. With this in mind, the overall cost of relocations can potentially be reduced, increasing the yield of carsharing provider, subsequently making carsharing not only a more sustainable transportation service, but also a more profitable one [12]. Secondly, it underlines how to introduce user-based relocation to a carsharing system. Before implementing any related carsharing projects, carsharing providers must survey their users to train the machine learning algorithm. As the artifact evaluations reveal, it shows potential to compute incentives to motivate users within the system to relocate vehicles.

Regarding any limitations, the two evaluations constitute a limitation of its own. The survey data is only partly representative for the special case of inhabitants of the city in which the carsharing provider is located. Hence, other cities and carsharing systems might find survey data to be insufficient as an initial training dataset. Additionally, the limited scope (20 participants) of the field-test constitutes a limitation. Secondly, in order to get initial results, we applied a research process composed of easy and affordable research and evaluation methods, e.g. expert interviews and small-scale single case application. This process ensures efficiency and iterative adaptation according to any forthcoming interim results. Thus, the next step is to carry out a larger-scaled field-test to ensure generalizability of results. In addition, we research opportunities in identifying and including further parameters in the computation process, such as customer information (e.g. age, rental frequency or attitude to sustainability), to potentially increase the accuracy for individual users. Lastly, during the research process, the participants were questioned directly on the street, following a structured questionnaire to derive a proper incentive. However, willingness-to-pay is difficult to convey in surveys, therefore an alternative approach such as the conjoint analysis has been developed (e.g. [46]). Thus, we see potential for future research in addressing this limitation by applying other methods to validate and expand our knowledge on finding the best incentive/pricing option, providing further input for the incentive computation process.

6 Conclusion

This article presents a self-learning algorithm to compute the necessary incentives for user-based relocation. It bases on a machine learning model and was developed following the DSR framework of Hevner et al. [35]. The algorithm was evaluated within a field study, in which it was revealed that the algorithm had the possibility be used in practice and compute sufficient incentives.

The algorithm enables user-based relocation to be implemented within real-world applications. This will help carsharing providers to improve the flexibility and cost-efficiency of their systems. Furthermore, IS researchers can now study user-based relocation within its intended field of application. In addition to that, with a simple and cost-efficient method, we provide the basis for further extensive and complex methods, so that our solution can be further optimized [35]. Accordingly, the results of this study enable benchmarking, which is an important area of DSR [47].

Overall, our study is in line with the demand to focus on applied Green IS research and the guidelines of vom Brocke [48] to develop tangible research results in the form of IS artifacts that contribute to minimizing the gap between sustainability research and practice, a field currently underrepresented in IS research [49]. Against this background, the facilitation of user-based vehicle relocation in carsharing, through the presented artifact, can be an important building block to further increase the sustainable impact of carsharing.

Sustainability's Coming Home:
Preliminary Design Principles for the Sustainable Smart District

Abstract. Consumer trends like local consumption, sharing of property, and environmental awareness change our habits and thereby our surroundings. These trends have their origin in our direct environment, in the districts of our city or community, where we live and socialize. Cities and districts are changing to "smart cities" and "smart districts" as a part of the ongoing digitalization. These changes offer the possibility to entrench the idea of sustainability and build a platform-based ecosystem for a sustainable smart district. This research aims to identify guidelines in form of preliminary design principles for sustainable smart districts. To achieve this, we conduct a structured literature review. On this basis, we derive and develop preliminary design principles with the help of semi-structured interviews and a non-representative sample of the German population. The resulting nine preliminary design principles describe a first insight into the design of sustainable smart districts.

Keywords: Sustainability, Smart District, Platform-based Ecosystem, Smart City, Design Principles

1 Introduction

Sustainability is a "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" [1]. The goal of a sustainable development unites the world population more than any other goal in the past [2]. One concept to face sustainability in the area of living are smart cities. These smart city concepts foster sustainable development and face current challenges of our society like immigration, demographic change, and environmental pollution by the means of technology [3–5]. This is one of many reasons why the term "smart city" gained much relevance in the last years [6, 7]. A smart city is able to provide a connected and sophisticated infrastructure to foster economic, ecologic, social, and cultural matters [6] as well as a social-technical view [4]. Current consumer trends with focus on local markets, sharing, mobility, living, and environmental awareness

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

influence the design of the smart cities and its contribution to sustainability [8–11]. Many companies like Uber or nextdoor already recognized the possibilities digital platforms offer in this context.

Since smart cities are very complex systems, it is much easier to plan them with a greenfield approach than on existing cities. To solve this problem, we reduce the complexity to a district perspective by focusing on smaller parts of existing cities. It is also possible to use this district idea for smaller municipalities like small towns, villages, or rural areas in general [12]. Furthermore, consumer trends often take place on a district level and contribute to the ecological, social, and economic development of the district. The implementation of sustainability in districts due to new mobility concepts, sharing concepts, and platform-based collaboration is already happening in many districts [9, 10]. Another example is the use of renewable energy sources for the electricity and heating demand of the district [13, 14]. However, to reach these benefits, there is a need for an adequate information and communications technology (ICT) infrastructure. This technological basis and the connection of all stakeholders lead to smart districts. There is no definition of smart districts in current research. Thus, we define a smart district, based on several smart city definitions and a statement on smart districts by the Smart Cities Information System (SCIS) initiative [7, 15, 16] as follows:

A smart district is a district performing in a forward-looking way in economy, people, governance, mobility, environment, energy, and living, built on a sophisticated, smart ICT infrastructure that ensures benefits for every stakeholder, in particular a high quality of life for every citizen.

The implementation of digital technologies in districts as well as a sustainable mindset, may lead to an ecosystem of a *sustainable* smart district (SSD). Since the term "ecosystem" has become pervasive over the past 20 years, it must be clearly characterized and classified for every research project [17]. For this, we see the SSD as an "ecosystem-as-affiliation" [17]. We consider a platform as the core, the SSD is affiliated with [18, 19]. Due to the central role of the platform, the wording "platform-based ecosystem" (PBE) gains relevance [18].
There are different kinds of platforms [20], which can be the core of a PBE. We see the platform in the SSD context as a digital platform from a sociotechnical point of view [20]. The definition contains not just soft- and hardware, but also organizational processes and standards [21]. Digital platforms stress the idea of modularity [22–24] especially regarding the peripheral components [25]. As Helfat and Raubitschek [18] state, digital platforms are often multi-sided platforms. Multi-sided platforms can be seen as markets that enable direct transactions among several customer groups, with strong network effects between these groups [26, 27]. Multi-sided platforms are of particular interest for us, since in the SSDs PBE many customer groups interact with each other and the value to one party depends on the number and quality of parties on the other sides of the multi-sided platforms [18].

PBEs are an emerging topic that demands extensive research. De Reuver et al. [20] set a research agenda for digital platforms and their surrounding ecosystems. Especially the question on '*how digital platform providers jointly shape platforms with other* *stakeholders*' is of particular interest for the present paper. However, there can be multiple stakeholders trying to influence the design of the PBE, and thus, the digital platform of the SSD and not necessarily one single platform provider. Therefore, we contribute to this scientific discourse by exemplarily analyzing one application: the PBE of the SSD.

Current literature is mostly dealing with sustainable smart city concepts [28–30]. This research often lacks a fine-grained district perspective. Since existing cities are very complex systems it could help transforming them piece by piece, using a district perspective. We identified various projects concerning smart districts like the district project “Smart District Gnigl” as part of the “Smart City Salzburg”. The district project focuses on network and platform effects for local heating, mobility, and education within the district. Furthermore, we also consider smart districts in towns, rural areas, or as new village [12]. Examples for this are the “Smart District Mödlingen” or the “Steimker Gärten”. However, there is little research tackling the adequate implementation and the theoretical background of the SSD. In times of global warming and social alienation, the guidance to a sustainable design is essential for the future smart district. Appropriate guidelines are necessary for understanding how smart districts become SSDs. In this paper we present a first step in this direction and build a theoretical foundation for the implementation of SSDs. We answer the following research question to identify preliminary guidelines for the SSDs PBE.

What are preliminary design principles for a platform-based ecosystem of a sustainable smart district?

2 Methodical Approach

Design Principles (DPs) are guidelines for building design artifacts within design science research [31]. The objectives of such design artifacts are to solve current problems [31] and provide an adequate level of novelty and utility [32]. Generalized prescriptions in the form of DPs aim at extending current design knowledge within this research domain [32]. Thus, DPs are recipes and guidelines for building or describing a specific artifact [33, 34], giving guidance on how to generate a new instance of a class of artifacts [35]. The DPs are usually derived from evaluating actual instances or more abstract conceptualizations [33, 34].

According to Hevner et al. [31], there are four possibilities for building artifacts: constructs, models, methods, and instantiations. For the PBE of the SSD the real-world instantiation is the most reasonable, because instantiations help researchers best to learn about the performance of the particular artifact in the real world [31].

Since there are not many realized smart districts and no SSDs, it is not possible to analyze an existing SSD PBE in detail. Before building an SSD PBE on our own, it is reasonable to first derive preliminary DPs (PDPs). Since there is not much research to SSDs yet, we created a first draft of these PDPs by deducing relevant content from related fields like smart cities with a structured literature review based on Webster and Watson [36] and Fettke [37]. Then, we further developed these PDPs in an iterative process with semi-structured expert interviews based on Myers and Newman [38] and Schultze and Avital [39]. Subsequently, we interviewed possible future inhabitants to gain insights from an additional perspective.

Our research is inspired by the design science cycles of Hevner [40]. In this paper, we were guided by the first rigor cycle by first conducting the structured literature review and then performing semi-structured interviews. The development of the PDPs is a deductive and conceptual process. On the one hand, our PDPs should incorporate already existing knowledge regarding SSDs [31]. Since there is not much research specifically to SSDs, our focus during the structured literature is deriving basic guidelines from related areas like smart city research. On the other hand, we follow a conceptual approach when grouping, formulating and narrowing down the first draft of principles. The interviews also helped us understanding requirements for the SSD, in terms of the relevance cycle. By focusing on the build cycle and deriving PDPs through a iterative process [32, 40], we contribute to the knowledge base on smart districts and form the basis for further operationalization of SSDs [34].

The evaluation framework by Sonnenberg and vom Brocke [41], consisting of four evaluation steps, inspired our research. During this process, we focused on their second step, to iteratively validate and justify our PDPs. Because this step should also encompass the stakeholders of the design artifact we have chosen expert interviews. In each of these interviews we received feedback regarding "ease of use", "efficiency", "generality", "operationality", "completeness", "elegance", meaning the language and structure of the formulations, "simplicity", and "understandability" [31, 32, 35, 41].

In order to contribute to design knowledge, we should ensure an appropriate level of applicability [31]. Therefore, we formulate our nine PDPs in a specific way, as described by March and Smith [32]. To guarantee a high degree of utility and efficiency, we follow the recommendations for precise formulations by Chandra et al. [33]. To consider these recommendations, we formulate our PDPs following the subsequent structure: "Provide the system with [material property – in terms of form and function] to [activity of user / group of users – in terms of action] […]." [33]. Therefore, our PDPs respond to efficiency requirements and maintain a consistent formulation [32].

3 Implementation of our Methodical Approach

To derive our PDPs for an SSD from current literature we conducted a structured literature review based on Webster and Watson [36] and Fettke [37]. We focus on inferring additional knowledge by the means of logical-deductive argumentation. For approaching the literature search in a systematic manner, we codified three search strings for three different research directions (Table 1). Then we evaluated the literature we found. Due to our focus on sustainability, we added this key word to every search string. The same applies to "ecosystem" and synonyms of "district". "smart" is the main prefix describing new digital concepts, no matter whether you look at "smart city", "smart home" or "smart living".

Table 1: Search Strings

Field	*Search string*
Energy and mobility	smart AND (sustainab* OR ecosystem) AND (city OR district OR town OR residential) AND energy AND (mobil* OR flexib* OR local)
Consumer trends	smart AND (sustainab* OR ecosystem) AND (city OR district OR town) AND (consum* OR local OR "sharing economy" OR governance OR residential)
Multi-sided platform	smart AND (sustainab* OR ecosystem) AND (city OR district OR town OR residential) AND ("multi-sided" OR platform)

We thoroughly selected the source material for the literature research. Webster and Watson [36] suggest starting the search within leading journals of the research field. "Sustainable Cities and Society", "Cities" or the journals included in "Senior Scholars' Basket of Journals" could represent important journals for our studies. Since the databases of the main academic publishing houses like SpringerLink or Elsevier contain each of these selected journals, we used these databases in combination with few others to also consider literature from other disciplines [36].

Our search-strings lead us to 4.076 papers, which we evaluated. After screening the titles, 265 publications were left and after reading the abstracts, 95 publications remained. Using those papers, we performed a backward and forward research.

To enhance our first draft of PDPs, which was solely based on the literature we found, we conducted eight expert interviews. We once interviewed three experts at the same time (E4, E5, and E6), and the remaining experts separately (Table 2). We recorded all interviews, which lasted approximately 60 to 90 minutes.

Table 2. Interviewees: Experts

	Business Domain	*Interviewee*	*Employees*
E1	Research Institute	Research Assistant	> 100
E2	Research Institute	Research Assistant	> 100
E3	Real Estate Management	Head of Fund Management	> 500
E4	Engineering Office	Managing Director	> 250
E5	Engineering Office	Consulting Engineer	> 250
E6	Engineering Office	Consulting Engineer	> 250
E7	Research Institute	Research Assistant	> 100
E8	Sustainable City Development	City Planer	> 50
E9	Research Institute	Business Development Manager	> 25.000
E10	Research Institute	Research Assistant	> 100

Inspired by the *design as a search process* of Hevner et al. [31], in the following paragraph, we first illustrate how we developed the PDPs. Subsequently, we present our resulting PDPs in Section 4.

We received relevant feedback in form of practical insights and improvements for the PDPs from the interviews. The feedback is the basis for changes of the PDPs, regarding the selected criteria "ease of use", "efficiency", "generality", "operationality", "completeness", "elegance", "simplicity", and "understandability" [31, 32, 35, 41]. Due to these we adjusted our first draft of PDPs and emphasize important aspects of the SSD. For instance, PDP7 was no part of our first draft. In this case, we got advice from research experts that visionary objectives and goals are crucial for the SSD. Following, the criteria of completeness was not fulfilled. Therefore, we revised relevant literature and formulated a corresponding PDP. One further adjustment was the division of a general IT PDP to PDP3 and PDP5 to reach the criteria "generality". However, some of the comments were contrary to literature or other experts. For example, E7 recommended the exclusionary use of the term "stakeholders" in all PDPs. We followed this recommendation except for PDP5, where we kept the term "user" instead of "stakeholder" in favor of the criteria "understandability". Most feedback faced the criteria "understandability" and "elegance". For example, we reformulated PDP2 after feedback from E4, E5, and E6, to make clear, that stakeholders can be physically outside of the district. With respect to "ease of use" and "operationality", our interview partners gave us valuable recommendations with respect to the implementation in practice. We mitigate PDP9 because E4 noted that complete legal certainty is not reachable in the scope of current legal processes. The demand for changes by the experts shrank from interview to interview. We conducted the major structural and content related changes during the first four interviews. In the last three interviews we did not conduct major changes in the PDPs. In these interviews the experts mainly confirmed the PDPs, sometimes with notes regarding "elegance" and "understandability". Due to their confirmation, we think that our PDPs reached a solid status [42].

We also started with an ex-post validation. Therefore, we conducted interviews with possible future inhabitants. Hence, an appropriate sample should include different groups of society to avoid a possible elite bias [43]. Patton [44] states that under the conditions of academic work such an evaluation is nearly impossible to reach. Therefore, each research should determine a minimum sample size [44]. We talked to 17 potential residents with diverse characteristics (Table 3).

Table 3. Interviewees: Sample of German population

Sex		*Age*		*Education*		*Gross Income*		*Household Size*	
female	8	18-29	6	academic	7	< 15.000 €	7	1 person	6
male	9	30-60	6	non-academic	10	15.000-60.000 €	5	2 persons	6
		> 60	5			> 60.000 €	5	>2 persons	5

4 Results: Preliminary Design Principles for the SSD

In this section we give an overview of our nine PDPs for the PBE of the SSD, which we derived through an iterative process [31, 40] based on a structured literature [36, 37] review and several semi-structured interviews [38, 39].

PDP1: Define adaptable spatial boundaries of the SSD to be able to identify the given characteristics and properties of the SSD.

"Spatial boundaries" stand for a physical connected area of an SSD. The spatial delineation impacts the quality of the SSD out of an environmental, social, and economic perspective [45]. A suitable layout of the SSD fosters sustainable projects and increases the quality of life within it [45]. "Characteristics" describe the geographical location as well as price levels and other intangible attributes. One of the most important distinctions for each SSD project is the difference between districts in cities and districts in rather rural areas. “Properties” stand for different kinds of buildings or public places in the SSD. The SSD should be mixed in its types of buildings, inhabitants, and institutions [45]. This also extends to the importance of mixing social classes and people with different backgrounds. This contributes to sustainability mostly in strengthening the social structures between the inhabitants. Mixing also leads to local labor and consumption within the SSD, which concludes in less transport efforts and more social cohesion. Many experts also emphasized, that these boundaries must be adaptable in case of a changing environment. Especially E9 and E10 stated that there are many different characteristics which can define the boundaries, like buildings or the electric grid.

PDP2: Identify stakeholders taking part in the PBE of the SSD to assign roles.

Hollands [6] concludes, that smart cities start from the human side. In the same way it holds for SSDs. Because of this, every SSD needs to aim for increasing the quality of life of their citizens [46]. For this Cacho et al. [46] suggest the identification of the different stakeholders as one of the first compulsory steps. According to Kennon et al. [47] and E10, the classification is important for designing the digital infrastructure in a suitable way. The identification of all relevant stakeholders is the foundation for cooperation and coordination of investments [48]. Since we focus on the PBE of SSDs, the producers, consumers, providers, and the owner are the basis, which should exist in every SSD [19]. Nevertheless, there are many more different roles in the SSD context [46, 48, 49]. One crucial role is the leader role [18, 50, 51]. This PDP contributes to sustainability by forming the foundation for a social sustainable togetherness. On the other side it also supports economical sustainability by helping to understand the needs of specific stakeholders.

PDP3: Provide the SSD with an adaptable and scalable digital infrastructure to integrate heterogeneous, connected IT systems and features, to facilitate the PBE.

Like smart cities, SSDs depend on the correct and meaningful applications of digital technologies like open data [52], large-scale distributed systems [53], internet of things (IoT) [54], cloud, and fog computing [55] to everyday life [4]. Since everybody in the SSD context should be able to easily design, develop, execute, and share content [49, 56], we consider a central digital platform as core of the whole ecosystem. Hence, we use the term PBE in this context [18]. One possible application of this platform is the field of energy. It can interconnect several energy and legacy providers, virtual power plants, and households [57]. The digital platform can automate network management, enable peer-to-peer energy sharing, minimize operating costs, lower the emission of greenhouse gases, control the electrical energy production as well as the electric vehicles charge/ discharge, and implement demand side integration [13, 58].

Due to the penetration of digital services through all areas of life, the SSD generates a vast amount of data [59]. Big data analysis can improve the performance of SSDs in many areas like energy or mobility, by accomplishing trend analyzes, forecasts or demand planning [59]. According to Cacho et al. [46], it is also possible to generate data from citizens by using social media. As Cacho et al. [46] and E10 stated, the SSD should use the ICT infrastructure and the platform primary as enabler to improve the life of citizens. This can be a chance, especially for SSDs in rural areas, to distinguish themselves from other municipalities, which often do not have the digital infrastructure to attract many people. Furthermore, the SSD should enable the development of innovative green solutions and services, to facilitate a more sustainable smart district.

PDP4: Establish a transparent, cooperative and participatory structure to enable collaboration and competition between stakeholders.

Darking et al. [60] as well as Helfat and Raubitschek [18] emphasize designing governance as a crucial issue. The structure of the SSDs PBE should be transparent and open for all stakeholders to foster cooperation and participation [61]. The claim for transparency comprises the political system, processes, services, market conditions, and the digital platform itself [62]. "Cooperative" means that stakeholders should form partnerships among each other and with actors from outside. Public participation in the form of collaborative decision-making empowers inhabitants of the SSD to express their needs [49, 56, 61]. This implicates market competition and collaboration regarding the distribution and control of resources and power within the SSD [62]. Such cooperative partnerships can lead to desirable synergy effects resulting in benefits for all stakeholders [63]. We do not see competition and collaboration as contrary extremes, but as driving forces for value creation within the SSD [64]. A transparent, cooperative, and participatory structure enables sustainable economic growth and fosters social cohesion. This follows from the involvement of people in the SSD processes and the open and integrating structure [50].

PDP5: Design the services of the SSD in a simple and accessible way to integrate all users.

This PDP prescribes that the services in the SSD have to be user-friendly and people-centric to integrate participants of all age and with every level of education [65]. Designing services in a simple way aims at the usability of these services. Hence, participants will use newly developed services within the SSD more frequently, if the offered solution is intuitive [66]. Including the stakeholders of the SSD in the service creation process strengthens the market competition. Hence, it improves the overall quality and price of the offered services [50].

PDP6: Determine tangible and intangible values to derive an incentive-structure and enable the development of value-adding services, to satisfy the stakeholders' needs.

Tangible values like financial gains are measurable, whereas intangible values are difficult to measure directly. An example for an intangible value is the provision of clean air. The values of the SSD lead to an incentive structure for the stakeholders to encourage their participation and value creation in the SSD [51, 67]. This means, the incentive-structure must be that attractive, that people want to collaborate, for example in either offering services for the SSD, or in using them. There is a strong connection between the services and the incentive-structure, because everybody offering a service wants to benefit. An appropriate incentive structure and value-adding services foster sustainability in various ways. For instance, the waste of food can be reduced by different kinds of food sharing concepts, implemented in the SSD. Additionally, there is potential value for local vendors, due to price reductions for surplus stocks or perishable goods. For the consumer it satisfies needs, by being economically beneficial, because he can purchase the food cheaper than in other circumstances.

PDP7: Continuously monitor the SSD and evaluate feedback to achieve or iteratively adapt visionary objectives and goals.

Literature and experts confirmed, that goals are necessary for the SSD, hence, they are a critical element of the PBE [68]. To ensure that all stakeholders work together, the planner should involve all relevant stakeholders in the finding process [69]. According to Slocombe [69], you should place additional visionary objectives on top of the goals, giving the stakeholders an overall vision for the future development of the SSD. These goals and visionary objectives should also target the implementation of sustainability actions in the SSD [28]. The responsible stakeholder groups should also accompany and reflect the process towards the optimal state [69]. We divide this control mechanism into two different elements. The first is rather quantitative monitoring, the second qualitative feedback. With the help of smart meters and similar devices authorities can automatically check goals. Resulting data sets give indications for future improvements [70]. The other approach of getting feedback from stakeholders of the SSD is more qualitative. This leads to better included stakeholders [56]. After monitoring and considering the feedback, it can make sense to adjust the objectives and goals. For this it is necessary to iteratively adapt these (E10).

PDP8: Integrate public and IT security concepts to provide safety for people, public, and private property.

We will reach sustainable development, if every stakeholder feels safe and protected within the SSD. According to Chifor et al. [71], applications or smart objects, which enable a new way of interaction between humans and their environment, have to consider security aspects. Furthermore, the huge amount of data gathered from different application and services is an issue [70]. It is necessary to ensure that the data is provided for the systems when it is needed. But at the same time, the SSD has to consider the privacy concerns of the people [70]. Furthermore, it is important to still be aware of the "traditional" security aspect for private and public property. For instance, countermeasures must be prepared if the energy supply breaks down.

PDP9: Comply with current law and regulations to aim for legal certainty.

The PBE of the SSD offers lots of chances but its value depends to the regulatory environment [58]. One exemplary regulatory aspect within the SSD is the energy market design. There are several laws that determine which designs are allowed and how taxes and fees are distributed [13]. Today, the regulation in most countries does not allow local peer-to-peer energy sharing [13]. If it were allowed, it would be a viable approach to integrate renewable energy sources in an economical way [13]. However, it is crucial for the SSD to meet current regulatory requirements [13] to target legal certainty. According to E4, it is not possible to achieve full legal certainty because the legal texts leave gaps whose interpretation depends on the opinion of a judge.

5 Discussion

We conducted interviews with ten experts from research, business, and the public sector. All our interviewees are originally from Germany. This represents a limitation of the paper. Experts with other cultural backgrounds could gain alternative insights and improve the PDPs. Furthermore, we conducted interviews, just with a small sample of the German population. The input of 17 people is a brief insight and should be pursued with a bigger number of participants to get representative results. With representative results the planning authorities can ensure that research and real-world projects fulfill the needs of potential inhabitants. Further, we did not conduct an empirical survey on the acceptance of the PDPs in the population.

These limitations in combination with statements of experts as well as parts of the German population point out the critical aspects of this research. Some experts emphasized certain arguments as very important for a successful SSD. According to E9, the trade-off between complexity and economic value is one of the most important aspects of the PBE of an SSD. The SSD must be financially viable and attractive for different stakeholders to successfully implement it in real life. Furthermore, E1, E8, E9, and E10 highlighted the importance of the human and their needs as center of attention within the PBE.

The interviews with a sample of the German population generated insights in the perspective of possible inhabitants. Almost all these interviewees stated that they can envision to live in an SSD. The main incentives they see are a more convenient and sustainable living. Especially the sample of the people above the age of 60 also stressed, that an SSD offers possibilities for people that need help in their everyday life. However, this part of the population was most concerned about losing control and responsibility for their lives. A part of the interviewees in the age between 18 and 60 raised questions about the financing of the SSD. The question who pays for the infrastructure is a relevant decision criterion to them. The question about the financing leads us to an even more relevant question: Who is in charge of the SSD. In the smart city context, current research discusses about private as well as public responsibility [63]. The success of the SSD depends significantly on the stakeholder of the district. Are there sufficient incentives for big and small stakeholders to participate? Which and how much stakeholder must be part of the district?

Some opinions about the concept of the SSD are very similar over the whole group of interviewees. For example, the demand for transparency of the PBE and to the same time the fear of data abuse. However, we found conversely opinions regarding the provided services and priorities of the SSD. Because of the different needs of the groups, there could be an increased risk of pooling inhabitants with similar backgrounds. The responsible authorities should counteract this development in an early stage by balancing the incentive structure and the price level of the SSD. Furthermore, it is questionable which influences multi-sided platforms have on the quality of the provided services. Cennamo et al. [72] illustrate that combining services on platforms can have significant influence on performance within the platform. In general, the SSD still contains open questions and potential undetected risks.

For regular cities, towns and rural areas the emergence of SSDs is a big opportunity. District projects like "Smart District Gnigl" from Salzburg or the German "Open District Hub" project promise to gain important insights in practical benefits of SSD projects. Especially the implications on remaining cities are very important for future district projects. It will help to evaluate a piece by piece approach for transforming cities with the help of SSD concepts.

6 Conclusion, Implication, and Further Research

The idea of a sustainable smart district as a platform-based ecosystem is very complex due to its variety of parties and implications. For this young field of research with rare practical applications, we enforce the awareness of sustainability within the concept. Due to that, the sustainable smart district has a need for preliminary design principles as a way of guidance. With these preliminary design principles, we ensure the consideration of ecologic, economic, and social factors in the district. In this paper we derive nine preliminary design principles from literature as a foundation for the design of the platform-based ecosystem of the sustainable smart district. We developed these principles in an iterative approach based on expert interviews. Furthermore, we interviewed a sample of the German population to ensure their acceptance.

There are many potential topics for further research in the sustainable smart district. First, a real-world instantiation enables the real-world evaluation of the preliminary design principles and carries on the research about sustainable smart districts. After carefully analyzing the results of this instantiation, we could finally evolve the preliminary design principles to design principles in the sense of design science research. Subsequently, we are able to evaluate these design principles according to Sonnenberg and vom Brocke [41], through an extension of the interviews on a complete average of the population. Third, experts from other disciplines and countries would gain further relevant insights to the topic. Fourth, a maturity model for the sustainable smart district would help to understand and classify potential districts. This is especially helpful to capture the current level of sustainability or digitalization within the sustainable smart district. We can also think of evaluating specific technologies or trends in the district context. For instance, future research could find out in which way sustainable smart districts could enable energy sharing within one, but also among several district and thus lead to ecological sustainability. To fully unpack the potential of SSDs, one must also investigate its links to emerging technologies such as electro mobility, smart traffic systems, big data analyses, and much more from a district point of view. Additionally, the three components of sustainability (social, environmental, economic) could be examined in detail, to derive specific recommendations to reach sustainability in the smart district. Furthermore, we raised some open questions in the discussion section, which serve as foundation for further research.

Our results represent a necessary foundation for the following applications in real-world and in science. For the realization of sustainable smart districts our guidelines can help to ensure a sustainable and feasible approach. New research projects can push the idea of the sustainable smart district to concrete concepts and prototypes. In this development a strong cooperation between research and practical application ensures a successful implementation. We believe that this paper contains applicable research, which guides real world projects in creating sustainable smart districts and develop districts, rural areas, and cities towards sustainable future living.

Abstract. Manufacturing companies in the European Union are obliged to regularly analyze their recipes to find safer alternatives for hazardous substances. Unfortunately, available substance information is dispersed, heterogeneous and stored in databases of many private and public entities. In addition, the number of existing chemical substances already surpassed 85,000 with over 200 attributes describing substance characteristics, which makes it impossible for experts to collect and manually review this data. We tackle these issues by introducing a novel machine learning approach for alternative assessment. After developing a central database, we design an approach that performs nearest neighbor search in latent space obtained by deep autoencoders. Furthermore, we implement a post-hoc explanation technique, t-SNE, to visualize deep embeddings that enables to justify model outcomes. The application in a real-world project with a manufacturer shows that this approach can help process experts to identify possible replacement candidates more quickly and fosters comprehensibility through visualization.

Keywords: worker safety, sustainability, alternatives assessment, deep learning, machine learning

1 Introduction

In the member countries of the European Union, many laws have been installed that aim at reducing the impact that industrial processes may have on the environment and the health of workers and consumers. A prominent example is the RoHS directive (*Restriction of Hazardous Substances*) which, among others, prohibited manufacturer from the use of leaded solder and the sale of any products that contain these regulated substances [1]. Apart from the prohibition to use certain substances, which are determined by the government, legislators within the EU impose companies to take individual action towards reducing the environmental or health-related impact of industrial processes.

As part of these regulations, companies must regularly evaluate the possibilities to substitute hazardous substances used in production with less harmful alternatives. Alternatives assessment (AA) is a process for identifying, comparing, and selecting

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

safer alternatives to chemicals of concern (including those in materials, processes, or technologies) on the basis of their hazards, performance, and economic viability [2].

The issue of AA is currently engaged by researchers, government agencies, as well as by NGOs [3, 4]. Government agencies like the European Chemical Agency (ECHA) primarily focus on the management aspect of chemicals by providing data for labeling and classification of substances. Researchers and NGOs, on the other hand, are working on process aspects when conducting AA, resulting in frameworks that support manufacturers in their AA activities [3]. Currently, there are several frameworks for alternatives assessment [3]. At the beginning of an AA process, most researchers suggest the identification of chemicals of concern that will be subject to AA [5–8]. The substances' physio-chemical properties, the human health hazards, and ecotoxicity are subject to evaluation in most of the ten available frameworks identified by [3]. In all frameworks, an economic assessment is part of the AA process after the ecotoxic and health hazard assessment is done [3]. Identifying alternative substances is considered critical in all frameworks, but mostly remains a manual task and is described only on a very vague level. The authors make suggestion on what factors to consider [8], to use market view or literature research for identifying alternative substances [5], or pose questions that should be addressed when trying to find alternative substances [9].

The limitation of available research is threefold. First, most of the existing frameworks are only guidelines for decision making or suited to a certain environment, rather than being a prescriptive protocol to follow. Currently, there is a lack of techniques and information systems (IS) that support companies in finding meaningful alternative substances by addressing some of the issues that come with AA. The second limitation is the complexity of data or the lack of data [3]. The ECHA provides a public database with over 85,000 registered substances on their website [10]. Each data set comes with a classification of the physio-chemical characteristics for each substance using more than 200 different attributes. In addition to the ECHA database, there exist more databases from individual manufacturers (e.g. BASF), trade associations (e.g. GISBAU), governmental agencies, or national social insurance carriers. Since these entities focus on other aspects than ECHA, their data is characterized by other attributes than the ECHA data. This makes it almost impossible for process experts to use this kind of data for AA due to the sheer number of substances and variety of the data, which brings us to the third limitation of current research. Apart from information systems that provide data for individual substances through a web site, there is currently no approach available that helps process experts in extracting and/or condensing meaningful information for their AA activities from existing data.

To the best of our knowledge, there is currently no approach available that specifically supports the identification of finding alternative substances using sophisticated methods from the area of machine learning. We aim at filling this void with the research provided in this paper. We tackle the latter two limitations by designing a software artifact that contains (i) a substance database, which captures the characteristics of the substances that we develop by extracting the data from different sources, (ii) a machine learning (ML) model that examines the substance data to uncover similarities among substances and identifies substitution candidates based on their physio-chemical and hazard-related attributes as well as their functional role [11],

(iii) an explanation interface for ratification of the generated list of substitution candidates. The ML component is based on a nearest neighbor search algorithm combined with the deep stacked autoencoders. For explainability purposes we use the recognized visualization technique, t-SNE, which is assumed to project the obtained autoencoder representations in a two-dimensional space. The resulting IS can potentially help process engineers from different domains to automatically check their bills of materials for the availability of alternative substances that fulfill the same purpose of the original substance, but which are less harmful for the environment, for the workforce, and end users. We demonstrate the applicability of the proposed IS artifact for the production process of a leading German manufacturer of ceramics.

The remainder of the paper is organized as follows: we provide the applied research method in-depth in Section 2. Section 3 introduces the architecture overview and the individual components of the proposed decision support system. More specifically, we explain the database that was created, the ML models that we applied on that data and the explanatory component of the ML technique. Insights on the applicability of our approach are provided in section 4 with a use-case and evaluation in a real company, before we conclude the paper with a summary and a brief overview of future work in section 5.

2 Research Method and Design

The research method applied in this paper shall be characterized as design science research (DSR) [12, 13]. DSR is an important paradigm in IS research and professional practice and serves as a guideline for the process of constructing socio-technical artifacts in the IS domain [14]. The goal of DSR is to solve existing problems with new or improved IS-based solutions [15]. We follow the process of Peffers et al. [13] for creating design science artifacts. The research environment is an interdisciplinary consortium research project that allows us to evaluate our artifacts in a real-world manufacturing situation and collect continuous feedback from project partners [16].

Table 1. Process of creating Design Science Artifacts (adapted from [13])

Step 1: Problem Identification & Motivation	**Step 2: Objectives of a Solution**	**Step 3: Design & Development**	**Step 4: Demonstration**	**Step 5: Evaluation Step 6: Communication**
– Lack of annotated data – Infeasibility of the manual search process – The opaqueness of the black box machine learning techniques	– Collecting data necessary for alternatives assessment – Searching alternative substances with ML techniques – Evaluating the alternatives in terms of ecological and health-related criteria	– Data model and database – ML techniques for reducing complexity of data set – Explanation Interface for ML techniques – Information system for alternative assessment	– Application of the artifacts in the problem context for 4 substances of concern	– Evaluation of the artifacts in a real-world scenario – Presentation of results to academics and to practitioners

At the beginning, the *problem* must be identified and the need for a new or better solution to the problem should be motivated. As mentioned before, the problem in our case is the current fragmentation of substance data in different databases of individual manufacturers and the lack of methods to process this data [3]. In most current applications such as *P2OASys*[1] or *COSHH*[2], the domain experts must seek for alternative substances manually by analyzing the multidimensional application purposes and the hazard profile of each individual substance, which results in high cognitive load and suboptimal results. Automating the search process with ML techniques is a good alternative, which in turn also requires a careful design and the suitable choice of the approaches. Finally, to embed the ML systems to the decision-making processes it is important to establish the trust to their outcomes, which requires making them explainable by considering the context of application and the user requirements.

In step 2 (*objectives*), the goal of the research must be emphasized. The objective of a solution serves as a baseline of knowledge on which to evaluate the novelty of the created artifacts [14]. The objectives of our approach are to tackle the lack of a sophisticated database with annotated substance data. We do this by extracting necessary data from various sources and creating a single database with harmonized data. We then apply ML techniques to provide means for the expert to evaluate and select alternative substances.

Step 3 (*design & development*) is the phase where the artifacts for the intended solution are created. This can be new constructs, models, methods, or instantiations [12]. We create the design of the database and ML models and implement them as a prototype.

The application of the new artifacts in a suitable context is subject to step 4 (*demonstration*). We chose the context of manufacturing in the ceramics industry to apply our prototype for AA and demonstrate the benefits in this domain.

Step 5 (*evaluation*) is where the final evaluation of the artifacts happens. Based on metrics or observations, the results of the artifacts are evaluated regarding their performance in the field. Since expert knowledge in this step is necessary, we included the ceramics manufacturer to evaluate the resulting list of substitution candidates for five substances that the manufacturer is currently using.

The process of DSR concludes with step 6, where the *communication of the results* to research communities and practitioners takes place.

3 Description of the Proposed Decision Support System

3.1 Architecture overview

With our adapted process (see fig. 1), we follow the framework of the National Research Council [17] for AA. The NRC recommends adopting a multi-perspective approach for AA that begins with the identification of substitution candidates. This is probably the most crucial part of AA due to the information overload for experts. We

[1] see https://p2oasys.turi.org/GetStarted/p2oasys.php

[2] see http://www.hse.gov.uk/coshh/essentials/coshh-tool.htm

support this process with our ML technique, which identifies similar substances, according to their attributes. The physio-chemical attributes must then be assessed by a domain expert to find out, which of the candidates are appropriate for the desired application purpose or product. A comparative exposure assessment for human health hazards as well as ecotoxicity should then be conducted with the remaining substitution candidates. This step is supposed to identify the substance with the smallest negative impact on environment or workforce. We support this step with a web application by providing visualization of the related health or environmental risk for the substitute candidates. Depending on the application environment, the process expert can weigh the attributes differently. For example, in a scenario where water is drained off to the environment after usage, a substance with less risk for causing aquatic toxicity would be more appropriate whereas a substance whose dust can be harmful to the workforce would be less problematic in a fully automated process. Finally, economic considerations like market prices or availability of substances are considered. These three steps are recommended by the majority of established AA frameworks [17].

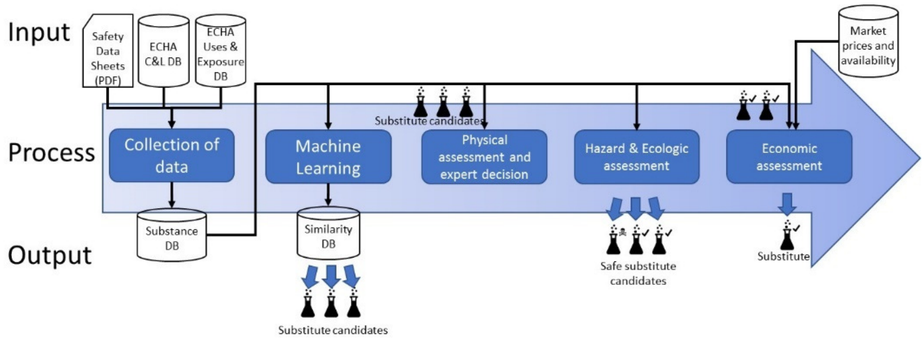

Figure 1. Architecture of the information system

Since the related research project is ongoing and we focus on environmental and health issues in this paper, we present the results up to the hazard & ecologic assessment and focus on the ML component in the following sections.

As mentioned in the introduction, there is currently a need for IS that support manufacturers in comparing available substances, e.g. for planning and maintaining product design. This IS must be capable of analyzing large sets of chemical substance data using ML models. Since many manufacturers have no data science experts available, the results of the ML techniques must be provided in a way that can easily be understood by domain experts.

The solution that we propose is based on a web application that we implemented using Java Enterprise for the user interface and business logic, and R statistical computing programming language for the ML components. In the end user perspective, the user can start a new AA process by providing the CAS# of the substance that is subject to the assessment along with meta data for the AA project. Thereafter, the user can choose how many possible substitutes should be presented and if potentially dangerous substances from the list of substances of very high concern (SVHC) which is maintained by ECHA should be included in the suggestions. The user will then be provided with the interactive scatter chart from Figure 3 with the initial substance highlighted. The samples near the examined instance are provided as colored dots depending on the number of suggestions that was selected. Once the users click these points, these substances will immediately be added to a table below the chart that shows the physio-chemical attributes of every selected substance. After a manual review of the relevant attributes, the user can select the remaining candidates for the next process step. In the next step, the remaining suggestions will be compared among each other regarding their hazard for human and environment. This is done using the GHS column model [18], where the hazard of each substance is benchmarked regarding six different dimensions (see fig. 4).

The administrator of the web app can access the machine learning perspective to start a new learning phase. During the learning, the substance data is retrieved from the database, the autoencoders and t-SNE models are applied to identify and to visualize the nearest neighbors for each substance. The results in the form of an x- and y-value for the position of each substance in a 2d space are stored in the database. The learning must be recomputed as soon as new substances considered are added to the database.

3.2 Database Component: Developing a Central Database

The design of a comprehensive database that can be used for AA in manufacturing companies requires collecting and processing available data. The objective of the ECHA is to collect data about hazardous substances that are imported to or produced in the European Union. ECHA is constantly assessing the chemical-related risks of many substances through manufacturer provided dossiers, own tests, and chemical analyses. Thus, ECHA has available a large volume of data, that is publicly available through their web site.

Most important for identifying initial substitute candidates is data regarding the physical attributes of substances. This kind of data is provided by ECHA through their *registered substances list*, where information about the use and exposure (U&E) of substances is available. The U&E data is classified by the following use descriptors.

Table 2. Attributes of the uses and exposure data set

Attribute type	**Sector of use** (SU, 24 attributes)	**Process category** (PROC, 31 attributes)	**Product category** (PC, 45 attributes)	**Article Category** (AC, 81 attributes)	**Environmental Release Category** (ERC, 26 attributes)
Description	The sector in which the substance is used (e.g. industrial, consumer)	The application techniques or process types	Types of chemical products in which a substance is used.	Type of article in which the substance has been processed.	Broad conditions of use from an environmental perspective.

A second type of data available from ECHA is the *classification and labelling inventory* (C&L). The C&L provides electronic public access to possible hazards for workforce and environment that can be caused by a substance. This data is important for the hazard and ecologic assessment step. The basis for the characterization is the

Globally Harmonized System of Classification and Labelling of Chemicals (GHS) with its 100 attributes in total. These binary-coded attributes describe, whether a substance is causing a certain physical, health, or environmental hazard or not.

As a third source for acquiring substance data we implemented a software tool for extracting relevant information from existing safety data sheets (SDS) in the PDF format. These sheets provide a standardized set of data regarding substance meta data (Manufacturer, retail name), composition/information on ingredients, or relevant identified uses of the substance or mixture. The matching between the data extracted from SDS and the C&L inventory was made through the chemical abstract number (CAS#), a unique identifier for every substance which is available at every SDS and in the C&L and U&E inventory.

Through these three data sources, we could collect 13,133 data instances regarding U&E of substances and 85,845 data instances of the C&L inventory.

3.3 Modelling Component: Nearest Neighbor Search and Deep Autoencoders

3.3.1 Finding Alternative Substances with Nearest Neighbor Search

Once the central database is developed, we aim to propose an intelligence component that presents the production experts the most suitable alternatives to the substances that are used in the current production processes. For this purpose, the most similar matches to high dimensional query vector that captures different aspects of the usage- and hazard profile can be extracted by using the nearest neighbor search algorithm. However, searching the similar items in large datasets is a challenging issue. Hence, the suitability of the retrieved neighbor instances via nearest neighbor search algorithm is affected negatively by the inappropriate adoption of distance/similarity measure and existence of various class irrelevant features [19]. Furthermore, the process of measuring the similarities between the query case and historical items with high feature dimensions from very large validation sets is very time consuming and suffers from the curse of dimensionality which makes infeasible to identify the exact matches in reasonable computational costs [20].

To alleviate these obstacles, various techniques have been proposed and extensively investigated [20]. Neighborhood identification in the latent space obtained by applying dimensionality reduction techniques is considered as the most promising approaches among others [21]. Earlier studies in this field investigated diverse linear approaches such as Principal Component Analysis (PCA), Linear Discriminant Analysis (LDA), Independent Component Analysis (ICA) among others to map the original high dimensional feature space to the low dimensional latent space linearly [19]. However, such a linear transformation shows an inability to model the higher-order correlation in the original data space and is deficient in capturing the intrinsic class-specific data manifold [19, 22]. On these grounds, we can argue that searching for similar instances in the latent space obtained by linear transformation may result in the retrieval of the inappropriate explanation items.

Different non-linear transformation and dimensionality reduction approaches have been proposed to surmount the problems arising from these shortcomings. These techniques are assumed to place the items having the same characteristics near to each other in the non-linearly transformed low-dimension feature space [19]. In our study, we employ the stacked autoencoder based deep neural networks, which extract features that constructs useful higher-level representations. The empirical experiment results on various datasets by [22, 23] provide confirmatory evidence that using the latent representations obtained by autoencoders shows superior performance compared to linear PCA, LDA and other non-linear approaches such as linear embeddings in retrieving similar items.

3.3.2 Autoencoder Neural Codes for Nearest Neighbor Search

Autoencoders is the type of unsupervised feed-forward neural networks with three layers namely, an input layer, a hidden layer and an output layer in which the training purpose is defined as reproducing the input data at the output layer. The component of autoencoder networks which computes the hidden layer activations from the input data are referred as encoders. The encoder employs a non-linear mapping function to obtain the hidden layer representation. Following this, the decoder component maps the latent representation of the input data obtained and presented in the hidden layer through the encoding process to a reconstructed vector in high-dimensional input space by using the chosen non-linear mapping function with reverse mapping parameter set. The parameter sets of both encoding and decoding layer are optimized simultaneously with the aim to minimize the average reconstruction error.

Deep neural networks can be built by stacking multiple layers of autoencoders which have already been trained locally as described in the previous section [24]. The training process of the stacked autoencoders with k layers is initialized by training first autoencoder in which the original input data are used both in input and output layers. The learned hidden layer activations are then wired to input and reconstruction layers of the second autoencoder with the purpose to obtain the corresponding hidden layer features and parameters. This greedy layer-wise learning is performed until all features including the ones from last k^{th} hidden layer are extracted and all relevant parameters, weights, and biases are initialized. An example training process of deep neural networks with two hidden layers is depicted in Figure 2.

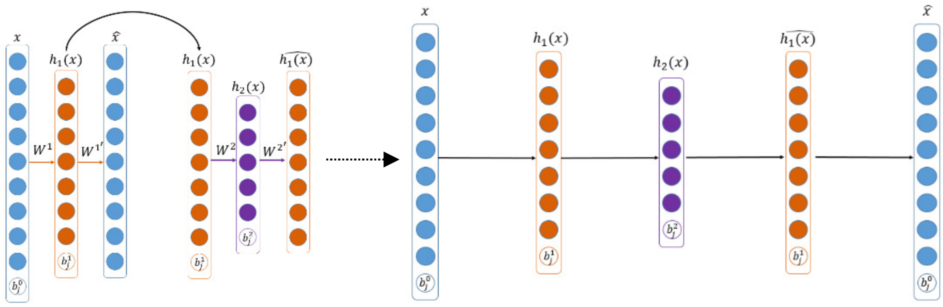

Figure 2. Layer-wise training of stacked autoencoders

As described above the main idea of (stacked) autoencoders is to learn the useful latent representations by teaching the network to copy the input to output. For this purpose, it is very important to add either architectural constraints or employ the regularization techniques during the learning process. In the last decade various autoencoder architectures such as stacked denoising autoencoders, variational autoencoders, contractive autoencoders, regularized autoencoders, undercomplete autoencoders and others have been proposed which are assumed to increase the quality of the extracted latent features. Since we aim in our study also to conduct the nearest neighbor search process based on hidden layer activations faster and more efficiently, it is reasonable to adopt an autoencoder architecture with the decreasing width (layer sizes) of hidden layers, namely undercomplete autoencoders. The main idea behind this type of the autoencoders is to constrain the number of nodes in the hidden layer and to force the model to learn the most important features form the inputs while minimizing the reconstruction error.

After mapping all substances in the dataset onto useful latent space with autoencoders we can find the similar instances to the given query instance by searching its neighbors in the latent space. For this purpose, we first extract the bottleneck features of the query instance by feeding its original input values to the learned deep autoencoder, by computing the hidden layer activations and by calculating the distances between them and the bottleneck features of all other instances. The list of substances with the smallest distance to the query instance is presented to the experts, which are later examined whether they are sustainable alternatives in terms of productions and economic factors.

3.4 Explanation Component: Visualization with t-SNE

In order to exploit the full potential of ML techniques, their outcomes have to be embedded to the production and business processes that creates value by extending the corporate ability to gain new insights [25]. However, a series of recent studies have indicated that the lack of trust in the machine learning model with opaque reasoning mechanisms is considered as one of the main obstacles in operationalizing the data driven analytics that in turn contributes to the extending gap in the scientific developments and their practical applications [26, 27]. Making the advanced black-box models such as deep learning techniques implemented in the current study or their outcomes explainable is considered a potential solutions that has recently received substantial interest [28]. The practicability and reliability of the explanations depend significantly on the context of explanation situation and the target audience that must be considered when choosing and designing the relevant techniques. In our use case, the machine learning explainability is required for the end users, namely the production domain experts, who have little interest in understanding the reasoning procedure of the implemented nearest neighbor search in latent space obtained by deep stacked autoencoders [29]. With this in mind, the post-hoc explanation family techniques are suitable for this purpose since they are assumed to increase the end users' confidence to the ML models by allowing to justify the outcomes delivered by the system [30].

Since the proposed ML model in this study provides the end users the list of similar alternatives to the query case, it already incorporates an intrinsic example-based explanation ability. The domain experts can ratify the suitability of the generated alternatives list by using their domain knowledge and evaluate their validity without a need for examining how and why it was generated by the system. However, such explanations facilitate the users to understand the model locally by providing the list of alternatives for one substance at a time. To enable the users to analyze and understand the entire model outcomes in the whole instance space we adopt another post-hoc explanation technique, visualization with t-Stochastic Neighborhood Embeddings (t-SNE). t-SNE is considered as one the most powerful dimensionality reduction and visualization techniques, that can effectively visualize the high dimensional data by assigning each data point a location in a two or three dimensional map [31]. The main superiority of the t-SNE is its ability to visualize the similarity data by retaining the local structure of the data while also providing the relevant information about the global structure. It is important to note that we visualize the embeddings obtained by the compression of the original data via deep stacked autoencoders with an extension of the original t-SNE technique, namely its implementation with Barnes-Hut approximation algorithm. Implementing the later approach leads to substantial computational efficiency by enabling to embed the high dimensional data with the runtime $O(N \log N)$ instead of $O(N^2)$.

4 Experimental Settings and Results

4.1 Use Case: Substitution of Hazardous Substances in Ceramics Industry

The research covered by this paper was conducted in the ceramic industry. The company that served as partner is a German manufacturer of sanitary ceramics with manufacturing facilities in different European countries. The company uses a variety of chemical substances and mixtures during the three steps of manufacturing. At the very beginning, substances are used, for example, as adhesive or cleansing agent for the construction of the molding tools (i.e. the negative). Then the compound for molding is mixed in a large pug mill from several substances. After the mix is ready, the molding tool is used for high-pressure injection molding of the mix which forms the workpiece. In a series of further manual steps, grinding and glazing of the workpiece takes place. In each of these steps, workers can be exposed to hazardous substances through skin contact or inhale of dust. Most substances have a wide range of short and long-term effects, ranging from skin irritation to carcinogenicity. To reduce the risk for workforce and environment, the firm is looking for new techniques of AA that are robust and can cope with the challenges that massive amount of data present today.

4.2 Tools and Model Parameters

All models for machine learning and explanation components of the proposed solution were developed by using the R statistical computing programming language. The stacked autoencoders were implemented on top of the h2o package [32]. The input layer consists of 208 nodes and the bottleneck code layer size was defined as 20. To avoid the overfitting, we adopted the early stopping technique in which the Mean Squared Error was used as stopping criterion. All layers of the implemented stacked autoencoders used the Tanh activation function. For nearest neighbor search we used the brute force nearest neighbor search in the latent space obtained by stacked autoencoders by computing the Euclidean distance between the query case and all other substances in the dataset. For this purpose we used the FNN package [33]. Performing the nearest neighbor search in the latent space has resulted in an acceleration by factor 11 compared to the search in original high dimensional space.

Table 3. t-SNE and stacked autoencoder parameters

t-SNE		Autoencoder	
Parameter	Value	Parameter	Value
Dimension of Embedded Space	2	Layers	208-50-20-50-208
Learning Rate	200	Activation	Tanh
Perplexity	30	Epochs	1000
Iterations	1000	Learning Rate	0.005
Initial Momentum	0.5	Rate Annealing	0.000001
Momentum Switch Iteration	250	Initial Momentum	0.5
Final Momentum	0.8	Final Momentum	0.99
Theta (Speed/Accuracy Trade-off Parameter)	0.5	Rate Decay	1
Early Exaggeration	12	Initial Weight Distribution	UniformAdaptive

Following this, we visualized all data represented in the bottleneck neural codes of the implemented autoencoder by using the t-SNE with Barnes-Hut approximation algorithm and follow the training instructions by its developers to obtain reliable results [34]. Particularly, a gradient descent optimization was performed for 1000 iterations. Furthermore, an early exaggeration trick was implemented when minimizing the KL-divergence. An additional momentum term of 0.5 was used for the first 250 iterations whereas it was increased to 0.8 for the rest. To perform t-SNE with Barnes-Hut approximation, we used the Rtsne package [35]. A comprehensive overview of parameters for deep stacked autoencoders and t-SNE are depicted in Table 3.

4.3 Demonstration and Evaluation

To demonstrate the contribution of our approach to AA, we examined four different substances that are currently being used in the production process of our industry partner, that are considered harmful for workers or the environment. These substances were selected by the ceramic manufacturer due to their individual risk profile: *Barium Carbonate, Instapak A, Sodium Borate,* and *Hydrogen Peroxide 30%.* We identified ten substitutes for every substance based on the proposed nearest neighbor search method (see fig. 3). The overall impression after an initial review of the ten suggestions by the expert was that for three of the four initial substances, at least one reasonable substitution candidate was provided through the machine learning process. Only in the case of *Instapak A*, substances cannot be easily exchanged since *Instapak A* is used as one component in a multi-component ready-to-use packaging foam provided by a third party. In other cases, a further investigation is necessary to back the positive first impression through professional literature and studies. An excerpt for the substance *Barium Carbonate* and the first five most important substitute candidates based on nearest neighbor search is listed in Table 4. We will explain the results of the evaluation in the case of *Barium Carbonate* in more detail. *Barium Carbonate* acts as a network converter in the glazing agent to increase the viscosity of the glaze mix in the fire kiln. It is also lowering the melting temperature of the glaze. At first sight, it is obvious that the first substitute candidate is related to the original substance based on its name. The base material of *Barium Carbonate* is *Barium*. The ML algorithm identified *Barium* as a substitute candidate for *Barium Carbonate* because the physio-chemical attributes of the two are almost identical. The second substitute, *Boron Nitride*, turned out to be impractical from the standpoint of technical product design. *Lead*, on the other hand, is a member of the SVHC list provided by ECHA and is even more dangerous than *Barium Carbonate*. Therefore, it was not considered in the further process. With *Carbonic Acid* we discovered a substance that fits the spectrum of substitute candidates from a technical, and safety standpoint. Thus, we proceeded with that substance to the next AA process step. What the evaluation of the first process step revealed is that the final choice of substitute candidates cannot be made by a data scientist or an algorithm alone. Instead, a domain expert from the manufacturing company must conduct a preliminary assessment to choose, which substitute candidates should be regarded in the further evaluation process. We also received the feedback that a function to exclude substances from the SVHC list from the suggestions would reduce the effort necessary for the manual review of the results.

Table 4. First five replacement substances for barium carbonate

Orig. substance	1st substitute	2nd substitute	3rd substitute	4th substitute	5th substitute
Barium carbonate CAS# 513-77-9	Barium CAS# 7440-39-3	Boron nitride CAS# 10043-11-5	Dicopper oxide CAS# 1317-39-1	Lead CAS# 7439-92-1	Carbonic acid CAS# 463-79-6

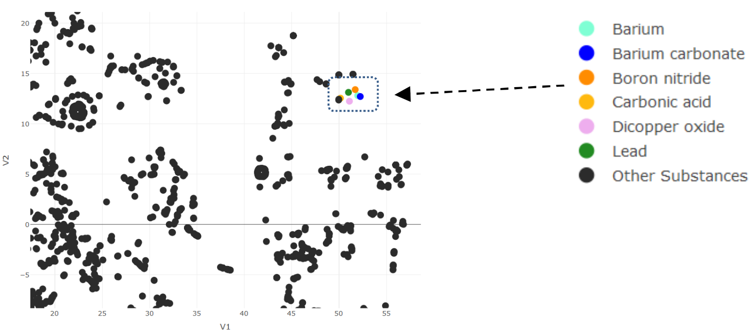

Figure 3. Visualization of substances with t-SNE (zoomed region)

The second step of our AA process was the comparison of the hazard and ecological factors that the new substances raise. Depending on the application context, a substitution should only take place, if the relevant risks for human and environment decrease due to the substitution. To compare the risks of both substances, we applied the GHS column model [18], which helps us to compare the two substances regarding the six criteria listed as columns in Figure 4.

	Barium carbonate CAS# 513-77-9					
	Acute health hazards (single exposure)	Chronic health hazards (repeated exposure)	Environmental hazards	Physico-chemical effects (fire, explosion, corrosion)	Hazards from release behaviour	Process-related hazards
	Acutely toxic substances/ mixtures, Cat. 4 (H302)	Safe substances on the basis of experience (e.g. water, paraffin and the like)	Substances/mixtures not hazardous to the aquatic environment (NWG, former WGK 0)	Non-combustible or only not at all readily flammable substances/mixtures (flash point of liquids > 100 °C, no H-phrase)	Non-dust-generating solids	Process index 0,25 according to TRGS 500
Risk potential:	2	0	0	0	0	0

Carbonic acid, zinc salt CAS# 51839-25-9					
Acute health hazards (single exposure)	Chronic health hazards (repeated exposure)	Environmental hazards	Physico-chemical effects (fire, explosion, corrosion)	Hazards from release behaviour	Process-related hazards
Safe substances on the basis of experience (e.g. water, paraffin and the like)		Substances/ mixtures not hazardous to the aquatic environment (NWG, former WGK 0)	Non-combustible or only not at all readily flammable substances/mixtures (flash point of liquids > 100 °C, no H-phrase)	Non-dust-generating solids	Process index 0,25 according to TRGS 500
0	0	0	0	0	0

Degree of Risk (numeric/colorized)

4	very high	very high	very high	very high	very high
3	high	high	high	high	high
2	medium	medium	medium	medium	medium
1	low	low	low	low	low
0	negligible	negligible	negligible	negligible	negligible

Figure 4. Hazard related comparison between substances

We compared *Barium Carbonate* and *Carbonic Acid*, which was ranked 5th on the substitute candidate list. As can be seen in Figure 4, *Barium Carbonate* and *Carbonic Acid* have an almost identical hazard profile. Acute health hazards that unfold at every exposure for *Carbonic Acid* pose only a low risk compared to a high risk of *Barium Carbonate*. That makes *Carbonic Acid* the substance of choice for manual tasks with substance exposure to the workforce.

5 Discussion of the Results and Conclusion

As ML is gaining momentum in many fields, new opportunities for solving information intensive tasks using ML techniques emerge. With alternatives assessment, we applied ML on an information intensive task. As emphasized before, the overload on information when it comes to assessing alternative substances along with the attitude to “never change a winning team” is what is causing many lost opportunities to transform production processes or recipes to more environmentally or workforce friendly variants.

The results of our research show that AA is a prime example for applying ML to ease existing problems, that are often not properly addressed due to lack of experts or due to resistance to change. Surveys reveal that *lack of information on alternatives* along with a *lack of relevant expertise and resources in companies* are two major inhibitors when it comes to AA [36]. We addressed the first issue by providing an IS and a database along with the identification of relevant data that fosters alternatives assessment. To approach the second problem, we proposed an ML technique that supports domain experts in finding reasonable substitution candidates that can be further assessed in terms of their economic aspects. The feedback that we received from our project partner so far was promising and the results are further evaluated by the product engineering department.

While the research project that is subject to this paper is still ongoing, future efforts shall focus on further aspects of AA. For example, on the integration of enterprise IS to improve the process of AA. Currently, each substance must be assessed manually in our application. Providing data of recipes directly from ERP systems would allow us to process large sets of data and find similar but less toxic substitute candidates on a broader scale. In addition, the economic aspect of a substitution will be focused on and added to our application.

6 Acknowledgment

The research described in this paper was supported by a grant from the German Ministry of Education and Research (BMBF), project name SiFa 4.0 (01IS17009B). Parts of the data was kindly provided by the European Chemicals Agency (ECHA).

Abstract. To support understanding and analysis of sustainability related aspects in organizations (e.g., via an assessment of a product's life-cycle from the cradle to the grave), various instruments, among others, in the field of conceptual modeling, have been proposed. Although existing tools and languages are, to some extent, indeed supporting the product Life-Cycle Assessment (LCA), our investigations show that a hierarchy of Domain-Specific Modeling Languages (DSMLs) is needed to satisfy advanced requirements. In this paper, as an innovation for the field of LCA, we propose an application of multi-level language architecture to design a hierarchy of DSMLs encompassing concepts for LCAs that can be detailed to specific industrial domains and local needs of enterprises. This enables a new generation of instruments allowing users to use and refine concepts, corresponding to their specific needs.

Keywords: LCA, sustainable development, multi-level modeling.

1 Introduction

To support the sustainable development (SD) of organizations, the awareness about ecological and social impacts of their products, potentially leading to unintended changes in the environment, needs to be increased. To increase that awareness, relevant information on potential impacts caused by all activities related to the production, usage and disposal of products, needs to be collected and used in decision-making processes [1, p. 226]. In this context *Life-Cycle Assessment* (LCA) has been established and used over the last decades to collect such information in a systematic manner [2]. Standardized by norms like ISO 14040 [3], LCA provides generic concepts and instructions that have been refined into several different assessment methods containing more specific concepts, which address the information needs within different industrial domains [4]. To support the application of LCA assessment methods various tools are provided, which produce complex results that are not easy to interpret and communicate, cf. [5]. In addition, currently existing LCA tools do not provide satisfactory support either [6,7], as results are not always transparent and traceable [8].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

To mitigate these challenges our earlier work shows how conceptual modeling can be used as an instrument to collect, structure, aggregate, and present data about potential ecological and social impacts of products along their entire life-cycle. For this, we proposed a modeling language *TracyML* [9] and a modeling method *ImpactM* [10]. Due to contestedness of the idea of SD [11] both methods do not provide a solution on their own, but allow to document relevant information required for the needs of the discursive decision-making like assumptions and information about system boundaries allowing for the comparison of results of different assessments.

Both languages are implemented in a *conventional language paradigm*, where the language specification is defined using a meta model that can be used to develop models one language-level below (i.e., on M_1). As both languages are based on ISO, therefore, for the sake of reuse, they are kept rather generic. As a result, although showing their applicability in different scenarios, those languages exhibit a similar deficiency as ISO 14040. Namely, to satisfy the specific information requirements of industrial domains or enterprises, first, a substantial effort needs to be invested to define and/or adjust the required concepts during the language use. Although it would be possible to propose a variety of Domain-Specific Modeling Languages (DSMLs) and various diagram types in LCA tools to avoid a need for such an adaptation, this approach would result in a threat to efficiency. Indeed, not only multiple DSMLs and diagram types would have to be developed and maintained, but also relevant information, e.g., on typical impacts related to domain-specific resources, would have to be provided during the language use, which results in considerable time and cost expenditures.

To overcome these challenges the goal of our research is to propose a hierarchy of DSMLs spanning through: (1) a *reference Domain-Specific Modeling Language* (rDSML) [12, p. 321], which includes generic concepts for LCA, that can be refined to (2) *specific industrial domains*, up to (3) languages with a high level of specificity for certain enterprises as *Enterprise-Specific Modeling Languages* (ESMLs), cf. [13]. Our proposal addresses advanced requirements, as there is a need to provide software support for different user groups and purposes. On the one hand, researchers need generic and flexible tools, which allow for modelling of standard and diverging scenarios. On the other hand, for industry users efficiency and effectiveness is most important. They need pre-specified and easy-to-use software that can be easily parameterized [14]. At the same time, a major challenge in LCA and weakness of available LCA software is ensuring comparability and compatibility of user models [6]. Within the concept presented in this paper, the industry- and enterprise-specific modeling languages form the basis for efficient and easy-to-use software tools that cater for the specific requirements of enterprises and industries. Hereby, the underlying integrated hierarchy provides the conceptual foundation for the specific modeling languages, and ensures the comparability and compatibility of user models.

This contribution follows the design-oriented research paradigm [15]. The resulting IT artifact (i.e., the hierarchy of DSMLs developed in an iterative manner) aims at providing a benefit to organizations by supporting LCA and addressing the above-mentioned challenges. To create the targeted hierarchy, we follow the language design method proposed by [16], which provides a macro-process and corresponding roles, as well as a set of guidelines. In this paper we focus on three selected outcomes, i.e., clarification of goals and scope of the solution, identified requirements, and a resulting hierarchy of DSMLs. We also present a realistic scenario to illustrate our vision.

The paper is structured as follows. First, a short overview on general ideas of product LCA is provided. Then, an exemplary scenario follows, which is used to explain the vision of our research. Next, requirements towards a language architecture are shortly discussed. Then, we present the hierarchy of DSMLs in form of a multi-level model.

2 (Product) Life-Cycle Assessment

LCA studies aim at identifying all relevant impacts through-out the life-cycle of a product. Thereby, the *product system* is defined as the life-cycle containing different states of a product, from extraction of the necessary raw materials, via production and assembly of its components to usage and final disposal or recycling [3]. The ISO 14040 standard lays out basic requirements to avoid biased studies and inappropriate claims [17]. Thus, it provides a common language and guidelines how to apply it. The four main steps for conducting an LCA study comprise [3]: (1) goal and scope definition, (2) life-cycle inventory analysis, (3) life-cycle impact assessment, and (4) interpretation. During the *goal and scope definition*, in particular the system boundary is to be defined. Depending on information needs and practical constraints, one may, e.g., choose to address the whole life-cycle from resource extraction to disposal ("cradle to grave"), or just the assembly of some parts ("gate to gate") and define cut-off criteria (e.g., excluding material below a specific weight). The second phase, the *life-cycle inventory analysis*, is where the data collection and definition of indicators takes place. Impacts are modeled in the third phase, *life-cycle impact assessment*. This is typically done using the concepts *impact category* and *category endpoint*, cf. Tab. 1. Note that these are very broad concepts and, as *different assessment methods* are available, cf. [18], their usage differs significantly. In the following, we use the term *impact* to describe an effect that may happen on a global (e.g., climate change), regional (e.g., smog, eutrophication) or local level (e.g., acidification of water), and can be traced back to a product system. Correspondingly, an *endpoint* may represent an entity that is affected by an impact (e.g., freshwater supply in a lake). Finally, in the last step, the assessment results are interpreted and communicated.

Table 1. Selected concepts proposed in ISO 14040 for LCA [3, pp. 7-14]

Term	*Definition*
product	"any goods or service"
product system	"collection of unit processes with elementary and product flows, performing one or more defined functions, and which models the life cycle of a product"
sys. boundary	"set of criteria specifying which unit processes are part of a product system"
funct. unit	"quantified perform. of a product system for use as a reference unit"
impact category	"class representing environmental issues of concern to which life cycle inventory analysis results may be assigned"
category endpoint	"attribute or aspect of natural environment, human health, or resources, identifying an environmental issue giving cause for concern"

Due to the applicability of the standard to various domains and contexts, the *concepts are specified on a general level* and the standard itself offers freedom to users in defining the functional unit, system boundary, data sources etc. As a result, a large amount of literature, standardization processes [19] and databases exists, which reference the ISO-concepts, e.g. [4]. Additionally, there are efforts to apply LCA to the social dimension of sustainability [20], and advance the method to provide an integrated ecological, social and economic perspective [21].

3 Motivating Scenario

Consider two companies intending to improve their sustainable development: Company T producing T-Shirts out of natural fiber, and Company S producing shelves composed out of wood and metal. In particular, those companies wish to reduce their ecological and social impact, while ensuring on-going and long-term economic success. The comprehensiveness of the LCA-approach as the "gold standard" of sustainability assessment has already convinced them to follow a life-cycle perspective on their products. They expect that this will help them identify all relevant impacts and avoid problem shifting between them.

However, once our companies start the analysis, it becomes unclear to them (as in-depth LCA expertise within companies is missing), what potential impacts would be relevant for the analysis in question. Likewise, both companies face difficulties with decisions to be made, e.g., what phases actually to include in the assessment. Thus, both companies are challenged with a need to reconstruct their domain knowledge and information needs using the generic concepts of the ISO-standard. As a result, due to practical constraints like data availability [19], and also different information interests, the resulting models created by companies are on various levels of abstraction and use data on various levels of detail.

Next, the *availability of resources* for raw materials on the local and world-wide level needs to be considered. While the growth-rate of different kinds of natural fiber is of interest for Company T, Company S has interest in the growth-rate of different kinds of wood. Because the shelves contain also metal parts, Company S is also interested in the availability of metal stocks (e.g., Bauxite as ore for aluminum), which can be expressed through the expected date of depletion of specific mines on a local level, or through resources expected in the earth crusts and anthropogenic stocks (e.g., used in cars) on a global level. Regarding the *raw materials* both companies share the interest in economic data, like sales and average prices, and the recycling code that might help at a later point in time determine the potentials for recycling raw materials.

Coming to discuss relevant potential and actual social and ecological impacts that can be traced back to raw materials, it becomes clear that a huge variety of impacts and related endpoints can be calculated by different assessment methods and related indicators. Indeed, regard, e.g., social impacts: while for the assessment of wood-based production systems impacts related to health & safety, employment or equal opportunities of forestry workers might be relevant, for fiber-based products impacts like toxic emissions related to the dying of cotton is of importance. Here it can be differentiated between effects from inhalation, which can get chronic or carcinogenic, and effects stemming from ingestion. Furthermore, because Company T intends to avoid the consumption of natural fiber as a raw material having a high need for water consumption with respect to its origin, this company defines the availability of water as an *endpoint.* Therefore, it requires information about the average amount of water for the raw material of natural fiber in general, as well as the amount of water for natural fiber consumed in a specific farm. Also, the soil of a farm is in this context important and treated as an endpoint, which is characterized by its fertility and erosion. In the long-term, Company T aims to lower the rate of farms supplying natural fiber, which have too high water consumption or a high grade of erosion. In turn, Company S intends to make use only of wood that stems from a forest management targeting at the production of wood and not from forests managed for other purposes, e.g., conservation, recreation. This information needs to be modeled as endpoints. In addition, since this company also intends to provide financial support for non-production forests that are untouched by human influence, the grade of hemeroby (e.g., ahemerobic for non-influenced forests) should be included in models too.

Finally, it is also important for both companies to have specific quality-related information on raw material used. Here, it is assumed that *branchiness* and the *durability class* in accordance to DIN EN 350-2 [22] are considered as relevant for the raw material of wooden products for Company S. In turn, Company T is interested in codes provided in the DIN 60001-1 [23] for textile materials, as well as in *elasticity* of different kinds of fiber, and in *tensile strength* assessing the capacity of fiber or other materials to elongate without tearing apart.

Table 2. Aspects of interest and related LCA concepts - overview

	Company T	*Company S*
Product	T-Shirts	Shelves
Raw material	Natural fiber (avg./sales price; recycling code)	Wood (avg. and sales price; recycling code); metal (avg. and sales price; recycling code)
Endpoint	Soil of farms (location; fertility; erosion)	Forest stands (location; commercial forest); mines (location; downhole)
Impact	Resource depletion natural fiber (kind; renewal rate; consump. worldw.; stock worldw.); virtual water	Resource depletion wood (kind of fiber; renewal rate; consumption worldw); resource depletion metals (kind; consumption worldw.; sum known resources); pot. social and environ. impacts
Resource	Stocks of different kinds of natural fiber, e.g., cotton, linen (global and local)	Stocks different kinds of wood, e.g. birch, spruce (global and local); stocks of different kinds of metal, e.g. aluminum
Level of detail	Typical / average information; specific stocks of resources	Typical/avg. inform.; resources specific stocks; individual product dependent information for certificates demanded by customers
Quality interests	Elasticity; tensile strength, Code DIN 60001-1	Branchiness (high, average, low); durability class ('1'=very durable, '5'=non-durable)

Tab. 2 gives a structured overview of the scenario. In the first three lines concepts from ISO 14040 are assigned to the specific interests of both companies. The fourth row presents different kinds of resources. Terms in the brackets should give an impression on possible exemplary attributes, values or further concepts that are necessary to support the impact assessment as sketched above. The two last lines indicate individual quality-related interests and levels of details that should be satisfied by conceptual models that support this scenario. Please note that only the ISO concepts themselves are readily available and all other ones need to be modeled or reconstructed, which significantly hampers the productivity of the analysis. Finally, due to, e.g., different modeling decisions and data/concepts used, comparing underlying models and obtained results would be challenging.

4 Vision and High-Level Goals

Our aim is to offer a hierarchy of DSMLs encompassing a *reference DSML* (rDSML) including concepts for conducting LCA, which are later refined to specific industrial domains with an increasing level of specificity, up to certain enterprises as *Enterprise-Specific Modeling Languages*, cf. Fig. 1. Thus, within the offered hierarchy, both companies would have an access to a domain-specific language for conducting LCAs in their industry, suited to their needs, supporting them in conducting the desired assessment, and ensuring required comparability and transparency of achieved results.

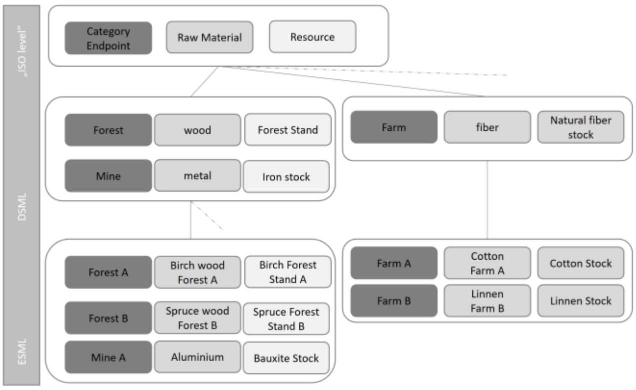

Figure 1. Vision: A hierarchy of DSMLs

And so, while the rDSML provides generic ISO concepts, the refined DSMLs provide specific, semantically rich concepts with a wide range of properties appropriate to describe the corresponding domain. These concepts store relevant information for the needs of assessment, which supports its productivity. Users of the language, even if they are not experts in LCA, can benefit from the incorporated (domain-specific) knowledge on how to conduct the desired analysis. This knowledge encompasses, among others, a set of impacts, their indicators, assessment methods, requirements regarding the data to be used, as well as, if possible, the required data itself.

The hierarchy allows both companies to conduct the analysis on the local and global scale on different levels. This means that they can use one of the more specialized

DSMLs to conduct the analysis of interest, and then aggregate (“bottom-up”) the results by moving up along the hierarchy. It is also possible to “drill down” in the model to individual localized impacts, that are relevant to specific stakeholder groups, e.g., to identify impacts on a specific ecosystem caused by water extraction from a lake (environmental), or to identify social problems like excessive working hours at a specific site. This would enable stakeholders’ engagement and provide the possibility to identify and address concrete problems. Finally, guidelines (e.g., for interpretation and presentation) are embedded into the language, enriched by a visual notation following cognitive principles of information design to facilitate communication and understanding of the process and its results.

In order to: (1) allow for application of concepts from different *impact assessment methods* in tandem, (2) allow users to access all classification (specificity) levels they are interested in, as well as (3) ensure the comparability of achieved results (e.g., by models explicating assumptions and information about the system boundaries, cf. [10]), all of the DSMLs in the hierarchy are integrated. This integration is achieved through the application of the same language architecture, through the refinement of concepts from the reference DSML (vertical integration), and also through the definition of aligning horizontal relationships between concepts. In consequence, the hierarchy of DSMLs offers the required transparency for evaluating and comparing the achieved assessment of product systems, cf. [6]. In addition, the presented hierarchy is adaptable, meaning that once new developments (e.g., new *impact assessment methods*) are known, they may be accounted for within the appropriate DSML.

Currently, there exists a wide range of LCA tools: generic expert tools and specialized ones focusing on specific areas [24]. Considering that the conflict of standardization versus extensibility is one of the major challenges discussed in LCA literature [5,6,14], this hierarchy of DSMLs should allow for a new generation of LCA tools enabling users to build semantically rich models while reusing existing concepts. In particular, the resulting tools should have flexible architecture allowing for integration of standards and best practices (on higher levels), while providing extensibility to account for different application scenarios and methodological advancements (on lower levels).

To summarize, the hierarchy of DSMLs is to support the following high-level goals: (G1) Provide a support for a wide range of different perspectives prospective users may be interested in, by providing a hierarchy of vertically and horizontally integrated DSMLs; (G2) Offer semantically rich concepts and required information to support the assessment process; (G3) Account for existing standards and branch-specific methods in a way to ensure comparability of achieved results, (G4) Support conducting analysis on a local and global level; (G5) Support extensibility and adaptation to account for the relevant changes; and (G6) Support both the productivity and reuse of the approach.

5 Requirements

In line with the method followed [16], based on the identified goals (Sect. 4), a set of identified application scenarios, analysis of LCA methods and instruments, as well as problems reported in the literature, e.g., [5,6,14], we have defined a set of requirements towards (1) the scope of the targeted solution (i.e., concepts and functionalities required to conduct LCA in different domains), and towards (2) the language architecture of the targeted artifact. Due to the space restriction, we discuss a few selected requirements towards language architecture only.

R1: Accounting for a hierarchy of professional terminology encompassing various classification levels. *Rationale*: Our goal is to provide support for a wide range of different perspectives of prospective users (cf. G1). Considering that different users consider involved concepts at different levels of specificity, there is a need to account for a hierarchy of professional terminology. For instance, the LCA concepts such as endpoint and raw material can be of interest on different levels of detail, e.g., as a raw material as such, as Plate of Wood, as Plate of Birch Wood only, or as instances of the latter, i.e., some specific forests. Therefore, the language should provide information on relevant aspects accounting for generic terms, their types, categories and instances. *Discussion:* In the current practice DSMLs are built by defining a meta model using some general-purpose modeling language, e.g., Meta Object Facility in UML [12]. This meta model describes concepts that users may use to create models. Thus, a modeling language usually encompasses two layers: specification (i.e., the definition of a DSML) and language application, cf. [25]. However, in our case, the language itself spans an arbitrary number of classification levels, not only two. Therefore, instead of emulating several meta-levels within two levels, or using artificial workarounds [26], a more natural way to define the desired hierarchy is the use of multi-level modeling [27]. Multi-level modeling refers to a language architecture that allows for an arbitrary number of classification levels being represented within a single body of model [27].

R2: Facilitating horizontal and vertical integration. *Rationale*: A rapid growth of various initiatives both horizontally (e.g., ecological and social aspects) and vertically (e.g., specific methods for some types of resources/some industries) causes a need for integration as well as ensuring comparability between achieved results (cf. G1 and G3). *Discussion:* In order to support integration (and also avoid redundancy), language users should be able to state what they know as soon as they know it, cf. [28]. For instance, already on the level of a rDSML encompassing, e.g., a concept *NaturalResource*, we would like to state that on the instance level (which is a few classification levels below) an attribute summing up production per year will be applicable. To be able to define it however, we would need a deep instantiation mechanism [27] that allows us to define some properties on a higher level and defer their instantiation to some not directly proceeding classification level. Such a mechanism is offered by multi-level modeling approaches and is not supported by traditional ones.

R3: Providing support for productivity of modeling and reuse. *Rationale*: The scenario indicates that a wide range of aspects of a concept (e.g., “resource”) should be accounted for in an integrated manner. Furthermore, their description should be rich enough to support various analyses regarding, e.g., their general character (e.g., hazardous) or specific characteristics (e.g., the rate of growth, societal relevance) [5, 19]. To this aim, we require domain-specific concepts with a rich set of attributes [29]. This is to support modeling productivity, i.e., productivity of creating, analyzing and modifying models (i.e., the time needed to accomplish those tasks [30]). However, on the other hand, at the same time we want to provide a set of generic concepts, so that they may be reused in a wide range of (not yet known) scenarios, cf. G6. *Discussion:* If we are modeling using the conventional approach and are limited to two classification levels, we need to face a well-known conflict between the level of reuse and modeling productivity [12]: the more specific a concept is, the lower range of reuse there is. On the other hand, the more general the concept is, the wider is the range of reuse, but also the lower is the productivity of modeling. As already discussed by other authors, e.g., [12], a satisfactory solution to this conflict comes with a multi-level modeling language architecture where we can account for both generic and specific concepts at the same time through multiple classification levels and, on demand, select those that suit our modeling needs.

R4: Incorporating relevant knowledge within the language. *Rationale*: Conducting a life-cycle assessment requires, among others, (1) information on potential impacts, their indicators as well as reference values; and (2) a level of expertise and experience that may not be available in many organizations [5, 19]. *Discussion:* Incorporating relevant knowledge within the language specification implies, among others, assigning states to (meta) classes (e.g., stating that the value of recycling code for Plate of Wood is 'FOR'). This however, is impossible in the traditional language architecture due to the iron rule of the type/instance dichotomy [12]. Therefore, we would need to always provide this information on the level of language application only. Considering it, application of multi-level modeling seems reasonable, as it offers "clabjects" [27], i.e., concepts having the characteristics of classes (defining a structure) and objects (having a state).

R5: Equipping models and their elements with behavior. *Rationale*: (Meta) classes (e.g., *NaturalResource*) have features that need to be derived or calculated based either on the content of the model (e.g., calculation of an impact profile), or based on the data acquired from external sources [7] (e.g., to obtain some environmental data for the needs of the assessment calculation), cf. G2. In addition, we would like to execute operations (automated analysis) on model elements not only on the level of objects, but also on the level of classes (e.g., calculation of global and local impact on the forest, cf. G4). *Discussion:* While it is possible to define language concepts having attributes constituting abstractions over desired data, the problems with the (automated) acquisition/calculation of those values emerge. The reason for this is not necessarily connected with the modeling paradigm as such, but rather with the programming languages used to create modeling tools. Modeling tools are usually developed using mainstream object-oriented programming languages, which feature only one classification level. Thus, types or even meta types are represented as objects by overloading the M_0 level of a programming language [28]. Therefore, a common representation of code and model is not possible and a model-code synchronization is required [28]. Thus, not only a recompilation step of modeling tools is required whenever we want to change something in the language specification (cf. R6), but also equipping model elements with operations (e.g., allowing to retrieve actual state of the environment) is hardly conceivable [28,31]. Therefore, a satisfactory solution seems to be the application of an integrated modeling and programming, i.e., using a modeling approach coming with a language execution engine.

R6: Ensuring extensibility and adaptability of the hierarchy without losing a corresponding tool support. *Rationale*: As already mentioned, there is a need to account for new developments and additional knowledge (G5), e.g., on impact caused by different substances. Therefore, the proposed hierarchy should be easily extensible and adaptable [19]. As an appropriate tool support is necessary to conduct the assessment process, those changes should not lead to losing this support. *Discussion:* If we decide to use a conventional approach and a tool based on the semantics of dominant object-oriented programming languages, even if users would have an access to language specification and would be able to extend it and adapt it to their needs, a recompilation step would be required to account for the changes in the corresponding tool [32]. A satisfactory solution to this problem again comes with the application of the multi-level approach, where the border between language specification and application is blurred, implying that by changing a multi-level model, a user may adapt the language to his/her needs [30]. If we use the integrated modeling and programming environment, also the tool-support will not be lost, cf. [28].

6 A Hierarchy of DSMLs for LCA

As discussed in the previous section, when it comes to the application of conventional two-level modeling paradigm, although its application is *technically* possible, it imposes limitations, which hinder us from delivering a satisfactory language specification, i.e., a solution without workarounds, overloaded levels, model redundancy and accidental complexity [12, 26, 33]. Therefore, we turn our attention to multi-level modeling with an integrated programming environment to propose a hierarchy of DSMLs.

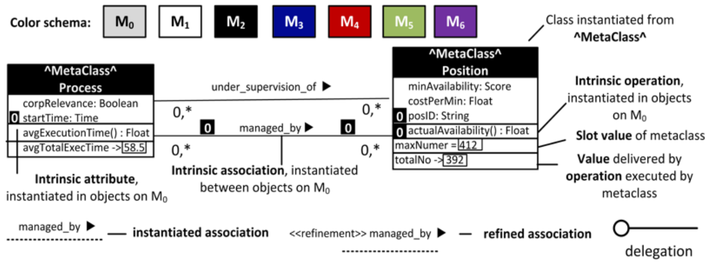

Figure 2. Concrete syntax of FMML^X, based on [12]

Multi-level modeling refers to a language architecture that allows for an arbitrary number of classification levels which are represented within a single body of model content, cf. [27]. As there is no strict division between language specification and language application, all languages (generic, regional, local ones) are integrated in one language architecture and thus, users can access all classification levels they are interested in. We can also benefit from such features as relaxed type/instance dichotomy, deferred instantiation, or defining level-crossing relations, cf. [31]. To illustrate the prospects of multi-level modeling, let us consider an excerpt of a multi-level model of resources created using a Flexible Meta Modeling and Execution Engine ($FMML^x$) [12]. We have selected $FMML^x$ for our design due to the fact that, to the best of our knowledge, $FMML^x$ as the only one has an integrated language execution engine offered by a supporting tool XModeler [12]. This feature allows us, among others, to equip models with behavior and provide support for computational analysis. Whereas the detailed description of $FMML^x$ may be found in [12, 28], Fig. 2 presents its concrete syntax. Apart from the "traditional" modeling constructs such as classes, attributes, operations and relationships, it is possible to defer an instantiation of all modeling constructs by assigning them so called level of *intrinsicness*, which tells at which level of classification a given property will be instantiated.

Fig. 3 presents an excerpt of the designed hierarchy of DSMLs in the form of a multi-level model. Please note that for readability purposes, only selected concepts, selected attributes and operations derived from our scenario assigned to different levels of classification are presented. By supporting multiple classification levels, $FMML^x$ offers the possibility to define and use concepts that correspond directly with the desired level of details (R1). Thus, we have a possibility to account for the fact that such concepts as *NaturalResource* or *RawMaterial* span multiple levels of classifications with categories, types and instances, cf. ① Fig. 3, without the need for overloading some level or applying some other workaround. At each level of classification, we have the possibility to express relevant information, making the model semantically rich (thus, we support the productivity of modeling as well as enable various analyses), and at the same time facilitate its reuse (R3). Regarding the latter, consider, e.g., attributes, operations and relationships defined for the concept *NaturalResource* (M_3), which reflect the domain knowledge derived out of the scenario on this classification level about this concept. Please note that a majority of those characteristics will be instantiated (i.e., assigned with values) only a few classification levels below (cf. the assigned level of intrinsicness). For example, the attribute *sum production per year local* (sumProdPyL) is instantiated in the local stocks of natural resources, be they stocks of cotton residing on farms or stocks of caolinite (mineral used for aluminum) residing on mines ②.

Now, while we move along the created hierarchy ③ (e.g., the chain starting from *RawMaterial* (M_4) via *PlateOfWood* (M_3) up to a *specific Plate of Wood* (M_2) and its instances), on the one hand, we instantiate the concepts, i.e., the relevant attributes are assigned with values (e.g., ④ the recycling code which is the same for all wooden products, and which is assigned on level M_3, cf. R4) and relevant operations aggregating, calculating or acquiring data from external sources may be executed (e.g., cf. ⑤, *calculateConsumptionWoW*(), or *sumAvailableResources*() defined for *NaturalResource*, M_4, cf. R5). On the other hand, we specialize those concepts, i.e., additional attributes, operations and relationships may be added to make concepts more and more specific (cf. ⑥, additional attributes defined for the concept *AbioticResource*, M_2). Furthermore, not only attributes are getting refined while moving along the hierarchy. This applies also to defined relationships. For instance, while we define that a *RawMaterial* (M_4) *stems from* some *NaturalResource* (M_3) and defer instantiation of this relationship to M_0, on the level of *CottonSheet* (M_2) we refine this relationship, and state that it can only stem from concepts instantiated from *CottonStock* (M_1) ⑦.

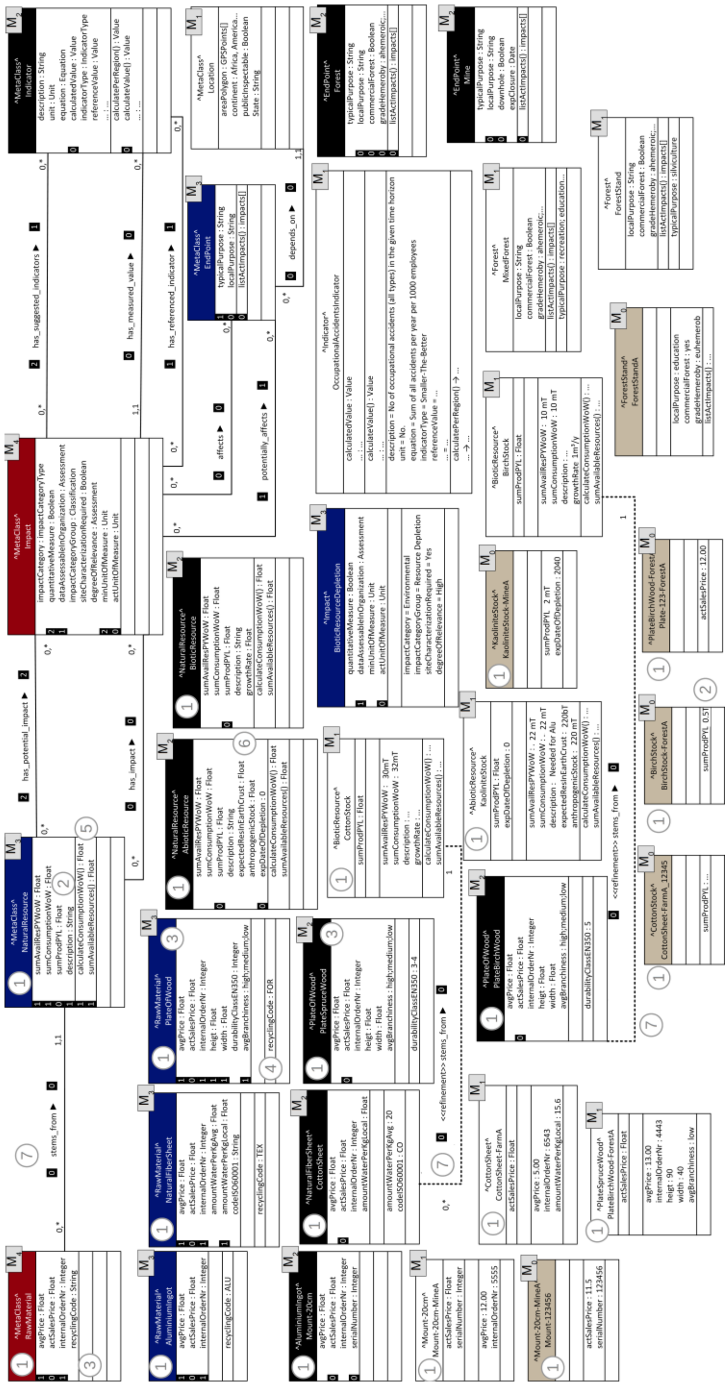

Figure 3. An excerpt of the designed hierarchy of DSMLs

The designed hierarchy fulfills the requirements (cf. Sect. 5) as summarized in Tab. 3. However, please note that the presented multi-level model may seem to be too complex for users [34]. The complex representation serves to exemplify how users can access concepts underlying their DSML and thus, benefit from greater transparency.

Table 3. Summary of evaluation against the requirements

Req.	*Evaluation and scenario-dependent solution*
R1	Concepts relevant for SD can be refined to domain specific concepts (e.g., Raw Material to Natural Fiber Sheet) up to enterprise specific concepts (types of Cotton Sheet) and instances.
R2	Domain-dependent attributes like recycling codes for Raw Material can be set once. Derived concepts on deeper levels are related to this information, but can be extended, as the vertical integration of Raw Material shows.
R3	By offering concepts on different classification levels we support both productivity and reuse at the same time (e.g., we offer both an abstract concept Resource as well as a set of its specific types and instances).
R4	Thanks to relaxed type/instance dichotomy we may assign state to classes, and thus, e.g., state what is the recycling code for a Plate of Wood.
R5	As in FMML^x a class is an object [12], operations can be not only specified for classes but also executed on them (e.g., calculateConsumptionWoW()).
R6	Thanks to a common representation of model and code provided by XModeler [12], a multi-level model may be extended without a need for recompilation.

7 Conclusion

In this paper, we argue that in order to support the LCA of products in a satisfactory manner, there is a need to design a hierarchy of DSMLs. To this aim we presented in this paper the clarification of the goals and scope of such a hierarchy, the requirements towards the language architecture as well as an excerpt of the current state of the resulting hierarchy of DSMLs. We also pointed that the results of our work can be used for building a new generation of LCA tools.

A few important limitations of our work need to be mentioned. Firstly, although the results of our work applied to different scenarios seem to be promising, they also point to the need for further extensions. Namely, additional work is required to incorporate further domain-specific LCA methods and techniques, and ensure integration to existing databases. In addition, as our ultimate goal is to support analysis targeting strong sustainability, or supporting at least a substitution strategy, cf. [10], there is a need to further extend the ecological, economic, and social aspects accounted for.

Secondly, additional work is required to reduce the complexity of a resulting multi-level model. While the complexity of multi-level models is not a novel phenomenon, cf. [31, 34], it should be addressed since it makes the models difficult to interpret, thus potentially inhibiting the added analysis capabilities we aim at. Here the integrated modeling and programming environment XModeler [12] comes into play with the promise of being able to define various perspectives adjusted to the information needs of prospective users. Finally, it has to be remarked, that further limitations need to be accounted for which are inherent to LCA itself. They comprise boundary issues as described by Hovorka et al. [35], uncertainty regarding ecological causes and effects [36], as well as the appropriateness of a systems' perspective for social aspects [37].

A Survey of Smart Energy Services for Private Households

Ute Paukstadt

University of Münster, European Research Center for Information Systems (ERCIS), Münster, Germany
ute.paukstadt@ercis.uni-muenster.de

Abstract. The energy sector is challenged by the ongoing digitalization with emerging smart energy products and services. Smart energy products such as smart meters leverage innovative smart energy services promising both new business opportunities and values for customers. Smart products and services could enhance energy efficiency as well as enable private households to produce their own energy. Although services are regarded as a bridge to the customer, research on smart energy services is scarce. To address the gap, we assess smart energy services discussed in research and in the German consumer market and compare the findings from literature with the real market. Our survey provides researchers and practitioners with an overview of smart energy services and can serve as a starting point for service design, which in turn can support the diffusion of energy saving technologies.

Keywords: smart energy services, smart grid services, smart services

1 Introduction

The energy industry is undergoing a transformation process resulting from various technological and economic developments [1]. The transformation is characterized by the expansion of Decentralized Energy Resources (DER) such as Photovoltaic (PV) systems and the emerging digitalization with smart technologies. With several directives (e.g. (2006/32/EC), (2009/72/EC), (2012/27/EU)) the European Union supports this transformation of the energy sector by market liberalization, investments in renewable energy, in smart energy infrastructures and services. As a result, the hierarchical structured power grid transforms towards an intelligent and decentralized grid, the so called smart grid [2].

Against the background of ongoing digitization with the smart grid, new digital energy services emerge which are referred to as smart energy services [3] and promise both new business opportunities and new values for customers [4]. Smart energy services build on smart energy products [4]. Smart meters, for instance, are smart energy products leveraging smart energy services such as energy consumption visualizations, and thus support customers to reduce their energy consumption. Smart energy products and services can not only improve energy efficiency, but can also

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

enable private households to become energy producers with microgeneration units ("prosumer") [5]. Furthermore, smart energy is expected to enhance the options for product differentiation by building on data and consumer usage pattern [6]. Since smart products include smart services by nature [7], research expects a strong shift from product-oriented towards service-oriented offerings [5, 8]. In this regard, a consumer would not need to own the product or technology any more, but would rather use the service [9].

Although smart energy services appear promising and are attributed much significance for the energy domain (e.g. [10]), there is a lack of research on energy services [11], and insights on smart energy services are even more scarce. In terms of smart energy services, research has mainly investigated single services in the past such as smart metering (e.g. [12]) and specific aspects such as willingness to pay (e.g. [13]). Until now, research has provided few overviews on different market available smart energy services for private customers (e.g. [14]). Research has not yet compared conceptualizations of smart energy services found in the literature with smart energy services that exist in a market (particularly in terms of covering a broad range of different smart energy services). Furthermore, there is less research on smart energy services through the lens of Information Systems (IS) and (smart) service science [3]. Against this background, we aim to answer the following research question: *How are existing conceptualizations of smart energy services captured by commercially available smart energy services for private households?* We answer the question by conducting a literature review and analyzing the German market of smart energy services. With this market study approach, we were able to compare the findings from literature with the real market, which is a further step towards existing research. Since smart energy services are eco-efficient by their nature [3], this study also contributes to the field of Energy Informatics [15]. Concerning the practical contribution, the survey provides companies with an up-to-date overview on smart energy services and can serve them as a first step when trying to design new services.

The remainder of this paper is structured as follows: The second section introduces relevant background information on smart energy services. After explaining our method, we present the services derived from the literature review and market analysis. We compare and discuss the findings in section six and seven before drawing a conclusion in the following section.

2 Smart Energy Products and Services

Kranz et al. [3] define smart energy "as the use of ICTs in energy generation, storage, transmission, and consumption, aiming at increasing efficiency, encouraging eco-friendly behavior, and decreasing the emission of GHG [Greenhouse Gas]" (p.8). Moreover, Lund et al. [16] consider smart energy systems as the broader concept in contrast to smart grid, which is an ICT enhanced intelligent grid, and thus, is a part of an overall smart energy system. Moreover, smart energy refers to several kinds of energy not only electricity [13]. A smart energy system can also exist on a household level (e.g. by using a PV-system, storage and intelligent energy manager), and thus does not necessarily need to be connected to the overall power grid [17, 18]. On the household level, smart energy involves smart energy products such as smart meters and intelligent battery storages. Smart energy products consist of physical objects embedding intelligent components, i.e. sensors, controls, software, micro-processors, data storage as well as connectivity, which enable monitoring, control, optimization and autonomous capabilities [4, 19]. Smart services are services made possible by intelligent products, since they use the generated and collected data from smart products, the user and the environment to create new and enhanced customer values such as more convenience and individualized offerings [4, 19]. Following this, smart energy services are an integrated aspect of smart products blurring traditional distinctions between goods and services [7]. Smart products are often regarded as product-service systems, since they combine physical products and digital services as a single solution to the customer [8, 20]. Apart from the use of single smart energy products, smart energy services are enabled by the combination of different integrated smart household appliances, PV-systems, storages, electric vehicles (EVs), etc. and the combination of the data they deliver and their controlling capabilities. Since smart energy services require smart products, which in turn frequently include supporting services, e.g. the financing and installation of DER (such as a PV-system and storage), we would also summarize these services in combination with smart products as smart service offerings [12, 14, 21]. In the following, we analyze smart energy services with a focus on end consumer values and by drawing on the concept of smart products and services (e.g. [4, 19]). Thus, smart energy services can be offered as a pure digital service (e.g. monitoring of energy consumption), but can also be an embedded part of a smart product (e.g. a smart light bulb) and include optional (physical) support services (e.g. installation by a technician).

3 Methodology

To assess a broad range of different smart energy services, we conducted a literature search followed up by a market analysis. For the literature review, we oriented ourselves to established guidelines [22, 23] to ensure a proper procedure and to find a comprehensive sample covering the most important smart energy services. As a first step in identifying relevant articles, we used different keyword combinations of the terms “service”, “services”, “smart energy”, “smart grid”, “smart grids”, “demand side management”, “smart meter”, “smart metering” and “smart home” to search common databases (EBSCOhost, Web of Science, Scopus) between February and April 2018. We restricted our scope to peer-reviewed articles from 2010-2018 and excluded literature not covering the private household sector. As we were primarily interested in literature describing, analyzing and classifying smart energy services from a (smart) service science understanding (e.g. [19, 24]), we did not consider strong technical papers, e.g. describing only system architectures or web-services without considering end consumer services. We also scanned the references (backward search) of proper texts and looked for articles citing these publications (forward search) [22]. After filtering the literature, we identified 28 relevant articles. Consequently, we analyzed the papers by trying to identify services that fulfill our understanding of smart energy services [4, 19]. We grouped related services into clusters by using a combination of deductive and inductive category building in an iterative way [25]. For instance, we grouped services which are often regarded as eco-feedback services in the category monitoring & guidance, whereas other services enable controlling and further autonomous services regarding the energy consumption [4, 9]. Where appropriate, we adopted some already proposed groups in literature, e.g. energy community services and e-mobility services [18, 26].

While the literature review sheds light on the theoretical as-is state on different smart energy services, the aim of the market analysis is to identify a wide range of existing smart energy services for private households in the consumer market. Since the overall research project is embedded in Germany, the search was limited to the German market. Various sources (e.g. rankings of energy companies, blogs, news portals, keyword search in Google) were searched to find a comprehensive amount of German companies offering smart energy services until we noticed a saturation in the findings. After the identification of the companies, we looked specifically for smart energy services on the company's websites. While analyzing the services [25], we tried to apply the service categories from our literature review. However, since the services are often product-oriented and bundled, we differentiated the services as the companies offer them to the customer. This means that one existing smart energy service offering could comprise several single services we identified before according to literature. Furthermore, we only considered services with enough information found on the company site (e.g. information on "smart" features). Since the boarders between different domains become increasingly blurred, we focused on services with a strong connection to energy. For example, we included smart home offerings with a focus on energy and EV charging services but did not include manufacturer of EV. After excluding 29 services not fulfilling our search criteria (e.g. smart home without energy efficiency use cases), our database from the market analysis consisted of an initial sample of 114 smart energy services. Since we were interested in the distinctive elements of different smart energy service offerings and many service providers provide similar offerings, we grouped together similar services.

4 Literature Review of Smart Energy Services

Based on the analysis of the literature, we grouped the smart energy services in superior service categories, which we describe in the following.

Energy Supply & Billing Services (ES&B): Energy supply as a service is the guarantee to supply a specific level of heat, lighting, cooling, which can be facilitated by the collected data (e.g. from smart meter) [11, 27]. In this regard, Pitì et al. [28] state that contracts can be customized based on the measurements. Remote and real-time metering can offer current, e.g. monthly, more accurate and informative billing based on smart metering data [9, 10]. Remote meter reading is also a new service, since no technician needs to get to the household's home to read the meter any more [10].

Monitoring & Guidance (M&G): In this category, we summarized smart energy services that use the data of smart metering and other smart appliances for monitoring the energy consumption and eventually production of private households. The resulting services can offer a wide range of real-time consumption information, feedback and advice. Monitoring and visualization of energy consumption can support consumers to save energy by identifying inefficient behavior and energy guzzlers [9, 13]. When combined with DER a service can also monitor and visualize the own production level [13]. Other services are appliance level energy monitoring, alarm notifications regarding irregular consumption, historical comparison, forecasting, simulation or the comparison of energy consumption with others [9, 13, 29]. Gamified energy consumption information and serious games where participants have to achieve challenges, earn points and can compete with others can also be combined with social media/ social comparison services [5, 30, 31]. Community level feedback provides users with feedback on a community level, e.g. when the neighbor's PV-system is available, or feedback on the contribution users make to the overall system [9]. More concrete feedback and guidance for energy efficiency is provided by setting and monitoring of goals combined with instructions given on how to best achieve certain objectives [21, 32]. Personalized real-time information combined with individual human advice for certain users, devices and user contexts, are particularly interesting for private households [29]. Personal consulting could even include to install the proposed energy efficiency measures [32]. Since the installation of energy efficient measures needs to consider the people and their consumption behavior, we assigned energy efficiency contracting in this category. Regarding this service an energy service company (ESCO) profits from the energy savings [5] in exchange for efficiency measures.

Control & Automation (C&A): Control and automation services enable private households to control smart energy products remotely [9, 21, 33]. Instead of direct control, advanced control mechanisms allow using automatic controls such as using pre-defined rules and settings, e.g. time-setting and configuration of scenarios [33]. By using artificial intelligence some services facilitate self-learning autonomous systems based on user pattern and optimize the energy consumption [34].

Energy Trading (ET): An energy company can undertake smart energy trading services to market the energy produced by consumers [12]. Energy brokering enables energy trading in online marketplaces by automated agents that act for the customers and consider, e.g. user behavior, his calendar, statistical information [6, 35, 36].

Demand Response (DR): Demand response (DR) services aim to induce behavioral change to shift loads to times when renewable energies are available or to hinder peak loads and thus help to stabilize the grid [13]. DR services can comprise incentives that are given to consumers for enabling the utility to shut off household's appliances. Other DR services send signals to the consumers who respond on their own to shift their loads in exchange for financial compensation. Flexible prices (real-time prices, time-of-use pricing etc.) can be further used for load shifting [6, 13, 14].

E-Mobility Services (EM): In the context of e-mobility Niesten and Alkemade [14] name EV batteries to offer "Vehicle to Grid" (V2G) and "Grid to Vehicle" (G2V) services. Further smart energy services are "Vehicle to Home" (V2H)/ "Vehicle as storage" and "Vehicles for DR" [18]. V2G means the use of a fleet of plugged-in EVs as power sources for the ancillary services market and as energy reserves for wholesale markets. Regarding G2V service the consumer charges the EV and pays for the electricity that is charged. V2H uses the storage of the EV to save energy and can be used within the Energy Management System (EMS). "Vehicle for DR" shifts the EV charging process at times of low energy demand or interrupts the charging due to grid instability [18]. Another smart energy service is the provision of EV charging solutions, which can include the sale, installation and management of charging points [32]. In our understanding this would imply smart charging technologies, e.g. a charging station which can respond to price signals and/ or can be integrated to the EMS [18, 28, 37].

Energy Community Services (EC): Smart energy services for community management support not only the pure exchange of information but also the share of energy resources, such as microgeneration units and storages. Private households can register financially or with their capacities such as energy storages and generation plants in a community. The smart energy services organize the generated energy intelligently to balance supply and demand within the community [9, 11]. The energy community services are also referred to as Microgrids (MGs) and Virtual Power Plants (VPPs). In contrast to MGs, VPPs do not need to be locally and physically connected to the smart grid but are virtually aggregated and thus are not bound to a local region [11]. MGs and VPPs can be used for aggregation purposes, i.e. the produced energy of the distributed small generation plants is bundled and is marketed [32].

Smart Home & Smart Metering Set-Up & Support Services (SH&SM): Although not smart in a narrow view, smart energy products must be installed at the customer site first before smart services can be used. In this regard, basic services are the offering of smart home (SH) and smart meter (SH) infrastructures, e.g. via an online marketplace [12, 32]. By SH, we understand smart home systems as part of the home infrastructure, Do-It-Yourself SH systems and corresponding smart electricity appliances from lighting, heating system, washing machine, air-condition, etc. Supporting services can consist of consulting, installing/ integrating, financing and technical support during usage [12, 21, 32]. During system operation the manufacturer can offer remote and predictive maintenance and security services, e.g. by monitoring the status of the appliances remotely, deploying upgrades to the firmware, detecting potential failures and notifying the customer or planning maintenance actions proactively [38].

Decentralized Energy Resources Set-Up & Support Services (DERS): DER can include different microgeneration types such as PV-systems, hybrid heat pumps, micro-combined heat and power (CHP) systems, wind turbines or mini gas turbines. Energy storages are also subsumed under this category, since they are primarily referred to in the context of microgeneration and interesting for prosumers. Especially for DER, supporting services are needed, which can have different contract depths from DER planning, installation/ integration, operation, maintenance and/ or financing. As an alternative for sale of DER, there are options for renting a DER, [11, 26, 32] or infrastructure contracting [26, 32]. Smart services can support asset management in terms of predictive maintenance, intelligent fraud detection and risk management.

Accordingly, the system can detect risks based on data and can take intelligent actions such as switching off assets or sending messages due to irregular events of assets [34].

Integrated Energy Management (IEM): An integrated energy management builds on monitoring and controlling capabilities [4] and intelligently manages and optimizes the consumption, storage and the production autonomously, e.g. in terms of feed-in of excess power and additional energy demand from the grid. The sophisticated services connect numerous production- and consumption-oriented smart energy technologies (e.g. EV, PV-systems, storages, household appliances) and consider diverse context, usage and external data (e.g. tariffs, user preferences, and weather conditions) [28, 34]. We regard an integrated energy management to take place primarily on a household level to optimize the energy flows within the own "smart energy home", but it can also contribute to the overall grid.

5 Market Analysis of Smart Energy Services

Building on our market sample of services, we formed groups according to the offerings made by the service providers, which we explain in the following.

Innovative Energy Supply Tariffs: Innovative energy tariffs are based on smart metering data. For example, Stadtwerke Bielefeld[1] offer a flexible tariff with a smart meter which divides the day into six different price categories.

Smart Home Packages: SH appliances with a focus on energy efficiency are bundled. Basic SH systems consist of a central hub/ gateway and a mobile Application (App), which enable monitoring and controlling features of SH products. Energy efficiency packages (e.g. "Smart Home Paket Energie"[2] by Innogy) bundle different components such as smart lighting, smart heating, smart plugs and different sensors and actuators. The "Viessmann ViCare App"[3], which is included when buying a Viessmann heating systems, enables not only App based automatic control of heating, e.g. scenarios away/ home, but also offers remote maintenance through the service provider.

Digital Add-Ons: In most cases the service provider supplies the physical products with the digital smart service included. However, Innogy sales the App "Storage vario control"[4] for monitoring and controlling its storage separately. Furthermore, on the website of Innogy the consumer can buy add-ons for their Innogy "Smart Home App". For example, the service "Premium-Auswertungen"[5] promises extended functionality for SH through the configuration of scenarios and visualization of consumption data, consumption in € and historic comparisons.

Smart Meter Packages: Another package are smart meters offered together with an App or web portal access for monitoring of energy consumption and further energy

4 https://www.innogy.com/smartstore/AppCatalog/Storage-Vario-Control-zid10175961

5 https://www.innogy.com/smartstore/SmarthomeCatalog/Apps/Premium-Auswertungen-zid70011714

efficiency guidance based on smart meter data. As an example, Discovergy[6] offers monitoring and visualizing of real-time, historical and appliance level consumption data. They further provide data-based personalized services in terms of energy reports (e.g. cost control, comparison with others), energy saving tips, tariff consulting and predictive maintenance through analysis of devices and plants to identify defects, consumption analysis with notifications in case of irregular consumption.

Storage Packages: Smart storages are not only provided in combination with PV-systems but also offered as single systems in combination with Apps for monitoring and controlling the storage (e.g. "Voltstorage Smart Storage"[7]). A very innovative service is the "Caterva-Sonne"[8], a smart battery storage. By intelligently networking all storages to a virtually connected intelligent huge storage, the "Caterva-Sonnensystem" provides flexibility to the grid. In exchange for the flexibility, the "Caterva-Sonne" owners earn a financial bonus.

Cloud Storage Services: Another service offering are energy cloud storages, such as the "SolarCloud"[9] by E.ON, which are virtual storages for solar power without the need to own a physical storage. The cloud storages primarily address prosumers with a PV-system and without a physical storage. They can save surplus energy produced by the PV-system in the cloud and get it later when needed.

EV Charging: In terms of e-mobility, the most identified service is the sale of EV charging stations including installation and an App for monitoring the EV charging process. In case of the EV charging station by smartRED[10] they further provide a billing tool, e.g. for billing guests and the integration with a PV-system in order to adapt the charging process to the availability of the produced electricity. Closely related to charging at home is the provision of a public charging infrastructure which is, for example, provided by Innogy and can be accessed with the "eCharge App"[11].

PV-System Bundles with (optional) Storage: Energy companies frequently offer bundles of a PV-system together with a storage and energy management system. It can include the installation, integration and further support services such as maintenance, additional guarantees and insurances. The smart services reach from simple monitoring of energy production and consumption (e.g. RheinEnergie AG "Solarkomfort"[12]) to an intelligent energy management to optimize the level of self-sufficiency (e.g. "E.ON Aura Manager" with PV-system/ storage[13]). Some systems even integrate and control SH appliances and EV charging intelligently for load shifting and further efficiency improvements. Accordingly, a good example for an integrated energy management

13 https://www.eon.de/de/pk/solar/aura/manager.html

solution is the "SWM Energiemanager"[14], which is provided in a PV-system and storage full-service bundle. It monitors the energy consumption, enables the control of household appliances with an App, provides recommendations for consumption activities and automatic control, e.g. via time-settings. Further, it considers the energy production, is self-learning and creates a revenue forecast for the PV-system and for the individual consumption. Based on forecast data, it optimizes own consumption and production to increase self-sufficiency, e.g. by scheduling and switching off- and off integrated appliances (e.g. dish washer, heat pumps, EV charging stations). The bundles can also include peer-to-peer (P2P) marketplaces, energy communities, cloud or battery-based flexibility services.

Energy Management Systems: EMSs are likewise offered as single software solutions with a central hub/ gateway and thus come without a PV-system or other smart energy products, e.g. "gridBox Energiemanager". They integrate different smart energy products to monitor, control and optimize (autonomously) the energy flows within the home.

Asset Management: We also identified single specialized smart services for asset management. By automatic remote monitoring "GreenSynergy"[15] provides predictive maintenance and asset performance optimization, e.g. detection of pollution and clouding which minimize the performance. The further deliver status reports as a service for owners of PV-systems.

Energy Communities: Prosumers with and partly without a storage can take part in an energy community in which surplus energy is fed into a "virtual cloud" or directly shared with other community members. Concerning storage provision, the energy community service offers additional benefits such as a free electricity flat rate. For example, the "sonnenFlathome" provides electricity for free, which comes from the community and is refinanced through provision of flexibility for power stabilization. The participation in the community costs a monthly contribution and requires a "sonnen" battery for the virtual network. In case of surplus energy in the "myEnergyCloud"[16] the service provider EWE markets the energy and the revenues are given back to the community. A vendor-independent open approach is the "Energiegruppe" [17] by buzzn GmbH that is open to consumers without a PV-system as well. This energy community is focused on local energy groups, e.g. multi-family houses with a PV-system on the roof. Furthermore, it assists distributed energy groups with the sharing of own produced energy with other energy groups, e.g. with friends or neighborhoods, and in exchange getting produced energy of others. The service provider takes over necessary administrative processes, e.g. billing, regulatory approvals, and change of tenants.

P2P Marketplaces: Energy communities that enable prosumers to buy and sell energy on their own (e.g. defining prices on their own), can be regarded as marketplaces. Digital peer-to-peer energy market platforms directly link decentralized

[17] https://www.buzzn.net/

generation and consumption ("peer-to-peer"). To be financial attractive, P2P marketplaces require highly automated processes, e.g. with blockchain technology to reduce administrative cost. One example here is "OEEX"[18], a blockchain based P2P energy trading platform.

6 Comparison and Analysis of Findings

The literature review and market analysis allowed us to identify smart energy services, which are currently discussed in literature and are already commercially available. To better illustrate and compare the findings, we wrote the number of occurrences of smart energy services in brackets behind the corresponding service types:

The literature frequently concentrates on flexibility and grid stabilization with *Demand Response* (20), but even more relates to energy *Monitoring & Guidance* (22). *Control & Automation* is also a group of services regularly named in the assessed papers (18). Less research is concerned with *Energy Trade* (10), *Energy Community Services* (8) and *Integrated Energy Management* (4).

Although the smart grid is not yet available in Germany, many smart energy services have already entered the German market. In this regard, the market analysis revealed a focus on offering smart products, particularly *SH Packages* (53). Another major part of smart energy services comprises *PV-System Bundles with (optional) Storage* (18), which is not surprising, since the German government has introduced the energy transition away from fossils to renewables and promotes this heavily. We only identified one *Innovative Energy Supply Tariff,* which is a flexible tariff. Furthermore, few offerings are made in terms of pure digital services such as *Digital Add-Ons* (2), *Asset Management* (1), *Cloud Storages* (2), or stand-alone *Energy Communities* (6) and *P2P Marketplaces* (2).

One reason for the product-oriented strategy by companies could be that the domain is still in its infancy and many households first need to have the smart products, such as a smart meter, before being able to buy or consume "pure" (i.e. digital) smart energy services. Moreover, it might not be financially attractive to offer small digital add-ons for private households.

To better contrast the findings from the literature with the market analysis, we assigned the categories from the literature review to the offerings (Table 1). Table 1 shows that most of the identified commercial services relate to *Monitoring & Guidance, Control and Automation, SH & SM Set-Up & Support Services* and *DER Set-Up & Support Services*. Among similar services in one group, different levels of maturity in terms of monitoring, controlling and autonomous actions can be identified, which depends on the integrated components and software algorithms. Above all, services providing control functions such as SH devices normally deliver monitoring functions as well [4].

Our literature review also revealed a fine granular perspective on smart energy services. For instance, we identified several atomic services for energy consumption

[18] http://www.oeex.org/

information (e.g. historic comparisons), which we summarized under the category *Energy Monitoring & Guidance*. In practice, these atomic services are not offered individually, but are also bundled to a comprehensive solution (e.g. smart meter or smart home App offering energy visualizations, historic comparisons, remote control options), which are often provided for free in a smart product bundle. One reason for this can be that literature is not focused on monetization aspects, and thus investigates single smart energy services. Moreover, some services from literature can hardly be monetized through the consumer, since they rather provide process optimizations and improve customer satisfaction, e.g. remote smart meter reading.

Table 1. Service categories mapped to service offerings (numbers in brackets are the frequency of occurrence in the market analysis; abbreviations correspond to the categories from literature)

Market Offering	*Smart Energy Service Category*	*Exemplary Market Offering*
Innovative Energy Supply Tariffs (1)	ES&B, M&G, DR, SH&SM	Stadtwerke Bielefeld Enerbest Strom Smart
SH Package (53)	M&G, C&A, SH&SM	Innogy “Smart Home Paket Energie”, Viessmann ViCare App
Digital Add-Ons (2)	M&G, C&A	Innogy “Premium Auswertungen”
SM Packages (9)	ES&B, M&G, SH&SM	Discovergy Smart Meter,
Storage Packages (8)	M&G, C&A, DERS, EC	Voltstorage Smart, Caterva-Sonne
Cloud Storages (2)	M&G	E.ON SolarCloud
EV Charging (7)	M&G, C&A, EM	smartRED EV Charging station, Innogy eCharge App
PV-System Bundles with (optional) Storage (18)	ES&B, M&G, C&A, DERS, EC, ET, IEM	RheinEnergie AG SolarKomfort, SWM Energiemanager, E.ON Aura Manager Leipziger Sorglos-Servicepaket, ENBW solar+
EMS (5)	M&G, C&A, IEM	gridBox Energiemanager
Energy Communities (6)	M&G, ET, EC, ES&B	EWE myEnergyCloud, sonnenFlathome, buzzn
P2P Marketplaces (2)	ET, IEM	OEEX
Asset Management (1)	DERS	GreenSynergy

When comparing the literature-based conceptualization with the existing services in the market, it becomes clear that some smart energy service offerings introduced in literature are up to now only existing theoretically, e.g. due to regulations, lack of smart grid infrastructures or financial attractiveness. For example, in terms of EV charging there is currently no provider who supports V2G services [18]. Similar demand response services are often not possible, and moreover are not economically feasible due to fixed energy prices [13]. Moreover, we could not find companies offering innovative *Energy Supply & Billing Services* such as tailored contracts or “energy as a service”. This can be due to the domain maturity, since in Germany smart meters are not widespread. Even though no company seems to offer demand response programs in terms of demand shifting, flexibility in forms of resource aggregation (e.g. the storages of Caterva GmbH) has already found its way in the consumer market. Moreover, the flexibility services are not offered separately, but are bundled in a comprehensive product-service offering. Intelligent EMS such as the "SWM Energiemanager" can provide DR on a micro-level by shifting loads to times of higher energy production of the integrated PV-system and storage. Such solutions enable high levels of energy self-sufficiency from the superior power grid and energy utilities. In this regard, "smart home grids" are already realized. Moreover, a commercial service we did not identify in our literature sample is the cloud storage.

7 Discussion

Since many smart energy services are embedded in product-oriented offerings, consumers often face high upfront costs. Apart from classical financing options (e.g. renting, leasing), attempts for a stronger (smart) service orientation can be seen in offering *Digital Add-Ons, Cloud Storages* and allowing consumers to participate in DER in form of communities without owning a PV-system. Digital add-ons can include lower prices for the basic product which then can be updated with additional content for an extra fee. Companies further try to lower adoption barriers by integrating more attractive smart energy services in smart products such as the smart battery storage of Caterva offering consumers extra revenues. Moreover, recent practice projects to study V2G under real conditions are being conducted in Germany, which could also support the diffusion of EVs in the future.[19] Another option to create more attractive offerings are combinations of different smart energy products and services. For instance, an EV can be more valuable if the EV battery storage can be used together with the PV-system in a household (V2H) [18]. Since this is often not yet realized in practice[20], there are promising options such as to use a cloud storage (e.g. E.ON SolarCloud) which can store the own produced energy. The stored energy in the cloud can then be accessed by public charging stations of the service provider. In this regard, (IS) research could study different bundles of smart energy offerings and their acceptance by consumers.

Moreover, to reduce the complexity of smart energy products, physical supporting services are needed, especially to integrate different products, e.g. PV-systems, smart appliances, and EV which is highlighted by the widespread of existing full-service bundles in the market. In this regard, companies should try to develop open systems which can integrate products from several manufacturers. Open systems could also facilitate more stand-alone digital offerings such as digital add-ons or energy communities. Furthermore, complexity is reduced by emerging "plug & play" systems such as PV-systems[21], which are moreover interesting for tenants. To lower financial barriers, literature refers to contracting of smart products and services and usage-based

payment modes such as refinancing in terms of energy savings or certificates on the private household level [5, 14] which could be tested and implemented in practice.

Data-based product differentiation and personalized smart energy services are only partly realized. Research could study both innovative ways for monetization and which data-based services (e.g. product recommendations for replacement purchases for old household appliances) could be attractive under which conditions (e.g. privacy, willingness to pay) for end consumers. Due to the forthcoming smart meter roll-out in Germany, more flexible tariffs and demand response programs could emerge for which research could conduct studies with German households to identify promising services. Since we concentrated the market analysis on Germany, there might be different services available in other countries which could be interesting for adopting in the German market as well.

8 Conclusion

Due to the digitalization in the energy industry, smart energy services appear promising for new business opportunities and customer values. Nevertheless, research on smart energy services is scarce. To shed more light on this, we reviewed the literature and the German market and identified not only important characteristics of smart energy services but also the differences in the conceptualizations in literature from the current market offerings. The overview of the as-is state of smart energy services in literature and in the German market landscape might help practitioners to find white spots for new service development and ways how to position their services best. Since smart energy services foster a more sustainable energy production and higher energy efficiency, our work contributes to the IS related Energy Informatics field [15].

One limitation of our paper is the assessment of market available services which relies on website data and is further focused on the German market. Moreover, we did not aim to identify the entirety of literature, but to find a proper sample covering the most important smart energy services. Additionally, we had partly difficulties assessing services to a group during the literature review as several authors do not define, but simply enumerate smart energy services. Accordingly, it also does not always become clear whether the authors refer to “smart” technologies and services. In general, trying to differentiate and describe services is a complex task, since services are partly challenging to isolate [13]. Due to the complexity of isolating single services, not all categories could be arranged without any overlaps.

Notwithstanding the limitations, we are convinced that our survey presents a recent and useful overview on the smart energy service landscape and indicates options for new smart energy service design and fruitful avenues for future research.

Abstract. Cities around the world face major mobility-related challenges, such as traffic congestion and air pollution. One primary cause of these challenges is the decision of citizens to use their private car instead of alternative mobility services such as public transport, car-sharing and bike-sharing. Technological progress offers new possibilities to address these challenges by making alternative mobility services easier and more convenient to use. This paper focuses on door-to-door (D2D) mobility integrators, which aim to offer citizens seamless D2D transport by packaging alternative mobility services. To better understand the practical barriers D2D mobility integrators face, this interdisciplinary literature review provides a holistic picture of their operand and operant resources, revealing significant gaps in our understanding of their capability to attract actors to their ecosystem and to manage value co-creation. Based on these gaps, we identify a potential avenue of future research.

Keywords: D2D Mobility Integrators, Literature Review, Operand Resources, Operant Resources, Value Co-Creation.

1 Introduction

Mobility is a basic need of modern society. Currently, most travel is achieved relying on private cars and motorbikes. For example, in Germany motorized private transport constitutes approximately 76% of the modal split of passenger transport [1]. One reason for the prevalence of private motorized transport is the (perceived) weaknesses of alternative mobility services. In the case of public transport, a lack of reliable information about the mobility service and the distance to a station are common perceived weaknesses [2]. Another reason for the prevalence of private motorized transport is that shared services, such as bike-sharing, car-sharing, or ride-sharing have only recently become more comfortable to use due to the increased digital connectivity of the population [3]. As a result, their modal split share has remained relatively low [1].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

However, the impact of such extensive use of motorized private transport is undeniable, especially in cities. Along with an expected rise in the share of people living in cities from 50% in 2015 to 66% by 2050 [4], the number of private cars worldwide is also expected to double by 2035 [5]. The predominant use of the private car causes air and noise pollution, which endangers the health and well-being of the citizens [6], and many cities already face serious traffic congestion and parking problems [7]. An expansion of the road and parking infrastructure is often impossible, prohibitively expensive, or not desirable because natural resources should be sustained. In order to meet these mobility-related challenges, a new mobility paradigm is needed. A promising approach is to combine different alternative mobility services, such as bike-sharing, car-sharing, and public transport, to ease door-to-door (D2D) mobility. This would involve providing up-to-date information about short-term cancellations and delays and adapting trip planning accordingly. If citizens didn't have to gather up-to-date information about multiple alternative mobility service options and undertake a complex comparison/combination and booking process themselves, they may use private cars less [7].

Providing integrated D2D mobility is only possible in an ecosystem of multiple mobility providers, whereby ecosystem is defined as a "system of mostly loosely coupled social and economic (resource-integrating) actors" [8, p. 161]. D2D mobility integrators act as important intermediaries between customers and these mobility providers [9]. Recently, D2D mobility integrators like Moovel (a subsidiary of Daimler AG) and Qixxit (founded by Deutsche Bahn AG) have entered the European mobility market. Their business relies heavily on advanced information technology (IT) and new methods such as business analytics [7, 10]. Analogous to concepts such as 'smart city', 'smart home' [11], or 'smart tourism' [12], the D2D mobility integrators aim to provide a smart service.

Extant research has focused mainly on describing and comparing the quality of different D2D mobility services [7, 10, 13]. Several studies indicate that D2D mobility services provided are often of inferior quality. For example, Albrecht and Ehmke [13] find that D2D mobility integrators struggle to integrate dynamic customer location data and it has been found that only a few mobility providers are willing to join their ecosystem [7, 13]. A valuable theoretical lens through which to investigate the common service provision of multiple actors is service-dominant (S-D) logic [14, 15]. One of the key assumptions of S-D logic is that all actors are engaged in value co-creation – the integration of resources and the exchange of service [15]. To date, however, insufficient attention has been paid to the operand and operant resources actors utilize to provide service in a digital environment [16, 17]. In the case of D2D mobility integrators, there is lack of holistic analysis of their resources and a lack of transparency about resource quality. As a result, it is difficult to appropriately guide the efforts of researchers and practitioners to provide higher quality D2D mobility service. To fill this gap, this study asks the research question:

RQ: What operand and operant resources do D2D mobility integrators utilize to provide D2D mobility services?

To answer this research question, we conduct an interdisciplinary literature review spanning information systems (IS), transportation management, service science and engineering.

The remainder of the paper is structured as follows. After a brief outline of the design of the literature review, we describe our findings. Based on the research gaps identified, we describe an avenue of possible future research. Finally, we discuss the limitations of our study and draw conclusions.

2 Design of the Literature Review

A rigorous and comprehensive literature review, according to Raghuram et al. [18, p. 984] can use "several methodologies such as meta-analysis, descriptive review, and bibliometrics approaches". Each methodology has advantages and disadvantages, giving it a unique "way of seeing [and] a way of not seeing" [19, p. 284]. In this literature review, we follow the guidelines proposed by Webster and Watson [20] in order to include qualitative studies, which are typical for research in emerging fields.

The review process comprises three steps: (1) search leading journals for relevant articles, (2) backward search references in identified articles, and (3) forward search articles referring to the identified articles. In the first step, we searched the Senior Scholars' Basket of Journals of the Association for Information Systems, which contains the leading journals in the IS field. In addition, following the recommendation of Webster and Watson [20], we searched articles presented at the following five important IS conferences – International Conference on Information Systems (ICIS), European Conference on Information Systems (ECIS), Americas Conference on Information Systems (AMCIS), Pacific Asia Conference on Information Systems (PACIS), and Hawaii International Conference on System Sciences (HICSS). Beyond IS, we searched articles contained in the Science Direct and IEEE Xplore databases, which include journal and conference articles published in various fields, such as transportation management, service science, and engineering. Our cut-off date was February 19, 2018. Our keyword search list contained 36 terms in English, including 'intermodal mobility' and 'mobility as a service', as well as the names of well-known D2D mobility integrators (a complete list of keywords can be found in Table 1 of the Appendix).

In addition, we defined the following exclusion and inclusion criteria: (a) we included articles focusing on D2D mobility integrators as part of a digital ecosystem that aims to combine various mobility services. We thus excluded articles dealing with models of transport planning [21, etc.] or physical and organizational transport system integration [e.g., 22]; (b) we excluded articles that focus solely on combining public transport services (e.g., bus, subway, tram) because regional public transport is very often provided by different subsidiaries of the same company [7]. As a result, the parent company faces very different challenges than a D2D mobility integrator cooperating with independent mobility providers; and (c) we excluded theses and books.

Our initial keyword search yielded 4,635 potential articles, which we assessed manually in two rounds. First, we screened the title and, if necessary, the abstract of each article for potential relevance to our research question, selecting 200 articles. Second, we read each remaining article, excluding a further 146 articles. In our backward search, we reviewed the references of the 54 remaining articles, and in our forward search we used the ‘cited by’ function in Google Scholar (https://scholar.google.com). Ten relevant articles could be identified. Furthermore, the anonymous reviewers have proposed one additional article. In all, we identified 65 relevant articles. Figure 1 illustrates our literature review process.

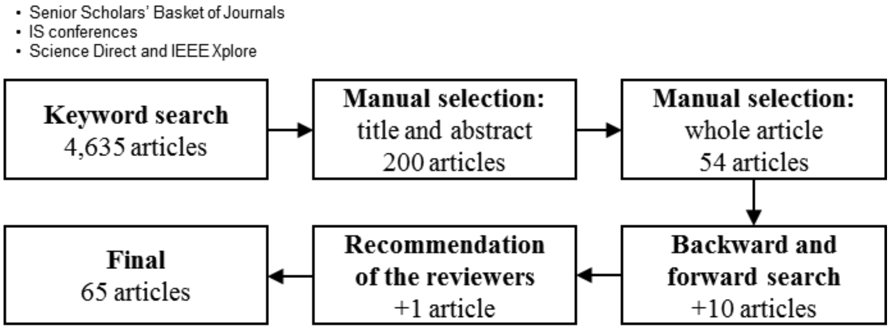

Figure 1. Overview of the literature review process.

We coded the selected articles using an iterative coding approach to ensure internal validity [23]. Our analysis focuses on two main coding categories: operand resources of D2D mobility integrators and operant resources of D2D mobility integrators.

3 Operand and Operant Resources of D2D Mobility Integrators

Operand resources are those “resources on which an operation or act is performed” (e.g., animal life, land, minerals), whereas operant resources “are employed to act on operand resources” (capabilities, competences, knowledge, organizational processes, skills, etc.) [14, p. 2, 24]. In order to provide a D2D mobility service, D2D mobility integrators rely on both types of resources. The classification as operand or operant resource depends on the evaluator’s perspective [25]. Adopting a D2D mobility integrator perspective at the company level, an algorithm for determining the best combination of mobility services is an operand resource. But if the perspective of the algorithm itself is taken, it is an operant resource that adds or does not add a single mobility service to a D2D mobility service. This research adopts the first perspective. The next two sections present the resources of D2D mobility integrators discussed in scientific literature. The identified resources are italicized.

3.1 Operand Resources

Fourteen articles provide a kind of *blueprint* and colloquially describe the basic idea of the new D2D mobility integrator role [26-28]. Frequently, one or more characteristics of the provided D2D mobility service are also discussed in detail. These studies often originated from scientific research projects, as, for instance, in the case of Boero et al. [29], Gogos and Letellier [30], and Motta et al. [31]. Possibly for this reason, the contents of the blueprints differ widely in terms of geographic focus, ranging from a single city [31], to a larger region like Piedmont [32], up to the European Union [29, 30]. Moreover, the authors of the blueprints also adopt differing perspectives in assessing the added value of D2D mobility integrators and their D2D mobility service. Only a few authors [e.g., 30] take a mobility provider perspective, whereas a majority [e.g., 29, 33] take the perspective of citizens and city administrations. Perhaps as a result of these differences, the blueprints take a varying number of mobility services and mobility providers into account [see, e.g., 7, 27, 34]. Nevertheless, they often strive to offer D2D mobility services with similar characteristics, including providing real-time updates and booking and paying for trips through the D2D mobility integrator [35-38].

A further operand resource are *representations* of the *business model* of D2D mobility integrators. Beutel et al. [39] examine how existing business model frameworks are subject of change in the case of D2D mobility integrators and propose a new business model framework for D2D mobility integrators. A similar approach is chosen by Willing et al. [10], who adapt a business model framework to classify multiple D2D mobility integrators. In particular, they highlight the importance of business analytics. Schulz et al. [40] introduce a new model for the roles of D2D mobility integrators based on the roles of an intermediary in the electronic commerce era. Table 2 provides an overview of the operand resources of D2D mobility integrators.

Table 2. Overview of operand resources of D2D mobility integrators.

Operand resource	Authors
Blueprint	[7]; [26]; [27]; [28]; [29]; [30]; [31]; [32]; [33]; [34]; [35]; [36]; [37]; [38]
Representation of the business model	[10]; [39]; [40]
Information system application	[41]; [42]; [43]
National framework architecture	[44]; [45]
Information system architecture	[46]; [47]; [48]; [49]; [50]; [51]; [52]; [53]; [54]; [55]; [56]; [57]; [58]; [59]; [60]; [61]; [62]; [63]
Interface	[64]; [65]
Model and algorithm	[66]; [67]; [68]; [69]; [70]; [71]; [72]; [73]; [74]
Compensation engine	[75]
Recommendation system	[76]; [77]; [78]; [79]

Other articles deal with operand resources which are technical in nature, such as the *information system application*. Based on the trip phases, Digmayer et al. [41] derive the activities of users and the support they require, drawing implications for app design, such as implementing a feedback feature. Stein et al. [42] designed an app, especially for the elderly. Based on their experience in the WISETRIP project, Spitadakis and

Fostieri [43] also make recommendations for improving the design of an app or a web interface.

A related operand resource is ARKTRANS, the *national framework architecture* for mobility information systems in Norway, which encompasses all transport modes and supports D2D mobility [44, 45].

Eighteen articles describe the *information system architecture* of a specific D2D mobility integrator. In line with our previous findings, most of the authors – with exception of Dotoli et al. [46], and Zoghlami et al. [47] – explain the architecture created within the time restraints of their scientific research projects [e.g., 48-51]. It should be noted that several articles focus on the architecture of the Mobility Broker project [52-54], and two articles each focus on the architecture of the IMA [55, 56], Instant Mobility [57, 58], and SMAll [59, 60] project. The authors apply varying architecture styles. For example, Hilgert et al. [61] use the concept of microservices, Motta et al. [62] adopt a service-oriented architecture – event driven architecture (SOA-EDA), whereas Evangelatos et al. [63] draw on the Super Travel API Architecture.

Natvig and Vennesland [64] emphasize the advantage of open *interfaces* for the provision of a D2D mobility service. They also describe the interface definition process and a pilot implementation. Kluth et al. [65] develop an interface that facilitates connecting the rental systems of car-sharing and bike-sharing providers with the information system of D2D mobility integrators. The new interface enables information exchange (e.g., vehicle data, price information) and the execution of bookings via D2D mobility integrators.

A *model* to map the transport system (train stations, bus lines, etc.) and an *algorithm* to identify the best combination of mobility services are further operand resources of D2D mobility integrators. The algorithms can determine the shortest [e.g., 66-69], the fastest [70, 71, etc.], the cheapest [71], the most energy-efficient [72], or the least complex [71] D2D trip. Some algorithms allow the selection from several criteria, while others are restricted to one criterion. In addition, the algorithms vary in terms of whether they work with real-time data [70, 72, etc.] or not [e.g., 71]. Another difference is the scope of mobility services taken into account. For example, Fahnenschreiber et al. [73] and Ma [74] focus on integrating ride-sharing services. Given long running times, the algorithms [e.g., 67, 68, 71] in part prove the basic feasibility of the optimization idea than its practical usability.

Rizzi et al. [75] provide a detailed description of one specific part of the information system, the so-called *compensation engine*, which is responsible for monitoring and re-scheduling the selected combination of mobility services. This technical component enables customers to switch to alternative mobility services in case of a delay or cancellation of a previously chosen mobility service.

While the articles in the last two sections deal with operand resources that are necessary to determine the optimal combination of mobility services based on pre-defined customer criteria, the following articles center on *recommendation systems*, which are deployed to measure and to learn customers' preferences. The framework developed by Samsel et al. [76] helps rate the possible combinations depending on the previously revealed preferences (e.g., tendency to choose the shortest trip), the context (weather, etc.), and the selection made by the crowd. A similar approach focusing on learning customers' preferences is described by Arentze [77], and Zhang and Arentze [78], whose customer criteria include, among others, travel time, monetary costs, environmental impact, and changeover safety. The authors also analyze mobility service preferences (bus, train, etc.). Poxrucker et al. [79] described a simulation tool that can be used to learn from customers' aggregated recommendations and selection. Such an approach is necessary to prevent a bus from overcrowding due to over-recommendation.

3.2 Operant Resources

In order to enable value co-creation, D2D mobility integrators also need different operant resources, such as capabilities, competences and organizational processes, to act on operand resources. Spickermann et al. [80] provide a strategic agenda that highlights the importance of pursuing a *transition strategy*. In particular, they emphasize the need for aspiring D2D mobility integrators to use advanced IT and change their business model. The necessity of a transition strategy is further demonstrated by the work of Sarasini et al. [81] suggesting a research agenda to examine the causes of change and inertia of business models.

Three articles deal with the *implementation process* of a D2D mobility concept. Smith et al. [82] analyze the procurement process of a Swedish public transport organization, which enables a successful bidder to act as a regional D2D mobility integrator. Their results identify seven topics, such as the allocation of responsibilities and technical integration that potential bidders consider important in creating an ecosystem. Khanna and Venters [83, 84] examine the implementation process in the case of the BeMobility project in Berlin. They focus on the D2D mobility integrator's designing an information system for integrating electric car-sharing into public transport infrastructure. Table 3 summarizes the identified operant resources of D2D mobility integrators.

Table 3. Overview of operant resources of D2D mobility integrators.

Operant resource	Authors
Transition strategy	[80]; [81]
Implementation process	[82]; [83]; [84]
Capability to ensure security and privacy	[85]; [86]; [87]; [88]

A further important operant resource of D2D mobility integrators is their *capability* to ensure the *security and privacy* of ecosystem actors. Referring to the SMAll project, Callegati et al. [85] describe the most relevant weaknesses in terms of data reliability, integrity, and authenticity and propose mitigation approaches. For instance, they argue for the implementation of a customer rating system in order to evaluate data sources and enhance data trustworthiness. Further studies deal with insider threats as one of the most prominent security and privacy concerns [86, 87], providing a classification of insider threats. For example, a D2D mobility integrator must be aware of potentially fraudulent data manipulation on behalf of mobility providers. To mitigate insider threats, a networking architecture that based on gossip protocols is introduced. The high relevance of security and privacy is also demonstrated through customer evaluation of the information system of the Mobility Broker project [88].

4 Central Issues for Future Research

This section presents core issues for future research into the operand and operant resources of D2D mobility integrators. We expect that research on these issues will contribute to a deeper understanding of the role of D2D mobility integrators and enable recommendations to put value co-creation into practice.

Our literature review shows that most studies are concerned with the **operand resources** of D2D mobility integrators, such as their information system architecture [e.g., 46, 47], and algorithms for determining the best combination of different mobility services [66, 70, 72, etc.]. We note that D2D mobility integrators should generally be able to access the required operand resources, particularly those of a technical nature. However, many operand resources have only been developed for/used by D2D mobility integrators in the context of scientific research projects. Their real-world practical usefulness remains to be seen. For example, the running times of some of the algorithms [e.g., 67, 68, 71] make them impractical. It is also important to examine how technological progress affects individual technical resources. Currently, the extent to which state-of-the-art IT is taken into account varies greatly. For instance, whereas big data and business analytics are used in the case of the recommendation systems of Poxrucker et al. [79] and Samsel et al. [76], its impact on information system architecture remains unclear [50, 52, etc.].

In contrast, **operant resources** have been largely neglected by scientific research, or, as in the case of pursuing a transition strategy, their importance has only been emphasized in terms of a research agenda [81] or practical implications [80]. In particular, there are no broad insights into the *capability* of D2D mobility integrators *to manage value co-creation* (i.e., the integration of resources and the exchange of service [15]), in the ecosystem. Only three articles [82-84] shed light on the development phase of the ecosystem. The sparsity of research into operant resource needs points to several research gaps, for example what resources are needed in various ecosystem maturation phases, what models of value co-creation are possible in each phase, and how business model transitions can be best managed. Analogously, the phases of the value co-creation process between a D2D mobility integrator and an ecosystem actor (e.g., customer, mobility provider) should also be analyzed.

Since only a few mobility providers have joined an ecosystem of D2D mobility integrators to date [7, 13], future research should provide insights into their *capability to attract actors* – a sub-capability of value co-creation management. In order to explain non-membership, we propose determining the (perceived) value for the actors. As shown in our findings, extant literature predominantly reflects the view of researchers and practitioners adopting the role of D2D mobility integrators [e.g., 30, 37], or working on the development of a single operand resource [56, 65, etc.]. The customer or mobility provider perspective was only seldom considered [42, 43, 88]. However, according to Akaka and Chandler [89, p. 251] (social) roles are important resources for value co-creation "because they guide expectations for the exchange of service". To date, little scholarship is available into how actors evaluate the role of D2D mobility integrators and its related set of practices. One exception is Beutel et al. [88], who find that providing price bundles is often evaluated negatively by customers due to data security and privacy concerns. Overall, we believe that identifying the divergent expectations of actors about the role of D2D mobility integrators can help to better understand what motivates their decision to join or not join a D2D mobility ecosystem.

The capability of D2D mobility integrators to attract actors to their ecosystem depends not only on whether they fulfill the expectations of potential customers and mobility providers. As seen through the lens of S-D logic [14, 15], which assumes that all actors are engaged in value co-creation, every actor is already embedded in multiple ecosystems coordinated by a set of rules, norms and beliefs, known as institutions, and higher-order collections of these institutions, known as institutional arrangements [15]. For instance, German mobility providers that provide bus and tram transport are often integrated into the ecosystem of a municipal utility which is acting as parent company [7]. Hence, the decision of potential customers and mobility providers on membership in the D2D mobility integrator ecosystem is influenced by the actors of their existing ecosystems.

This literature review indicates that no research has been done on this topic. One avenue of possible future research is how the existing institutional arrangements of potential customers and mobility providers influence their decision whether or not to join the ecosystem of D2D mobility integrators. This might be viewed through the theoretical lens of legitimacy [90]. A potential study could consider the interests and authority of all actors of established ecosystems, such as parent companies, city administrations and industry associations in terms of preventing or mandating collaboration with D2D mobility integrators. Relying on power-based theory [91], this approach would help D2D mobility integrators better understand the relevant actors and their interests, and adapt their role and the institutional arrangements established in the ecosystem to increase value co-creation.

In summary, we argue for a two-step analysis to enhance our knowledge about the capability of D2D mobility integrators to attract actors to their ecosystem – the evaluation of the fulfillment of the role expectations by D2D mobility integrators and the actors' embeddedness in existing ecosystems. We assume that this approach can also be used to investigate the capability of D2D mobility integrators to manage value co-creation in the later phases of the ecosystem and better understand why mobility providers, for instance, provide real-time timetable data but are not able or willing to participate in a common ticketing.

5 Conclusion

In this paper, we conduct a literature review on the operand and operant resources required by D2D mobility integrators. Based on our findings, we propose several avenues of future research, including analyzing the operand resources used by D2D mobility integrators outside the project environment, D2D mobility integrators' capability to manage value co-creation in the different phases of the ecosystem, and the sub-capability of D2D mobility integrators to attract actors to their ecosystem in the first phase.

By reviewing scientific literature and deriving avenues of future research, our study contributes to IS and S-D logic literature in several ways. First, it provides a holistic view on research on the operand and operant resources of D2D mobility integrators. Our study integrates previously unrelated studies focusing on a single resource. This overview of the current state of research and, to a degree, practice, enables us to identify research gaps and practical challenges, which serve as the basis for developing avenues of future research. Practitioners can benefit from our work by understanding the resources necessary to put value co-creation into practice.

Our study is subject to some limitations. First, despite our backward and forward searches, our selection of outlets and keywords may have excluded some relevant scholarship. Second, the level of granularity and aggregation we choose in terms of analyzing resources may have excluded some insights into additional resources.

Ein Entscheidungsunterstützungssystem zur ökonomischen Bewertung von Mieterstrom auf Basis der Clusteranalyse

Jannick Töppel[1]

[1] Universität Augsburg, Kernkompetenzzentrum Finanz- & Informationsmanagement, Augsburg, Deutschland
jannick.toeppel@fim-rc.de

Abstract. Für den Erfolg der Energiewende spielt die dezentrale Stromerzeugung eine entscheidende Rolle. Aus diesem Grund wurde das Geschäftsmodell Mieterstrom entwickelt, welches sich über die Erzeugung und Lieferung von Strom in direktem räumlichen Zusammenhang definiert. Dabei soll durch den direkten Verkauf von Strom an Mieter ein höherer Gewinn erzielt werden, im Vergleich zur klassischen Stromeinspeisung ins Netz. Zur Förderung von Mieterstrom in Deutschland wurde 2017 von politischer Seite ein umfassendes Förderprogramm beschlossen und somit die Rahmenbedingungen deutlich verbessert. Basierend auf Smart Meter Daten wird in diesem Beitrag deshalb ein Entscheidungsunterstützungsmodell zur Investitionsbewertung von Mieterstrommodellen entwickelt und evaluiert. Dafür wird in einem ersten Schritt eine Clusteranalyse durchgeführt, um anschließend auf Basis der durchschnittlichen Stromverbrauchsprofile der Cluster sowie bedingter Wahrscheinlichkeiten die Rentabilität eines Mieterstrommodells vorherzusagen. Die in einer Fallstudie evaluierten Investitionen weisen eine Amortisationszeit von 8 bis 14 Jahren sowie eine CO_2-Einsparung von über 60% auf.

Keywords: Mieterstrom, Investitionsbewertung, Clusteranalyse, Smart Meter Daten.

1 Einleitung

Vor dem Hintergrund des voranschreitenden Klimawandels sowie knapper werdender Ressourcen, wurden in den vergangenen Jahren weltweit erste Anstrengungen unternommen, um diesen negativen Entwicklungen entgegenzuwirken [1]. In Deutschland spielt zur Erreichung der internationalen Klimaziele die sogenannte Energiewende eine zentrale Rolle, wohinter sich der kurzfristige Ausstieg aus der Atomenergie und der mittelfristige Ausstieg aus der Kohleenergie verbirgt [2]. Eine wichtige Voraussetzung für das Erreichen dieser Ziele ist der Aufbau einer dezentralen Energieversorgung, für welche der Deutsche Bundesrat am 7. Juli 2017 mit dem Gesetz zur Förderung von Mieterstrom einen wichtigen Grundstein legte [3]. Mieterstrom stammt aus einer Photovoltaikanlage (PV-Anlage) oder einem Blockheizkraftwerk

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

(BHKW) eines Wohngebäudes und wird direkt den ansässigen Mietern zur Verfügung gestellt [4]. Überschüssiger Strom kann gegen die übliche EEG-Einspeisevergütung dem Stromnetz zugeführt werden. Diverse steuerliche Erleichterungen und Zuschüsse machen es für Vermieter nun deutlich attraktiver, den produzierten Strom möglichst vollständig an ihre Mieter zu verkaufen. Um den Mietern die Teilnahme am Mieterstrommodell interessant zu machen, wird in der Regel der Marktpreis für Strom leicht unterboten. Für den Vermieter wird dadurch der Eigenverbrauch, also der direkt im Gebäude verbrauchte Anteil des erzeugten Stroms, zu einer entscheidenden Performancekennzahl. Um die Stromverbräuche und Stromeinspeisungen präzise messen zu können, spielen Smart Meter eine zentrale Rolle in Mieterstrommodellen. Die erfassten, hochauflösenden Messergebnisse werden insbesondere für die komplexe Abrechnung benötigt, welche in der Regel über eine unterstützende IT Infrastruktur abgewickelt wird [5].

Die durch die Gesetzesänderung geschaffene Ausgangslage hat bereits erste Wohnbaugesellschaften zu Investitionen in das Mieterstrommodell bewegt [6]. Deren Rentabilität hängt, neben der Entwicklung des Strompreises, maßgeblich vom Eigenverbrauch im Tagesverlauf ab [7]. Ein Beispiel: Wenn die meisten Mieter tagsüber während der sonnenreichen Stunden nicht zuhause sind, muss der Investor den Großteil des produzierten Photovoltaikstroms ins Netz einspeisen und profitiert daher nicht von den höheren Preisen, welche er von den Mietern verlangen könnte. Ex ante sind, in Abwesenheit von Smart Metern, die Verbrauchsprofile in der Regel nicht bekannt oder nur in aggregierter Form (Jahresverbräuche) verfügbar und können so nicht bzw. kaum zur Investitionsbewertung herangezogen werden.

Auf Basis von Smart Meter Stromdaten wurden in den vergangenen Jahren eine Vielzahl von Data Analytics Lösungen entwickelt. So wurden Haushalte in Abhängigkeit von Verbrauchsprofilen in verschiedene Cluster eingeteilt [8] und anhand des Verbrauchsprofils auf Eigenschaften, wie z.B. das Gebäudealter, die Art der Warmwasserversorgung [9] sowie den Beschäftigungsstatus oder die Wohnform [10], geschlossen. Dabei liegt der Fokus der meisten Arbeiten jedoch nicht auf der Entscheidungsunterstützung durch Informationssysteme (IS) bei der Investitionsbewertung, sondern vielmehr auf der Unterstützung von politischen Entscheidungen oder der Entwicklung neuer Dienstleistungen für Endkunden, Netzbetreiber und Stromanbieter.

Aus den vorangegangen Überlegungen resultiert die folgende Forschungsfrage: Wie kann ein Entscheidungsunterstützungssystem basierenden auf Smart Meter Daten das Verbrauchsprofil einer Immobilie vorhersagen, um Mieterstrommodelle ökonomisch zu bewerten?

Die datenbasierte Vorhersage von Verbrauchsprofilen für Mieterstrommodelle ist ein Beitrag zur Energie Informatik, welche als Teilgebiet der IS-Forschung Informationssysteme zur Steigerung der Energieeffizienz und der Nachhaltigkeit entwickelt [11]. Um die formulierte Forschungsfrage zu beantworten, wurde der Design Science Ansatz gewählt [12]. Dieser Ansatz zeichnet sich durch die Entwicklung und anschließende Evaluation eines Artefakts aus. Hevner et al. [12] heben hervor, dass ein entwickeltes Artefakt (Modell) eine praktische Implikation zeigen sollte. Diese Anforderung wird in Kapitel 2 durch die Einbettung des Artefakts in ein Geschäftsmodell gewährleistet, welches auf Basis einer kurzen Einführung zu Mieterstrom und Datenanalysen von Smart Meter Daten skizziert wird. Anschließend wird in Kapitel 3 ein datenbasiertes Modell zur Vorhersage von Eigenverbräuchen entwickelt, welches zur ökonomischen Bewertung von Mieterstrommodellen verwendet werden kann. In Kapitel 4 wird das entwickelte Modell anhand realer Daten evaluiert und erprobt. Abschließend werden in Kapitel 5 die Ergebnisse und Limitationen zusammengefasst sowie auf weitere Forschungsfragen eingegangen.

2 Mieterstrom und Datenanalyse

Mit sinkenden Kosten für die lokale Stromerzeugung [13] und steigenden Endkundenpreisen für Strom, wird die dezentrale Stromerzeugung und der direkte Konsum vor Ort immer attraktiver. Der wirtschaftliche Rahmen, in welchem ein Investor (Vermieter) von diesen Entwicklungen profitieren kann, ist das oben eingeführte Mieterstrommodell. Behr und Großklos [4] definieren Mieterstrom anhand vier wesentlicher Elemente: (1) Die dezentrale Erzeugung von Strom, welche entweder regenerativ oder mit hoher Effizienz in Kraft-Wärme-Kopplung erfolgt, (2) der Standort der Energieerzeugungsanlage befindet sich in einem Gebäude oder auf dem Wohngelände, (3) zwischen der Energieerzeugungsanlage und den Mietern besteht ein räumlicher Zusammenhang sowie (4) für die Belieferung der Mieter werden keine allgemeinen Versorgungsnetze verwendet. Darüber hinaus regelt der deutsche Gesetzgeber in diversen Gesetzen und Verordnungen weitere Detailpunkte des Mieterstroms. Neben dem Stromverkauf an Mieter kann der Vermieter nach wie vor den erzeugten Strom auch ins Stromnetz einspeisen und erhält dafür eine garantierte Einspeisevergütung. Diese liegt jedoch in der Regel um ca. 30 bis 50% niedriger als die Rückflüsse aus dem Direktverkauf an die Mieter. Aus diesem Grund muss für die ökonomische Rentabilität eine entsprechende Strommenge von den Mietern abgenommen werden, um die Mehrkosten für Smart Meter und Abrechnungssysteme zu kompensieren. Diese Mehrkosten sowie weitere Aspekte der Implementierung wurden daher bereits in ersten Studien für den deutschen Markt zusammengefasst [5], [14]. In Abbildung 1 ist ein typisches Verbrauchsprofil einer Immobilie mit vier Haushalten abgebildet, welche über eine Photovoltaikanlange (10kWp) sowie über eine Brennstoffzelle (3kW) verfügen. Es ist zu erkennen, dass nachts die Brennstoffzelle die Grundlast des Gebäudes vollständig deckt und die Photovoltaikanlage von ca. 4 bis 20 Uhr Strom produziert, allerdings nicht genug um den Peak am Abend abzudecken. Die dargestellten Verläufe sind hochgradig stochastisch, da sie von diversen Faktoren abhängen. So ist die Stromproduktion einer Photovoltaikanlange stark von Wettereinflüssen abhängig [15] und das Verbrauchsprofil vom Nutzerverhalten oder der Anwesenheit der Mieter [16]. Für ein Mieterstrommodell ergibt sich folglich eine doppelte Unsicherheit, bestehend aus der produzierten Strommenge sowie dem Strombedarf der Mieter.

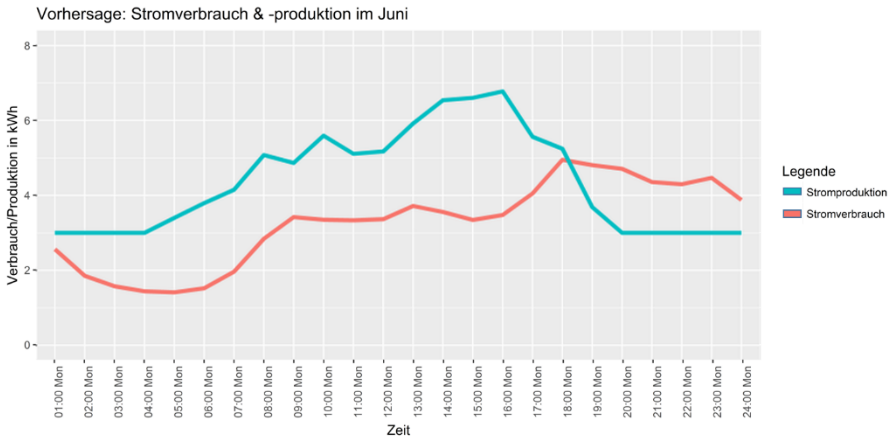

Abbildung 1. Beispielhafter Stromverbrauch und -produktion (3kW Brennstoffzelle und 10kWp Photovoltaikanlage) eines Mehrfamilienhauses (vier Einheiten)

Die für Mieterstrom eingesetzten Stromerzeugungstechniken Photovoltaik (PV) und BHKW weisen unterschiedliche Erzeugungsprofile auf. Die PV-Anlage besitzt sowohl einen Tages- als auch einen Jahresgang mit höchster Stromerzeugung zu der Mittagszeit und im Sommer. Dabei wird die Leistung einer PV-Anlage maßgeblich von der Umgebungstemperatur sowie der Globalstrahlung beeinflusst, und kann so zwischen einzelnen Tagen deutlich schwanken [15]. In der wissenschaftlichen Literatur ist daher in den vergangenen Jahren eine Vielzahl von Publikationen zur Vorhersage von Erzeugerprofilen bei PV-Anlagen entstanden. In der Regel werden dabei hybride Modelle verwendet, sodass auf Basis von Ingenieursgleichungen [17] lediglich die Eingangsvariablen der Gleichungen wie Temperatur- und Globalstrahlungsverläufe u.a. durch Neuronale Netze [18], Markov Modelle [19] oder Zeitreihen [20] stochastisch modelliert werden. Ein weiterer Teil der Literatur beschäftigt sich darüber hinaus mit Randparametern, wie zum Beispiel der Verschattung von PV-Anlagen [21] oder dem Anlagendesign [22]. Ein BHKW liefert dahingegen im durchgängigen Betrieb eine nahezu konstante Strommenge. Sollte die zusätzlich anfallende Wärmemenge im Sommer nicht benötigt werden, kann das Abschalten der Anlage rentabel sein. Die Berechnung des Eigenverbrauchs hat in den letzten Jahren durch den vermehrten Einsatz von Stromspeichern an Relevanz gewonnen [15], wobei zur Berechnung von Eigenverbräuchen in der Regel einzelne Objekte betrachtet oder Standardprofile verwendet werden.

Großklos [7] misst daher im Zuge der Investitionsbewertung von Mieterstrommodellen neben der Energieerzeugungsvorhersage auch dem Verbrauch und der tatsächlichen Stromabnahme eine wichtige Rolle bei. Da Stromverbrauchsprofile sowohl große Schwankungen im Tagesverlauf aufweisen als auch einem saisonalen Jahresverlauf unterliegen, sind für die Berechnung des Eigenverbrauchs möglichst hochauflösende Vorhersagen notwendig. Die verschiedenen Einflüsse auf Stromverbrauchsprofile untersuchen Sodenkamp et al. [9], indem sie mit Machine Learning Algorithmen und Verbrauchsdaten aus der Schweiz versuchen, anhand des Stromverbrauchs auf Eigenschaften eines Haushalts zu schließen (z.B. Alter des Hauses, die Verwendung von Wärmepumpen oder elektrischen Kochgeräten). In dieselbe Richtung arbeiten auch Beckel et al. [23], indem sie für einen irischen Datensatz diverse Eigenschaften zu Haushaltsbewohnern sowie des Gebäudes mit einer Trefferquote von zum Teil 70 bis 80% bestimmen. Für denselben Datensatz untersuchen McLouglin et al. [16] den Einfluss auf den Stromverbrauch von Faktoren, wie die Anzahl der Schlafzimmer, Zusammensetzung des Haushaltes oder den Wohnungstyp mit Hilfe einer multiplen linearen Regression. In einer späteren Arbeit wenden die Autoren dann statistische Clustermethoden wie k-Means, k-Medoids und Self Organising Maps an, um anhand des Stromverbrauches die Haushalte in verschiedene Klassen aufzuteilen [8]. Insgesamt identifizieren sie 10 Cluster, die jeweils charakteristische Verbrauchsverläufe aufweisen. Zu der gleichen Anzahl an Clustern kommen auch Haben et al. [24], unter Verwendung eines sogenannten Finite Mixture Clustering. Einen etwas anderen Weg schlagen Wang et al. [25] ein, indem sie erst die Verbrauchsdaten jedes Haushalts in ein Markov-Modell überführen und anschließend die Haushalte nach deren Wahrscheinlichkeitsdichten clustern, um so bestimmte Verhaltensweisen zu identifizieren. Abschließend schätzen Al-Wakeel et al. [26] fehlende Stromverbrauchswerte anhand des k-Means Algorithmus, indem sie verschiedene Distanzmaße von den Ausgangsdaten zu den Clusterzentren verwenden.

Die vorgestellten statistischen Methoden werden in der Praxis bei der ökonomischen Bewertung von Mieterstrom kaum angewandt, sodass bis heute Standardprofile oder Referenzprojekte zur Bewertung von Mieterstrommodellen herangezogen werden [7]. Ziel dieser Arbeit ist es daher, ein datenbasiertes Modell zur Vorhersage des haushaltsspezifischen Stromverbrauchprofils auf Basis weniger Faktoren, wie zum Beispiel der Anzahl der Zimmer, dem Beschäftigungsverhältnis des Mieters und der Haushaltsgröße zu entwickeln. Dieses Stromverbrauchsprofil kann anschließend zur Berechnung des Eigenverbrauchs verwendet werden, der wiederum als Grundlage für die Investitionsbewertung von Mieterstrommodellen dient.

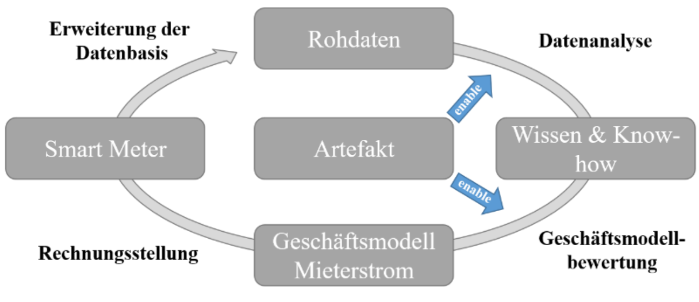

Abbildung 2. Datenkreislauf eines Geschäftsmodells zur Beratung bei Mieterstrom

Abbildung 2 zeigt das Artefakt dieses Beitrags entlang eines Datenkreislaufs für ein Geschäftsmodell zur Verwaltung und Beratung von Mieterstrom. Hierzu wird, ausgehend von Rohdaten zu Verbrauch und Haushaltseigenschaften, Know-how auf Grundlage von Datenanalysen aufgebaut. Dies ermöglicht im zweiten Schritt, in Form eines Bewertungsalgorithmus, die ökonomische Bewertung des Mieterstrommodells. Nach Umsetzung des Mieterstroms werden dann insbesondere zu Abrechnungszwecken weitere Daten über Smart Meter gesammelt, welche den Datenpool erweitern und so den gesamten Kreislauf kontinuierlich verbessern.

3 Modellteil

Im Folgenden werden die notwendigen Gleichungen zur Modellierung eines Mieterstrommodells auf Basis von PV und BHKW eingeführt. Um die ökonomische Bewertung eines Mieterstrommodells durchführen zu können, ist eine möglichst exakte Schätzung des Eigenverbrauchs notwendig. Auf dieser Basis lässt sich für ein Mieterstrommodell die folgende Gleichung des Cashflows im Jahr $t \in \{1, \ldots, T\}$ aufstellen, die Steuereffekte nicht berücksichtigt:

$$CF_t = E_t^G \cdot \varepsilon_t \cdot P_t^{MS} + E_t^G \cdot (1 - \varepsilon_t) \cdot P_t^{Netz} - K_t, \tag{1}$$

wobei $E_t^G \in \mathbb{R}^+$ die erzeugte Strommenge in kWh bezeichnet, $\varepsilon_t \in [0,1]$ den Eigenverbrauchsfaktor und P_t^{MS} den erzielten Preis pro kWh durch den Verkauf von Mieterstrom sowie P_t^{Netz} dementsprechend die Einspeisevergütung für die Stromabgabe ins Netz. Die Kosten K_t zum Zeitpunkt t setzen sich aus den Verwaltungskosten, den Abrechnungskosten (Smart Meter und IT-Infrastruktur) sowie ggf. anfallenden Kosten für Energieträger zusammen. Zur Vereinfachung werden die Erlöse aus der Wärmeerzeugung eines BHKW nicht berücksichtigt, können aber über verminderte Kosten modelliert werden. Hinter Gleichung (1) steckt die Annahme, dass zusätzlich benötigter Strom aus dem Stromnetz gewinnneutral an die Mieter weiterverkauft wird. Der Eigenverbrauchsfaktor ε_t lässt sich als Bruch von erzeugter Strommenge E_t^G und der von den Mietern abgenommenen Strommenge E_t^{MS} darstellen:

$$\varepsilon_t = \frac{E_t^{MS}}{E_t^G}. \tag{2}$$

Für eine gegebene Partition, welche einen Tag anhand von N Messpunkten in $N-1$ gleich große Intervalle teilt, kann die abgenommene Mieterstrommenge E_t^{MS} (auf Jahresbasis) wie folgt geschätzt werden:

$$E_t^{MS} \approx \sum_{i=1}^{365} \sum_{j=1}^{N} \min(e_{ij}, v_{ij}), \tag{3}$$

mit e_{ij} als die erzeugte Strommenge in kWh am Tag i zwischen Messpunkt j und $j-1$ sowie v_{ij} als der dazugehörige Stromverbrauch der Mieter. Dabei wird innerhalb der Summenzeichen der limitierende Faktor für den Mieterstrom berechnet, also die verfügbare Strommenge oder der Strombedarf der Mieter und dieser anschließend für alle Intervalle aufaddiert. Die gesamte erzeugte Strommenge E_t^G kann analog zu Gleichung (3) berechnet werden, indem lediglich die e_{ij} aufsummiert werden. Als nächster Schritt wird nun eine Methode zur Modellierung der erzeugten sowie verbrauchten Strommengen e_{ij} und v_{ij} eingeführt. Für die Modellierung der erzeugten Strommenge aus einer PV-Anlage e_{ij}^{PV} wird die Osterwald Methode [27] verwendet, welche trotz ihrer Einfachheit eine hohe Prognosegüte aufweist [17]. Demnach kann die Leistung L_{ij}^{PV} einer PV-Anlage über die folgende Gleichung definiert werden:

$$L_{ij}^{PV} = L_{ij}^{max}\left(G_{ij}, T_{ij}^{c}\right) \cdot (1 - L_V) \cdot (1 - L_R) \cdot (1 - L_T) \cdot (1 - L_S). \quad (4)$$

$L_V \in [0,1]$ bezeichnet die Verluste durch Verschattung, $L_R \in [0,1]$ definiert die Verluste durch Reflexion des Lichtes, $L_T \in [0,1]$ definiert die Verluste in den Leitungen des PV-Moduls beim Stromtransport sowie $L_S \in [0,1]$ die Systemverluste u.a. bei der Stromumwandlung. Die maximale Leistung $L_{ij}^{max}\left(G_{ij}, T_{ij}^{c}\right)$ in Abhängigkeit der Globalstrahlung G_{ij} und der Zellentemperatur der PV-Anlage T_{ij}^{c} ist definiert als:

$$L_{ij}^{max}\left(G_{ij}, T_{ij}^{c}\right) = L^{peak} \cdot G_{ij} \cdot \left[1 + 0{,}0035 \cdot \left(T_{ij}^{c} - T^{*}\right)\right] / G^{*}, \quad (5)$$

mit L^{peak} als die Gesamtleistung der PV-Anlage unter genormten Bedingungen bei einer Temperatur von $T^{*} = 25^{\circ}C$ und $G^{*} = 1000\, W/m^2$. Die Zellentemperatur T_{ij}^{c} einer PV-Anlage kann auf Basis der Außentemperatur T_{ij}^{A} sowie der Globalstrahlung G_{ij} wie folgt geschätzt werden [28]:

$$T_{ij}^{c} = T_{ij}^{A} + (T^{PV} - 20) + G_{ij}/800, \quad (6)$$

wobei T^{PV} die ausgelegte Zellentemperatur im Betriebsmodus ist. An dieser Stelle sei ergänzend vermerkt, dass die einfallende Globalstrahlung G_{ij} maßgeblich von der Ausrichtung der PV-Anlage und des Sonnenwinkels abhängt. Nach Reikard [20] sowie Fang und Lahdelma [29] können die Globalstrahlung G_{ij} und die Außentemperatur T_{ij}^{A} aufgrund ihrer statistischen Eigenschaft adäquat über Seasonal Autoregressive Integrated Moving Average (SARIMA) Modelle quantifiziert werden. Abschließend kann die Leistung L^{BHKW} eines BHKW vereinfachend als konstant angenommen werden, sodass sich die folgende Gleichung für die produzierte Strommenge e_{ij} ergibt:

$$e_{ij} = (L_{ij}^{PV} + L^{BHKW}) \cdot 24h/N. \quad (7)$$

Hinter Gleichung (7) steckt die Annahme, dass innerhalb eines Zeitschrittes die Leistungen der PV-Anlage wie auch des BHKWs konstant sind. Als zweiter Schritt wird nun die Modellierung des Stromverbrauchsprofils v_{ij} der am Mieterstrommodell beteiligten $K \in \mathbb{N}$ Haushalte eingeführt. Der Gesamtverbrauch v_{ij} lässt sich als die Summe der Einzelverbräuche der Haushalte darstellen:

$$v_{ij} = \sum_{k=1}^{K} v_{kij}, \quad (8)$$

wobei v_{kij} der Stromverbrauch des k-ten Haushaltes am i-ten Tag zwischen Messpunkt j und $j-1$ bezeichnet. Über jeden Haushalt sei ferner ein Merkmalsvektor $x \in \mathbb{N}^D$ bekannt, welcher aus $D \in \mathbb{N}$ einzelnen Merkmalen besteht. Zusätzlich sei bekannt, dass für Haushaltsstromverbräuche $Q \in \mathbb{N}$ Standardstromverbrauchsprofile existieren, anhand welcher sich Haushalte in verschiedene Cluster aufteilen lassen. Für jedes Cluster $q = 1, \dots Q$ seien $f_1, \dots, f_Q$ die Dichtefunktionen von $\mathbb{R}^D \to \mathbb{R}$, welche die Verteilung und Häufigkeit des Merkmalsvektors x in jedem Cluster charakterisieren. Zusätzlich seien die allgemeinen Wahrscheinlichkeiten $\pi_1, \dots, \pi_Q$ der Cluster bekannt, welche die Häufigkeiten der einzelnen Cluster charakterisieren und deshalb auch $\sum_{q=1}^{Q} \pi_q = 1$ gelten muss. Nach dem Satz von Bayes gilt dann für jeden Haushalt mit Merkmalsvektor x:

$$f_x(q) \coloneqq P(Haushalt\ gehört\ zu\ Cluster\ q\ |X = x) = \frac{\pi_q f_q(x)}{\sum_{l=1}^{Q} \pi_l f_l(x)}. \tag{9}$$

Mit Hilfe von Gleichung (9) kann somit die Wahrscheinlichkeit, dass ein Haushalt zu einem Cluster q gehört, anhand von verschiedenen Dichtefunktionen und Wahrscheinlichkeiten berechnet werden, die sich nach einer Clusteranalyse bestimmen lassen. Seien zum Beispiel $M \in \mathbb{N}$ Haushalte mit Merkmalsvektoren $x_1, \dots, x_M \in \mathbb{N}^D$, welche anhand ihres Stromverbrauchprofils in Q Cluster aufgeteilt wurden, gegeben, dann lassen sich die Schätzer $\hat{\pi}_q$ und $\hat{f}_q$ definieren durch:

$$\hat{\pi}_q = \frac{\#Anzahl\ Haushalte\ in\ Cluster\ q}{M}, \tag{10}$$

sowie

$$\hat{f}_q(x) = \frac{\#Anzahl\ Haushalte\ in\ Cluster\ q\ mit\ Merkmalsvektor\ x}{\#Anzahl\ Haushalte\ in\ Cluster\ q}. \tag{11}$$

Durch Einsetzen der beiden Schätzer in Gleichung (9) erhalten wir dann den kombinierten Schätzer:

$$\hat{f}_x(q) = \begin{cases} \dfrac{\hat{\pi}_q \hat{f}_q(x)}{\sum_{l=1}^{Q} \hat{\pi}_l \hat{f}_l(x)}, wenn \sum_{l=1}^{Q} \hat{f}_l(x) > 0 \\ \quad \hat{\pi}_q \qquad , sonst. \end{cases} \tag{12}$$

Der zweite Teil der Gleichung (12) dient der Robustheit des Schätzers, da der Nenner den Wert 0 annehmen würde, falls ein Merkmalsvektor x nicht in den ursprünglichen Daten enthalten wäre. Nun seien die durchschnittlichen Stromverbräuche innerhalb eines Clusters $\hat{v}_{ij}^q$ am Tag i zwischen Messpunkt j und $j-1$ bekannt für $q = 1, \dots, Q$. Dazu sei ergänzend bemerkt, dass die Verbräuche eines Clusters zu einer bestimmten Partition aus den historischen Verbräuchen zu den einzelnen Monaten, an einem durchschnittlichen Wochentag, über den betroffenen Zeitraum gemittelt werden können und so Schätzwerte für v_{ij}^q ableitbar sind. Daraus lässt sich der erwartete Verbrauch $\hat{v}_{kij}$ des k-ten Haushalts mit Merkmalsvektor x_k wie folgt berechnen:

$$\hat{v}_{kij} = \sum_{l=1}^{Q} \hat{f}_x(l) \cdot \hat{v}_{ij}^l. \tag{13}$$

Wird dieser Schätzer in die Ausgangsgleichung (8) eingesetzt, erhält man den entsprechenden Schätzer für den Stromverbrauch der Haushalte. Hinter dem eingeführten Merkmalsvektor x stehen numerisch codierte Merkmale, welche einen Haushalt charakterisieren und so auf den Verbrauch schließen lassen. Diese Merkmale, wie zum Beispiel die Anzahl der Haushaltsmitglieder, können sich über die Zeit ändern. Es wird jedoch zur Vereinfachung angenommen, dass dieser Vektor konstant ist.

Abschließend lässt sich nun der Kapitelwert (KW) des Mieterstrommodells mit Kalkulationszinssatz r und Investitionskosten I_0 zum Zeitpunkt $t = 0$ wie folgt berechnen:

$$KW = \sum_{t=1}^{T} \frac{CF_t}{(1+r)^t} - I_0. \tag{14}$$

Zudem ergibt sich die folgende Amortisationszeit (AZ):

$$AZ = \min_{t \in [1,T]} t + T \cdot \mathrm{I}_{\sum_{i=1}^{t} CF_i < I_o} \tag{15}$$

wobei $\mathrm{I} \in \{0,1\}$ definiert ist als Indikatorfunktion und somit AZ die Anzahl der Perioden definiert, bis die jährlichen Cashflows in Summe die anfänglichen Investitionskosten I_0 übersteigen, unter der Annahme das $AZ \leq T$.

4 Evaluation des Modells

In der folgenden Evaluation werden zwei Mieterstrominvestitionen auf Basis von Realweltdaten ökonomisch bewertet und versucht die Vorhersagegüte des Modells zu bestimmen [14]. Dabei wird ein Mieterstrommodell für vier Haushalte und eines für eine Quartierslösung (30 Haushalte) bewertet. Es wird angenommen, dass der Wärmebedarf der Beispielgebäude für die Heizung und Warmwasser nicht über Strom zur Verfügung gestellt wird. Zur Stromerzeugung werden bei den vier Haushalten eine $3kW$ Brennstoffzelle und eine $10kWp$ PV-Anlage installiert, welche annahmegemäß über 20 Jahre konstante Leistungen erbringen. In der Quartierlösung wird jeweils das 7,5-Fache dieser Leistung installiert. Damit liegt die Quartierslösung noch unter der vom Gesetzgeber vorgegeben Fördergrenze für Anlagen von insgesamt bis zu $100\ kW$. Zusätzlich wird über den Betrachtungszeitraum ein konstantes Nutzerverhalten der Mieter angenommen. Die Kostenersparnis durch Skaleneffekte bei der Quartierslösung entsprechen 10% pro kW-Leistung, wohingegen die Vergütung der Netzeinspeisung vom Fördergeber für Großprojekte, nach deutscher Förderrichtlinie, um 2 Cent reduziert wird. Weitere Annahmen und Parameter sind in Tabelle 1 zusammengefasst.

Tabelle 1. Modellparameter und Annahmen der Evaluation

Variante	T	r	I_0	K	P_t^{Netz}	P_t^{MS}	L_V	L_R	L_T	L_S	T^{PV}
4-Mieter	20	2%	50.000€	3.000€	0,12€	0,25€	0,16	0,07	0,00	0,12	47°C
Quartier			337.500€	20.250€	0,10€						

4.1 Vorstellung der Daten und Datenaufbereitung

Als Stromverbrauchsdaten werden öffentliche Smart Meter Daten von 4225 Haushalten der irischen Kommission für Energieregulierung (CER) verwendet, welche über einen Zeitraum von Juli 2009 bis Dezember 2010 alle 30 Minuten erfasst wurden [30]. Neben den Stromverbräuchen wurden diverse weitere Haushaltsmerkmale erfasst. Die verwendeten Merkmale für das Modell sind in Tabelle 2 zusammengefasst. Da die betrachteten Immobilien annahmegemäß über keine Stromheizung verfügen, werden sämtliche Haushalte aus den Daten entfernt, welche nicht dieser Annahme entsprechen oder deren Daten nicht vollständig sind. Danach werden für die vier meteorologischen Jahreszeiten, für einen durchschnittlichen Werktag, in jeweils dreistündigen Zeitintervallen ab 0 Uhr, der durchschnittliche Stromverbrauch je Haushalt sowie die Änderungsraten berechnet (64 Kennzahlen). Für die Modellierung der Temperatur und der Globalstrahlung (hor.) werden Daten vom Deutschen Wetterdienst für die Stadt Würzburg über den Zeitraum 2005 bis 2017 in stündlicher Auflösung verwendet [31].

Tabelle 2. Verwendete Merkmale zur Charakterisierung der Haushalte. In Klammern sind die Ausprägungen der vier Beispielhaushalte der ersten Investition dargestellt

Merkmale des Mieters	*Ausprägungsmöglichkeiten*
Alter Hauptmieter	<35$_{(4)}$, 36-45$_{(2)}$, 46-55$_{(3)}$, 56-65, >65$_{(1)}$
Beschäftigungsstatus	Angestellt$_{(2-4)}$, Selbstständig, Rente$_{(1)}$, Arbeitslos
Wohnform	Single$_{(1,4)}$, Eltern mit Kindern ≤ 15J.$_{(2)}$, Sonstige$_{(3)}$
Anzahl Bewohner > 15 Jahren	0$_{(1,4)}$, 1-2$_{(2,3)}$, >2
Anzahl Kinder ≤ 15 Jahren	0$_{(1,3,4)}$, 1$_{(2)}$, >1
Anzahl Schlafzimmer	1-2$_{(1,3,4)}$, 3$_{(2)}$, >3
Internetanschluss	vorhanden(v)$_{(2-4)}$, nicht vorhanden(n.v.)$_{(1)}$
Geschirrspülmaschine	vorhanden$_{(2-4)}$, nicht vorhanden$_{(1)}$
Spielekonsole	vorhanden, nicht vorhanden$_{(1-4)}$

4.2 Empirische Ergebnisse der Clusteranalyse

Zur Clusteranalyse wird der Partitioning Around Medoids (PAM) Algorithmus [32] und die Plattform R-CRAN sowie das Paket ‘cluster’ [33] genutzt. Die Auswahl der Clusteranzahl erfolgt über das Elbow-Kriterium, für welches ein Fehlermaß gegen die Anzahl der Cluster geplottet wird. Als Fehlermaß wird dabei die Summe der Entfernungsquadrate zwischen den Clustern zum Gruppenmittelpunkt des Clusters verwendet (Total within Sum of Squares). Mit zunehmender Anzahl der Cluster nimmt das Fehlermaß der Cluster ab, bis ab einem bestimmten Punkt eine deutliche Verflachung zu erkennen ist. Dieser Punkt markiert für die verwendeten Daten bei $Q = 6$ die optimale Anzahl der Cluster. Damit ist die gewählte Clusteranzahl etwas geringer als die vergleichbarer Arbeiten [8], was insbesondere darauf zurückzuführen ist, dass nur Haushalte betrachtet werden, die nicht mit Strom geheizt werden. In Abbildung 6 werden die durchschnittlichen Stromverbräuche an einem Werktag je Cluster dargestellt, worin sich die unterschiedlichen Verbrauchsprofile erkennen lassen. In Tabelle 3 sind die Ausprägungen dargestellt, welche im Vergleich zum Durchschnitt besonders häufig in den Clustern auftreten. Daraus lassen sich grob ein Cluster für Singles (1), drei Cluster für Familien in den unterschiedlichsten Lebensphasen (2-4), ein Cluster für Paare (5) und eines für Rentner (6) ableiten. Zur Modellierung der SARIMA-Prozesse für den Verlauf der Globalstrahlung und der Temperaturkurven wird die Plattform R CRAN und das Paket 'forecast' verwendet [34]. Dabei werden für jeden Kalendermonat auf stündlicher Basis, für die Stunden zwischen Sonnenaufgang und -untergang mit Dauer $s_i \in \mathrm{N}$, für $i = 1, ..12$ jeweils zwei SARIMA$(p, d, q) \times (P, D, Q)_{s_i}$ Modelle für $p, d, q, P, D, Q \leq 1$, gefittet und nach dem AIC-Kriterium ausgewählt, sodass sich 24 Zeitreihen ergeben. Um die Modellgüte der Zeitreihen als gegeben beurteilen zu können, werden im Anschluss die Modellparameter auf Signifikanz ($\alpha = 0.05$) untersucht, die Residuen mit Hilfe des Ljung–Box Tests auf Autokorrelation getestet sowie auf die Standardnormalverteilung untersucht.

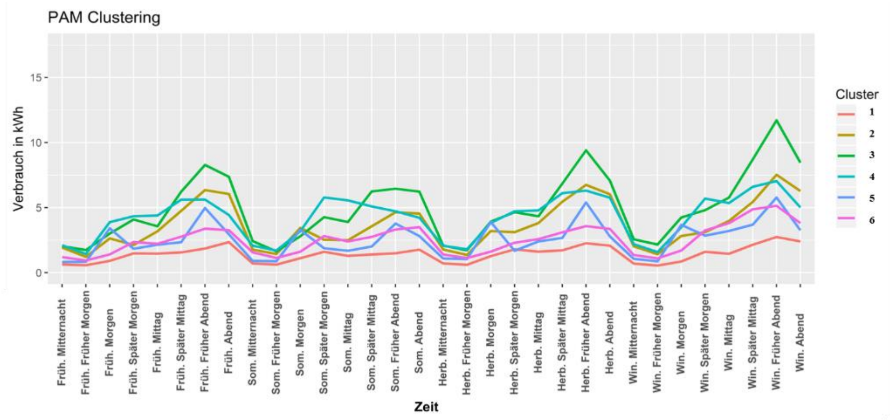

Abbildung 3. Stromverbräuche der Cluster nach Jahres- und Tageszeiten (Werktag) auf Basis von Smart Meter Daten der irischen Kommission für Energieregulierung (CER) [30]

Tabelle 3. Darstellung der Merkmale je Cluster die um 10 Prozentpunkte gestiegen sind zum Durchschnitt (~) auf Basis des Clusterings von Stromverbrauchsdaten [30]

Merkmale /Cluster	*1(rot)*	*2(braun)*	*3(grün)*	*4(h.blau)*	*5(blau)*	*6(pink)*
Alter des Hauptmieters	~	36-55	46-55	~	~	>65
Beschäftigungsstatus	~	Angest.	Selbst.	~	Angest.	Rentner
Wohnform	Single	Familie	Familie	Sonstige	~	Sonstige
Anzahl Mitbewohner über 15 Jahren	0	1-2	>2	>2	1-2	~
Anzahl Kinder unter 15 Jahren	0	1,>1	>1	~	~	0
Anzahl Schlafzimmer	1-2, 3	>3	>3	>3	~	~
Internetanschluss	n.v.	v.	v.	v.	~	~
Geschirrspülmaschine	n.v.	v.	v.	v.	~	~
Spielekonsolen	n.v.	v.	v.	v.	~	n.v.
Anteil Haushalte (%)	27,3	15,4	9,1	9,6	11,8	26,8

4.3 Monte Carlo Simulation und empirische Ergebnisse

Auf Basis der in Abschnitt 4.2 kalibrierten Modelle werden nun für vier bzw. dreißig zufällig ausgewählte Haushalte aus dem Datensatz die in Tabelle 1 beschriebenen Mieterstrommodelle ökonomisch und ökologisch bewertet. Ziel ist es, die Erwartungswerte des Eigenverbrauchsfaktors ε_t sowie den der erzeugten Strommenge E_t^G auf Basis einer Monte Carlo Simulation mit 1.000 Durchläufen vorherzusagen. Auf dieser Basis können dann der Kapitalwert und die Amortisationszeit der Investitionen berechnet werden. Mit Erwartungswerten in Höhe von 33.400 kWh/a für die erzeugte Strommenge sowie von 65% für den Eigenverbrauchsfaktor, ergeben sich bei dem Mieterstrommodell mit vier Haushalten eine Amortisationszeit von 13 Jahren sowie ein erwarteter Kapitalwert von ca. 12.000€ über den Betrachtungszeitraum. Dem gegenüber steht die Quartierslösung mit einer erwarteten Amortisationszeit von 10 Jahren sowie einem erwarteten Kapitelwert von ca. 220.000€. Trotz der geringeren Einspeisevergütung amortisiert sich die Quartierslösung somit im Schnitt drei Jahre vor dem Mieterstrommodell mit nur vier Haushalten. Dies liegt unter anderem an dem höheren Eigenverbrauchsfaktor der Quartierslösung von insgesamt 76%, welcher in Tabelle 4 auf monatlicher Basis dargestellt ist. Der höhere Eigenverbrauchsfaktor lässt sich über die rechtsschiefe Verteilung der Stromverbräuche erklären, sodass mit einer steigenden Anzahl an Mietern, Haushalte mit hohen Verbräuchen statistisch häufiger auftreten und somit auch mehr Strom abgenommen wird. Insgesamt wird auf Grundlage des Anlagendesigns die 7,5-Fache Strommenge im Quartier produziert. Würden sich die Investitionskosten I_0 und die jährlichen Kosten K der Quartierslösung im Vergleich zum Mieterstrommodell mit vier Haushalte um jeweils 20% verringern pro kW-Leistung (davor 10%), wird eine Amortisationszeit von 8 Jahren erreicht. Diese Einsparungen können in etwa als obere Grenze für die betrachtete Quartierslösung gelten [35]. Wie in Tabelle 4 dargestellt, tritt bei der Vorhersage des monatlichen Eigenverbrauchsfaktors bei der Investition mit vier Mietern ein absoluter Fehler von 3,5 Prozentpunkten und bei der Quartierslösung von 2,5 Prozentpunkten auf.

Table 4: Empirische Ergebnisse des Entscheidungsunterstützungsmodells

4-Mieter	Jan.	Feb.	Mär.	Apr.	Mai	Jun.	Jul.	Aug.	Sep.	Okt.	Nov.	Dez.
$E[\varepsilon]$	0,79	0,72	0,65	0,59	0,56	0,55	0,57	0,58	0,62	0,67	0,74	0,84
ε_{real}	0,75	0,69	0,60	0,58	0,54	0,53	0,55	0,55	0,58	0,63	0,69	0,77
Quartier												
$E[\varepsilon]$	0,88	0,83	0,77	0,70	0,69	0,67	0,69	0,70	0,74	0,79	0,84	0,90
ε_{real}	0,86	0,83	0,77	0,65	0,63	0,67	0,67	0,67	0,70	0,78	0,82	0,87

Wird unter Betrachtung des gesamten Lebenszyklus der Mieterstrominvestition die CO_2-Einsparung berechnet, ergeben sich für die Quartierslösung eine jährliche Einsparung in Höhe von 95 Tonnen CO_2, was einer Reduktion von 64% im Vergleich zum deutschen Kraftwerksmix gleichkommt.[1] Dies entspricht in etwa dem CO_2-

[1] Es wurde ein CO_2-Ausstoß pro kWh Strom von 100 Gramm bei PV, 240 Gramm bei einer Brennstoffzelle und 550 Gramm im deutschen Kraftwerksmix angenommen [36].

Ausstoß eines Mittelklassewagens über ca. 600.000 km Fahrstrecke. Für das zweite Szenario ergibt sich eine jährliche Einsparung von 13 Tonnen CO_2. Der durchschnittliche Stromverbrauch pro irischem Haushalt von 3.700 kWh/a, auf dessen Basis die Ergebnisse berechnet wurden, liegt leicht über dem durchschnittlichen Verbrauch von 3.200 kWh/a in Deutschland [37]. Ein auf dieser Grundlage kalibriertes Modell wird den Strombedarf deutscher Haushalte überschätzen und dadurch tendenziell zu kurze Amortisationszeiten berechnen. Wird der durchschnittliche Mehrverbrauch der irischen Haushalte pauschal abgezogen, ergeben sich für Deutschland im Schnitt ein Jahr längere Amortisationszeiten.

5 Zusammenfassung, Limitationen und Ausblick

Für den Erfolg der Energiewende spielt die dezentrale Stromerzeugung eine entscheidende Rolle. Dabei bietet Mieterstrom für die auftretenden Herausforderungen einen vielversprechenden Lösungsansatz, welcher insbesondere durch die Nutzung des steigenden Datenvolumens durch Smart Meter zu neuen Geschäftsmodellen führen kann. In dieser Arbeit wurde deshalb zur Investitionsbewertung von Mieterstrommodellen ein Entscheidungsunterstützungssystem entwickelt und evaluiert. Die Ergebnisse der Wirtschaftlichkeitsbetrachtung zeigen, dass sich Mieterstrommodelle unter den getroffenen Annahmen je nach Größe nach 8 bis 14 Jahren amortisieren. Zusätzlich konnten bei der hybriden Nutzung von PV-Anlagen und Brennstoffzellen $C0_2$-Einsparungen von über 60% nachgewiesen werden. Zu den Defiziten der Annahmen: (1) Ein gleichbleibendes Nutzverhalten kann nur schwer über lange Zeiträume angenommen werden, da die natürliche Veränderung der Lebenssituation eines Haushaltes zu Veränderungen im Verbrauchsverhalten führen kann. Diese Annahme könnte jedoch mit einem zusätzlichen Teilmodell zur Fortschreibung der Haushaltsmerkmale entkräftet werden. (2) Es werden keine Ausfälle durch Vertragskündigungen berücksichtigt, wie sie zum Beispiel durch Mieterwechsel entstehen. An dieser Stelle könnten Langzeitstudien den notwendigen Aufschluss über die Häufigkeit dieser Ausfälle liefern. (3) Die berechneten Amortisationszeiten sollten auf Basis deutscher Verbrauchsdaten validiert werden, um so die vollständige Übertragbarkeit auf Deutschland zu gewährleisten. (4) Entstehende Preisrisiken durch die stochastische Preisentwicklung für Energieträger und die zukünftige Entwicklung der Betriebskosten des Mieterstrommodells werden aktuell noch nicht abgebildet. Dies kann jedoch auf Basis von bestehender Literatur ergänzt werden. Zukünftige Erweiterungen des Modells sollten neben den vier genannten Limitationen insbesondere die Integration von Speichertechnologien sowie das Zusammenspiel von Mieterstrom und Elektrofahrzeugen berücksichtigen. Durch diese Trends könnten sich die Profile von abgerufenen und bereitgestellten Strommengen signifikant ändern und so zu neuen Rahmenbedingungen für Mieterstrommodelle führen. Um ein beratungs- und serviceorientiertes Geschäftsmodell basierend auf dem entwickelten Ansatz zu realisieren, ist zusätzlich eine allumfassende IT-Unterstützung notwendig. Hier ist es weiterhin notwendig die technische Ausgestaltung solcher IT-Anwendungen im Detail zu betrachten. In diesem Zusammenhang spielt auch das

Thema Datenschutz eine wichtige Rollte, da die Privatsphäre der Mieter ebenfalls geschützt werden muss. Trotz der genannten Limitation zeigt der vorliegende Beitrag auf, wie ein Entscheidungsunterstützungssystem für Mieterstrom konzipiert sein müsste und kann somit zukünftig zur Identifikation und Umsetzung erfolgreicher Investitionen beitragen.

{jannis.vogel,simon.hagen,oliver.thomas}@uni-osnabrueck.de

Abstract. An increasing amount of use cases is discovered for blockchain technology, since it promises tamper-proof recording of product-related data. It has the potential to improve the reliability of information management for whole supply chains and thus enables new ecologically and economically service offerings. Integrating products and services into one marketable bundle is no new concept and is referred to as product-service systems (PSS). Therefore, the methodical integration of knowledge on sustainable businesses, PSS and blockchain is a promising approach to overcome current barriers to achieve an applicable circular economy. Our study contributes a structured literature review on ongoing research in the field of sustainability-focused blockchain applications. From this, we elaborate a holistic perspective by the integration of key concepts from two additional literature reviews for blockchain and PSS. As a result, we point out potential benefits and present the effect of blockchain on sustainable PSS with a product-life cycle model.

Keywords: Blockchain, Product-Service Systems, Circular Economy, Supply Chain

1 Introduction and Motivation

Circular Economy is a concept to increase the efficiency of resources and to implement sustainability in product-life cycles that will interrupt the phase of pure resource extraction, production, usage, and waste [1]. Barriers such as the customer's perception, information management, and missing performance indicators hinder a comprehensive application in businesses [2]. Hence new approaches are necessary to solve current problems in the domain of circular economy. One promising approach is the technology Blockchain. Blockchain has evolved as a capable technology to enhance information exchanges between individuals [3]. This contribution investigates how blockchain technology can improve sustainable business activities in particular regarding the circular economy.

However, in Gartner's Hype Cycle of uprising technologies, the blockchain is currently in the "trough of disillusion", expectations were thus not met [4]. From an environmental perspective, the blockchain is even more in a negative focus since it has a high demand for resources (e.g. for mining the cryptocurrency Bitcoin) [5]. The new

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

technology raises many unanswered research questions, e.g. how blockchain systems have to be designed to be sustainable itself and follow concepts like Green by IT. In contrast, a disseminated research approach is the design of product-service systems (PSS) that have an evidenced impact on sustainability [6].

Hence, we propose the integration of blockchain as a technology, i.e. as enabler, and PSS as a business strategy to create ecologic and economic sustainable offerings. Blockchain allows the independent and tamper-proof record of product-related data and the traceable accountability regarding reuse or recycling [7]. Furthermore, the enhanced transparency of product components and materials they are made of contributes to a simplified recycling process and the estimation of resource values [8]. To obtain a holistic view on the concerned fields (blockchain, PSS and sustainability, i.e. circular economy) we conducted a literature review to identify current sustainable-, product- and service-related blockchain-based use cases. In a next step, we combined our research results with blockchain [3] and sustainable PSS characteristics [6] to determine which blockchain-based use cases subject to precise blockchain characteristics and how they influence existing sustainable PSS characteristics. By doing so, we answer the following research questions:

1.) *What are current blockchain-based use cases and how do they influence sustainable PSS characteristics?*
2.) *How do blockchain-based sustainable PSS influence the use of resources and enhance the circular economy?*

By the combination, we designed a blockchain-based product-life cycle model for PSS according to Blinn et al. [9]. Thereby the model demonstrates what kind of impact the application of blockchain in PSS has onto the product-life and resource efficiency. Overall the paper contributes first proposals how blockchain and PSS can be combined to achieve sustainable potentials in the circular economy. The blockchain-based product-life cycle model can be used to redesign PSS with the application of blockchain in a more sustainable manner and to overcome barriers in the circular economy. The remainder of this article is structured as follows: Section 2 explains the applied method to streamline this research. Followed by section 3 that describes the fundamentals regarding blockchain and product-service systems. Section 4 presents the findings based on the conducted literature research and the combination of blockchain and PSS characteristics. Section 5 presents based on the literature review the blockchain-based product-life cycle model. Finally, section 6 discusses limitations and further research needs.

2 Method

In order to clarify the research questions stated above, we conducted a literature review [10] to obtain an overview of current use cases regarding the application of blockchain technology in product, service and sustainability domains. The applied literature search process (cf. figure 1) is based on Dybå and Dingsøyr [11]. We queried the scientific databases *AISeL*, *Google Scholar*, *ScienceDirect*, *SpringerLink* and *Web of Science* with the term "Blockchain" AND ("Circular Economy" OR "Supply Chain" OR "Sustainability" OR "Environment" OR "Recycling" OR "Provenance" OR "WEEE" OR "Service") and their German translations. No limitations regarding the year of publication or any other attribute were made. Initially, this brought up 2393 sources in total, from which we removed articles by title and abstract. The process revealed 51 relevant articles that were then used for an in-depth analysis. In doing so, we focused on practical use cases of blockchain technology for sustainability with particular importance on saving data of a product during its complete lifecycle, cp. Blinn et al. [9]. The findings of the remaining 22 publications were then transferred into a concept matrix according to Webster and Watson [12] (cf. figure 3).

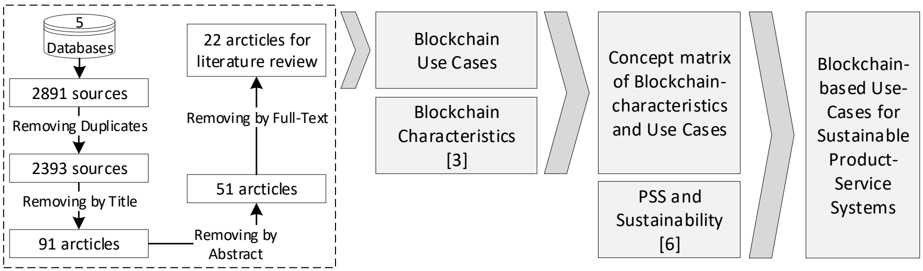

Figure 1. Literature Research Process and derived Research Outcome

The identified blockchain use cases were then combined with the blockchain characteristics examined in a literature review by Seebacher and Schüritz [3], in order to classify which blockchain-related characteristics realize the identified use cases. In a next step, the combined matrix is compared to factors of sustainability of PSS, which were analyzed by Hüer et al. [6], who also performed a literature review. The combination enables us to link all three literature reviews in an intertwined matrix (cf. figure 3) to answer what kind of blockchain-based use cases are realized by which blockchain characteristics and how they influence sustainable PSS characteristics. The related impacts on a circular economy are examined with a product-life cycle model for blockchain-based PSS (cf. figure 4) in accordance to Blinn et al. [9].

3 Fundamentals

3.1 Blockchain

We follow the Blockchain definition by Seebacher and Schürlitz for this paper [3]: “A blockchain is a distributed database, which is shared among and agreed upon a peer-to-peer network. It consists of a linked sequence of blocks, holding timestamped transactions that are secured by public-key cryptography and verified by the network community. Once an element is appended to the blockchain, it cannot be altered, turning a blockchain into an immutable record of past activity.” Thereby blockchain fundamentals are based on the whitepaper by Nakamoto [13] in 2008. In the last decade, different application areas evolved as postulated by Nofer et al. [14]. Li et al. [15] also investigate current blockchain applications within the business context with a literature review. They discovered that most blockchain-based articles focus on how the blockchain technology works and neglect to answer on what and why in terms of potential use cases and motivation factors that make blockchain favorable. Further related work that identified business application areas were contributed by Konstantinidis et al. [16] and by Witt and Richter [17] showing a high interest in practice and academic. Finally, Risius and Spohrer [18] developed a research framework for blockchain systems to guide researches and practitioners.

3.2 Product-Service Systems

PSS follow the idea of combining physical products and intangible services into one marketable bundle, which in combination serves the demand of the user [19, 20] and have a holistic view on the life-cycle of an offering, realized in an "extended value creation network" [21]. This is to be achieved by providing the right amount of product and service share (cf. figure 2) and therefore generating value for the customer, not by onetime selling a product or service solely. An example how this can be achieved is by providing the "solution" for a certain period, which leads to constant revenue for the offering company and calculable value and costs for the customer [22], e.g. by leasing a machine. Morelli [23] defines a PSS from three perspectives: First, from a traditional marketing point of view, where an entity can be reduced to its material components, to "an entity whose material component is inseparable from an immaterial one". Second, from a marketing service perspective, which shifts from "standardized services towards personalized ones". Lastly, from a product management perspective, the substitution of (physical) product shares by services and vice versa.

According to this, the "bundle" is not required to have a certain product or service share [24] and can be offered by a single company or a company-network [25]. The different shares of the components within a PSS are shown in figure 2. As one can see, the transition is fluent and Tukker [26] groups the different partitions into three core types, namely product, use, and result-oriented PSS.

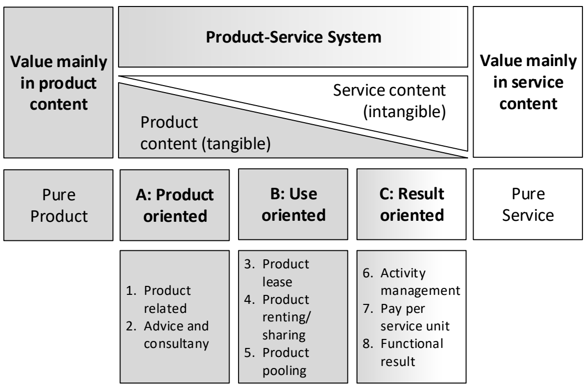

Figure 2. Product-Service System Classification according to Tukker [26]

Since PSS have a holistic view of the product itself and its life-cycle, many scientific publications examine the potentials of PSS regarding sustainability, e.g. by Tukker [26]. However, even though different PSS enabled business models, like renting or leasing, seem to have a positive influence on sustainability in the first instance, PSS are not a "sustainability panacea" [27]. Hüer et al. [6] performed a literature review on how PSS influence the sustainability and found six distinct characteristics: Substitution, Ownership, Product-Life, Cooperation, Sharing, Consumption. Though, the characteristics identified have both positive and negative influences on sustainability. Also, only a few practical methods on how to develop or use PSS in a sustainable way were proposed [6]. This circumstance is, amongst others, due to a perceived reduced user experience of PSS compared to "regular" products and the very different skills required to implement PSS. Thus, they have the potential to enable resource efficiency and ecologic sustainability, but key drivers, e.g. technologies or user experience, are missing for wide implementation.

4 Literature Review on Blockchain-based Use Cases

4.1 Classification of Blockchain-based Use Cases

We identified 22 relevant papers in our literature study, which revealed four closely related categories during their analysis. The first category contains literature that addresses the aforementioned research domain directly, referring to blockchain-based applications in the circular economy and sustainability domain. The second category consists of blockchain-based literature that focuses mainly on products while the third category relates to service and sharing economy aspects. The fourth category includes blockchain-based applications that support a tamper-proof track and traceability of supply chains to collect additional information that can lead to new services. An overview of the identified use cases, how they are realized and what kind of influence they have on PSS is shown in figure 3 and addresses the first research question.

In total 14 blockchain-based use cases are identified in the literature review which are explained in more detail in the following sections (4.2 – 4.5). Four blockchain characteristics mainly implement the identified use cases: Trust, shared and public, immutability, and decentralization. According to Seebacher and Schürlitz [3] trust is achieved amongst other blockchain characteristics principal through the tamper-proof data recording and the shared and public data transmission in a network. Decentralization is supported by the characteristics stated above and allow the creation of a network. Furthermore, decentralization enables trust with the consensus mechanism that removes the need for a trusted third-party [3].

The identified blockchain use cases have an impact on existing PSS characteristics. The concept of *substitution*, i.e. replacing products with customer-oriented services [6], is affected by new blockchain-based concepts for a sharing economy [28], [29] that allow a higher customer acceptance. Furthermore, blockchain influences the *ownership* concept. The PSS characteristic assumes that a product is designed more sustainable if the ownership belongs to the producers since they have direct incentives to create a robust product, perform maintenances and to design more recyclable products [6]. We expect a decreased influence of ownership in a sustainable PSS concept. This is justified with blockchain use cases such as product stewardship [7], [30], [31], [32], product history [30], [31], [33–36] and track and tracing systems [31], [34], [37–40] that allow a constant product traceability and a shared disclosure of product quality ensuring a permanent incentive to generate sustainable PSS without the importance of ownership. *Sharing* activities can enhance the utilization of products [6] due to simplified reselling [30], [32], [35], [41], [42] and sharing of goods [28], [29] with blockchain based on continuous tracking of the product's life and value that increases sharing activities. The *product life* is influenced by collaboration [6] and has a close relationship with the *ownership* concept. For instance, blockchain can influence collaboration with increased efficiency in the overhaul process of products with a more effortlessly access to maintenance-related data [31] or reduces adverse selection [42] and facilitate collaboration regarding the sales process. Moreover, blockchain has an impact on *consumption* by changing the customer's awareness for product quality and sustainability. Through a transparent supply chain e.g. corporate social responsibility activities can be tracked and communicated more reliably [33], [41]. Additionally, new services that are linked with the product using new information exchange and coordination mechanisms can be created [3], [43]. Overall the explicit information about the product's origin and quality lead to a higher willingness-to-pay for excellent quality products [36]. Blockchain-based supply chain management [7], [31], [40], [44–46] leads to a transparent tamper-proof product history. This can result in increased *cooperation* activities because of higher trust and shared information without the need of a third-party. In terms of PSS – cooperation has an overall positive effect on sustainability [6].

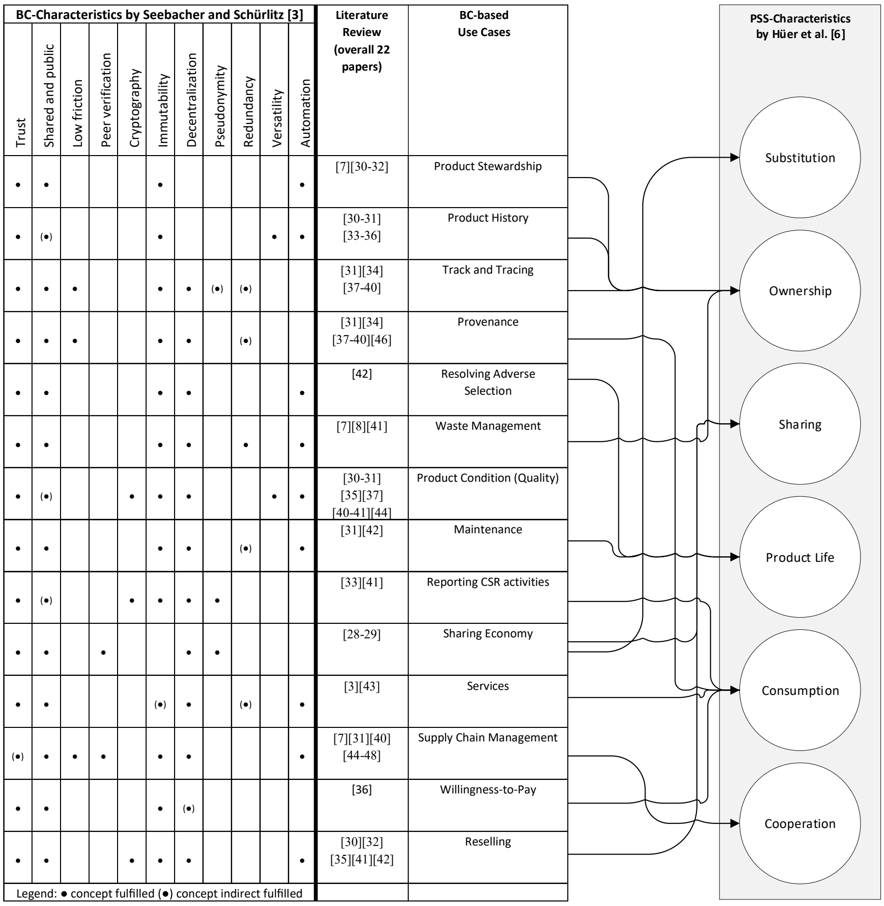

Figure 3. BC-based Use Cases realized by BC-Characteristics influencing PSS-Characteristics

4.2 Sustainability-related Blockchain-based Use Cases

Saberi et al. [7] propose a sustainable supply chain management concept that applies to electronic components which have to accomplish the Waste Electrical and Electronic Equipment Directive (WEEE Directive). They suggest blockchain as a feasible technology to effect higher product stewardship that positively affects the circular economy. In their point of view, the main benefits of blockchain are an easily accessible product history for every stakeholder in the supply chain, the tamper-proof storing of information and the resulting trust, smart contracts that enable to trace products and Internet of Things (IoT) devices that deliver reliable information gathered from the product or during processes. Ongena et al. [8] have a similar approach by working on waste management in general. They implemented a blockchain-based prototype and investigated if blockchain is a suitable technology to solve current issues in waste management. They discovered that a blockchain-based system for waste management addresses the deficits of information losses with the help of digitalization. However, they also found that blockchain-based systems solely cannot solve fraud and manipulations in waste management, due to the lack of control over the correctness of source data from other actors in the supply chain.

This shortcoming is tackled by Askoxylakis et al. [30] by using IoT devices to collect the "location, condition and availability" of assets to realize a blockchain-based system to exchange and collect the condition of assets. They propose to use these three properties to gather the value of specific assets. In addition, they suggest saving additional information that are relevant for customers into the blockchain, such as defects, maintenances or changes. In their opinion blockchain and IoT are the key drivers to enhance the circular economy with the gained data. Düring and Fishbeck [41] propose to use the blockchain and IoT components to create transparency in supply chains. Thereby, they especially mention the processes after a product is sold such as usage, reselling and recycling. Manufacturers could gain highly useful information to enhance their products with this kind of approach.

Due to e.g. the European Directive 2014/95/EU large enterprises are obligated to track their sustainability activities, also known as corporate social responsibilities (CSR), and publish an annual report [47]. Given that smaller companies are the contractor of obligated firms and perform services within the supply chain, they are indirectly concerned as well and have to provide information about their activities, too. Thereby, the challenge arises that firms often can only control and gain information from their direct corporate partners, which prevents a completely transparent supply chain. Schwarzkopf et al. [33] recommend using blockchain technology to comply with the legislative requirements to create a transparent supply chain that delivers extended information from all companies affected in the supply chain that exceed information from direct suppliers.

4.3 Product-related Blockchain-based Use Cases

One widespread proposed application area for blockchain-based systems is to track and trace food and deliver provenance data for customers such as in [34], [37–40]. For instance, in a study by IBM [34], two blockchain-based food traceability systems for pork and mangos were developed. Such systems should hinder food scandals and create trust in food products. Further, a retailer, in this case Walmart, can deliver additional services to their customers that create a competitive advantage.

Tian [37] conceptualizes a blockchain-based framework for an agri-food supply chain traceability system where Radio Frequency Identification (RFID) realizes the track and traceability system. This blockchain approach has several advantages compared to a centralized system combined with RFID. Firstly, due to the blockchain's decentralization every authorized actor in the supply chain can read and save data which creates higher flexibility to include new actors. Secondly, the decentralization of the blockchain leads technically to a non-existence of institutions, e.g. government departments or companies, and as a result no frauds or corruptions can happen. Thirdly, tracked and traced foods that have a unique ID in the RFID system can be used to protect against imitations. A similar approach like in [37] suggests Biswas et al. [39]

for a wine supply chain traceability system. Mentionable is that they identified mostly the same reasons for the implementation of a blockchain-based system to prevent imitations, food chemicals and in general bad handling of the products.

Besides food, the automotive industry is another suitable application area for blockchain-based systems. Notheisen et al. [42] developed a system to trade cars on the blockchain, more precisely they choose the domain of the Danish Motor Register. The solution tries to stop the adverse selection effect for used cars by recording the history of the vehicles. Moreover, it aims to replace today's institutional centralized registers with a decentralized autonomous system. A slightly different use case present Hua et al. [35], who implemented a blockchain-based system to track the status of batteries in electric vehicles to enable a battery swapping mode that allows a fast battery "refueling". In this concept trust regarding the battery's status and history is essential. According to Hua et al. [35] blockchain is appropriate to create the necessary trust between the electronic vehicle driver and the battery swapping provider. In addition, it allows correct billing due to the record of both batteries.

Another field of application, which has an interest in blockchain technology is the aviation industry. The supply chain in this industry is complex due to globally widespread assembly hubs. Further, systematic capturing of the condition and lifetime expectations from the observed parts is beneficial when scheduling airplane maintenance or overhaul. Besides a transparent supply chain, blockchain leads to a proper monitoring and prevents black market [31]. Also, Toyoda et al. [32] encountered imitations with their conceptualized and implemented "Product Ownership Management System (POMS)" that is based on blockchain and specially designed for processes after the first sale e.g. reselling. Marfia and Esposti [36] suggest using blockchain technology and sensors to elicit the quality of products for customers. The system should replace vulnerable certification systems and increase or stabilize the customer's willingness-to-pay. As a result, reshoring activities of businesses should grow because the customer can gain transparency and evidence regarding excellent quality.

4.4 Service and Sharing Economy-related Blockchain-based Use Cases

Although the aforementioned blockchain applications have a product-centric focus, they allow offering special services that are related to the product. Seebacher and Schürtz [3] carried out a systematic literature review to investigate the applicability of blockchain for service systems and found a high impact of blockchain to service systems. In their point of view, the blockchain characteristics such as trusted environment and decentralization are especially suitable to improve service systems. Hans et al. [43] focus in their study on insurances: One application area is to enhance the contract management for catastrophe swaps (CAT swaps) in the domain of natural catastrophe insurances. Smart contracts and the underlying blockchain technology can represent CAT swaps and trigger specific processes if the negotiated conditions are fulfilled. The second use case is within day-based insurances that can be requested for special circumstances e.g. time-based flight insurance against delayed or canceled flights. A sharing economy relies on information exchanges, Pazaitis et al. [28]

developed the framework named Backfeed that uses blockchain to realize decentralized cooperation. Thereby the framework addresses a more efficient approach for value exchanges in the sharing economy. Hawlitschek et al. [29] explore the effects of blockchain in the sharing economy, too. They discovered the challenges that arise with their implementation. Despite blockchain technology should deliver trust-free systems – the concept is not fully applicable within the sharing economy. A shift from trust in institutions into trust in algorithms was observed. Additionally, in their point of view trust build upon technology is not sufficient and therefore propose a supplementary feedback system.

4.5 Supply Chain-related Blockchain-based Use Cases

In a Delphi study, White [44] figured out that supply chain management systems and independent certification of product quality are possible blockchain-based applications in the future. Overall, the use case of supply chain management systems based on blockchain is evaluated with four of the most probable application scenarios with the highest impact in their Delphi study. Korpela et al. [45] investigate the application of blockchain into supply chains. In focus groups with business experts they elicit requirements and evaluate the applicability of blockchain within digital supply chains. They discovered that several of today's unsolved business requirements e.g. to accelerate digital supply chains could be met by blockchain technology. In a consortium research project, Sternberg and Baruffaldi [46] conceptualized and developed the ReLog concept that saves supply chain information into the Blockchain and thereby collects data along the value chain. Kim and Laskowski [38] try to enhance the specification of blockchain-based applications with ontologies. A formal ontology is used for the design of the blockchain and smart contracts. They developed a proof-of-concept in the domain of supply chains to realize traceability for products.

5 Blockchain-based Use Cases for Sustainable Product-Service Systems

We address the second research question with a product-life cycle model in accordance to Blinn et al. [9] to illustrate the impact of the blockchain technology. The presented blockchain-based product-life cycle model (cf. figure 4) is based on the identified blockchain-based use cases (cf. section 4) and explains the influence of blockchain on product consumption and recycling activities. Hence the model explains what kind of blockchain use cases cause sustainable effects on PSS. The product-life cycle is divided on the horizontal axis into RFID/IoT supply chain and post supply chain according to Toyoda et al. [32]. Thus the switch occurs when the product is first sold. On the vertical axis, the lower quadrants illustrate efforts to implement blockchain with track and tracing systems, e.g. RFID or IoT and to realize PSS. The upper quadrants constitute the perceived value of the entire solution, i.e. the blockchain system in combination with PSS. Due to the application of blockchain, inherent effects will be achieved that have an impact on PSS usage. In the process, the perceived PSS value will be stretched and increased by the application of blockchain, which results in an improved resource efficiency that supports the circular economy. The following concepts influence the graph of the perceived value:

A) *Provenance and Product History:* The perceived value of products and services will be increased because the customer's retrieve transparent information about the product assuming that the declared product quality will be reflected in the data. The provision of information reduces information asymmetry and returns trust in products that got lost in the past e.g. in the food industry [34], [39]. Furthermore, it prevents black market [31] and thereby reduces potential customer's distrust again. Overall to provide information about the origin of the product results in a higher willingness-to-pay for high-quality products [36].

B) *Life Time Expiration:* The lifetime of PSS will be stretched. Within reselling or sharing activities, we assume that no decrease of the perceived PSS value will take place. This can be explained by transparency and information exchange that reduces adverse selection [42] when products are resold or to track the estimated consumption when products are shared [35]. Further, the provision of information for maintenance [31] which is also imaginable for self-service and smart contracts that extends guarantees [43] can stretch the product lifetime.

C) *Waste Management:* The recycling phase occurred as a result of decreased perceived value during the lifetime due to consumption, aging or abrasion and the perceived PSS value is almost equal to the material value. Especially for complex PSS blockchain can support the waste management process [8] and ensure a higher probability to reuse product components [7]. Furthermore, product stewardship will increase because of information transparency, i.e. collecting historical data, that results in the design of more recyclable products.

D) *Track and Tracing Supply Chain:* The overall track and tracing of products in the supply chain will decrease frauds [31] and bad behavior [39] in PSS. In contrast, we expect a higher probability of good behavior and extra efforts to ensure high-quality outcomes.

E) *Data Analysis for Product Design:* The collected product-life cycle data can be used during the product design phase to receive new insights and to create more durable and sustainable PSS [31], [41].

6 Limitations, Further Research, and Conclusion

6.1 Limitations and Further Research

We are aware of the limitations in our research. Therefore, we mention further research topics to overcome the existing limitations. The paper contributes an initial step and combines the three subjects blockchain, PSS and circular economy. Thereby, one limitation is that the findings are mainly based on academic contributions and theoretical assumptions. These expectations have to be validated with further research that is focusing on practical evidence and implementation. Further, the identified blockchain use cases resulting from different domains. Therefore, it is questionable if all use cases can affect each PSS in the same way, i.e. the limitation is an abstract perspective. Furthermore, the developed blockchain-based product-life cycle model is based on scientific literature but was conceptualized in a subjective view by the authors. However, the model serves to understand the different impacts of blockchain on the product-life cycle and how technology enhances resource utilization related to the circular economy. Future long-term studies (5 – 10 years) have to investigate each mentioned impact with practical blockchain implementations. During the studies, additional requirements from practitioners ought to be included and the existing list of blockchain-based use cases should be extended and prioritized. Additionally, investigations have to be made regarding the feasibility – not every product category is suitable to record the product-life cycle and estimated costs have to be relatively low. For instance, Toyoda et al. [32] assumes 1$ for six transfer actions with their blockchain solution and suggest to apply products above 100$. Finally, deeper research how blockchain, IoT, PSS, and circular economy relate together should be conducted.

6.2 Conclusion

The circular economy faces different implementation barriers [2]. We address these obstacles with the combination of blockchain and PSS. Thereby blockchain-based advances such as trust, information exchange, and immutability enable new potentials to solve current issues in the circular economy domain. PSS serves as the application area due to already proven positive effects on sustainability [6]. Based on a conducted literature review we identified 14 unique blockchain-based use cases that have a sustainable effect on PSS that are related to the circular economy. Hence, the paper presents for the first time to the best of our knowledge a holistic view on blockchain, PSS and circular economy.

The evolved blockchain-based product-life cycle model in consideration of perceived value illustrates the positive impact of blockchain on resource utilization. In addition, the model explains how a more effective information provision by blockchain cause a higher perceived value of products and services during the whole product life for society, which results in improved resource utilization and a realization of the circular economy. Thus, the paper contributes new insights how blockchain can be used to gain ecological and economic benefits through a new digital technology.

7 Acknowledgements

This research is partly funded by the European Regional Development Fund and the State of Lower Saxony (NBank) in the scope of the research project SmartHybrid – Service Engineering (ID: 6-85003236). We would like to thank them for their support.

Abstract. Die Globalisierung führt zu immer komplexeren, für die Einzelnen kaum nachvollziehbaren Wertschöpfungsketten in der Lebensmittelindustrie. Zugleich eröffnet die Digitalisierung neue Möglichkeiten, Informationen entlang der Kette zu sammeln, und so mehr Transparenz und Vertrauen für den Verbraucher beziehungsweise die Verbraucherin zu schaffen. Jedoch finden Verbraucherinformations-Apps wie *fTRACE* bisher nur eine geringe Verbreitung. Daher haben wir in einer qualitativen Studie mit 16 Teilnehmer/-innen Bedürfnisse und Nutzungshürden von Verbraucher/-innen im Zusammenhang mit Verbraucherinformations-Apps analysiert. Es zeigt sich, dass das Vertrauen in die Informationen, sowie der einfache Zugang dazu für Verbraucher/-innen zentral sind. Durch die gut sichtbare Bereitstellung der Informationen am Point-of-Sale, sowie der automatisierten Informationsversorgung z. B. mittels digitaler Kassenzettel in Kombination mit weiteren Verbraucher-Services kann die Bekanntheit und Akzeptanz von Rückverfolgbarkeitssystemen weiter gesteigert werden.

Keywords: Traceability, Lebensmittelindustrie, Supply Chain Management, Verbraucherinformatik.

1 Einleitung

Durch die komplexer werdenden Wertschöpfungsnetzwerke einer globalisierten Nahrungsproduktion und -distribution, das Aufkommen genetisch veränderter Organismen (GVO), sowie wiederkehrende Lebensmittelskandale (BSE, „Gammelfleisch“, Pferdefleisch in als Rindfleischprodukten deklarierten Lebensmitteln, etc.) steigt die Nachfrage nach einer besser nachprüfbaren Qualität und Sicherheit von Lebensmitteln. Insbesondere bei tierischen Produkten ist das Wissen um eine tiergerechte Haltung, saubere Verarbeitung und Frische zu einem wichtigen Kaufkriterium für Verbraucher/-innen geworden. Um dem Wunsch der Verbraucher/-innen nach einer gleichbleibenden Versorgung mit hochwertigen, sicheren und nährstoffreichen Lebensmitteln gerecht zu

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

werden, sowie für den Wiederaufbau von Vertrauen der Öffentlichkeit in die Nahrungsmittelkette, bedarf es der Gestaltung und Umsetzung vollständig rückwärts und vorwärts verfolgbarer Lieferketten vom Erzeuger bis zum/zur Verbraucher/-in. In den letzten Jahren wurden zunehmend digitalisierte Rückverfolgbarkeitssysteme in der Lieferkette der Lebensmittel- und Agrarwirtschaft etabliert [1]. Während diese im Business-to-Business Bereich relativ gut erforscht wurden [2, 3], gibt es bisher kaum Studien zur „letzten Meile" hin zum/zur Endverbraucher/-in. Der vorliegende Beitrag analysiert deshalb die Bedarfe, die Nutzung und Akzeptanz von Rückverfolgbarkeitssystemen aus Verbrauchersicht. Hierzu stellen wir in unserem Beitrag den aktuellen Forschungsstand und die Ergebnisse einer qualitativen Studie vor, die Bedarfe und Nutzungshürden von Verbraucher/-innen auf Basis des Systems *fTRACE* analysiert, um daraus Anforderungen zur Verbesserung der Rückverfolgbarkeit aus Verbrauchersicht zu erarbeiten.

2 Rückverfolgbarkeit von Lebensmitteln

Die von Endverbraucher/-innen konsumierten Lebensmittel sind das Ergebnis eines langen Produktionsprozesses, der über mehrere Wertschöpfungsstufen verläuft [2]. Rückverfolgbarkeit meint dabei die Fähigkeit, Ereignisse in allen Stufen einer Prozesskette chronologisch zu erfassen und zu überprüfen [4]. Nach der EU Verordnung 178/2002 umfasst dies bei Lebensmitteln alle Produktions-, Verarbeitungs- und Vertriebsstufen [5].

Ziele der Rückverfolgbarkeit sind u. a. die Optimierung von Produktions- und Logistikprozessen, die Verbesserung der Lebensmittelsicherheit, die Ursachenforschung z. B. bei Verkeimung, sowie die Ermöglichung eines Rückrufs von bestimmten Produktchargen [1, 3, 6–8]. In einer Literaturübersicht haben Karlsen et al. [9] weitere Treiber zur Umsetzung von Rückverfolgbarkeitssystemen identifiziert, wie rechtliche Anforderungen, Nachhaltigkeitsanforderungen, Zertifizierungsanforderungen, Erlangung eines Wettbewerbsvorteils oder Schutz vor biologischen Anschlägen. Verschiedene Studien belegen, dass eine Reihe von Faktoren bei der Umsetzung eine Rolle spielen. Eine hohe Herausforderung besteht dabei in der Komplexität von Wertschöpfungsnetzwerken [4]. Dabei sind Kosten und Nutzen von Rückverfolgbarkeitssystemen in der Wertschöpfungsketten nicht immer gleich verteilt [9]. Die Motivation zur Einführung bzw. Teilnahme an einem Rückverfolgbarkeitssystem ist daher eng verbunden mit der Identifizierung individueller Kosten- und Nutzenfaktoren bei den einzelnen Akteuren innerhalb der Wertschöpfungskette [10]. Rückverfolgbarkeit ist deshalb vor allem eine verteilte Managementaufgabe, bei der die Aktivitäten verschiedener Akteure koordiniert werden müssen [2, 8, 9].

Zentral für die Implementierung einer Rückverfolgbarkeit ist eine effektive und effiziente Informationslogistik, da vollständige Informationen über Prozessketten notwendig sind, um einerseits die Einhaltung der Spezifikationen zu überprüfen, und andererseits die Ursachen von Ausfällen und unerwünschten Ereignissen zu identifizieren [3]. Verschiedene Autoren sehen dabei die Digitalisierung als Kernelement für die signifikante Verbesserung der Rückverfolgbarkeit von Produkten [3, 11, 12]. Im Wesentlichen basieren Rückverfolgbarkeitssysteme technisch auf vier Säulen [3]: 1) Merkmale zur eindeutigen Produktidentifikation, 2) Daten zur Rückverfolgbarkeit entlang von Wertschöpfungsketten, 3) Unterstützung von Produktrouting und 4) Werkzeuge und Standards zur Rückverfolgung.

In der Industrie haben vor allem die Standards der GS1 (Global Standards One) eine weite Verbreitung gefunden [13–15]. Zur Synchronisation von Stammdaten über die einzelnen Stufen der Wertschöpfungskette gibt es z. B. das Global Data Synchronisation Network (GDSN), welches den automatischen elektronischen Austausch von standardisierten Produktinformationen zwischen Handelspartnern ermöglicht. Mittels Electronic Data Interchange (EDI) können elektronische Transaktionsdaten zwischen Handelspartnern ausgetauscht werden. Hierfür werden die Informationen aus dem Warenwirtschaftssystem vor der Übertragung in ein Standardformat (GS1 XML, EANCOM) konvertiert [13]. Um die Rückverfolgbarkeit von Produkten und Transparenz über die gesamte Lieferkette hinweg gewährleisten zu können, sind dabei insbesondere Ereignisdaten hochrelevant. Diese fallen bei der Auslösung bestimmter Prozesse an, wie beispielsweise der Auslieferung durch einen Logistikdienstleister. Durch die Aufzeichnung von Ereignissen wird die detaillierte Verfolgung von Prozessen in Echtzeit ermöglicht. Die erfassten Ereignisdaten können dann mithilfe des Schnittstellenstandards EPCIS (Electronic Product Code Information Service) verarbeitet und weitergeleitet werden [13].

2.1 Verbraucherinformationen

Die einfache Verfügbarkeit vertrauenswürdiger Verbraucherinformationen stellt eine wesentliche Säule des Verbraucherschutzes dar [16]. Der besondere Schutzbedarf findet seinen Niederschlag z. B. in diversen Verbraucherschutzgesetzen und -verordnungen, wie z. B. der EU-Verordnung Nr. 1169/2011 zur Kennzeichnung von Lebensmitteln. Die Informationen stammen entweder freiwillig oder gesetzlich verpflichtend vom Hersteller, sowie von Verbraucherinstitutionen und Verbrauchermedien.

Die Informationen lassen sich in Bezug auf ihre Eigenschaften wie folgt unterscheiden [16, 17]: 1. *Suchinformationen*, die der/die Käufer/-in vor dem Erwerb eines Produkts durch die eigene Wahrnehmung identifizieren und beurteilen kann; 2. *Erfahrungsinformationen,* die erst durch den Gebrauch eines Produkts nach dem Kauf beurteilt werden können; 3. *Vertrauensinformationen*, die nur langfristig nach dem Kauf eines Produktes beurteilt werden können. Der Käufer oder die Käuferin muss hier darauf vertrauen, dass ein Produkt tatsächlich die gewünschten Eigenschaften erfüllt. Bei der Rückverfolgbarkeit handelt es sich meist um Vertrauensinformationen, da die gesammelten Informationen entlang der Produktions-, Verarbeitungs- und Vertriebsstufen vom Verbraucher beziehungsweise der Verbraucherin selbst nicht überprüft werden können. Hierdurch steigen die Anreize für opportunistisches Verhalten auf Anbieterseite, da bei zunehmender Informationsasymmetrie die Wahrscheinlichkeit von unbeobachteten Qualitätsverschlechterungen steigt.

Verschiedene Studien haben die positive Wirkung von Verbraucherinformationen auf das Verbraucherverhalten gezeigt, insbesondere beim Thema Food Labels [18]. Die Nutzung und das Verständnis von Food Labels hängt jedoch von einer Reihe soziodemographischer Faktoren wie Alter, Einkommen, Bildung und Lebensstil ab [19]. Ferner zeigen Studien dass Verbraucherinformationen zum Teil falsch interpretiert werden, zu komplex sind bzw. darunter leiden, dass sie für Nicht-Experten konzipiert wurden [18, 20]. Hinzu kommt, dass Lebensmittel ein vielschichtiges Qualitätsbündel bestehend aus einer ganzen Reihe von Teileigenschaften darstellen.

Aus Verbrauchersicht sind diese einzelnen Eigenschaften oft nur schwierig oder gar nicht überprüfbar. Daher besteht die Gefahr, dass Verbraucher/-innen durch die Aufmachung der Produkte oder durch Werbung in Bezug auf die tatsächlichen Eigenschaften getäuscht werden [21]. Die Zunahme an Informationen führt deshalb nicht automatisch dazu, dass Verbraucher/-innen besser informiert sind [22]. Bei der Gestaltung von Verbraucherinformationen gilt es deshalb, das Ziel objektiver und vertrauenswürdiger Informationen mit dem Ziel leicht verständlicher, ästhetisch-emotional ansprechender und handlungsorientierter Informationen aus Verbrauchersicht in Einklang zu bringen [23].

2.2 Verbraucher-Apps zur Rückverfolgbarkeit

Der wichtigste Informationskanal für Verbraucher/-innen ist nach wie vor die Kennzeichnung auf Lebensmittelverpackungen, während z. B. die von Behörden bereitgestellten Informationen sowie Beratungsmöglichkeiten im Handel kaum genutzt werden [16]. Darüber hinaus gewannen digitale Verbraucherinformationen wie z. B. Preis- und Vergleichsportale in den letzten Jahren an Bedeutung [24].

Die steigende Verbreitung von Smartphones erlaubt dabei die Entwicklung mobil nutzbarer Verbraucherinformationssysteme (VIS) zur Abfrage von Lebensmittelinformationen [25]. So haben etwa González-Miranda et al. [26] einen VIS-Prototypen vorgestellt, der Kundenprofile nutzt, um passgenauere Verbraucherinformationen zur Verfügung zu stellen. Das Konzept my2cents der ETH Zürich stellt eine mobile VIS-Anwendung dar, bei der Verbraucher/-innen den Barcode einscannen können, um Kommentare und Meinungen zu Produkten teilen zu können [27]. Stevens et al. [28, 29] stellen ein Konzept eines digitalen Kassenzettels vor, mittels dessen Verbraucher/-innen kontextspezifische, sowie aggregierte Informationen zum Einkauf bekommen können. Ozarslan und Eren stellen ein kontextbasiertes VIS-Konzept vor, das Verbraucher/-innen entlang des Entscheidungsprozesses vor, während und nach dem Kauf unterstützen soll [30]. Diese Ansätze unterstützen bisher jedoch noch nicht die Rückverfolgbarkeit von Lebensmitteln.

Daneben gibt es eine Reihe kommerzieller Lösungen, wie z. B. die App barcoo oder Codecheck, bei der der Nutzer oder die Nutzerin den Barcode eines Produkts einscannt, um Informationen zu Inhaltsstoffen, Lebensmittel-Ampeln, Preisvergleiche, sowie Testberichte und Nutzerrezensionen angezeigt zu bekommen. Einen etwas anderen Ansatz hat die Web-Plattform WikiProducts, die ein offenes, nicht moderiertes Forum bietet, in welchem Informationen zu Produkten gesammelt und strukturiert werden. Neben Verbraucher/-innen, Herstellern und Händlern zählen auch Universitäten und nichtstaatliche Organisationen (NGOs) zu den beteiligten Akteuren. Die genannten Lösungen unterstützen bisher jedoch ebenfalls nicht die digitale Rückverfolgung von Produkten, insbesondere von Lebensmitteln.

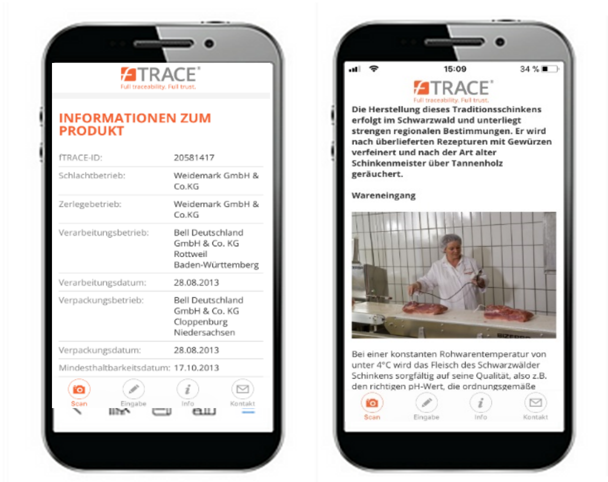

Abbildung 1: Screenshot der Rückverfolgbarkeits-App *fTRACE*

Einen Ansatz für Rückverfolgung bietet derzeit vor allem die cloudbasierte Traceability-Plattform *fTRACE*, die technisch auf den oben skizzierten Standards der GS1 aufsetzt [31]. Die Verbraucher/-innen können mit der *fTRACE* App den auf der Verpackung angebrachten QR-Code (in den DataMatrix, d. h. GTIN, Chargennummer plus Zusatzangaben kodiert ist) einscannen, um Informationen zum Produkt abzurufen (vgl. Abbildung 1). Die Daten zur Herkunft, Verarbeitung und Produktqualität werden dabei aus erster Hand von Herstellern und Händlern bereitgestellt, welche auf diesem Weg auch häufig freiwillige Informationen zur Qualitätsüberwachung oder Rezepttipps zu ihren Produkten anbieten.

3 Methodik

Um die Bedarfe von Verbraucher/-innen und die Kontexte zur Nutzung von Werkzeugen zur digitalen Rückverfolgbarkeit von Lebensmitteln genauer zu verstehen, haben wir 16 problemzentrierte Interviews durchgeführt [32]. Teilnehmer/-innen wurden nach dem Schneeballsystem ausgewählt (Alter: 17 - 59, Ø: 34,4; männlich: 9, weiblich: 7; 9 Berufstätige, 6 Studierende, 1 Schüler). Die durchschnittliche Länge der Interviews betrug 23 Minuten. Zwölf Interviews wurden zur Auswertung vollständig transkribiert, in vier Fällen wurde das Gespräch aus technischen oder persönlichen Gründen der Teilnehmer/-innen nicht aufgezeichnet und stattdessen ein ausführliches Feldprotokoll angefertigt.

Die Struktur der Interviews war zweigeteilt: Im ersten Teil wurden die Teilnehmer/-innen anhand eines offenen Gesprächsleitfadens zu ihrem Einkaufsverhalten, ihrem Umgang mit Verbraucherinformationen und zum Konzept der digitalen Rückverfolgbarkeit von Lebensmitteln befragt. Die Interviewsituation hatte dabei einen offenen Charakter, um so den Teilnehmer/-innen Raum für das Äußern eigener Begründungen und Meinungen zu geben. Teilweise wurde das Gespräch jedoch wieder auf die zugrundeliegende Problemstellung zurückgeführt, um eine Strukturierung zu erzielen.

Im zweiten Teil der Studie wurde die oben beschriebene führende Rückverfolgbarkeits-App *fTRACE* im Sinne eines Design Probe genutzt, um durch die Nutzung der App konkrete Gestaltungsprobleme zu identifizieren, aber insbesondere die Reflektion über Bedarfe und potentielle Nutzungskontexte anzuregen [33]. Hierzu wurde die Verpackung eines typischen Beispielprodukts zur Verfügung gestellt, welche mit der App eingescannt werden konnte. Aufgrund der Homogenität der durch die App abgedeckten Produktpalette und um die Interviews nicht zu sehr in die Länge zu ziehen, wurde auf einen Vergleich mehrerer Produkte verzichtet. Stattdessen wurde die Interaktion mit dem Beispielprodukt tiefergehend untersucht. So sollten die Befragten ihre Eindrücke zu den angezeigten Informationen, der Gestaltung und der Bedienung der App detailliert im Sinne von „Thinking Aloud" schildern. Abschließend erfolgte eine Diskussion in Bezug auf deren praktische Nutzbarkeit bzw. erwünschte Verbesserungen und Ergänzungen.

Die Transkripte und Feldprotokolle wurden kodiert und hieraus übergeordnete Kategorien abgeleitet. Die Analyse fußte auf der Annahme der konstruktivistischen Grounded Theory [34], dass die Interviews und das hierauf aufbauende Kategoriensystem eine gegenseitige Leistung und Interpretation des Interviewers und des Interviewten darstellen. Zum Aufbau des Kategoriensystems wurden die Textabschnitte relevanten Kategorien zugeordnet, die bei der Vorbereitung der Studie identifiziert wurden und auch im Gesprächsleitfaden ihren Niederschlag gefunden haben. Im Rahmen der Analyse wurde das System iterativ erweitert und angepasst, um so den Sichtweisen der Interviewten besser gerecht zu werden.

Bei der Analyse des ersten Teils der Studie wurde zunächst der allgemeine Umgang der befragten Personen mit Verbraucherinformationen (bezüglich Lebensmitteln) betrachtet. Eine zentrale Kategorie war hier generelles Vertrauen in digitale Informationen, da dies für die Studie eine zentrale Rolle spielte. Weitere zentrale Kategorien waren erwartete Effekte (wie etwa weniger Lebensmittelverschwendung) sowie die generelle Einstellung der befragten Personen zur Rückverfolgbarkeit von Lebensmitteln.

Für den zweiten Teil der Studie wurden die Erwartungen der Befragten vor der Nutzung der App reflektiert. Relevante Kategorien waren hier die Bewertung der angezeigten Informationen und der mögliche Nutzungskontext der Anwendung, sowie die Zufriedenheit mit der Darstellung und Bedienung. Die letzte Kategorie umfasste Aussagen dazu, welche zusätzlichen Funktionen und Mehrwertdienste die Teilnehmer/-innen im Zusammenhang mit entsprechenden Systemen für sinnvoll hielten.

4 Ergebnisse

4.1 Allgemeines Interesse, jedoch geringer Bekanntheits- und Nutzungsgrad

Generell fanden zwölf der 16 Teilnehmer/-innen das Konzept der Rückverfolgbarkeit von Lebensmitteln gut und hilfreich, auch wenn zehn davon beim Einkauf nach eigenen

Angaben bisher nicht explizit auf diese Möglichkeit geachtet haben. Auch die vier Befragten, denen die Möglichkeit der Rückverfolgbarkeit tendenziell nicht so wichtig war, sahen durchaus Vorteile, beispielsweise, dass insgesamt ein besseres Bewusstsein für Lebensmittel und deren Herstellung geschaffen werden könnte. Von vier Teilnehmer/-innen wurde sogar der Wunsch geäußert, dass eine digitale lückenlose Rückverfolgbarkeit generell möglich sein sollte und in gewisser Hinsicht ein Recht des/der Verbraucher/-in darstellt:

> *„Ich find' das sollte eigentlich Standard sein, dass das lückenlos der Verbraucher, wenn er das möchte, abrufen kann. Grade wenn er irgendwelche Bedenken hat, dass er da Schritt für Schritt nachverfolgen kann." (I1, 56, Angestellte im öffentlichen Dienst)*

> *„Fleisch ist da doch wahrscheinlich das Paradebeispiel. Da würd' ich's wissen wollen. Da find' ich, hab' ich ,nen Recht drauf, zu erfahren, wie, wo, was mit dem Tier passiert." (I4, 23, Maschinenbau-Studentin)*

Es zeigte sich, dass der Wunsch nach Rückverfolgbarkeit bei tierischen Produkten, vor allem bei Fleisch und anderen leicht verderblichen Lebensmitteln besonders hoch (13-mal) war. Ebenfalls ausgeprägt (6-mal) war der Wunsch nach einer besseren Nachvollziehbarkeit von im Ausland hergestellten oder verarbeiteten Lebensmitteln, um die wahrgenommenen Unsicherheiten bezüglich solcher Produkte zu mindern.

In den Interviews zeigte sich ferner eine große Diskrepanz zwischen Interesse und tatsächlicher Nutzung der digitalen Rückverfolgbarkeit. Insgesamt war das Wissen zu Möglichkeiten digitaler Rückverfolgbarkeit bei den Verbraucher/-innen eher vage. Selbst die zehn Nutzer/-innen, die davon schon einmal gehört hatten, wussten oft nur, dass bei manchen Produkten Informationen durch das Scannen eines QR-Codes angezeigt werden können. Genutzt hatte diese Möglichkeit jedoch bisher keine/-r der Teilnehmer/-innen:

> *„Davor war's mir nicht bekannt. Also ich wusste, dass es sowas in der Art gibt, aber ich wusste auch nicht, dass zum Beispiel das schon bei großen Supermarktketten wirklich vorhanden ist, sondern ich dacht' das wären halt so kleine Versuchsobjekte, wo man das mal ausprobiert hat." (I5, 21, Maschinenbau-Studentin)*

Die in unserer Studie exemplarisch genutzte App *fTRACE* kannte vor der Befragung keine/-r der befragten Verbraucher/-innen. Diese Unkenntnis der existierenden Möglichkeiten führte unter anderem auch dazu, dass Verbraucher/-innen im ersten Teil der Interviews wiederholt Wünsche nach Innovationen äußerten, die bereits von verfügbaren Apps wie *fTRACE* oder *barcoo* angeboten werden:

> *„Da es im Moment praktisch nicht verfügbar ist, wär das natürlich super, wenn's da ein System geben würde, das grade über Scan von einem Code, eben alle Informationen zu dem Produkt zur Verfügung stellt." (I7, 59, Ingenieur)*

Nachdem die Befragten im Interview auf *fTRACE* aufmerksam gemacht wurden, waren 13 der 16 Teilnehmer/-innen positiv überrascht von der Existenz dieses Werkzeugs. Der geringe Nutzungsgrad hängt demnach vor allem mit dem geringen Bekanntheitsgrad solcher Apps zusammen.

„Also (…) ohne die Befragung hätte es wahrscheinlich noch lange gedauert, bis ich auf die App jetzt vielleicht gestoßen wär'. (…) Also ich glaub' das ist noch nicht so in der Bevölkerung oder in der Öffentlichkeit so richtig angekommen, aber ich fänd's toll, wenn das irgendwie mehr beworben wird und (…) wenn man da halt mehr Zugang zu hätte einfach." (I9, 25, VWL-Student)

An dem Zitat zeigt sich auch die wiederholt geäußerte Kritik an der Lebensmittelindustrie und den Verbraucherorganisationen, bisher das Konzept digitaler Rückverfolgung nicht ausreichend gegenüber den Verbraucher/-innen zu kommunizieren. Hierzu trüge auch bei, dass das *fTRACE*-Logo auf Produkten beim Einkauf nicht groß auffällt und man auch nicht durch andere Hinweise darauf gestoßen wird.

„War mir nicht bekannt, nein. Weil ich auch in den Supermärkten vorab keine Informationen über ähnliche oder andere Systeme direkt am POS [Anm. d. Verf.: Point-of-Sale, d. h. am Verkaufsort] finde." (I12, 34, Logistikplaner)

Hier zeigt unsere Studie ein deutliches Potential einer besseren Sichtbarkeit der verfügbaren Informationssysteme auf den Verpackungen bzw. im Handel.

4.2 Informationsbedarfe, -angebote und -darstellung

Die Bedienung, der Informationsumfang und die Darstellung der getesteten Version der *fTRACE* App (siehe Screenshot Abbildung 1) wurde von zwölf der befragten Teilnehmer/-innen in weiten Teilen gelobt, da die von den Teilnehmer/-innen gewünschten wichtigen Informationen überwiegend vorhanden und übersichtlich gestaltet waren. Vier Befragte fanden allerdings, dass z. B. die Herstellungsangaben zu wenig detailliert und daher nur begrenzt informativ seien. Die Bedienung und Navigation wurde von 13 Teilnehmer/-innen als einfach und intuitiv empfunden. Hierzu trug auch die Scan-Funktion bei. Sie erlaubte den Teilnehmer/-innen, ohne hohen Aufwand Informationen zu einem Produkt abzurufen. Jedoch wurde hier bemängelt, dass man teilweise z. B. beim Wechseln des Reiters ein Produkt mehrfach einscannen musste, bevor es funktionierte.
Bei den Informationsbedarfen äußerten die Befragten im ersten Teil des Interviews, dass sie sich für Herkunft, Tierhaltung, Transport und die Verwendung schädlicher Stoffe interessierten. Sie interessierten sich ebenfalls für eine Möglichkeit zur Rückverfolgung, um die Frische der Produkte besser überprüfen zu können, da dies bisher als eher schwierig empfunden wurde.

„(…) bei Geflügelprodukten, weil da das Thema antibiotischer Einsatz in der Zucht, beziehungsweise die Art der Haltung für mich schon 'nen großen Stellenwert hat, ob ich 'nen Produkt kaufe oder nicht. Zumindest hätte ich gerne umfangreiche Informationen darüber." (I12, 34, Logistikplaner)

Die bereitgestellten Informationstexte wurden von 13 der Befragten als gut verständlich und auch die Einteilung als hilfreich bewertet. Von vier Teilnehmer/-innen wurde jedoch angemerkt, dass die Darstellung zur Produktqualität als zu textreich empfunden wird. Hier wurde z. B. von einem Befragten vorgeschlagen, erst einmal nur eine stichpunktartige Übersicht anzuzeigen. Diese sollte Verweise zu weiteren Quellen beinhalten, um sich bei Bedarf genauer informieren zu können. Ferner wurde aussagekräftiges Bild- und Videomaterial z. B. zu Herstellungsbetrieben gewünscht.

Beim Informationsumfang äußerten sich zehn der Teilnehmer/-innen positiv überrascht, wie umfangreich die Informationen zu den Produkten sind. Dabei wurde besonders die Genauigkeit der Daten gelobt, z. B. zu genauen Schlacht- und Zerlegezeiten in chronologischer Anordnung, da dies einen detaillierten Überblick über den zeitlichen Ablauf der einzelnen Produktionsschritte ermöglicht. Ein/-e Teilnehmer/-in nutzte dies zum Beispiel, um den tatsächlichen Zeitraum zwischen Schlachtung und Verpackung bis zum Verkauf einzuschätzen. Positiv hervorgehoben wurde von fünf Teilnehmer/-innen auch, dass in der App Angaben zum EU-Bio-Siegel und Bio-Kontrollen bereitgestellt wurden. Jedoch wurden auch von sechs Teilnehmer/-innen zusätzliche Angaben vermisst, wie z. B. dem Preis des Produkts, Nährwertangaben, Bewertungen anderer Verbraucher/-innen, etc. Gelobt wurden wiederum vermehrt die Angaben zur Herkunft und deren Darstellung in einer geografischen Karte.

> *„Und ich kann's mir in der Karte anschauen, wie ich das grade seh'. Sehr cool, genau sowas stell' ich mir vor, weil dann kann man auch Entfernungen abschätzen (…)“ (I12, 34, Logistikplaner)*

Die Angaben zur Herstellung wurden von sieben Befragten als relevant eingestuft, besonders bei Lebensmitteln, deren Herstellungsprozess bisher nicht bekannt war. Drei davon empfanden die Angaben jedoch als nur begrenzt informativ. So fehlten laut fünf Teilnehmer/-innen auch weiterführende Informationen zu Erzeugungs- bzw. Aufzuchtort, sowie genauere Informationen zu den einzelnen angeführten Betrieben.

> *„Also der Schlachtbetrieb sagt einem wahrscheinlich nicht wirklich viel, wenn man das jetzt so liest. Vielleicht noch irgendwas, was den näher beschreibt (…) Weil es gibt ja solche und solche, denk ich.“ (I3, 23, Lehramt-Studentin)*

Ferner wurden von sechs Teilnehmer/-innen genauere Angaben auch zu den Haltungs- und Produktionsbedingungen gefordert. Im Zusammenhang hiermit wurde von den befragten Personen geäußert, dass sie gerne Informationen zum Einsatz von Antibiotikum oder Pestiziden hätten, und sie sich beispielsweise auch für das verwendete Futter in der Massentierhaltung interessieren würden.

Die Sicherung der Informationsqualität hat für den/die Verbraucher/-in einen hohen Stellenwert, zugleich wird die Qualitätskontrolle durch die Komplexität der Informationsketten erschwert. So wurde z. B. bei dem zufällig ausgewählten Testprodukt eines Rindfleisch Steaks bei den bereitgestellten Rezeptideen die mangelnde Informationsgüte angemerkt, da hier Rezepte zu Geflügel angezeigt wurden:

> *„Das ist aber doof, bei ‚weitere Rezepte‘ kommt dann Geflügel. Ja, das ist wahrscheinlich nicht ganz ausgereift.“ (I7, 59, Ingenieur)*

4.3 Nutzungskontexte und gesteigerte Attraktivität durch Mehrwertdienste

Für acht der befragten Personen spielten digitale Medien wie das Smartphone beim Einkauf von Lebensmitteln und auch beim anschließenden Konsum aktuell bereits eine Rolle. Diese gaben an, ihr Smartphone regelmäßig zum Notieren oder Abfotografieren von Einkaufslisten, zur Suche nach Rezepten oder neuen Produkten im Internet, oder während des Kochens als Timer zu nutzen und z. B. Kalorien und Nährstoffe mittels einer App zu tracken.

Da keiner der Befragten die *fTRACE* App vor dem Interview kannte, fokussierte unsere Befragung auf deren intendierter Nutzung. Hierbei gaben acht Teilnehmer/-innen an, die durch die App bereitgestellten Informationen hauptsächlich im Laden, vor dem Kauf nutzen zu wollen, um so eine bessere Kaufentscheidung treffen zu können:

> *„Direkt beim Kauf, also wenn ich in dem Laden bin und das Produkt in die Hand nehme, würde ich da schon gerne die Informationen sehn, weil ich dann entscheide ob ich's kaufe oder ob ich's nicht kaufe." (I8, 26, Einzelhandelskaufmann)*

Hierbei wurde von einem Befragten auch gewünscht, durch die App eine Kaufempfehlung zu erhalten. Diese sollte die persönlichen Präferenzen des/der Verbrauchers/-in berücksichtigen und könnte beispielsweise in Form einer Ampel angezeigt werden.

> *„Und man könnte dann so 'ne Art Farbcode entwickeln, (…) wo man dann selber auch einstellen kann, wie bei codecheck auch, mir sind diese Kriterien wichtig und das Produkt stimmt mit den voreingestellten Kriterien überein, dann Grün." (I7, 59, Ingenieur)*

Während sich fünf Teilnehmer/-innen eine regelmäßige Nutzung vorstellen konnten, äußerten acht andere, die App eher gelegentlich nutzen zu wollen, wenn sie gerade Zeit dafür fänden. Von drei Personen wurde auch angegeben, die App nur in speziellen Einzelfällen nutzen zu wollen, wenn man ein Produkt eines Herstellers das erste Mal kauft:

> *„Aber ich würde mir das halt wahrscheinlich dann wirklich nur einmal ankucken und nicht für jedes Fleisch, weil das ist wirklich nur für mich, für die Information, einmal zu wissen, wie's tatsächlich abläuft, interessant und danach immer das gleiche." (I5, 21, Maschinenbau-Studentin)*

Von drei der Befragten wurde angeregt, die Attraktivität und damit die Akzeptanz zu steigern, indem man die Nutzung mit weiteren Mehrwerten kombiniert. Es wurde z. B. die Möglichkeit angesprochen, mit Hilfe eines entsprechenden Systems bei Rückrufaktionen betroffene Produkte schnellstmöglich zu identifizieren und die Verbraucher/-innen besser und schneller, noch vor dem Konsum selbiger, warnen zu können. Auch wurde von sechs Befragten die Angabe eines Rezepts als Zubereitungsvorschlag für das gescannte Produkt zwar als grundsätzlich gute Idee bewertet, allerdings war ihnen die Auswahl dabei zu gering, da lediglich eine Rezeptidee angezeigt wurde:

> *„Hier ist die Kategorie Rezepte aufgelistet. Find' ich allgemein sehr gut, weil man dann direkt 'ne Idee hat, was man mit dem Produkt zubereiten kann. Hier ist aber leider nur ein Rezept dargestellt, vielleicht könnte man da noch ein, zwei vielleicht*

dazu tun, um nochmal bisschen mehr Auswahl zu haben." (I8, 26, Einzelhandelskaufmann)

Von drei Verbraucher/-innen wurde diesbezüglich erwähnt, dass sie eher auf eigene Rezepte oder andere Quellen, z. B. *chefkoch.de* oder *Google*, zurückgreifen würden. Für diese Teilnehmer/-innen war die Angabe einer Rezeptidee deshalb weniger interessant, und könnte stattdessen durch eine Verlinkung mit anderen Informationssystemen für Verbraucher/-innen ergänzt oder ersetzt werden.

4.4 Vertrauen

In Abschnitt 2.1 wurde dargelegt, dass es sich bei der Rückverfolgbarkeit in weiten Teilen um Vertrauensinformationen handelt. Für die Akzeptanz solcher Systeme wie *fTRACE* ist es deshalb zentral, dass Verbraucher/-innen der Quelle der Informationen vertrauen, glaubwürdige und zuverlässige Angaben zu machen. In den Interviews zeigte sich jedoch, dass dreizehn der Teilnehmer/-innen der Lebensmittelindustrie generell misstrauisch gegenüberstehen:

„Wie ja das Wort Industrie schon sagt, eher schlecht. Also Industrie ist immer auf Gewinn optimiert und wenig auf vordergründige Qualität, wenn der Preis zum Tragen kommt. Also mein Vertrauen ist nicht so groß." (I12, 34, Logistikplaner)

Es zeigte sich, dass dieses generelle Misstrauen sich in vielfacher Hinsicht auch auf eine kritische Bewertung bereitgestellter Informationen übertrug. Diese geraten in Verdacht von Werbung, bei der die Glaubwürdigkeit und die Objektivität zweifelhaft ist:

„Auch ist es interessant, dass hier bei der Herstellung dann ein Video angeboten wird, wo's per Hand geschnitten wird, was ich definitiv für nicht glaubwürdig halte, dass da wirklich einer mit dem Messer sitzt." (I11, 25, Philosophie-Student)

„Es gibt hier ja auch die Kategorie Qualität, da ist jetzt nicht ersichtlich, wo die Informationen herstammen." (I6, 22, Studentin Kommunikationswissenschaften)

„Allerdings muss man jetzt sagen, das ist 'ne eigene Seite, von denen erstellt. Das (…) ist deren Meinung. (…) Das ist halt Werbung auf 'nem höheren Level." (I4, 23, Maschinenbau-Studentin)

„(…) irgendwie find' ich das kurios, dass (…) es kein Drittkontrolleur ist, sondern man selber macht das dann. Wenn man grade bei Vertrauen ist, irgendwie find' ich's grade 'nen bisschen fragwürdig vielleicht." (I11, 25, Philosophie-Student)

Trotz dieses generellen Misstrauens sahen neun Teilnehmer/-innen in Ansätzen wie *fTRACE* eine Chance, das Vertrauen der Verbraucher/-innen in die Qualität von Lebensmitteln und in die Lebensmittelindustrie zu erhöhen. Der größte Vorteil wurde in der Schaffung von mehr Transparenz gesehen, die Verbraucher/-innen helfe, die Produktionsprozesse besser nachzuvollziehen. Zudem sahen fünf der Befragten darin einen positiven Effekt, dass durch die bessere Dokumentation der Prozesse der Betrug mit Lebensmitteln zwar nicht vollständig verhindert, aber zumindest reduziert und die Verantwortlichen besser zur Rechenschafft gezogen werden können.

„Ja, das würde das Vertrauen bestimmt erhöhen. Ich find' da kann's nicht genug Transparenz geben eigentlich." (I9, 25, VWL-Student)

„Es würde besser werden, weil ich ja dann einfach 'nen Einblick hätte über die gesamte Lieferkette und somit auch 'nen gesteigertes Vertrauen." (I12, 34, Logistikplaner)

„Da [bei der Rückverfolgbarkeit] gibt's dann viel weniger Möglichkeiten zu tricksen. Wobei […] kriminelle Energie kann natürlich auch solche Prozesse betreffen, ja." (I7, 59, Ingenieur)

Insgesamt zeigt sich, dass das Vertrauen in Informationsquelle und die von ihr bereitgestellten Informationen ein kritischer Faktor für die Nutzerakzeptanz sind.

5 Diskussion

Die Rückverfolgbarkeit stellt eine wichtige Maßnahme zur Qualitätssicherheit in der Lebensmittelindustrie dar. Obwohl Verbraucher/-innen eine wichtige Zielgruppe darstellen, wurden sie in der Forschung zu Rückverfolgbarkeitssystemen bisher kaum betrachtet. Wenngleich unser Sample von 16 Verbraucher/-innen sowie der Fokus der Studie auf eine bestimmte App und ein bestimmtes Produkt keine repräsentativen Schlüsse erlaubt, liefert sie dennoch wichtige Erkenntnisse zu Bedürfnissen von Verbraucher/-innen und möglichen Nutzungshürden, die bei der Gestaltung von Verbraucherinformations-Apps berücksichtigt werden sollten.

Eine wichtige Erkenntnis unserer Studie ist, dass die Verbraucher/-innen aus unserem Sample der digitalen Rückverfolgbarkeit gerade von frischen Lebensmitteln generell positiv gegenüberstehen und bestehende Lösungen wie *fTRACE* prinzipiell begrüßen, diese ihnen aber bisher weitestgehend unbekannt sind und deshalb im Alltag nicht genutzt werden. Eine erste Maßnahme wäre daher die bessere Kommunikation der vorhandenen Lösungen.

Unsere Studie zeigt ferner, dass eine ansprechende Informationsvisualisierung für die Nutzerakzeptanz wichtig sein kann. Dabei können visuelle Elemente wie Bilder, Karten und Ampelsysteme helfen, die Informationen nutzergerecht zu kommunizieren. Wie unsere Ergebnisse erkennen lassen, kann die Informationsaufbereitung jedoch eine Gratwanderung sein. Sie sollte nüchtern, aber ansprechend gestaltet sein, damit beim Verbraucher oder der Verbraucherin nicht der Eindruck entsteht, dass es sich um Werbung handelt. Dabei hat unsere Studie gezeigt, dass vor allem der Aspekt des Vertrauens in die dargestellten Informationen zentral ist. Unsere Teilnehmer/-innen bringen der Lebensmittelindustrie insgesamt ein geringes Vertrauen entgegen, was auch das Vertrauen in die Informationen aus Rückverfolgbarkeits-Apps schwächt. Eine Zertifizierung der Rückverfolgungsinformationen durch unabhängige Stellen sowie digitale Signaturen und neue technische Ansätze (wie z. B. Blockchain zum Nachweis von Kühlketten, vgl. [35–37]) könnten dazu beitragen, das Vertrauen in die Korrektheit der dargestellten Informationen zu steigern. Zudem könnte die Einbindung von Informationen von Verbraucherzentralen und NGOs sowie Benutzerbewertungen der Informationen und Produkte das Vertrauen stärken.

Ein genereller Nachteil von App-Ansätzen wie *fTRACE* ist, dass sie eine aktive Suche nach Informationen voraussetzen und von der Initiative der Verbraucher/-innen abhängig sind. Deshalb ist zu vermuten, dass solche Apps von vielen Verbraucher/-innen nur sporadisch und in bestimmten Situationen genutzt werden – z. B. wenn Verbraucher/-innen ein neues Produkt von einem bisher unbekannten Hersteller kaufen, sich mit Muße „einfach mal" informieren wollen, oder durch einen neuen Bericht zu einem Lebensmittelskandal verunsichert sind. Jedoch sollte daraus nicht der Schluss gezogen werden, dass die digitale Rückverfolgbarkeit für den/die Verbraucher/-in unwichtig ist. Für die Nutzer/-innen aus unserem Sample scheint es vielmehr wichtig zu sein, sich bei Bedarf gezielt über ein Lebensmittel, seine Herstellung und seine Verarbeitung informieren zu können, was sicherlich besonders bei frischen Lebensmitteln eine Rolle spielt. Technisch gesehen sollte jedoch mittelfristig das aktive Einscannen durch die Bereitstellung eines digitalen Kassenzettels ergänzt werden, bei dem Rückverfolgbarkeitsinformationen integriert sind und so eine proaktive Informationsversorgung ermöglicht [28, 29] wird. Darüber hinaus haben wir gezeigt, dass die Nutzerakzeptanz durch die Einbindung weiterer Informationsdienste gesteigert werden kann, wie z. B. Rezeptvorschläge, Vergleichsangebote für nachhaltige Produkte, sowie die Möglichkeit, sich bei Rückrufaktionen oder beim Ablaufen des Verzehrdatums (VD) des Produkts automatisch benachrichtigen zu lassen.

Unsere Ergebnisse machen nicht zuletzt auch deutlich, dass der Gestaltung des Point-of-Sale eine zentrale Rolle zukommt. Hierbei kann der Lebensmitteleinzelhandel eine wichtige Funktion übernehmen, indem er prominenter auf *fTRACE*-Produkte aufmerksam macht und z. B. durch das Aufstellen interaktiver Public-Displays Kundinnen und Kunden erlaubt, Produkte ohne Zuhilfenahme des eigenen Smartphones einzuscannen und Informationen abzufragen. Hierdurch ließe sich zum einen der Bekanntheitsgrad von Rückverfolgbarkeitssystemen stark verbessern, zum anderen unterstützte man dadurch die Verbraucher/-innen dabei, informierte Kaufentscheidungen zu treffen.

Für die weitere Arbeit an dem Thema wäre es interessant, unsere qualitativen Ergebnisse durch repräsentative Befragungen und Langzeitstudien zur Nutzung von Apps und Diensten wie *fTRACE* zu ergänzen. Unser Artikel hat dazu einen wichtigen, ersten Beitrag geleistet.

Umweltbewusstsein durch audiovisuelles Content Marketing? Eine experimentelle Untersuchung zur Konsumentenbewertung nachhaltiger Smartphones

Danielle Warnecke[1], Felix Redepenning[1], Frank Teuteberg[1]

[1] Universität Osnabrück, Unternehmensrechnung und Wirtschaftsinformatik, Osnabrück, Deutschland.
{danielle.warnecke,fredepenning,frank.teuteberg}@uni-osnabrueck.de

Abstract.
Informations- und Kommunikationstechnologie (IKT) hat heute einen hohen Stellenwert in unserer Gesellschaft, wobei insbesondere Smartphones sich mit immer kürzeren Produktlebenszyklen zur Lifestyle-Komponente entwickeln. Dabei werden sowohl im Herstellungsprozess als auch bei der Kaufentscheidung vorrangig ökonomische Entscheidungskriterien betrachtet, wodurch die sozio-ökologischen Folgen für Mensch und Umwelt an Produktions- und Entsorgungsorten vernachlässigt werden. Der Markt für nachhaltige Produkte leidet zudem unter erheblichen Informationsineffizienzen. Transparente Kommunikation zwischen nachhaltig agierenden Unternehmen und verantwortungsbewussten Konsumenten kann somit als essenziell für die Kaufentscheidung in diesem Bereich angesehen werden. Eine systematische Literatursuche und das gewählte Fallbeispiel des Fairphone2 bilden die Basis der experimentellen Untersuchung eines entwickelten Content Marketing Videos, dessen zugrundeliegendes Hypothesenmodell innerhalb einer Online-Befragung mit 284 Teilnehmenden evaluiert wird. Der vermutete Effekt auf die Konsumentensensibilität gegenüber Nachhaltigkeitsaspekten konnte in der Erhebung beobachtet werden und bietet somit eine Orientierung für weitere Forschungsansätze zur Werbewirkung im Bereich nachhaltiger IKT.

Keywords: Nachhaltigkeitsmarketing, Content Marketing, nachhaltige Smartphones, audiovisuelles Marketing.

1 Einleitung

Nachhaltigkeit rückt immer mehr in den Fokus politischen und gesellschaftlichen Handelns und sensibilisiert eine breite Öffentlichkeit für soziale, ethische und ökologische Aspekte [1]. Insbesondere im Bereich der Unterhaltungselektronik steht der Konsument als Nachfrager im Fokus nachhaltigen Entscheidens [2]. Dass Hersteller von Smartphones sich nur vereinzelt an Nachhaltigkeitsaspekten bei der Produktgestaltung orientieren, zeigen aktuelle Studien und Berichterstattung zu den Arbeits- und Produktionsbedingungen [3,4] sowie dem Ressourcenverbrauch bei der Herstel-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

lung [5,6]. Trotzdem sind die Verkaufszahlen für Smartphones in den letzten Jahren stark angestiegen [7], was auch auf die immer kürzer werdenden Produktlebenszyklen zurückzuführen ist [8], sodass ein Smartphone im Schnitt bereits nach zwei Jahren gegen ein neueres Modell ausgetauscht wird [9].

Die stärksten Belastungen entstehen bei der Rohstoffgewinnung und Altgeräteentsorgung durch Kontakt mit toxischen Mineralien und Verbrennungsdämpfen [9,10]. Aufgrund dieser gefährlichen Arbeitsbedingungen und mangelhafter Ausrüstung kommt es hierbei zu erheblichen Schäden für Mensch und Umwelt [9,10].

Hersteller wie z. B. Fairphone B. V. oder Shift GmbH setzen mit ihrer Produkt- und Firmenphilosophie an dieser Stelle an und entwickeln Smartphones nach nachhaltigen Gesichtspunkten [11,12]. Allerdings orientierten sich bisherige Kampagnen des Nachhaltigkeitsmarketings häufig an Kampagnen für konventionelle Güter, obwohl sich die Wege zur Kaufentscheidung (auch Customer Journey) bei nachhaltig orientierten Konsumenten stark von weniger Umweltbewussten unterscheiden [13,14,15].

Der Nutzen von nachhaltigen Produkten für Konsumenten resultiert aus der Übereinstimmung persönlicher Werte mit den Markenwerten und einer Gewissensentlastung [16]. Es bestehen jedoch gravierende Informationsineffizienzen, sodass nachhaltige Produkte oftmals vom Verbraucher nicht als solche wahrgenommen werden [16]. Transparente Kommunikation zwischen Unternehmen und Konsumenten kann somit als entscheidend für den Erfolg nachhaltiger Produkte angesehen werden [18]. Im Rahmen des Content Marketings werden Tatsachen ansprechend aufbereitet und zu Werbezwecken genutzt [19]. Insbesondere audiovisuelle Kommunikation wirkt dabei sehr einprägsam [20].

Die diesem Beitrag zugrundeliegende Forschungsfrage lautet daher: Kann Konsumentenaufklärung in Form eines Content Marketing Videos für nachhaltige Smartphones zu einem verbesserten Umweltbewusstsein und somit zu einer erhöhten Kaufbereitschaft gegenüber nachhaltigen Smartphones beitragen? Zur Beantwortung dieser Frage wird zunächst anhand von Literatur und dem Fallbeispiel Fairphone 2 ein solches Video konzipiert und umgesetzt. Es wird als Stimulus in einem Online-Experiment (N=195) eingesetzt und entsprechend der entwickelten Hypothesen auf seine Wirksamkeit hin untersucht. Die Ergebnisse werden abschließend aus wissenschaftlicher und wirtschaftlicher Perspektive diskutiert.

2 Forschungsdesign

2.1 Methodisches Vorgehen

Es wird ein deduktiver Forschungsansatz in Anlehnung an [21] gewählt, bei dem Theoriebildung und Evaluation auf Basis wissenschaftlicher Literatur und Beobachtungswerten erfolgen. Die einzelnen Prozessschritte sind in Abb. 1 dargestellt.

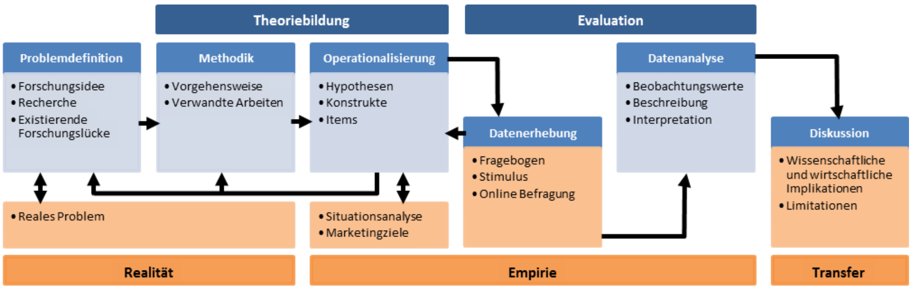

Abbildung 1. Deduktiver Forschungsprozesses modifiziert nach [21]

Nach der Problemdefinition und Skizzierung der Forschungsidee dient die Vorrecherche zur Überprüfung der Forschungslücke und zur Identifikation verwandter Arbeiten (siehe 2.2). Da durch diesen Teil der Untersuchung keine vollständige Beantwortung der Forschungsfrage ermöglicht wurde, wird im nächsten Schritt ein Fallbeispiel zur konkreten Betrachtung ausgewählt. Hierzu wird die Ausgangssituation des gewählten Unternehmens in Form einer Fallstudie systematisch analysiert, wobei kaufrelevante Faktoren, wie z. B. Unternehmensphilosophie, umweltschonende Ressourcen und Langlebigkeit des Smartphones berücksichtigt werden [22]. Die Ergebnisse der Situationsanalyse (siehe 3.1) dienen anschließend als Ausgangspunkt der formulierten Marketingziele (3.2) und der Entwicklung eines Content Marketing Videos (3.3).

Zur Evaluation dieses Lösungsansatzes werden die Marketingziele in ein Hypothesenmodell überführt (4.1) und anhand standardisierter Items operationalisiert (4.2). Neben den Items ist das Video als Stimulus zentraler Bestandteil des durchgeführten Online Experiments. Die Datenerhebung und -analyse (siehe Kap. 5) liefern die Basis zur anschließenden Diskussion (siehe Kap. 6) von Implikationen und Limitationen der Forschungsarbeit.

2.2 Verwandte Arbeiten

Es wurde eine systematische Literatursuche nach [23] in wissenschaftlichen Datenbanken[1] anhand der Suchbegriffe: *„Content Marketing, Nachhaltigkeitsmarketing, Marketing, Smartphone, Green IT, nachhaltig** und *IKT“* durchgeführt, wobei deutsche und englische Synonyme in verschiedenen Kombinationen verwendet wurden. Hierbei wurden 16 verwandte Arbeiten identifiziert, die die Bereiche IKT und Nachhaltigkeit oder Marketing und Nachhaltigkeit verbanden.

Die identifizierte Literatur des Nachhaltigkeitsmarketings lässt sich in drei Themengebiete einteilen, wobei keine dieser Arbeiten einen konkreten IKT-Bezug aufweist: Nachhaltigkeitsmarketing als Teildisziplin des Marketings, wobei vordergründig Eigenschaften und Entstehungsgeschichte behandelt werden [18,24], der Beitrag des Nachhaltigkeitsmarketings zur Lösung sozio-ökologischer Probleme [25] und

[1] EBSCO host, Science Direct, WISO-Net, AIS Electronic Library, Springer Link.

Reaktionen von Konsumenten auf Nachhaltigkeit sowie unterschiedliche Kategorien nachhaltig orientierter Konsumenten [26,27].

Mit Bezug zu nachhaltiger IKT haben [28], ein umfassendes Lehrbuch, das durch die Entwicklung nachhaltiger IKT gekennzeichnet ist und unterschiedliche Fallstudien zu nachhaltiger IKT zusammenfasst, veröffentlicht. [29] tragen die Vorteile nachhaltiger IKT aus Unternehmenssicht zusammen, während [9] und [30] explizit die Nachhaltigkeit von Mobiltelefonen untersuchen, wobei keine dieser Arbeiten Aspekte der Wissensvermittlung oder Kaufentscheidung durch Marketingmaßnahmen berücksichtigt.

Die größten Parallelen zur vorliegenden Untersuchung weist die Arbeit von [31] auf. Es wird untersucht, inwiefern nachhaltige Produkte von einer speziellen Marketingstrategie profitieren können. Jedoch wird hier der Einfluss klassischer Marketingmethoden auf die Konsumentenakzeptanz von Biokraftstoffen behandelt, die einer völlig anderen Produktkategorie als Smartphones angehören [32]. Demgegenüber wurde innerhalb des „B2B Technology Content Survey Report 2014" herausgestellt, dass Content Marketing (CM) die Kaufentscheidung auch für erklärungsbedürftige Produkte positiv beeinflussen kann [19,33]. Anhand der Arbeiten von [34], [35] und [36] wird insbesondere der Nutzen von CM bei der Informationsvermittlung hervorgehoben. Diese Eigenschaften werden im hier vorliegenden Beitrag genutzt, um den nötigen Informationstransfer zu unterstützen.

3 Audiovisuelles Content Marketing als experimenteller Stimulus

Das Ziel des zu entwickelnden Stimulus ist es, das Umweltbewusstsein und somit die Kaufbereitschaft für ein nachhaltiges Smartphone bei Konsumenten durch Wissenstransfer signifikant zu erhöhen. Als Fallbeispiel wird hierzu das niederländische Unternehmen Fairphone B. V. herangezogen, da dieses mit dem Fairphone 2 das aktuell bekannteste nachhaltige Smartphone vertreibt [37]. Im ersten Schritt wird hierzu die Situation des Unternehmens mit Hilfe der SWOT-Methode analysiert, woraus dann die Marketingziele abgeleitet werden, die als Rahmen zur Gestaltung des audiovisuellen Reizes in Form eines Videos dienen.

3.1 Situationsanalyse von Fairphone

Für die Situationsanalyse wird die SWOT-Methode genutzt, wobei Stärken, Schwächen, Chancen und Risiken des Unternehmens identifiziert werden. Eine externe Analyse betrachtet zunächst Chancen und Risiken, eine anschließende interne Analyse fokussiert Stärken und Schwächen des Unternehmens [22]. Die Ergebnisse der Analyse (siehe Tab.1) dienen als Ausgangspunkt für die Entwicklung von Marketingzielen [38].

Tabelle 1. Ergebnisse der SWOT-Analyse

Interne Analyse	
Stärken	Schwächen
• Fähigkeit zur Verbesserung von Funktionalität (Fairphone 1 zu Fairphone 2) • Mitarbeiterloyalität • Große Medienpräsenz • Guter Ruf	• Geringe produzierte Stückzahl • Geringer Umsatz • Geringes Unternehmensbudget • Wenige mögliche Zulieferer • Höhere Kosten (durch faire Rohstoffe)
Externe Analyse	
Chancen	Risiken
• Produktlanglebigkeit (mind. 5 Jahre) • Zusammenarbeit mit fairen Minen • Recyclingmaterialen verstärkt einsetzen • Gute Arbeitsbedingungen für Mitarbeiter an Produktionsorten • Recyclingprogramm für Altgeräte	• Geringe technische Performance • Preis ab 530 € • Tests und Rankings berücksichtigen selten sozio-ökologische Kriterien, sodass die Stärken des Fairphone 2 nicht honoriert werden.

Die identifizierten *Stärken* des Unternehmens liegen vor allem in der starken Unternehmensphilosophie [39], die auch durch Mitarbeiter und Medien wiedergegeben wird [37]. Die *Schwächen* hingegen liegen in geringem Produktionsvolumen, Umsatz und Kapitalausstattung im Branchenvergleich [40]. Zum einen limitiert die Unternehmenspolitik größtmöglicher Nachhaltigkeit und Transparenz die Auswahl potentieller Lieferanten [41,42], zum anderen besitzt Fairphone als Hersteller dieses Volumens geringe Verhandlungsmacht [43].

Die *Chancen* leiten sich aus den nachhaltigen Unternehmenszielen ab. Als primäres Unternehmensziel verfolgt Fairphone ein langlebiges Produktdesign, wobei die Lebensdauer eines Fairphone 2 auf fünf Jahre ausgerichtet ist [44]. Ein weiteres Ziel des Unternehmens ist die intensivere Zusammenarbeit mit fairen Minen und die vorrangige Verwendung recycelter oder erneuerbaren Ressourcen, außerdem sollen die Arbeitsbedingungen für Mitarbeiter an den Produktionsorten verbessert werden [44]. Schließlich fördert Fairphone durch ein eigenes Recyclingprogramm die Wiederverwendung alter Smartphones und die Weiterverwertung ihrer Komponenten [45].

Als *Risiken* zu betrachten sind der hohe Innovationsdruck der Smartphone-Branche [8], die vergleichsweise geringe Performance und der Preis (ab 530€) des Fairphones [46]. Fairphone sieht sich nicht als ein wettbewerbsorientiertes Unternehmen, sondern möchte stattdessen „als Inspiration für Kunden und andere Unternehmen der Industrie" dienen [47].

3.2 Marketingziele

Aus Mangel an Bewertungsnormen für nachhaltige IKT wurde häufig „Green Washing" durch falsche oder geschönte Nachhaltigkeitsberichte und Ökobilanzen praktiziert [15,48]. Aus diesem Grund sollten Werbebotschaften im Rahmen des Nachhaltigkeitsmarketings Konsumenten mit umfassenden Informationen versorgen und dabei vordergründig Tatsachen vermitteln [9,15,49]. Konsumenten könnten somit für die Notwendigkeit von nachhaltigen Smartphones sensibilisiert werden, sodass deren Wertschätzung (Zahlungsbereitschaft) für nachhaltige Rohstoffe, Arbeitsbedingungen und Kooperationen steigt [50,51]. Daraus lassen sich drei Hauptziele für die Unternehmenskommunikation ableiten:

- Wissen über sozio-ökologische Probleme in Minen und Produktionsstätten vermitteln,
- Wissen über nachhaltige Ansatzpunkte des Fairphone 2 vermitteln,
- Inhalte wahrheitsgemäß und transparent kommunizieren, um Vertrauen zu schaffen.

Besonders einprägsam wirken audiovisuelle Elemente der Unternehmenskommunikation [19]. Daher wird im Abschnitt 3.3 ein Video konzipiert, das über die Folgen herkömmlicher Smartphones und die Vorteile des Fairphone 2 anhand von Tatsachen im Sinne des Content Marketings aufklärt.

3.3 Audiovisuelles Konzept und Design

Das Video „Aus dem Leben eines Smartphones" wurde entsprechend der genannten Marketingziele anhand realer Produkt- und Unternehmenseigenschaften von Fairphone umgesetzt (abrufbar unter: http://bit.ly/audioCM (Anhang A)).

Nach einer kurzen thematischen Einführung werden die sozio- ökologischen Probleme genannt, die während der Rohstoffgewinnung und -herstellung, der Produktion, der Nutzung und dem Recycling von Smartphones entstehen. Im Anschluss werden Fairphones Lösungsansätze für jede der einzelnen Lebenszyklusphasen genannt und visualisiert. Die Animation mit gesprochenem Text und Hintergrundmusik hat eine Gesamtlänge von vier Minuten. Um ein Vertrautheitsgefühl zu erzeugen, werden die Zusehenden konsequent geduzt. Bei der Formulierung der Unternehmensziele wird weiterhin darauf geachtet „Wir-Botschaften" zu senden, um den Community-Gedanken von Fairphone auszudrücken. Drei Zitate der bekannten Film- und Serienfiguren Barney Stinson („Herausforderung angenommen!"), Meister Yoda („Tue es oder tue es nicht. Es gibt kein Versuchen.") und Remus Lupin („Es ist der Wert der Überzeugung, der den Erfolg ausmacht. Nicht die Anzahl der Anhänger.") motivieren zum vollständigen Anschauen des Videos.

4 Konzeption und Operationalisierung des Experiments

4.1 Konstrukte und Hypothesen gemäß Marketingzielen

Ausgangspunkt des Modellentwurfs sind die aus dem Fallbeispiel abgeleiteten Marketingziele [52]. Diese werden den Konstrukten „Wissen über Umweltprobleme", „Wissen über Nachhaltigkeitsvorteile des Produkts", „Vertrauen zum Unternehmen" und „Kaufbereitschaft für ein nachhaltiges Smartphone" wie in Tab. 2 zu sehen, zugeordnet und die vermuteten Zusammenhänge als überprüfbare Hypothesen umformuliert.
Die im Hypothesenmodell vermuteten Zusammenhänge werden in Abschnitt 4.2 anhand standardisierter Items in einem Fragebogen zusammengefasst.

Tabelle 2. Gegenüberstellung der Marketingziele und Konstrukte mit Hypothesen

Marketingziel	*Hypothesen je Konstrukt*	
Wissen über sozio-ökologische Probleme in Minen und Produktionsstätten vermitteln	*Wissen über Umweltprobleme (WüU)* H1: Informativ gestaltete Aufklärungsvideos beeinflussen das Wissen über Umweltprobleme beim Betrachter positiv. H2: Je größer das WüU ist, desto größer wird auch die Kaufbereitschaft für ein nachhaltiges Smartphone sein.	*Kaufbereitschaft für ein nachhaltiges Smartphone*
Wissen über nachhaltige Ansatzpunkte des Fairphone 2 vermitteln.	*Wissen über Nachhaltigkeitsvorteile des Produkts (WüN)* H3: Objektiv informativ gestaltete Aufklärungsvideos beeinflussen das Wissen über Nachhaltigkeitsvorteile des Produkts beim Betrachter positiv. H4: Je größer das WüN ist, desto größer wird auch die Kaufbereitschaft für dieses nachhaltiges Smartphone ausfallen.	
Vertrauen schaffen durch wahre und transparente Inhalte	*Vertrauen zum Unternehmen (V)* H5: Objektiv informativ gestaltete Aufklärungsvideos beeinflussen das Vertrauen zum Unternehmen positiv. H6: Je größer das V ist, desto größer wird auch die Kaufbereitschaft für ein nachhaltiges Smartphone ausfallen.	

4.2 Fragebogenentwurf

Da beim vorliegenden Hypothesenmodell ausschließlich latente Variablen mit festgelegter Beziehungsrichtung vorliegen, handelt es sich um ein reflektives Messmodell [53]. Die Verwendung multipler Items bei reflektiven Messmodellen gilt bei einer Anzahl von mind. 3 Items pro Konstrukt als wissenschaftlich anerkannt [54], da somit Verzerrungen sowie zufällige Messfehler einzelner Indikatoren ausgeglichen und die Reliabilität erhöht werden können [53,55]. Außerdem werden, wie in Tab. 3 beispielhaft für WüU dargestellt, mehrere Indikatoren als Aussagen in Fragebatterien zusammengefasst, um eine bestmögliche Validität zu erreichen [55]. Es wurden angepasste Formulierungen verwendet und ein Wechsel zwischen positiv und negativ formulierten Items umgesetzt (vollständige Liste der Items in Anhang B), um unaufmerksame Probanden und inkonsistentes Antwortverhalten aufzudecken [53]. Die Erhebung erfolgt mittels einer fünfstufigen Likert-Skala von „stimme überhaupt nicht zu“ (1Punkt) bis „stimme voll zu“ (5 Punkte). Die Antworten der Teilnehmenden lassen sich zu einem Testwert addieren, der die Einstellung der Person gegenüber dem Konstrukt widerspiegelt [56].

Tabelle 3. Items des Konstrukts WüU

Chiffre	*Item*	*Quelle*
WüU1	Ich würde mich selbst als jemanden beschreiben, der Ahnung von den sozio- ökologischen Problemen eines Smartphones hat.	[57]
WüU2	Ich kann jemand anderem die Vorteile eines nachhaltigen Smartphones erklären.	[57]
WüU3	Das ökologische Gleichgewicht ist sehr empfindlich und leicht durcheinander zu bringen.	[58]
WüU4	Natürliche Ressourcen sollten für zukünftige Generationen bewahrt werden.	[59]
WüU5	Der Zustand unserer Umwelt kann unsere Gesundheit beeinflussen.	[59]

Der Fragebogen umfasst 35 Fragen entlang der vier Item-Batterien zu den Konstrukten WüU, WüN, V und KB, sozio-demographischen Angaben sowie Einleitung und Schlusswort. Zu Beginn des Fragebogens erfolgt eine Randomisierung der Teilnehmenden, sodass diese zufällig der Kontrollgruppe (KG) oder Experimentiergruppe (EG) zugewiesen werden. Im Anschluss an die Einleitung erhält die EG den audiovisuellen Stimulus. Für die EG wurde eine durchschnittliche Bearbeitungsdauer von 18 Minuten im Pre-Test (14 Teilnehmende) beobachtet.

5 Datenerhebung und -analyse des Experiments

Die Datenerhebung erfolgt mithilfe einer Online-Befragung, eines Computer Self-Administered Questionnaire (CSAQ). Es wird ein Posttest-Only Control Group Design angewandt, um die Wirksamkeit des Videos (Stimulus) durch die Gegenüberstellung von Experimentier- und Kontrollgruppe zu überprüfen [55]. Die Befragung wird online im Zeitraum von April bis Juli 2018 per LimeSurvey durchgeführt, wobei die Probanden via Facebook, Whatsapp und E-Mail-Verteiler zur Teilnahme aufgefordert werden. Von 284 Teilnehmenden wurden unvollständig und inkonsistent beantwortete Fragebögen eliminiert, sodass der vollständig bereinigte Datensatz für die statistische Analyse 195 Fälle umfasst. Die statistische Auswertung der erhobenen Daten erfolgt mithilfe der Statistik- und Analyse-Software SPSS von IBM. Hypothesen werden bis zum Zehn-Prozent Signifikanzniveau angenommen.

5.1 Deskriptive Statistik

Das Convenience Sample setzt sich aus 58% männlichen und 41% weibliche Teilnehmenden zusammen. 89% besitzen als höchsten Schulabschluss das Fachabitur oder besser, wobei 50% der Teilnehmer zwischen 20 und 29 Jahren sind. 49% der Smartphones nutzen iOS, 48% Android und 3% sonstige Betriebssysteme. Laut der Probanden sind 56% dieser Smartphones neuer als 2 Jahre, wobei das älteste 10 Jahre alt ist. 10% der Geräte wurden im Dezember 2016 gekauft und 30% kosteten 499€ oder mehr. Hierin zeigt sich eine überraschend hohe Zahlungsbereitschaft, wobei nur

5% angaben, ihr Smartphone nach sozio-ökologischen Gesichtspunkten ausgewählt zu haben.

Die beiden Items „Natürliche Ressourcen sollten für zukünftige Generationen bewahrt werden." und „Der Zustand unserer Umwelt kann unsere Gesundheit beeinflussen." des Konstrukts WüU wurden mit durchschnittlichen Werten von 4,7 und 4,8 sehr hoch bewertet. Der Durchschnitt über alle fünf Items lag für WüU bei 3,9.

Das Konstrukt WüN wurde im Durchschnitt mit 3,9 bewertet, wobei die Items „Die Nutzung nachhaltiger Smartphones ist ein guter Ansatz, um den verschwenderischen Umgang mit natürlichen Ressourcen zu reduzieren." und „Die Nutzung eines nachhaltigen Smartphones ist ein guter Ansatz, um natürliche Ressourcen zu schützen." am höchsten bewertet wurden.

Den niedrigsten Durchschnittswert von 3,4 erreichte V, wobei die Aussage „Es besteht die Möglichkeit, dass die Nutzung eines nachhaltigen Smartphones der Umwelt schadet." mit 3,7 (nach Invertierung der Skala) am stärksten abgelehnt wurde.

5.2 Inferenzstatistik

Im Folgenden werden die erhobenen Testwerte der Konstrukte WüU, WüN, V und KB abhängig von verschiedenen Gruppierungsvariablen mithilfe des nichtparametrischen Mann-Whitney-U-Tests miteinander verglichen. Der MWU-Test prüft, ob eine signifikante Differenz zwischen den Mittelwerten zweier Verteilungen besteht. Dazu werden Rangreihenfolgen gebildet, indem die Testwerte aufsteigend angeordnet und die durchschnittlichen Ränge von Gruppen miteinander verglichen werden [60,61]. Die Nullhypothese des MWU-Tests besagt, dass es keinen Unterschied zwischen den abhängigen Variablen gibt [60]. Es wird somit überprüft, ob sich die Werte beider Gruppen signifikant voneinander unterscheiden. Dadurch kann eine Aussage über den Einfluss der jeweiligen Gruppierungsvariablen getroffen werden. Zuerst wird der Unterschied zwischen der KG und EG in der Konstruktbewertung gemessen, wobei die Werte zeigen, ob die Nullhypothese des Tests verworfen werden kann. Für das erste Konstrukt WüU kann die Nullhypothese verworfen werden, seit $p = 0{,}01 < \alpha = 0{,}1$. Für das zweite Konstrukt WüN kann die Nullhypothese ebenfalls verworfen werden, seit $p = 0{,}07 < \alpha = 0{,}1$. Für das dritte Konstrukt V kann die Nullhypothese nicht verworfen werden, da seit $p = 0{,}39 > \alpha = 0{,}1$ ist. Die Ränge der Experiment- und Kontrollgruppe unterscheiden sich für die Testwerte dieses Konstrukts folglich nicht.

Mithilfe des MWU-Tests werden außerdem die Durchschnittsränge der drei erstellten Testwerte für die Gruppe mit und ohne Kaufbereitschaft für ein nachhaltiges Smartphone miteinander verglichen. Dabei weist sich anhand der p-Werte ein signifikanter Zusammenhang zwischen WüU und KB ($p = .00$) aus. Es weist sich jedoch kein signifikanter Zusammenhang zwischen WüN und KB ($p = .20$) sowie zwischen V und KB ($p = .24$) aus. Die Nullhypothese wird hier demnach für zwei der drei Konstrukte beibehalten (siehe Abb.2).

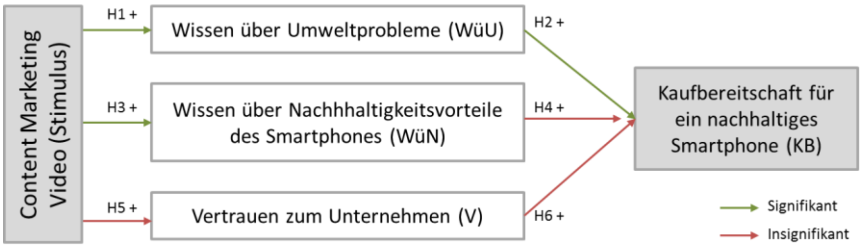

Abbildung 2. Hypothesenmodell nach Überprüfung

Weitere mögliche Zusammenhänge zwischen den sozio-demographischen Merkmalen und der KB werden mithilfe des Chi-Quadrat (χ^2) -Tests untersucht. Dieser ebenfalls nichtparametrische Test prüft, ob die beobachtete Verteilung der Variablen mit der erwarteten Verteilung übereinstimmt. Die Nullhypothese des χ^2-Tests besagt, dass die Variablen statistisch unabhängig sind bzw. kein Zusammenhang zwischen ihnen besteht [60]. Der Anpassungsgütetest beweist zunächst einen signifikanten Unterschied der Häufigkeiten zwischen erhöhter KB und niedriger KB (χ^2 = 74,06; df = 1; p = 0,00). Das zeigt, dass mehr Befragungspersonen eine niedrige KB aufweisen. Es zeigt sich ebenfalls eine signifikante Beziehung zwischen dem Geschlecht und der Kaufbereitschaft (χ^2 = 3.47; df = 1; p = 0,06). Frauen weisen demnach eine höhere KB als Männer auf. Eine signifikante Beziehung zwischen Alter und der KB konnte nicht identifiziert werden (χ^2 = 4,50; df = 5; p =0,48). Darüber hinaus ergibt sich eine signifikante Beziehung zwischen KB und Fachhochschulabschluss (χ^2 = 2.86; df = 1; p = 0,09) und zwischen KB und Universitätsabschluss (χ^2 = 3.26; df = 1; p =0,07).

6 Diskussion

Orientierungshilfen für den Konsumenten im Bereich nachhaltiger Produkte mit Aufklärungsfunktion wie das Biosiegel in der Lebensmittelindustrie [62] sowie das Fairtrade Siegel in der Lebensmittel- und Textilindustrie, das für sozial nachhaltig gehandelte Waren steht, sind bereits gesellschaftlich etabliert [63]. Siegel dieser Art kommen jedoch im Bereich IKT bislang nur vereinzelt zum Einsatz[32].

Da sich neben signalgebenden Labels besonders visuelle und audiovisuelle Medien zur produktbezogenen Wissensvermittlung eignen [34], geht der hier gewählte Experimentstimulus über reine Symbolwirkung hinaus und klärt den potenziellen Konsumenten über die Nachhaltigkeitsaspekte des beworbenen Smartphones (Fairphone2) in Form eines animierten Videos auf. Der Stil des Aufklärungsvideos folgt einem Mix aus emotionaler Ansprache (Aufmerksamkeit halten) und objektiver Informationsvermittlung (Mehrwert), wobei die persönliche Ansprache per Du und Wir-Formulierungen die Fairphone-Philosophie widerspiegelt. Das WüU und das WüN konnten laut Probandenbewertung dadurch positiv beeinflusst werden, wobei 16 von 18 freiwilligen Kommentaren der Befragungspersonen zu dem Video zustimmend ausfallen (siehe Anhang C). Der vermutete positive Effekt kann folglich in Form der

H1 (Stimulus beeinflusst das WüU positiv) und H3 (Stimulus beeinflusst das WüN positiv) durch die beobachteten Werte jeweils bestätigt werden. Hierbei werden insbesondere die Schäden an Menschen und Umwelt als Folge des Konsums konventioneller Geräte stärker (negativ) bewertet als die alleinige Hervorhebung sozio-ökologischer Vorteile nachhaltiger Smartphones (positiv). Außerdem werden Erklärungen anhand der Produktlebensphasen und der jeweiligen unternehmerischen Ansätze, wie z.B. Metalle aus fairen Minen als Rohstoff für die Herstellung, modulare Bauweise bei der Produktentwicklung, Reparaturanleitungen auf der Webseite, Rücknahme und Recyclingangebote für Altgeräte, etc. positiv bewertet. Jedoch konnte kein Effekt auf den Vertrauensaufbau beobachtet werden (Ablehnung H5). Die sachliche, weniger emotionale und einmalige Kontaktaufnahme ist für den Vertrauensaufbau demnach als ungeeignet einzustufen, denn sie verbessert das Vertrauen zum Unternehmen nicht.

Da in dieser Untersuchung das WüU, die ein Smartphone verursachen kann im Zusammenhang mit der gemessenen KB für dieses steht, kann außerdem ein positiver Effekt des Videos auf die Kaufbereitschaft beobachtet und somit die H2 angenommen werden. Ein Zusammenhang zwischen dem WüN eines Produktes und der KB sowie V und der KB konnte hingegen nicht nachgewiesen werden. H4 und H6 werden demzufolge abgelehnt. Dieses Ergebnis deutet daraufhin, dass die Kommunikation einer nachhaltigen Unternehmensphilosophie als noch wichtiger einzustufen ist als die transparente Kommunikation nachhaltiger Produkteigenschaften.

Die Auswertung der sozio-demographischen Merkmale ergab weiterhin, dass Universitätsabsolventen einen signifikant höheren WüU-Durchschnittsrang erreichen. Anhand der durchgeführten Chi-Quadrat Tests konnte außerdem nachgewiesen werden, dass Absolventen einer Universität oder einer Fachhochschule eine signifikant höhere KB für ein nachhaltiges Smartphone besitzen. Die Chi-Quadrat Tests zeigten weiterhin, dass Frauen eine höhere KB als Männer aufweisen. Ein statistisch zuverlässiger Zusammenhang zwischen Alter und der KB konnte hingegen in dieser Untersuchung nicht beobachtet werden. Daraus ergibt sich zunächst das Bild einer weiblichen Akademikerin, die Ziel von CM nachhaltiger Smartphones sein könnte.

Limitierend auf dieses Ergebnis wirkt sich aus, dass die beobachtete Kaufbereitschaft insbesondere bei sozial erwünschten Produkten nicht zwingend der realen Kaufentscheidung entspricht [64]. Jedoch lässt sich die Aussagekraft dieser Variable durch eine sehr konkrete Produktvorstellung (Eigenschaften des Fairphone2) erhöhen und sich somit mindestens als Näherungswert heranziehen [65]. Die erzielte Stichprobe ist ferner als nicht vollständig repräsentativ einzustufen, da 50% der Befragungspersonen zwischen 20 und 29 Jahren alt sind und 50% der Probanden einen Universitätsabschluss haben. Die Stichprobe stellt kein Abbild der Grundgesamtheit dar, jedoch bildet dieser Personenkreis einen wesentlichen Bestandteil des LOHAS[2] und somit der Zielgruppe für nachhaltige Smartphones [66].

Letztlich konnte durch das Experiment gezeigt werden, dass audiovisuelles Content Marketing zu einem besseren Umweltbewusstsein in Form von Wissen über

[2] LOHAS (Lifestyle of Health and Sustainability): Dieser Lifestyle verbindet Nachhaltigkeit, Verantwortung und Gemeinschaft mit Gesundheit, Wellness und Genuss [66].

Umweltprobleme und dem Wissen über die Nachhaltigkeitsvorteile von Smartphones beim Konsumenten signifikant beitragen kann, wohingegen ein Vertrauensaufbau durch einmalige Ansprache nicht zu beobachten war und die angegebene Kaufbereitschaft als Näherungswert, nicht als Faktum, betrachtet werden sollte.

7 Fazit

Aufbauend auf den Ergebnissen der Literaturanalyse werden anhand des Fallbeispiels Fairphone 2 Marketingziele hergeleitet, die für die theoretische Betrachtung in Hypothesen und Konstrukte überführt werden und anwendungsorientiert als Grundlage zur Entwicklung eines Content Marketing Videos dienen. Die Hypothesen werden im Rahmen eines Experiments per Online-Befragung mit 195 Teilnehmenden, bei der das entwickelte Aufklärungsvideo als Stimulus dient, überprüft. Der vermutete Effekt des Videos auf WüU und WüN und somit indirekt auf die Kaufbereitschaft nachhaltiger Smartphones konnte in der Untersuchung festgestellt werden, während ein Einfluss auf das Vertrauen zum Unternehmen durch das Video nicht beobachtet wurde. Content Marketing, insbesondere in Form eines Aufklärungsvideos ist folglich geeignet, um Wissen zu vermitteln. Ist dieses Wissen zielführend und zielgruppengerecht aufbereitet, kann es bei entsprechender Unternehmensphilosophie und Transparenz positiven Einfluss auf die Kaufbereitschaft des Konsumenten nehmen. Um das Zielgruppenprofil weiter zu spezifizieren kann zukünftige Forschung z. B. durch Forenanalyse der Fairphone-Community oder vertiefende Fallstudien in Unternehmenskooperation mit Fairphone, Shift GmbH oder anderen Anbietern zu weiterführenden Erkenntnissen beitragen.

Abstract. The progressive energy transition, driven by the growing number of renewable energies, the increasing social importance of sustainable actions, as well as new technologies, causes major challenges for enterprises and power supply companies (PSCs). While the electricity price fluctuations will continue to increase in the future, the installation of smart meters and smart meter gateways is aimed to ensure grid stability. They provide the basis for communication between companies and PSCs. In order to make companies energy consumption predictable even before the energy is needed, an automated data exchange between an energy management system (EnMS) and enterprise resource planning (ERP) system is essential. Therefore, we address this problem by following five research steps to develop a prototype for predictive energy management in information systems.

Keywords: Energy transition, predictive energy management, information systems, demand-side management

1 Motivation and Current Developments

A predictive energy management system provides the foundation for a secure, eco-friendly and economical operation of the energy system. In the future, the produced amount of electricity should be consumed in order to exploit renewable energies and to avoid the current problem of buffer storage. The German Federal Government's goal is to cover 35 % of its electricity requirements by 2020 and 80 % by 2050 from renewable energies [1-3]. This leads to increased volatility on the electricity market [4], [5]. The far-reaching transition, driven by the liberalization of the energy market, the growing number of renewable supply, as well as increasing socially importance of sustainable actions and the change of paradigm (consumption must adapt to production) in the energy industry to decentralized feed-in causes major challenges in terms of information processing and business models [3], [6].

The resulting growing complexity of internal processes, increased customer requirements and rapidly changing economic conditions can be counteracted by the use of adequate information and communication systems [4]. Nowadays, ERP systems are an important component of companies' IT infrastructure. When implemented successfully, they support business processes by linking all areas of a

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

company and enable the integrated management of all enterprise resources [7]. This includes also production-relevant data such as orders, production planning and machine occupancy.

On the other hand, companies are increasingly using EnMS, which are tools used to control and monitor organizations energy flows. The ISO 50001 standard, published in June 2011, is the first international standard for EnMS and supports organizations in all industries in implementing such systems [8]. The main objective of such systems is to increase energy efficiency in order to achieve energy savings, thus optimizing energy consumption and saving costs [9]. With regard to production-relevant data, an EnMS provides information about the energy consumption of machines and production lines as well as their load profiles [10].

By combining the data from both systems, it is possible to calculate a predicted progression over time [4]. Based on this information, PSCs can use them to predict energy demand more precisely and, if necessary, to take appropriate countermeasures. Furthermore, companies can benefit from this development and optimize their production costs. At the same time, the enormous increase in electricity costs means that variable electricity rates can gain even more importance for companies [11], [12]. Significant cost savings potential can be generated even when production processes are postponed within the day. Due to Singhal and Swarup [13] energy prices can be highly volatile to systems conditions. While the magnitude of electricity price fluctuations will continue to increase in the future [14], companies can generate sustainable competitive advantages through intelligent production planning. Price fluctuations result in particular from the availability of renewable energies that cannot be planned precisely and are therefore dependent on external factors. Changes with regard to price fluctuations can be observed in particular in countries that are already increasingly relying on renewable energies [15-17]. An oversupply of electricity on the short-term energy market can result in negative prices. The number of hours during which negative electricity prices occur have increased significantly since 2010 [18]. Current research projects in the field of energy management, such as TechPlan[1], SynEnergie[2], FOREnergy[3], and PHI-Factory[4] underline the relevance of our research topic, but do not consider our approach in this way. An initial overview of the literature shows, that there are several publications on ERP-Systems and EnMS [4], [19-21]. However, the combination of both systems is currently not considered [22], [23].

2 Research Approach

The goal of our approach is to develop a prototype that allows an automated data exchange between ERP systems and EnMS. This should enable companies, to link their energy consumption with the current amount of available energy and the prices on the energy market. By aggregating this information across many companies, PSCs can more accurately predict demand and react if the amount of energy is not available at the moment. The aim of a bidirectional data exchange between companies and PSCs is to ensure grid stability and create incentive models for energy consumption.

This can be achieved, for example, by creating price incentives to shift the production of the companies to periods when demand of energy is lower.

In order to adequately address this problem, we divided our research approach into five steps, as shown in figure 1. The first step, we are working on, is to create an initial overview of current research projects, as mentioned in chapter 1, as well as several publications on ERP systems and EnMS. An exact breakdown of the scientific literature with the help of a structured literature review according to Webster & Watson [24] will be our second step. The focus of the review is on the differentiation between ERP systems and EnMS, as well as their functions. The literature and technology overview will represent our knowledge base as a basis for our iterative adjustments during the development of the prototype.

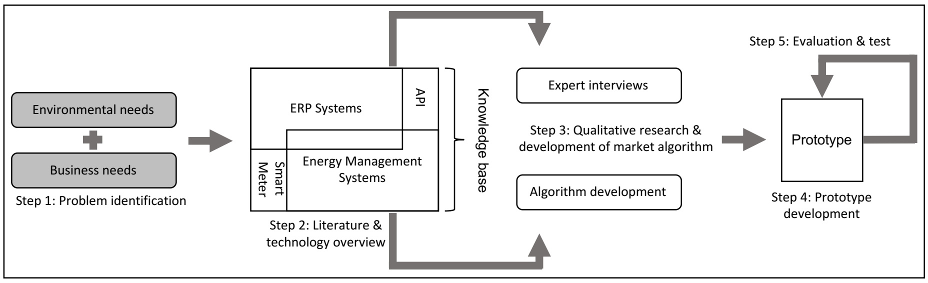

Figure 1. Research Approach

In order to adequately consider current issues and practical experiences, the requirements of companies for such a prototype have to be analyzed in the third step. To determine these, qualitative interviews with experts from different industries and company sizes are suitable [16]. Additionally, a matching algorithm should be developed, which can connect the data from the ERP system with the data from EnMS.

In the fourth step, this algorithm will be implemented into the existing infrastructures of the companies. To ensure a bidirectional data exchange between ERP systems and EnMS, the prototype contains standardized API's. This is required to enable the prototype to interact with both systems. The evaluation and test of the prototype will be an iterative process. In this case the evaluation is followed by further surveys through experts. The method of delphi studies is selected to gain these insights [25]. Ultimately, this project is intended to lead to a constantly improving tool, with a deep learning algorithm, that supports companies in their digitization.

3 Conclusion and Expected Contribution

Our research will provide the PSCs with more reliable data for their energy planning. However, the main condition, and therefore also a limitation, is that an ERP must be available at the company. At the same time, it aims to support companies in optimizing costs and enables new business models to be developed in the long term.

These new business areas are, for example, in the previously unknown topic of the energy broker. Furthermore, new services can also be created in the areas of billing, procurement and consulting [6]. Precisely, the supply fluctuations will arise from the increase in renewable energies, we assume that electricity price fluctuations will increase in line with market equilibria [15-17]. This offers both, companies and PSCs the opportunity to achieve competitive advantages through elaborated strategic action. However, these advantages can only be achieved on a reliable data basis. In our point of view, this is only possible on the basis of existing systems (ERP systems and EnMS) and the combination as well as the expansion of those. The ERP system already provides all necessary production data and the EnMS provides the corresponding energy data. By linking them, it is possible to adequately predict the required energy consumption. The linking of these systems leads to a better basis for decision-making and thus to greater insights. On the other hand, PSCs can use historical and weather data to calculate the amount of energy available and react to bottlenecks at an early stage. In this context, new technologies, like the smart meter can also be used in a meaningful way and contribute to the general objective of the energy turnaround. Here, smart meters and smart meter gateways provide the platform for the transmission of electricity prices as well as the respective demand levels. In addition, the solution to be developed will be established in familiar ecosystems, so that no transaction costs will arise for companies. One thing remains certain despite the change: Energy is the backbone of new innovations and will become an immanently important asset over the coming decades. In order to handle our planet carefully and to support the change in the energy industry, we saw ourselves induced to this research approach and have the noble goals to contribute to it. In our opinion, no major new system solution is required. Information systems have the necessary functions and the corresponding data foundation. The main objective here is to exploit the advantages of these mature systems by means of an adequate connection. This allows the potential of the systems to be expanded and enhanced. This research project is intended to test and evaluate this thought-provoking impulse.

A Web Browser-Based Application for Processing and Analyzing Material Flow Models using the MFCA Methodology

Christian Kunisch, Volker Wohlgemuth

HTW Berlin - University of Applied Sciences, Faculty 2: School of Engineering, Technology and Life, Berlin, Germany
Christian.Kunisch@htw-berlin.de, Volker.Wohlgemuth@htw-berlin.de

Abstract. In the context of IT for Green, the potential of the Material Flow Cost Accounting (MFCA) method has not yet been fully unleashed. Using the advantages of mobile data acquisition for material and energy flows, for instance right at a production plant, makes it easier to identify optimization potentials in sustainability management. Tapping this potential, for example through continuous data acquisition of sensor data from sensors in a production plant, can also be made more convenient. Studies conducted that the introduction and application of MFCA has brought significant ecological and economic benefits. They also revealed that there is very little MFCA specialized software on the market. This paper describes the objective and concept of a web browser-based application for the processing and analysis of material flow models and their evaluation with the MFCA methodology.

Keywords: MFCA, IT for Green, Web browser-based application, Angular, Material flow model.

1 Introduction

Reducing energy consumption, waste emissions and the use of primary resources helps to achieve sustainable development [1], which is why resource efficiency is a recent issue on the EU's policy agenda [1]. In the political orientation of the Federal Republic of Germany (German Resource Efficiency Programme II), too, the goal of resource-saving production is anchored as a field of action in the coming years [2]. Particularly the industrial sector should focus its current path towards more sustainable development, such as resource efficiency and cleaner production.

One way to increase material efficiency, i.e. to reduce the sum of input compared to output, is, among others, to uncover the true monetary value of waste generated in production processes through the methodology of material flow cost accounting (MFCA) and thus encourage entrepreneurs to recycle it or sell it to other entrepreneurs. This paper first briefly describes the current scientific status of the MFCA concept and then gives a detailed insight into the structure of the web browser-based application.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

2 Material Flow Cost Accounting

In the late 1990s MFCA has been developed in Germany [3-5], starting with first approaches of flow cost accounting [6]. In the following decade the Japanese Ministry of Trade and Industry (METI) strongly popularized MFCA in Japan [4]. To date, more than 300 Japanese companies have integrated material flow cost accounting [4].
Meanwhile MFCA is ISO-standardized to 14051:2011 (General framework) and 14052:2017 (Guidance for practical implementation in a supply chain). Now ISO 14053 is under development addressing MFCA in small and medium sized enterprises.

MFCA quantifies "the flows and stocks of materials within an organization in physical units (e.g. mass, volume) and the costs associated with those material flows are also evaluated. The resulting information can act as a motivator for organizations and managers to seek opportunities to simultaneously generate financial benefits and reduce adverse environmental impacts" [7].

The application of MFCA and the subsequent implementation of appropriate measures have shown that remarkable ecological and economic benefits can be achieved [4, 8]. A case study of an Argentinean sugar cane company proves that the use of MFCA and the resulting decision to acquire new facilities worth 350,000 US dollars saves 72,000 US dollars annually [9]. There is only a very limited number of software solutions specialized on MFCA, inter alia a desktop application „Umberto NXT MFCA" and "bw!MFCA" from the ifu Institut für Umweltinformatik Hamburg GmbH [10, 11] and the web application "Materialflusskostenrechner" of the VDI Zentrum Ressourceneffizienz GmbH [12].

Material flow cost accounting is to be promoted as a method because it optimally supports the combination of three perspectives. Firstly, the consideration of physical energy and material flows, secondly the monetary evaluation of savings potentials and thirdly the reduction potential of the climate impact. The material flow cost accounting method provides companies with information on waste and scrap losses. In particular, the true value of these losses is reported. This topic is therefore relevant for manufacturing SMEs, not least for reasons of increasing yields through increased resource efficiency. Based on achieved MFCA results, SMEs are enabled to optimize products and/or processes, to improve their business balance sheets and ultimately to contribute to securing Germany as a business location.

3 Web Browser-Based Application

Due to a lack of supporting software solutions for mobile data recording where the material and energy flows occur and for displaying the volume flows during tours of the production areas to support the development of process optimizations on site [13] the research project "MFCA mobile" was started in November 2017. The "Institut für Umweltinformatik Hamburg" (ifu) already developed a software for CO_2 balancing, material flow costing and visualization of material flows.

It also includes a material flow cost accounting component. But the software exists exclusively as a so-called desktop application for Microsoft Windows and can therefore only be used locally. A decentralized (mobile) data acquisition or an efficient on-site presentation of the collected data and models in the production areas is therefore not supported [13].

The central concept of the project is the combination of flexible data acquisition, validation and visualization on site with the opportunity of subsequent processing the data on the workstation computer using advanced tools that demonstrate optimization potential. One of the main objectives of the project is to implement a mobile variant to exchange data with the desktop version via a cloud service, creating new usage scenarios in the mobile context for material flow management and MFCA.

Through the mobile data acquisition and visualization and through the combination with an existing desktop application for MFCA, the application of the method for resource efficiency questions is significantly simplified. A further developed concept for data acquisition and representation of material flows will be developed and implemented. This should enable SMEs in the future to record their production processes in a structured way and thus implement operational material flow management. As an alternative to the autonomous approach, the efficient cooperation with experts/consultants will be optimally supported. Sankey diagrams are ideal for visualizing material and energy flows in production processes. They therefore also form a good basis for collecting material and energy flows as well as other data in production processes.

The interaction with a powerful desktop software should be used to intensify the cooperation between consultants and specialists in the company and to link the method of material flow cost accounting with an elegant data collection. The data collector in the company benefits from being able to check and modify the process modeling directly in the production environment on the tablet and to complete the model with data. The smooth and fast data exchange between consultant (desktop PC) and data supplier (tablet) in connection with the graphical representation of the production model leads to faster and better results. A special focus in the expansion of the concept will therefore be on the secure transmission of data by a cloud server including rights management. A commentary function for the work processes allows important work to be documented during the data acquisition tour in order to increase efficiency and to be noted for later implementation. The data to be entered i.e. can be:

- material and energy flows, the quantities of which are,
- Process specifications, their recipe factors, new inputs and outputs,
- Process parameters whose values are,
- Material properties, such as specific weight, price and more,
- Substance concentrations, substance properties and stocks.

The web browser-based application which is under development offers the following features:

- written in TypeScript with the frontend web application framework Angular,
- supports at least Chrome, Firefox and Edge,
- operable by mouse as well as by multitouch and
- is usable on smartphones, tablets and desktop.

The following Figure 1 shows an overview of the structure of the Web Browser-based application.

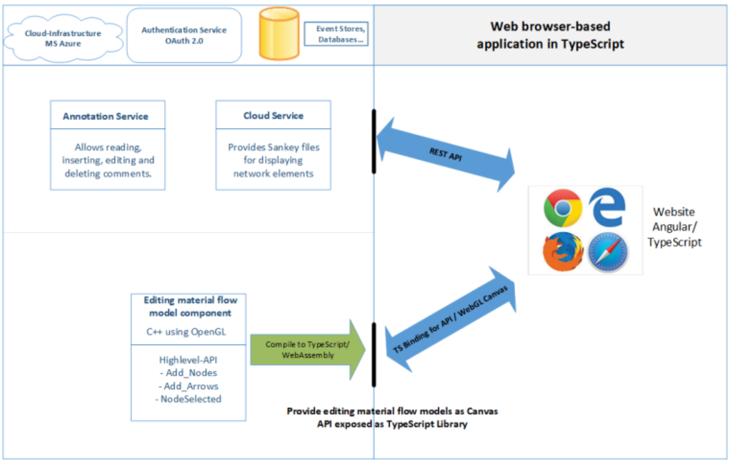

Figure 1. Overview of the structure of the web browser-based application

The Annotation-Service specifies metadata that is associated with web service implementations. It allows reading, inserting, editing and deleting of comments to the processes. The RESTful API is used for the communication between client and server [14]. Authentication and Authorization is implemented by the open protocol OAuth 2.0. It is the industry-standard protocol for authorization [15].

It allows secure authorization in a simple and standard method from web, mobile and desktop applications [16]. Other tools used in the infrastructure are GitLab Repositories [17], automated builds, deployment and test execution, a Build server at GitLab which consists of docker containers for building, deploying and testing and Microsoft Azure [18] for hosting the website whereat deployment can be started manually or automatically in GitLab.

4 Discussion and Outlook

The fact to gather data from mobile devices and push them into an existing material flow model offers the chance for an almost live calculation of the material flows and therefore the MFCA results too. This provides the opportunity to create a continuous and automated MFCA analysis. It is planned to have a mature prototype with these properties available in the first quarter of 2019. Completion is scheduled for January 2020. Currently we are implementing the authorization and authentication service for the web application. Further we are working on the routing and the router guards. With guards it is possible to add checks to restrict access to a user to certain pages [19].

This research project is funded by the "Deutsche Bundesstiftung Umwelt" (DBU). We would like to thank the DBU for their support.

Abstract. Conversational agents (CA), i.e. software that interacts with its users through natural language, are becoming increasingly prevalent in everyday life as technological advances continue to significantly drive their capabilities. CA exhibit the potential to support and collaborate with humans in a multitude of tasks and can be used for innovation and automation across a variety of business functions, such as customer service or marketing and sales. Parallel to the increasing popularity in practice, IS researchers have engaged in studying a variety of aspects related to CA in the last few years, applying different research methods and producing different types of theories. In this paper, we review 36 studies to assess the status quo of CA research in IS, identify gaps regarding both the studied aspects as well as applied methods and theoretical approaches, and propose directions for future work in this research area.

Keywords: Conversational agent, virtual assistant, machine collaboration, literature review

1 Introduction

Conversational agents (CA), i.e. software that interacts with users via written or spoken natural language, increasingly permeate our lives. Nowadays, mobile devices are equipped with powerful agents by default, such as Siri or Google Assistant, offering support for a variety of tasks such as researching information, scheduling meetings, or sending messages. At its 2018 developer conference, Google demonstrated the potential of CA in the (near) future by showing their assistant autonomously making an appointment with a hairdresser in a live phone conversation [1]. For organizations, capable CA offer a variety of applications ranging from team collaboration, such as in the form of cognitive assistants in workshops [2], to service provision at the customer interface [3–5], and have attracted increasing interest in practical implementation in recent years [6]. CA have been around for several decades, starting with the agent ELIZA developed by Joseph Weizenbaum in 1966 which simulated a psychotherapist [7], yet several agents did not fulfill expectations in the past [4]. As most of these agents were primarily rule-based, their potential and capabilities were rather limited. However,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

driven by advances in natural language processing and machine learning, modern CA emerge into seemingly intelligent software that can be used to support various tasks and enhance human cognitive capabilities [8], hereby changing the allocation of task between humans and machines [9]. As CA become an integral part of our lives and application grows increasingly versatile, we believe there are multiple aspects to study ranging from the design of such artifacts, understanding emerging, collaborative work practices to the introduction of CA in organizations for automation and innovation.

While CA have been researched extensively in human-computer interaction (HCI) and computer science (CS) with the different foci prevalent in these disciplines, such as user trust in CA in HCI or optimizing natural language understanding in CS [4], they attracted the interest of the IS community recently [10] because of their profound impact on both organizational as well as individual level. As of now, a variety of IS studies address different aspects, such as design principles [4], information disclosure by the user [11, 12] or the impact of the CA on user's cognitive abilities [13]. Against this background, we aim to structure and analyze what is already known in IS research regarding CA and derive directions for future studies with the following research question:

RQ: What is the status quo and what are future directions for IS research on CA?

In order to address this question, we conduct a systematic review of IS literature with a focus on highly-regarded journals and conferences. We analyze 36 publications in terms of studied CA characteristics as well as the produced IS theory types and applied research methods. This allows us to better understand and structure existing work as well as to derive future research directions. We continue by providing the theoretical background of CA and outlining our research approach, a systematic, concept-centric review of IS literature [14]. We then present the insights from our analysis, discuss the results and close this paper by formulating research directions for future studies on CA.

2 Research Background

CA are systems that interact with people using natural language, thus simulating behavior of a human being [4, 15, 16]. Terms, such as virtual assistants, chatbots or dialogue systems are often used synonymously [4, 10]. As natural language can be written or spoken, CA communicate with their users via written language, speech, or both [17]. CA that communicate with users via written language, often referred to as chatbots, include agents such as Rose (a bot with the personality of a security analyst and hacker from San Francisco) or Mitsuku who can play games or reason with specific objects while simulating a 18-year old woman from Leeds. Examples in a company context are the CA of KLM, called BlueBot [18], that allows to find and book flights, the chatbot by H&M that provides personal shopping recommendations [10] or Amtrak's customer service bot that handles more than one million customer requests per year [19]. The most popular CA with speech-based input can be found on mobile devices that are used in our daily lives, such as Alexa, Siri, Microsoft's Cortana, or Google's Assistant.

Nowadays, more than 100.000 bots engage with users on a global scale on Facebook, and companies are showing great interest as more than 80% have already implemented bots for customer service or plan to do so by 2020 [6]. With several enterprise platforms in the market, such as IBM's Watson Conversation Service, the Microsoft Bot Platform or DialogFlow by Google, companies can now easily procure and customize off-the-shelf solutions to introduce CA in their organizations.

Due to the significant improvements of CA, the widespread diffusion of powerful mobile devices, and continuing trends toward digitization, a variety of CA has emerged in the past few years both in private as well as professional life. While general-purpose CA, such as Siri or Google Assistant cover a wide range of functions, domain-specific agents focus on specific tasks or domains. For example, CA can be used for automation in customer service [3, 4, 20], as digital sales assistants [21, 22] or in human resources to provide support for new employees [23]. Thus, in addition to the communication mode, CA can also be differentiated by the context in which they are used [4].

Furthermore, CA can be represented in different forms, such as with static virtual avatars [8, 24], interactive virtual avatars [25, 26], physical embodiment [27, 28] or be disembodied, i.e. lack any form of representation and only provide a natural language interface [29]. These different forms offer a variety of design options and provide non-verbal cues that influence how a CA is perceived by a user [30, 31]. For example, the experiments of Qiu and Benbasat [32] on the virtual static representation of a CA indicate that matching the ethnicity leads users to perceiving the CA as more enjoyable, sociable and useful. Additionally, Al-Natour et al. [33] investigated online shopping assistants with a focus on personality and behavioral similarity and found that customers evaluate CA that are similar to themselves more positively and show higher intentions to reuse them.

3 Research Approach

To review existing work on CA in IS research, we follow a literature review process based on the approaches of Webster and Watson [14], Brocke et al. [34], and Bandara et al. [35]. Our review consists of three phases. First, we gather studies regarding CA from established and relevant IS journals and conferences. Second, we code the identified literature along five dimensions: CA mode of communication, CA context, CA embodiment, IS theory type, and IS research method. Finally, we analyze the literature by using a concept matrix to assess the status quo of CA research and derive directions for future studies.

Table 1. Research approach phases

	Phase 1: Gather literature	**Phase 2: Code literature**	**Phase 3: Analyze literature**
Inputs	Publication databases and outlets	Literature database	Coded literature database
Methods	Literature search	Coding	Literature analysis
Steps	Conduct search and filter literature	Define coding dimensions and code literature	Create and interpret concept matrix
Results	Literature database	Coded literature database	Overview of CA research and implications

For the literature search process, the relevant literature outlets had to be identified. We decided to focus on highly-ranked publication outlets [36] and extend them by current studies from IS conferences. Hence, we focused on articles published in the basket of eight [37] and complemented these with selected conferences (ICIS, ECIS, WI, MKWI, HICSS, AMCIS, PACIS) to incorporate recent research because CA have just recently started to attract the attention of the IS community [10]. To gather publications, we used the Web of Science and AIS Electronic Library databases. Furthermore, we also included the website of the respective journal or conference if the outlet was not already included in the databases. The following search query was used:

Conversational Agent OR Virtual Assistant OR Dialogue System OR Chatbot

The full-text search was conducted in November 2018 by two of the authors. We omitted identical results and briefly scanned titles as well as abstracts to remove irrelevant articles. For example, studies with a focus on agents could research autonomous software agents that are used to fulfill specific tasks, e.g. in e-commerce, yet lack the conversational nature of the agents analyzed in this study. Similarly, the term agent included studies on human service agents, such as in customer service, which are not the focus of our review and thus were excluded. After this search and filtering process, 36 articles remained (see Table 2, outlets without relevant results are omitted).

Table 2. Literature search results

Pacific Asia Conference on Information Systems	198	4
Hawaii Int. Conference on System Sciences	100	5
Americas Conference on Information Systems	518	7
	Total	36

In phase two of our work we coded the literature along different dimensions. To assess the status quo, we chose a combination of dimensions related to the content of the studies (communication mode, context, embodiment) as well as regarding the methodological approach (research method) and type of produced knowledge (theory type). Thus, we were able to identify research gaps both related to the content as well as from a methodological and theoretical perspective. Difficult decisions during the coding process, such as assigning a research method in a study that uses a combination of methods, were discussed by both authors. For example, the study by Seeger et al. [38] develops a design framework and evaluates it based on an online experiment. In this case, we assigned the method "framework/conceptual model" as this can be considered the main contribution of the study. Furthermore, we differentiated the theory types "explanation" and "design and action" by the explicit formulation of design principles and patterns [39] whereas studies that explain user interaction with a CA often also provide valuable implications for the design (e.g. [40]).

Regarding the content-related dimensions, we determined the communication mode of the CA (text-based, speech-based, or both) to account for the fact that natural language can be written or spoken [17]. Furthermore, we assessed whether the study deals with a general-purpose CA or an agent that is domain-specific, i.e. used for a specific task or function [4]. Finally, we considered the embodiment of the CA [41], i.e. whether it has a static virtual representation, an interactive virtual representation, a physical representation or no form of representation at all. We extended these dimensions by the research methods and produced IS theory types. Palvia et al. [42, 43] assessed the research methods specifically in IS, thus we selected their methods to code our studies. With regard to the IS theory types, Gregor [44] distinguishes five types, which we used in our coding: Analysis (theory that describes and analyzes reality without the identification and structuring of cause-effect relations), explanation (theory that provides explanations for cause-effect relations but does not formulate propositions), prediction (theory that contains testable propositions but does not provide justification or explanation), explanation and prediction (theory that provides both causal explanation and testable propositions), as well as design and action (theory that informs the development of artifacts). In total, we coded the studies along five dimensions (Table 3) and all studies were assigned one characteristic per dimension.

In the third and final phase, we analyzed the coded literature by means of a concept matrix [14]. A concept matrix helps to view literature from a concept-centric [45] position and thus fosters an understanding of research beyond descriptive content summarization [14]. Furthermore, it helps to study the distribution of characteristics within the dimensions and paves the way for answering our research questions.

4 Results

To summarize the insights gained from the literature review, we created a concept matrix (Table 4, characteristics not present in the literature database were omitted). In the following, we present the results of this structured literature analysis in detail.

Concerning the primary mode of communication, all three interaction types (text-based, speech-based, and combined) are addressed. Text-based CA (16 of 36) were for example explored in the context of user information disclosure behavior for sensitive topics [26], user perception of customer service agents with a focus on different agent- and communication-related cues [8], and the design of a natural search agent for legal research [29]. Research on CA that interact with users via speech (8 of 36) addressed for example lie detection by the CA [41] or service satisfaction with and continued use voice assistants [46]. Studies that focus on combined modes of interaction (12 of 36) include, for example, a study by Schroeder and Schroeder [11] comparing differences between interaction modes regarding users' willingness to share personal information and the development of overarching design principles for CA [4].

With regard to the agent context, multiple studies research general-purpose CA (16 of 36) with a focus on aspects such as CA influence on decision-making [47] or the relation between CA capabilities and user experience [48]. Domain-specific CA (20 of 36) are studied in different contexts. Half of the studies on CA in specific domains focus on marketing and sales [21, 40, 49, 57, 59, 60, 64, 66–68], e.g. as product recommendation agents [40, 49] or in-store shopping assistants [21]. Furthermore, four studies investigate the use of CA in customer service [4, 8, 55, 56]. The six remaining domain-specific CA studies focus on a variety of specific contexts: Automated interviewing [41], gamified environments [52], workshop moderation [62], idea platforms [65], contracting [53], and legal research [29].

Concerning the embodiment of CA, most studies examine CA that do not have a virtual or physical representation (21 of 36), such as simple natural language systems [12, 29] or disembodied voice assistants [57, 64]. Further studies (10 of 36) explore CA with a virtual and static embodiment. For example, Wünderlich and Paluch [8] argue that the image of a CA represents an agent-related cue and describe its (potential) helpfulness for the user for perceiving a CA in a service encounter as authentic. Few studies address CA with a virtual interactive embodiment (3 of 36) or a physical embodiment (2 of 36). The three studies with a focus on CA with a virtual interactive representation indicate that interactive avatars can contribute to user affinity towards the CA through matching common human non-verbal cues [25], use facial expressions and gestures to increase perceived human-likeness [62], and might lead to more socially desirable responding for sensitive topics by users [26]. In addition, Nunamaker et al. [41] present a physically embodied CA with multiple sensors for interviewing and study different aspects of user interaction, such as perception of different CA genders or smiling. Finally, Stock and Merkle [56] study the use of a physically embodied, humanoid CA in a service encounter and find in their laboratory experiment that customer responded rather positively to innovative service behavior.

Regarding the produced IS theory types in the studies, most of the reviewed articles provide theories that intend to explain (21 of 36) different aspects of human-CA interaction, such as trust [44, 66], self-disclosure of information [66], or perceived authenticity [8]. Studies with a theoretical orientation towards design and action (12 of 36) for example provide design principles for CA in customer service [4] or for assistance in creative workshops [62], study the effect of dynamic response times on perceived social presence, perceived human-likeness and social presence [55] or evaluate anthropomorphic product recommendation agents [49]. Studies that focus on analysis (3 of 36) study capabilities of CA and user experience through the analysis of app reviews [48], consider the use of CA in e-commerce [68] or for information resource management [50].

The research methods used in the reviewed studies revealed a focus on laboratory experiments (18 of 36) which is one of most common methods in IS research [42, 43] and seems to be suitable to CA research as these experiments can provide useful insights into human-computer interaction. In addition, secondary data (4 of 36), such as data on consumption behavior for digital content through CA [57] or app reviews for virtual assistants [48] is used in the reviewed studies. Further research methods applied in the reviewed studies include the development of frameworks or conceptual models, interviews, literature analyses (each 3 of 36), case studies and speculation/commentary (each 2 of 36) as well as a field experiment by Al-Natour et al. [21].

5 Discussion

The goal of this literature review was to examine the status quo of CA within the field of IS research and provide directions for future work. In the following, we discuss our results and propose directions for prospective studies on CA.

5.1 State of CA Research in IS

Overall, our literature review shows a strongly increasing interest in CA in IS research, confirming similar statements by other scholars [4, 8, 55]. More than half of the identified studies were published in the last two years. The reviewed studies explore different communication modes, various application domains for CA and use different research methods to primarily produce theories for explanation and prediction as well as design and action.

Concerning the context in which the CA are studied, our results indicate a variety of different application domains of CA ranging from product recommendations [40, 49] over workshop moderation [62] to the use of CA for legal research [29]. In particular, marketing and sales (10 of 20 domain-specific studies) as well as customer service (4 of 20 domain-specific studies) were explored frequently, which are the two most popular application domains in an enterprise context for text-based CA [69, 70]. However, studies on CA as collaborators in team settings, i.e. machines as teammates [2], are limited to a single study on virtual workshop assistance [62].

With regard to the theory types, we find that only 12 of 36 studies produce theories to inform and guide the design of CA whereas successful design represents a major challenge in practice [16, 77, 78]. Interestingly, nearly all design-oriented studies focus on domain-specific CA, such as the design principles formulated by Gnewuch et al. [4] for CA in customer service or by Al-Natour et al. [21] for CA as shopping assistants.

We further observe a research focus on disembodied CA or CA with a virtual static embodiment (31 of 36) whereas studies on CA with virtual interactive embodiment or physical embodiment remain sparse. Many of the reviewed studies examine text-based CA, or chatbots, that are typically represented by means of a static avatar or lack any form of (virtual) embodiment [4]. A notable exception is the study by Stock and Merkle [56] who explore the use of the humanoid robot Pepper in a service encounter. Finally, our review of the applied research methods shows a focus on laboratory experiments (16 of 36) while the exploration of CA in the field, for example with the help of case studies (2 of 36) or field experiments (1 of 36) is limited.

5.2 Research Directions

Based on our assessment of the status quo, we propose four directions for future CA studies in IS research (Table 5): First, we suggest to extend the investigated application domains with regard to team settings in which a CA serves as a collaboration partner. While CA have the potential to support collaborative work [2], for example through the ad-hoc provision of information, we found only one study that addresses this context by developing design guidelines for CA as assistants for workshop moderation [62].

Second, we propose to conduct more and contrast design-oriented studies due to the rather limited number of studies that inform CA design and the fact that design remains a major challenge in practice [16, 71, 72]. As the contexts in which CA design is investigated become increasingly diverse, we believe it can be useful to contrast design knowledge across different contexts to identify common design principles as well as domain-specific aspects. For example, CA design for marketing and sales could place emphasis on increasing the persuasiveness of the agent [73] while a CA in customer service could benefit from being particularly empathetic in service encounters [20].

As a third research direction, we recommend to specifically study CA with a virtual interactive or physical embodiment as only five of the reviewed studies investigate embodied CA. Compared to disembodied CA or agents with a virtual static representation, embodied CA offer an increased variety of cues, such as facial expressions or gestures, that impact user interaction and provide additional options for design [30]. As technological approaches to create virtual interactive avatars improve [25] and physically embodied CA emerge, such as SoftBank's Pepper, we argue that studying their special features becomes increasingly relevant.

Table 5: Research directions and rationale

Direction	Description	Rationale
Investigate CA in team collaboration settings	Exploration of CA as innovative collaboration partners in team settings	CA in collaboration are only addressed by a single study despite their potential
Conduct more and contrast design-oriented CA studies	Formulation of design principles and design as well as evaluation of expository instantiations	Lack of design-oriented studies and successful CA design as a practical challenge
Explore virtually or physically embodied CA	Study of interaction with and design of embodied, both virtually and physically, CA	Existing focus on disembodied or virtually static embodied CA with limited social cues
Study CA introduction and use in the field	Expansion of CA research to the field, for example through case studies or field experiments	Half of the reviewed studies apply laboratory experiments in controlled settings

Finally, we propose to investigate real-life settings, for example through case studies or field experiments as half of the identified studies used laboratory experiments for their work. From our point of view, these experiments are useful for investigating different aspects in user and CA interactions in controlled settings. Nonetheless, we believe that future research can benefit from applying additional methods in the field [42, 43] regarding actual CA introduction and usage in enterprises in real-world settings. With these methods, results from CA studies can also provide stronger practical insights and thus ensure the relevance of our work for practitioners.

6 Concluding remarks

The aim of this research essay was to assess the status quo of CA in IS research and derive directions for future work. We conducted a systematic literature review and analyzed 36 studies with regard to five dimensions: CA context, CA communication mode, CA embodiment, IS theory type, and IS research method. Based on our findings we propose to move CA research in IS forward by the investigation of CA in collaborative settings, a stronger focus on design-oriented research, the exploration of embodied CA, and the study of CA in the field. While our study contributes to the understanding of the current state of CA research, it will require future updating and re-analysis as new studies emerge. Furthermore, we deliberately included only IS research in our study without incorporating work from other disciplines, such as human-computer interaction or computer science, to capture the status quo in IS research. We suggest that future work expands the view towards these disciplines when investigating design of or interaction with CA.

Overall, we believe that studying CA is a valuable research endeavor. In particular due the increasing capabilities of these agents and the variety of applications in private and professional life, they are an interesting, dynamic phenomenon to investigate in the context of digital transformation and can provide insights into new forms of human-computer interaction.

Abstract. Accidents at work can happen at any time, but employees often do not feel prepared for such situations and therefore provide inadequate first aid. Using the Design Science approach, we developed a concept for an Augmented Reality (AR) application which uses voice assistance and visual AR overlays to support occupational first aiders with instructions in accident situations. The concept was implemented in the form of a video prototype and evaluated through interviews. The evaluation revealed that the application would enable employees without first aid training to apply first aid measures quickly and correctly; thus, reducing the probability of serious consequential injuries and costs in connection with occupational accidents.

Keywords: Augmented Reality, Digital Work, Occupational First Aid, Design Science, Design Thinking

1 Introduction

Digital technologies have not only become an integral part of our daily lives but also continuously change the way we work [1]. As a result of this development, digital transformation defined as "the use of digital technologies to enable major business improvement [2]" has emerged as an important topic for academics and practitioners alike. A major challenge companies currently face, is the development of new digital business models and the optimization of internal work processes through the use of emerging technologies [3]. These emerging technologies include, for example, Augmented Reality (AR) which allows virtual elements to be displayed in a person's field of vision [4]. Large companies like Facebook are already investing a lot in the further development of this technology, which is why AR has evolved into a trend topic [5]. According to the Gartner Hype Cycle, however, AR has already exceeded the peak of inflated expectations and it is therefore time to realistically evaluate the added value of the technology [6]. In this paper, we focus on the potential of AR instructions for improving the first aid measures provided after work-related accidents. We argue that using technology support in this area represents an opportunity for major business improvement, as the direct U.S. workers compensation costs of the ten most disabling workplace injuries in 2017 accounted for nearly 60 billion US dollars [7]. After an

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

accident at work, the immediate provision of appropriate first aid measures is of high importance for the prevention of more severe long-term injuries associated with higher costs [8]. Nevertheless, studies have repeatedly shown that appropriate first aid is often not provided because of a lack of first aid knowledge [9, 10].

We therefore used the Design Science approach [11] to develop a concept for solving this organizational problem. Early studies have already revealed that AR instructions can improve task performance and reduce mental workload while performing assembly tasks [12–14]. We propose that AR instructions could be well suited to guide workers while performing occupational first aid as well. The AR guidance could reduce uncertainties of workers while performing first aid leading to improved first aid measures and lower costs as a result of work-related accidents. The first goal of our research was to propose occupational first aid support as an additional use case for AR. In this regard, we developed a concept describing which functionalities an AR application would need to improve occupational first aid. The second goal of our research was to evaluate whether the proposed concept could solve the organizational problem of insufficient first aid measures after work-related accidents. Therefore, we implemented the app concept in the form of a video prototype and conducted evaluation interviews to receive feedback from potential users. Hence, we examine the following research question: **How can AR be used to improve occupational first aid?**

In the next chapter, we provide a theoretical background on occupational first aid and AR. Then, we describe how we developed the AR application concept and the corresponding video prototype by conducting a design thinking workshop. Afterwards, we present our concept and explain how we used the video prototype in combination with interviews to evaluate our concept. We conclude with a presentation of the evaluation results and a discussion on the added value of our AR concept.

2 Background

2.1 Occupational First Aid

In Germany, every person is legally obligated to provide first aid and non-assistance of an injured person can be sanctioned with imprisonment of up to one year or a fine (§323 StGB). Furthermore, employers are required to ensure that first aid is provided to their employees in case of an accident at work (§10 ArbSchG). Depending on the size and industry of a company, up to 10% of employees must complete a first aid course and repeat this course every two years (§26 DGUV Vorschrift 1). Similar legal regulations exist in other countries as well (e.g. US Occupational Safety and Health Act).

The training of occupational first aiders is essential because the survival rate and severity of an injury caused by an accident at work strongly depend on the provision of immediate and correct first aid measures. In this regard, it was already demonstrated that the provision of appropriate first aid measures can significantly reduce the hospital stay of workers who suffered from chemical burns after an accident at work [8]. The importance of performing cardiopulmonary resuscitation (CPR) correctly and immediately after a cardiac arrest to increase the injured person's survival chance has also been emphasized in prior research [15]. Occupational first aid training can contribute to preventing more severe injuries or casualties after an accident at work. Several studies revealed that bystanders who are trained in first aid respond more frequently in medical emergency situations and provided first aid measures of higher quality [16, 17]. However, other studies revealed that bystanders are often hesitating to provide first aid for several reasons such as fear of liability, lack of confidence, fear of making things worse and anxiety about performing in front of an audience [18]. Related to this, the usefulness of first aid training is often questioned as many studies show a quick decline of first aid knowledge and skills shortly after completing a first aid course. In a study with occupational first aiders, only 12% of the participants were able to perform CPR correctly six months after participating in a certified first aid course [9]. Similar results were also obtained in a more recent study in which only 5% of industry workers who completed a first aid course were able to answer questions about the estimation of vital signs and performance of CPR [10]. Moreover, a simulated scenario showed that trained participants tried to respond in a medical emergency situation but performed inappropriate first aid measures further damaging the injured person [19]. The researchers who conducted the aforementioned studies concluded that the repetition of a first aid course every two years is not sufficient to ensure an immediate and appropriate medical emergency response at work.

Summarized can be said that most research on occupational first aid comes from the medical field and focuses on assessing the effectiveness of first aid training and improving education in first aid. However, prior studies have continuously shown a quick decline of first aid knowledge and skills after course completion. Therefore, we assume that providing occupational first aiders with AR instructions during a medical emergency situation might be a more effective approach to ensure an immediate and appropriate response to an accident at work.

2.2 Augmented Reality

Milgram and Kishino [20] describe a virtual environment as “one in which the participant observer is totally immersed in and able to interact with, a completely synthetic world”. Information systems researchers agree that virtual environments enable users to experience a higher level of immersion, presence and interactivity than other systems [21]. Not all technologies, however, are able to present virtuality to the same degree. Thus, Milgram and Kishino [20] align physical reality, mixed reality and virtual reality along the so-called virtuality continuum. In physical reality, only objects that exist in the real world can be perceived, while virtual reality entirely consists of objects that do not exist in the real world. On the virtuality continuum, mixed reality is located in between and defined as an environment “in which real world and virtual world objects are presented together within a single display” [20]. Thus, AR becomes a subset of mixed reality which 1) combines real and virtual objects, 2) is interactive in real time and 3) registered in three dimensions [4]. This definition illustrates that the user of an AR application still maintains a sense of presence in the real world while the perception of his or her environment is enhanced by virtual objects [22]. Due to these characteristics, AR is most useful when “the success [of a task] is increased or made more likely (…) through additional visual information being presented alongside the physical world" [22].

A systematic literature review on AR in the field of information systems revealed that many previous studies focused on the use of the technology in the context of gaming, communication and collaboration processes, e-commerce, manufacturing, maintenance, education and health care [23]. Some of these studies have already demonstrated how the use of AR can lead to major business improvements. For example, Niemöller et al. [24] identified 38 work processes in the logistics industry which could benefit from the use of smart glasses. Furthermore, prototypical AR systems for providing manufacturing workers with assembly instructions have been implemented [13, 14]. An experimental study also revealed that AR instruction systems could improve task performance and reduce mental workload while performing assembly tasks [12]. In this paper, we propose that AR instructions could also be used to improve occupational first aid reducing consequential damage as a result of work-related accidents and costs for continued payment of compensation.

3 Research Approach

3.1 Design Science Research

The goal of Design Science Research (DSR) is the development and evaluation of an "IT artifact created to address an important organizational problem" [25]. According to March and Smith [26], artifacts can be either constructs (vocabulary and symbols), models (abstractions and representations), methods (algorithms and practices) or instantiations (implementations and prototypes). In this research, we developed a concept for an AR first aid application and instantiated this concept in the form of a video prototype. In information systems research, prototypes have been defined as the "first embodiment of an idea" [27] and they should "capture the essential features of a later system" [28]. Most important is that an innovative concept can be tested and to accomplish this goal "neither the prototype's form nor the materials used in its construction have to be those of the final design" [29]. As the main goal of this research was not to explore the technological limitations of AR but to demonstrate an innovative AR use case and gain feedback from potential users, we considered the implementation of the AR application concept as a video prototype to be appropriate. During our research process, we adhered to the seven DSR guidelines by Hevner et al. [25] and followed the DSR methodology process model which is widely accepted in information systems research [11]. A key element of DSR is to use feedback gained through evaluation to further refine the initial design. Therefore, we plan to transform the video prototype into a functional prototype based on the evaluation results in future research. The methods we applied to perform each step of the DSR methodology process are summarized in Figure 1 and further explained in the following chapters.

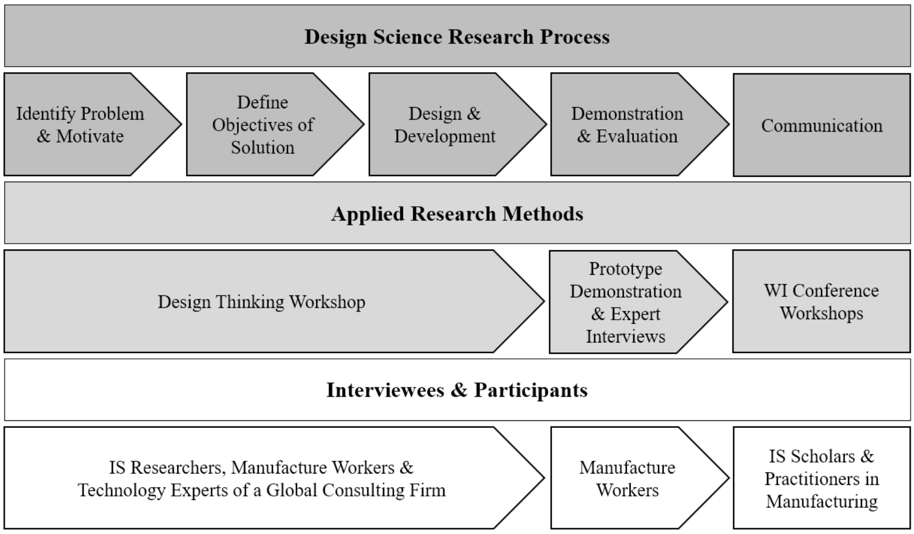

Figure 1. Research Design based on the DSRM Process Model [11]

3.2 Design Thinking Workshop

Though the DSR methodology process model specifies the different phases of DSR, "not much guidance is provided in information systems literature" [30] when it comes to how the goals of each phase can be achieved rigorously. Dolak, Uebernickel and Brenner [31], however, argue for an extension of DSR through Design Thinking (DT) and propose that considering DT as a valid DSR method would provide an added value for the field of information systems. We therefore decided to conduct a DT workshop with three teams including information systems researchers, manufacture workers and technology experts of a leading global consulting firm. We made the decision to invite manufacture workers as participants because the manufacturing sector belongs to the ones in which the highest number of accidents at work occur [32].

DT is a systematic, human-centered innovation approach utilizing design tools for solving organizational problems [33]. Brenner et al. [34] describe the DT process, methods and mindset as the three core elements of DT. A typical DT workshop is structured as follows [35]: The aim at the beginning of the DT process is to gain an understanding for a business problem and develop empathy for future users of the designed solution. Afterwards, ideas for a user-centered solution are developed and transformed into a prototype which is then evaluated with relevant stakeholders. Specific DT methods were developed for each phase of the DT process, for example, the empathy map technique is suitable for developing an understanding for stakeholders' needs in the initial phase [36]. The DT mindset frames the DT process and includes requirements for an effective collaboration such as multidisciplinary team constellations, unconstrained thinking and openness to unexpected ideas [37]. The structure of the DT workshop conducted in this research including the sequence of phases and applied methods can be found in Figure 2.

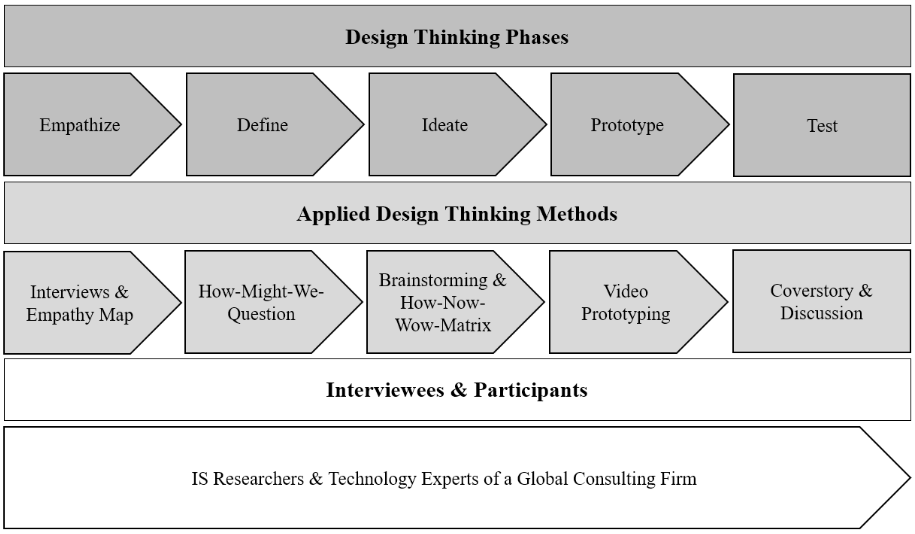

Figure 2. Structure of the Design Thinking Workshop Based on the Hasso-Plattner Institute D-SCHOOL Design Thinking Process [35]

The participants were informed in advance that an innovative AR solution for the improvement of occupational first aid measures should be developed during the workshop. In the first phase of the DT workshop, each researcher interviewed one of the participating manufacture workers using the empathy map technique. The workers were asked to share their experiences about accidents at work and the provided first aid. At the same time, the remaining team member took notes on the four quadrants of the empathy map: 1) what the person thinks and feels, 2) what the person sees, 3) what the person says and does and 4) what the person hears. For example, the first quadrant includes interviewee statements about thoughts and feels when he or she witnessed how a colleague had an accident at work.

The interviews revealed that work-related accidents occur frequently at the workplaces of the interviewees, although their employers invest a lot of money in occupational safety measures. Frequently mentioned work-related injuries were cuts, bruises and, in some cases, separated limbs because employees did not always wear protective clothing or disregarded road markings. Each participating worker had already experienced an accident at his or her workplace and was able to describe the treatment of an injured worker. In most cases, another person informed an occupational first aider who called an ambulance and provided first aid. The workers who participated in the DT workshop did not provide first aid in these situations because they were unsure whether they were allowed to do so without occupational first aid training and because they were not sure how they could help their injured colleague. Some interviewees also doubted that occupational first aiders are well prepared for every situation, as the obligatory first aid courses were described as rather short and superficial. All interviewees would welcome technological support in accident situations at the workplace. However, some thought that their employers would not be

willing to invest money in technological first aid support, as they already have to spend money on the obligatory training of occupational first aiders. Based on these insights, we defined the following how-might-we-question as guidance for the ideate phase:
How might we use AR to support occupational first aiders during an accident situation in a way that employers are willing to invest in this solution?

A brainstorming session followed in which each team generated ideas for an AR solution to address the problem stated in the how-might-we-question. To select one promising idea to pursue further, the teams made use of the how-now-wow-matrix. The x-axis of this matrix denotes the innovativeness of the ideas and the y-axis shows the feasibility. Ideas which were original but difficult to implement were sorted into the how-sector while the now-sector included ideas which were unoriginal but easy to implement. Most promising is the wow-sector including the most innovative and simultaneously feasible ideas. Each team then selected one idea of the wow-sector and created a video prototype demonstrating their idea to the other participants. As a last step, all teams imagined how their workplace could look like in the future after their solution has been implemented. Their visions were presented to the other participants in the form of a cover story about the successful implementation of their solution at their workplace. At the end of the workshop, the participants discussed which of the presented ideas provides the best solution for the problem stated in the how-might-we question and is technologically feasible as well. It was decided to further develop the idea of an AR mobile application which uses AR overlays and voice assistance to guide occupational first aiders in a medical emergency situation. The participants considered the combination of AR overlays and voice assistance as particularly innovative and assumed that this application would also be technologically feasible.

3.3 Further Development of the Artifact

After the workshop, the initial prototype of the AR mobile application was developed further. We used the design toolkit Sketch to design the user interface of the application. For each screen or interaction within a screen we created an artboard on a Sketch page. Then, we determined the logical user flow by linking artboards with their trigger action. We integrated pictures of a simulated accident situation into the Sketch artboards and used Photoshop to design AR overlays visualizing first aid instructions. Furthermore, we recorded ourselves to simulate the instructions of the voice assistant. The video prototype demonstrates how the application could be used to put an unconscious person in the recovery position. Of course, the final application should support employees in providing various other first aid measures. Screenshots of the visual first aid instructions demonstrated in the video prototype can be found in Figure 3. The figure also includes the voice assistant's instructions which are based on an online tutorial provided by the first aid charity organization St Johns Ambulance [38].

Figure 3. Screenshots of the Video Prototype Including Voice Assistant Instructions

3.4 Demonstration and Evaluation

To evaluate the usefulness of our artifact for the defined organizational problem, we demonstrated the video prototype to manufacture workers and conducted evaluation interviews. Though video prototypes do not yet provide complete functionality, different studies have shown that evaluation feedback gained through the demonstration of a video prototype does not significantly differ from the feedback gained through usability testing [39, 40]. Moreover, video prototypes have already been used in previous research to evaluate AR mobile applications [41, 42]. The interviews were transcribed and analyzed using the qualitative content analysis approach of Mayring [43] to assess the usefulness of the artifact and identify areas for further improvement. An overview about the interviewed manufacture workers can be found in Table 1.

Table 1. Description of Interviewees

No.	*Sex*	*Age*	*Job Title*
1	male	51	metal worker and safety coordinator
2	male	35	logistics specialist and safety coordinator
3	female	25	electronics technician
4	male	23	machine and equipment operator
5	male	25	car mechanic
6	male	25	assembly line worker

Prior to the interview, the participants were informed that they were about to evaluate an AR application for the assistance of occupational first aiders. Furthermore, we gave them a short introduction to AR and voice assistants. Then, the video prototype demonstrating the use of the application in an exemplary accident situation was shown to the participants. Afterwards, they were asked about their first impression of the presented application and to describe the functionalities of the application in their own words to identify potential misunderstandings. The interviewees then explained in detail what they like about the application and which improvements they would like to see. Furthermore, they indicated whether they would use the application.

4 Description of the AR First Aid Application Concept

The mobile AR application ImmediAID supports employees in providing first aid during medical emergency situations at the workplace. It is envisaged that an integrated voice assistant gives the user instructions and that these are visualized through AR overlays, so that even employees without any knowledge about first aid would be able to help an injured colleague at the workplace. The proposed functionalities of ImmediAID are explained in the following:

Emergency call: In the case of an accident, the employee uses the voice command "I am in an accident situation!" to activate the integrated voice assistant. The voice assistant then asks the employee whether an ambulance is required. If the employee answers "Yes" an emergency call is automatically initiated, the employee reports the accident and stays in the line until the emergency call center personnel ends the call. If the employee answers "No", the emergency call is not initiated and the voice assistant of ImmediAID continues to assist the employee.

Injury detection: The integrated voice assistant is able to detect the type of injury to guide the employee through the necessary first aid measures. If an emergency call was initiated, the voice assistant uses natural language processing and an interaction model to analyze the call between employee and emergency call center personnel in the background. If the emergency call was not initiated, the voice assistant asks the employee closed questions to assess the type of accident situation.

AR first aid support: Once the voice assistant has detected the type of injury, the appropriate first aid measure is looked up in a database which should be created in cooperation with medical personnel. Then, the voice assistant helps the employee to provide first aid by giving verbal instructions. Now, the employee aims with the smartphone camera at the injured person. AR overlays are shown on the smartphone display to visualize the verbal instructions of the voice assistant or the emergency call center personnel. ImmediAID is, for example, able to show the employee how to place an injured person in the recovery position by visualizing the correct angle and position for each body part with AR overlays. The accuracy of the AR overlays is ensured by using the OpenPose key point detection for identifying the body parts and axes of the injured person. An accuracy analysis of OpenPose demonstrated that the algorithm based on convolutional neural networks classified human postures in 95% of all images included in the test dataset [44].

AR first aid training: ImmediAID cannot only be used when an accident has already happened but also to prepare employees for a case of emergency. The app includes several AR first aid training tasks, for example, employees can practice how to place an injured person in the recovery position or how to perform CPR. Similar as in a real accident situation, the employee aims with the smartphone camera at a training partner or dummy. Then, the voice assistant guides the employee through the first aid exercise and each step is visualized on the smartphone display with AR overlays.

5 Evaluation Results

The evaluation revealed that the majority of the interviewees could imagine using an AR first aid app in an accident situation at the workplace. All interviewees stated that they would have felt able to carry out the instructions correctly as the instructions of the voice assistant and the displayed AR overlays were clear and easy to understand. It was also mentioned that the app would enable even staff members without first aid training to help. One interviewee liked the fact that the correct position of body parts was displayed in the form of AR overlays, as this makes it easier to follow the instructions. Related to this, one interviewee rated it positively that not only a video tutorial was shown, but AR overlays were displayed directly on the affected person. Most interviewees said that they would be glad to have such an app in an emergency, as it would give them a feeling of security. In this context, one interviewee could imagine that a well-chosen voice of the assistant could have a calming effect on first responders. A further interviewee found the voice input practical, so that one does not have to use one's hands to operate the smartphone when providing first aid. More than half of the interviewees were convinced that their employer would invest in AR support for occupational first-aiders. The interviewees described that their employers are already investing a lot of money in the occupational safety of their employees as work-related accidents are always associated with high costs such as rising contributions to the employers' liability insurance association. At the same time, costs are incurred for recruiting and training new employees if an injured person is absent for a longer period due to severe consequential damage as a result of a work-related accident. In addition, frequent occupational accidents are subject to increased controls by occupational safety authorities which are associated with costs and obligations.

Overall, the app idea was rated very positively, nevertheless, some of the interviewees also made suggestions for improvement. Most interviewees described the sound of the voice assistant as too mechanical and choppy. In this regard, the choice of a calming voice was recommended to reduce panic in an emergency. Another interviewee stated that he would be able to follow the instructions better if the voice assistant would speak more slowly. Due to his red-green visual impairment, one interviewee had difficulties to see the red AR overlays while another interviewee mentioned that the AR overlays were difficult to see in bright sunlight. It was therefore suggested that the app should automatically detect the brightness, background color, and color of the affected person's clothing to dynamically adjust the color of the AR overlays. As the video prototype demonstrated how the app could support occupational first aiders in placing an unconscious person in the recovery position, several interviewees noted that the app should be able to support more typical workplace injuries. Specifically, instructions for the treatment of cuts, bruises, bone fractures, strains, foreign bodies in the eye, electric shocks and severed limbs were mentioned. It should be noted that the video was only a prototypical realization of the app concept and that the concept indeed envisaged the support of such typical injuries. Another interviewee wished for a simple possibility to repeat the last instruction by voice command (e.g. "Again!"). Of course, there might be situations in which the voice assistant may not be able to detect an injury or suggest a suitable first aid measure. In this case, it was important to an interviewee that the app would still give general instructions such as "Keep calm!" or "Do not leave the affected person alone!" instead of an error message. One interviewee explained that mobile phones are forbidden at her workplace and that there is no fast internet connection available. The interviewee suggested placing a charged mobile phone with the app next to first aid boxes or equipping employees with company mobiles. If the app would not be able to process the images quickly enough due to a slow internet connection, the interviewee further suggested that the app should preload instructions in the form of videos. An overview about the mentioned strengths of the presented AR first aid application and suggestions for improvement can be found in Table 2.

Table 2. Strengths and Improvement Suggestions

Main Category	*Sub Category*	*Occurrence*
Strengths	Clarity of instructions	6
Strengths	Reduction of uncertainties	4
Strengths	Visualization of the body parts' target position	2
Strengths	Visualization of the actually affected person	1
Strengths	Calming effect of the voice assistant	1
Strengths	Mobility through speech input	1
Improvement	Sound of the voice assistant	5
Improvement	Visibility of the AR overlays	2
Improvement	Instructions for other accident situations	2
Improvement	Voice command to repeat the last instruction	1
Improvement	App behavior in case of malfunctions	1
Improvement	Necessity of mobile phones and internet	1

6 Conclusion

The aim of this research was to propose and evaluate occupational first aid support as an innovative use case of AR. We therefore conducted a DT workshop with information systems researchers, manufacture workers and technology experts of a global consulting firm to develop a concept for an AR mobile first aid application. The proposed application supports occupational first aiders by providing instructions through visual AR overlays and voice assistance. We further proposed to use the OpenPose key point detection algorithm to locate body parts of an injured person and calculate the optimal position for AR overlays. The concept was implemented as a video prototype and evaluated by conducting interviews with manufacture workers. The evaluation revealed that AR instructions would enable employees without first aid training to act quickly and correctly in accident situations. The interviewees were also convinced that their employer would invest in such a solution because inadequate first aid measures are often associated with long-term staff absenteeism and thus incur high costs.

The evaluation interviews further revealed some challenges which have to be addressed before the proposed application can be used in practice. The most critical challenge will be to ensure accessibility to the application in medical emergency situations. An interviewee reported that the use of smartphones is forbidden at her workplace and that it would be difficult to provide first aid measures while pointing the smartphone camera at an injured person. A solution would be to use smart glasses, as particularly manufacturing and logistics companies are already using these to improve the efficiency of internal work processes. The proposed application should further be able to identify the required first aid measure by analyzing the camera recordings and voice inputs of the user. To ensure a high accuracy, medical personnel should be involved in the development process of the application. Nevertheless, innovative ideas involving artificial intelligence always raise questions of liability which must be addressed in future research. Who is liable if an injured person dies or takes further damage due to false recommendations of an artificial intelligence? Related to this question, the interviewees stated that in most accident situations they would not be able to provide the correct first aid measure on their own – so they would be willing to use the application even if following the instructions might be harmful in some cases.

The AR application concept was developed as part of a DT workshop with practitioners. DT is a popular innovation approach that promotes creative thinking, however, the approach prescribes setting fixed time limits for each DT method. As a result, ideas are often not yet entirely mature after a workshop. Although we have further refined the concept and the video prototype after the workshop, the implementation of the concept as a video prototype represents a limitation. We therefore plan to implement a functional prototype in future research to evaluate the technological possibilities and limitations of AR for occupational first aid support. The implementation of a functional prototype would allow to assess the accuracy of the OpenPose key point detection, position of the AR overlays and recognition of required first aid measures. The functional prototype should also be used to quantitatively measure whether first aid instructions are implemented faster and more correctly than without the application. Moreover, it should be tested how different representations of AR overlays affect the correctness and timeliness of provided first aid measures. In this regard, the evaluation interviews already revealed that the brightness and coloring of visual AR overlays plays an important role and should adapt dynamically.

Prevent a Vicious Circle!

The Role of Organizational IT-Capability in Attracting IT-affine Applicants

Andrea Fürst-Graßl[1]

[1] University of Passau, Chair of Business Information Systems, Passau, Germany
andrea.fuerst@uni-passau.de

Abstract. Organizational IT-capability is a key to meet the challenges of digital transformation. Its advancement requires the attraction of IT-affine applicants. Their application intentions, however, depend on positive perceptions of an employer's existing IT-capability. Merging findings from Information Systems Research, Human Resource Research, and Psychology, this study conducts an experimental survey to investigate how the perception of organizational IT-capability influences job seekers' application intentions. 228 observations were analyzed using the PLS-SEM method. It provides empirical evidence that (1) the perception of organizational IT-capability influences job seekers' application intentions and that (2) this influence is of particular strength for IT-affine job seekers. This knowledge is fundamental to understand the outstanding role of organizational IT-capability in the current 'war for talents'.

Keywords: Digital Transformation, IT-Capability, Person-Organization Fit, Intention to Apply, Applicants' Self-Selection

1 Introduction

Organizational Information Technology (IT)-capability is considered a key factor to transform IT into a competitive advantage [1–3]. In a Resource Based View, organizational IT-capability is a complex package of IT-related resources including human skills and knowledge [4, 5]. As employees' knowledge and skills play a major part in the enhancement of a firm's IT-capability it is crucial for firms to attract and employ technically high-skilled employees [4].

Current shortages on the labor market, however, are creating a 'war for talents', especially with regard to high-skilled IT-specialists. A managerial study of Capgemini Consulting, for example, revealed that "77% of [the] companies considered missing digital skills as the key hurdle to their digital transformation" [6]. Therefore, it is crucial for organizations to know about the specific drivers of IT-affine job seekers' application intentions.

Following P-O-fit theory, job seekers generally prefer organizations that match their individual characteristics [7–11]. This fosters a feeling of 'fit' with a potential

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

employer, which was found to be essential for application intentions [10]. Applying this fit-perspective, it seems especially important for IT-affine job seekers that their individual IT-capability matches the potential employer's organizational IT-capability. Consequently, job seekers with a high level of individual IT-capability are likely to prefer organizations with an equally high level of organizational IT-capability, whereas they are likely to eschew employers with a minor level of IT-capability.

This endangers low-capability organizations to enter a vicious circle: From a resource based perspective, the development of their organizational IT-capability requires the attraction of high-skilled employees [4] – which they probably cannot attract. Consequently, their organizational IT-capability will further diminish, which makes it more and more difficult to attract savvy employees. To prevent such a vicious circle, it is crucial to empirically investigate the underlying mechanisms to develop proper countermeasures.

Therefore, this study addresses two primary research questions:

1. Does the perception of organizational IT-capability influence job seekers' intention to apply?
2. Is this influence of particular strength for job seekers with a high level of individual IT-capability?

To answer these questions this research takes a new perspective on IT-Capability and combines it with existing theories and metatheories anchored in Human Resource Research and Psychology, (1) to investigate how the perception of organizational IT-Capability influences job seekers' application intention and (2) to explain applicants' self-selection behavior in this context. From a practical point of view, this knowledge is fundamental to understand the outstanding role of organizational IT-capability in the current 'war for talents'.

2 Theoretical Background and Hypotheses Development

2.1 Theoretical Framing

Previous research pointed out that the attraction of potential applicants is – from a theoretical point of view – a complex issue that results from an interaction of various theories concerning information processing, perception development and subjective fit [12]. Therefore, this study does not built on a single theory but merges findings from different relevant theories.

This merge primarily bases on the directive theoretical contribution of Ehrhart and Ziegert [12] who presented relevant theories from human resource research and psychology and organized them along their key-aspects in respective meta-theories. Especially the first two meta-theories provide a valuable theoretical background for this study: The first meta-theory – *Environmental-Processing Theory* (including, inter alia, *image theory* and *signaling theory*) emphasizes that (1) there is a difference between objective and individually perceived characteristics of an organization and that (2) there is a relationship between those perceptions of organizational characteristics and attraction [12]. The second meta-theory – *Interactionist Processing Metatheory* – strongly builds on *P-O-fit theory* [9] and primarily considers the interaction between person characteristics and environmental characteristics [12]. Both meta-theories (and their underlying theories) feed in the subsequent hypotheses development sections.

Additionally, research from the field of value-driven marketing (see [13] for an overview) is taken into account to further support the basic idea of this study that particularly *perceptions* of organizational IT-Capability matter for the attraction of proper applicants – as this research stream clearly points out, that the value of a product or service process (including a vendor's resources and capabilities) depends on the customer's perception and appreciation [14].

2.2 Organizational IT-Capability and Intention to Apply

Organizational IT-capability "is a firm's ability to acquire, deploy, combine, and reconfigure IT-resources in support and enhancement of business strategies and work processes" [2]. Following the established conceptualization of IT-capability in Information Systems Research, it reflects the three dimensions: IT Infrastructure Capability, IT Business Spanning Capability, and IT Proactive Stance [2]. IT Infrastructure Capability captures the extent to which a firm is good at data management, network communication, architecture and application management, IT Business Spanning Capability considers a successful interaction between business and IT strategy, and IT Proactive Stance reflects, whether a firm is open for IT-innovations [2].

As an organization's IT-capability reflects a complex interaction between these three dimensions including technical and human resources, it is rare and difficult to imitate [4]. It was found to be an important enabler of organizational agility [2] and a key factor to meet the current challenges of digital transformation [15]. Therefore, previous research pointed out, that organizational IT-capability constitutes a competitive advantage [4]. As it determines an employer's competitive standing and sustainability it may be of high relevance for potential employees.

An organization's IT-capability is, however, not an externally observable attribute. Outsiders can only develop perceptions of an organization's IT-capability based on the provided information. This information can, for example, be included into job ads – which were identified as an important source of information for applicants [16].

However, as an organization's IT-capability must be kept rare and inimitable to further constitute a competitive advantage, an organization can not disclose any IT-related information. It will probably not disclose detailed insider knowledge about its database technology, application landscape, IT-architecture, or future IT-related business options. It can, however, provide rather general IT-related information that reflects a certain level of IT-expertise without jeopardizing its competitive advantage. For example, an organization could provide general information about the extent to which IT is integrated in its products, services, and business processes, whether they align business and IT strategy or about its fundamental stance towards IT innovations.

Following Signaling Theory, this information serves as a signal for potential applicants to develop perceptions of the respective organization's IT-Capability. [12, 17]. This *Perceived Organizational IT-Capability* can be defined as the degree to which a person believes that an organization is capable of using IT to support its business strategy and processes. This perceived organizational IT-capability may influence job seekers' application intentions for two main reasons:

1. Following Social Identity Theory, individuals prefer organizations they identify as superior to appear more successful in the eyes of others [10, 18]. Following Image Theory individuals prefer organizations that may foster a desired image [19, 20]. Building on these theories, previous studies for example revealed a clear relationship between a superior employer reputation [21–25] or a superior corporate image [10, 26, 27] and job seekers' application intentions. Therefore, a (perceived) superior level of organizational IT-capability is likely to positively influence job seekers application intentions as well.
2. As an organization's IT-capability constitutes a competitive advantage and is the key to manage the current challenges of digital transformation [2, 4, 15], it determines an employer's long-term sustainability and future economic success. It, therefore, ensures security of employment and employee salaries and provides the base for advancement possibilities. As these are important issues for potential employees [7, 10, 16], it is likely that they prefer employers they perceive as high-capable for this reasons as well.

Therefore I hypothesize:
H1: Perceived Organizational IT-Capability is positively associated with job seekers' Intention to Apply.

2.3 The Moderating Role of Individual IT-capability

The term IT-capability is usually used in an organizational context. However, the overall ability to acquire and purposefully use IT is not limited to organizations. In fact, each job seeker is characterized by a certain level of individual IT-capability. Reflecting his IT affinity in a professional sense, this *Individual IT-Capability* can be defined as a job seeker's ability to professionally use IT to support an employer's business goals.

This individual characteristic may affect the strength of the hypothesized influence of *Perceived Organizational IT-Capability* on *Intention to Apply*. This influence is supposed to be of particular strength for job seekers with a high level of *Individual IT-Capability* and weaker for job seekers with a rather low level of *Individual IT-Capability* for two main reasons:

1. Individual perception development generally depends on individual characteristics and preferences. People process information selectively and limit their attention to decision relevant aspects [12, 17, 19, 20]. Knowledgeable individuals were found to include more attributes in their perception development processes than less savvy individuals [28]. Therefore, IT-affine job seekers are likely to pay particular

attention to IT-related information about a potential employer and develop a sounder perception of a potential employer's organizational IT-capability than less savvy job seekers. This sounder perception of organizational IT-capability is likely to constitute a clearer influence of *Perceived Organizational IT-Capability* on *Intention to Apply*.
2. Person-Organization (P-O) Fit Theory emphasizes the importance of perceived similarity between a person and its working environment. Reflecting the perceived congruence between individual and organizational attributes, interests, and values, P-O fit turned out to significantly influence job seekers' application intentions and subsequent job choice decisions [8, 10, 29–31]. Consequently, job seekers with a high level of *Individual IT-Capability* are likely to clearly prefer employers with a similar high level of IT-capability which match their interests, use their IT-related skills and knowledge, and provide proper advancement opportunities. On the other hand, these IT-affine job seekers are likely to clearly eschew employers with an inferior level of IT-capability due to the missing 'fit'. In contrast, job seekers with a rather low level of *Individual IT-Capability* may be somewhat discouraged by an exceedingly high level of employer IT-capability, so that the hypothesized positive relationship between *Perceived Organizational IT-Capability* and *Intention to Apply* may be weaker for less IT-affine job seekers.

Therefore, I hypothesize:
H2: The relationship between Perceived Organizational IT-Capability and Intention to Apply is stronger for job seekers with a high level of Individual IT-Capability compared to job seekers with a minor Individual IT-Capability.

3 Research Method

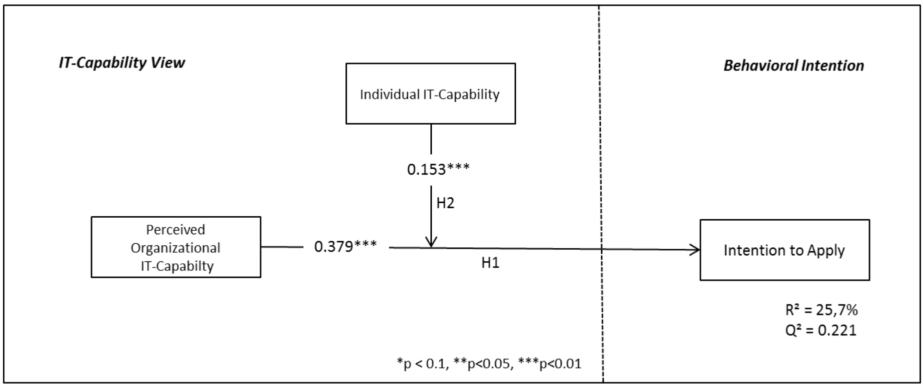

Figure 1. Research Model (Including Results of the PLS Estimation)

3.1 Study Design and Data Collection

To empirically test the hypothesized relationships this study applied an experimental survey approach. It was based on four hypothetical job ads: Whereas the company descriptions differed reflecting different levels of organizational IT-capability, all other factors (job description, company size and starting salary) were kept constant (see Appendix).

Confronting each participant with multiple hypothetical job ads seemed especially important as perception development processes were found to be comparative by nature [28]. Therefore, it seems – on the one hand – reasonable to confront each participant with multiple descriptions as a reference group to gain a proper assessment of each firm's IT-Capability. On the other hand, this research design may include the risk of gaining not entirely independent observations. To take both aspects into account I decided to confront each participant with four job ads – as a good middle – and to apply an additional test to ensure the validity of my results (see section 4.2).

Data were collected using two surveys (a pretest and a main survey) of students from the Department of Business, Economics and Information Systems of a German university during summer term 2017. To ensure a high response rate, the two surveys were conducted during class time in two IT-related classes. Business students of IT-related classes seemed a proper sample for three main reasons: First, they presumably have enough IT-related knowledge to assess their individual IT-Capability properly. Second, they are presumably more open-minded towards different job offers than professionals, as they are less influenced by prior work experiences. And third, this sample provides realistic and valuable results for the current labor as the questioned students are available for the labor market in the near future.

To ensure this last point, all participants were asked whether they can imagine applying for a job within the next twelve months at the beginning of the questionnaire. Only questionnaires with a positive answer to this question were taken into account and included in the further analysis. The participants were also questioned about their degree program, current semester, age and gender.

Thereupon, each participant was asked about a self-evaluation of his individual IT-Capability. This variable forms the base for the following moderation analysis. Afterwards, each participant was confronted with the aforementioned four hypothetical job ads reflecting different levels of organizational IT-capability. As previous research pointed out, that the sole quantity of information in job ads may influence job seekers' perceptions [16], particular attention was paid to a similar length of all provided company descriptions. These descriptions were all placed above the related questions to ensure that each participant has all descriptions in mind when answering the questionnaire. Each participant was then asked about his perception of each organization's IT-capability and his intention to apply to the respective organization.

The questionnaire (including the hypothetical job ads) was pretested for understandability and proper construct measurement with 16 students from a software development class. The pretest showed a good understandability of the provided information and the measurement scales as well.

The main survey was conducted in an information system class at the end of summer term 2017. From the main survey, I received 57 completed and usable questionnaires, each including assessments of the four different firms. This resulted in 57*4=228 total observations for further analysis. Among the 57 participants, 59.6% were female, 40.4% were male. The average age was 22.7 years. The participants were distributed over the Bachelor Degree Programs “International Cultural and Business Studies” (14.0%), “Business Administration and Economics” (78.9%) and “Information Systems” (7.0%).

As the study was conducted with German-speaking participants the questionnaire was provided in German language as well to prevent language-based problems. (The English translation of the provided information can be found in the Appendix). To ensure content equivalence of the German and English version, I followed the translation and back-translation procedure recommended in Brislin [32].

3.2 Construct Measurement

A job seeker’s ‘Intention to Apply’ (INTA) is an established and widely applied construct in recruitment research. Therefore, its measurement items were derived and adapted from the established measurement scales [10, 24, 33].

The established measurement scales for IT-Capability, however, are not entirely suitable for this study. The established view on IT-Capability is limited to organizations and demands deep insider knowledge about the respective firm. This study, however, requires – on the one hand – a measure to capture an outsider’s perception of an (potential) employer’s IT-Capability and – on the other hand – a measure that reflects each job seeker’s individual IT-Capability. These ‘views’ on IT-Capability both differ from the established conceptualization of IT-Capability and its related measurement scales. Therefore, this study develops two ‘new’ constructs *Perceived Organizational IT-Capability* (POITC) and *Individual IT-Capability* (IITC) – both derived from the ‘traditional’ IT-Capability perspective. This development procedure was realized in several steps:

1. To form a theoretical foundation for the formulation of proper measurement items, relevant prior research was reviewed – particularly focusing on different conceptualizations of IT-Capability, perception development processes, and individual aspects (e.g., the individual attitude towards IT). Thereupon, reflective measurement scales were formulated, which seemed suitable to capture a job seeker’s perception of an organization’s IT-Capability and to give an analogous self-evaluation of his individual IT-Capability.
2. These self-developed measures were afterwards discussed with several experienced researchers to ensure a proper measurement design with regard to explanatory value and understandable formulation. Adaptions were made where necessary.
3. Finally, a pretest was conducted with 16 students, to further evaluate the developed indicators’ understandability, validity and reliability. After finishing the pretest-questionnaire, all participants agreed that the questionnaire was clearly formulated

and well understandable. Additionally, the indicators' validity and reliability were tested by applying the evaluation procedure recommended in Hair et al. [34].

As the pretest showed good results, the measurement items were afterwards included in the questionnaire of the main study (see Table 1).

Table 1. Measurement Items of the Applied Constructs

Perceived Organizational IT-Capability (POITC) *(self-developed)*
from 1='poorer than most' to 7='superior to most'
In relation to other medium-sized companies in this industry, I have the following perception of company A/B/C/D: (POITC1) Overall, the company's IT-capability is… (POITC2) The professional and target-oriented use of IT is… (POITC3) The capability to integrate IT in products and processes is…
Individual IT-Capability (IITC) *(self-developed)*
from 1='poorer than most' to 7='superior to most'
In relation to other students in economic degree programs… (IITC1) I evaluate my overall IT-capability… (IITC2) I evaluate my professional and target-oriented use of IT… (IITC3) I evaluate my capability to integrate IT in products and processes…
Intention to Apply (INTA) [based on 10, 24, 33]
from 1='strongly disagree' to 7='strongly agree'
I evaluate the following statements with regard to company A/B/C/D: (INTA1) If I saw a job opening for this company after graduation, I would apply for it. (INTA2) If I were searching for a job, I would apply to this organization. (INTA3) I would be pleased to work for this organization after my graduation.

4 Data Analysis and Results

The research model was evaluated by applying the PLS-SEM method – implemented in SmartPLS [35] – which is a widely applied method to analyze survey data. It is especially suitable to meet the exploratory nature of this study and works well with small sample sizes [34, 36]. Therefore, it seems a better choice for this study than a covariance-based approach.

4.1 Measurement Validation

The validation of the measurement model followed the established procedure recommended in Hair et al. [34].

To evaluate **internal consistency reliability** the composite reliability value (CR) and Cronbach's α (Cr. α) were computed for each reflectively measured construct. With Cronbach's α >0.7 and CR >0.7 all constructs meet the proposed quality criteria [34, 37] (see Table 2). **Indicator reliability** demands that each indicator's outer loading exceeds 0.7 [34]. With values between 0.816 and 0.970, indicator reliability is also given for each indicator. **Convergent Validity** is ensured with an Average Variance Extracted (AVE) higher than 0.5 [34] for each construct. Therefore, Convergent Validity is also fulfilled (see Table 2). To assess **Discriminant Validity**, the hetereotrait-monotrait ration (HTMT) of the correlations was computed as proposed in Hair et al. [34] and Henseler et al. [38]. As Henseler et al. [38] propose a limit of 0.85 for HTMT values, the HTMT criterion is perfectly fulfilled in this study (see Table 2, bolded values). In summary, the evaluation of the measurement model showed that all constructs and indicators applied in this study meet the established quality criteria for reflective measurement models.

Table 2. Cronbach's Alpha, CR, AVE and HTMT

Construct	*Cr. α*	*CR*	*AVE*	*IITC*	*INTA*
IITC	.863	.915	.782		
INTA	.967	.978	.938	**.323**	
POITC	.939	.961	.891	**.035**	**.390**

4.2 Hypotheses Testing

The evaluation of the structural model including hypotheses testing also followed the established evaluation procedure recommended in Hair et al. [34]: The **structural model** was evaluated for collinearity issues to avoid critical levels of collinearity among the predictor constructs. The VIF values for POITC (1.003) and for IITC (1.001) are both clearly lower than the proposed threshold of 5 [34]. Thus, collinearity is not a critical issue. The amount of **variance explained** in the endogenous variable INTA was 25.7%, which is a high value for behavioral studies [34]. Predictive relevance was assessed using the cross-validated redundancy Q^2 [39, 40]. Q^2 is 0.221 for the sole endogenous variable *Intention to Apply* and therefore indicates predictive relevance ($Q^2>0$ is recommended in Chin [41]).

To evaluate the **significance of the proposed hypotheses** the path coefficients and t-values of the research model were computed applying the PLS Algorithm and PLS SEM Bootstrapping Routine with 5000 subsamples. All hypothesized paths turned out to be significant at a 1% level. The hypothesized direction of the paths was confirmed (see Figure 1). The link between *Perceived Organizational IT-Capability* and *Intention to Apply* (the so-called 'Simple Link') had a path coefficient of 0.379 and a t-value of 6.970 (>2.57) for a two-tailed test. The moderating path had a path coefficient of 0.153 and a t-value of 2.750 (>2.57) for a two-tailed test. The f^2 value, as an indicator of effect size, was 0.193 (>0.15) for the link between POITC and INTA, which is classified as a medium effect [42]. The moderation has an effect size f^2 of 0.038 (>0.025), which indicates a large moderation effect [43].

As the research design may include the risk of not entirely independent observations (see section 3.1), an additional test was conducted to exclude the threat of biased results: The research model was additionally tested with a reduced data set. This reduced set contained only one, randomly selected observation per participant.

The evaluation of the model based on this reduced data set showed very similar results as for the main evaluation. All hypotheses were supported in this analysis as well.

5 Discussion and Implications and Conclusions

This study posed two research questions:

1. Does the perception of organizational IT-capability influence job seekers' intention to apply?
2. Is this influence of particular strength for job seekers with a high level of individual IT-capability?

With regard to the first question, a clear link between the *Perceived Organizational IT-Capability* and job seekers' *Intention to Apply* was found. With regard to the second question, the job seekers' *Individual IT-Capability* turned out to significantly influence the strength of this relationship. Consequently, the perception of a potential employer's IT-capability affects job seekers with a high level of individual IT-capability significantly stronger than job seekers with a low level of individual IT-capability. These findings are consistent with the proposed hypotheses based on implications from prior research.

The study responds to a call for more research with regard to the attraction of proper employees in the initial stage of recruitment [16, 21, 44], especially with a focus on the influence of individual characteristics [12]. It provides initial empirical evidence, how the perception of a specific competition-critical organizational property influences job seekers' application intentions and fosters applicants' self-selection behavior. This knowledge is – in a broader sense – fundamental to better understand the outstanding role of organizational IT-capability in the current 'war for talents'. It provides theoretical and managerial implications as well:

From a theoretical point of view, this research extends the 'traditional' IT-capability perspective, anchored in information systems research, by transferring the common conceptualization of organizational IT-capability (1) to an outsider's perspective and (2) to an individual level. It advances theory and measurement by implementing and validating the concepts of *Perceived Organizational IT-Capability* and *Individual IT-Capability*. These views on IT-capability may provide a proper base for future studies in this context.

As this study bases on 'pure' perceptions of organizational IT-capability without providing any 'hard' data of the organizations' resources and capabilities, it clearly shows that perceptions matter for job seekers' application intentions. In this context, it is in line with (1) prior Marketing-related Research, which showed that the value of a firm's products, resources, and capabilities depends on the perception and appreciation of the customer and with (2) prior Human Resource Research considering the influence of positive perceptions on job seekers' application intentions. It shifts, however, the focus from rather general positive perceptions (e.g., an employer's corporate image) to a specific competition-critical organizational property – an employer's IT-capability. Therefore, this study identified an additional specific driver of job seekers' application intentions. In times of increasing digitization, this 'new' driver will probably continue to grow in importance.

Furthermore, this study helps to better understand the basic mechanisms of applicants' self-selection behavior by combining an applicant's view on an organization's IT-capability and his individual IT-Capability. It clearly shows that individual characteristics affect the strength of the identified relationship between *Perceived Organizational IT-Capability* and *Intention to Apply*. As the question "whether certain individual characteristics or individual differences may have a direct effect on attraction" is poorly investigated so far [12], this study may considerably contribute to this under-investigated field of recruitment research.

As the study provides a deeper understanding of applicants' self-selection behavior especially with regard to the recruitment of IT-specialists, it may help **from a managerial perspective** employers (1) to develop targeted recruitment strategies and (2) to prevent the emergence of vicious circles. Both contributions are of high practical relevance in the current 'War for IT-Specialists':

As the attraction of proper applicants is essential for companies but the goal of attracting the greatest possible number of applicants is questionable [27, 45], employers have to develop an understanding of applicants self-selection mechanisms to particularly address employees with profiles matching the organizations' requirements [44, 45]. In this context, this study clearly showed that information about an organization's IT-capability particularly influences the application intentions of IT-affine job seekers. Keeping all other factors (job description, salary, etc.) constant, they clearly prefer organizations with a (perceived) high level of organizational IT-capability and clearly eschew low-capability organizations, whereas this influence is weaker for less savvy job seekers. Consequently, organizations should clearly promote their IT-capability in recruitment campaigns to attract IT-affine applicants.

This promoting effect of IT-related information in e.g., job ads is of particular relevance for organizations with a rather low level of organizational IT-capability. These firms face the risk to be trapped in a vicious circle, if they do not manage to attract IT-affine employees. They may, however, take advantage from the fact that there is a difference between their objectively existing organizational IT-Capability and applicants' subjective perceptions of this IT-Capability. As these two issues may fundamentally differ, companies can (to some extent) shape job seekers' perceptions of their IT-Capability by providing appropriate information [12]. For example, previous research indicated that the pure amount and specificity of IT-related information may positively influence job seekers' perception development [16].

As the study is an exploratory approach to provide first insights into how *Perceived Organizational IT-Capability* affects job seekers' *Intention to Apply* and IT-affine applicants' self-selection behavior, it has a few **limitations** as well:

First, the study focusses on the perception of organizational IT-Capability. The perception of an organization's IT-capability, however, is only one piece of the puzzle to fully understand job seekers' application intentions. Future research should extend this research and examine – in a comprehensive view – how different drivers of intention to apply interact and if their influence depends on the individual characteristics of a job seeker.

Second, the focus of this study was on advanced students who stated to possibly apply for a job within the next twelve months. As life-circumstances and presumed job opportunities may be different for more experienced job seekers, this study needs to be repeated with a respective sample to investigate parallels and deviations.

Finally, this study bases on hypothetical job ads without giving any 'hard' facts about the respective organizations' IT-Capabilities. It focusses on 'pure' perceptions and questions these perceptions and the resulting behavioral intentions at a single point in time. Ehrhart and Ziegert [12], however, pointed out that the attraction to an organization is a dynamic process. Once attracted by an organization, job seekers are likely to seek additional information to support or adjust their original evaluation [12]. This multi-stage process may gradually diminish the relevance of the job ad information in a real-world scenario.

Appendix

The following job and company descriptions were provided in the study:
The following section provides four extracts of job ads each announcing a job of an internal IT-project manager in a medium-sized manufacturing company with approx. 3000 employees. The standard starting salary is 60,000 Euros. The job profile is characterized as follows for all job ads:

IT-Project Manager As a project manager you are responsible for the successful execution of our internal IT-Projects. You serve as an interface between management and software developer and take responsibility for the further development of our internal IT-Landscape. You are particularly responsible for the steering of the projects with regard to defined objectives, the implementation of development processes, as well as the alignment of IT-Projects and the company's business strategy.

The job is announced by four different companies which differ with regard to their company description. The four companies provide the following information in their job ads:

Company A: We value Information Technology as a foundation of an efficient management and the continuous evolution of our company. We pay special attention to benefit from the opportunities of Information Technology to continuously develop our business value. We pursue a clear IT-strategy to reach our goals. Our IT team keeps its finger on the pulse by applying agile methods and the latest technologies. We see our strength particularly in the area of data management and mobile applications. We continuously seek new ways to develop and deploy our IT-landscape even more effective.

Company B:
As a medium-sized manufacturing company, we traditionally focus on the sector of classical engineering. As Information Technology is continuously gaining influence on the efficient organization of our internal processes as well as on our supply chain, we aim at continuously developing our rather traditional IT-landscape. We are looking for a creative employee to develop and implement proper IT-solutions and encourage innovative suggestions with regard to flexible IT-architectures and data structures.

Company C:
We are a regionally rooted company with a long tradition in the manufacturing industry. We combine tradition with the innovative opportunities of Information Technology. We particularly focus on the storage and usage of data to support our supply chain (e.g., Shared Data Base) and as a basis of interconnected ERP-Systems. Our special concern is to view IT as an integrative part of our business strategy and to identify and efficiently deploy economically viable IT projects. As we are continuously looking for new ways, we provide an open and supportive environment for new ideas.

Company D:
Our company bundles the know-how from purchasing, logistics, and supply-chain management in interdisciplinary teams aiming at an efficient manufacturing of our products. In this context, Information Technology is an important component to develop this efficiency. We focus on the cross-linking of business processes, data bases and information systems and are already applying agile methods of process and project management. We are open-minded towards innovative, data-driven extensions of our existing business models and strive for further optimizations of our supply chain processes.

Good, Bad, or Both? Conceptualization and Measurement of Ambivalent User Attitudes Towards AI

Sophia Bettina Maier[1], Ekaterina Jussupow[1], and Armin Heinzl[1]

heinzl@uni-mannheim.de

Abstract. Artificial intelligence is currently one of the most controversial discussed technologies across various work domains. In healthcare, AI as decision aid fosters physicians' fears of being replaced and strong positive beliefs of increasing quality of care. This causes ambivalence as individuals hold both strong positive and negative attitudes simultaneously. Yet, most studies on technology adoption conceptualize attitudes as unidimensional and do not capture ambivalent attitudes. Furthermore, there is a lack of quantitative studies on ambivalence and thereby a lack of insights on characteristics and impact of ambivalent attitudes. Our study measures different states of ambivalence in the context of healthcare and links it to resistance to change. We are able to show that ambivalent attitudes do cause resistance to change when individuals who hold both strong positive and negative evaluations also experience an inner conflict (felt ambivalence). Furthermore, we are able to identify distinct context-specific attitudes which foster physicians' ambivalence.

A Case Study on Cross-Hierarchical Communication in Digital Work Environments

Christian Meske[1], Tobias Kissmer[2], Stefan Stieglitz[2]

Abstract. Hierarchies are vital for organizations. However, in the workplace they can also act as invisible barriers for the communication between individuals from different hierarchical levels, thus impeding the exchange of information and knowledge. This effect is particularly assumed to be true for country cultures with high power distance characteristics. Based on a unique Skype for Business dataset, we test the potential impact of country culture for cross-hierarchical communication. Finally, we aggregate the data of all countries and provide insights into specific communication patterns for each hierarchical level across the organization. We conclude our case study by providing distinct lessons learned, such as the irrelevance of cultural predictions in this context and the essential focus on the middle levels of hierarchy.

‘Show Me Your People Skills’ - Employing CEO Branding for Corporate Reputation Management in Social Media

Milad Mirbabaie[1], Julian Marx[1], and Stefan Stieglitz[1]

[1] University of Duisburg-Essen, Department of Computer Science and Applied Cognitive Science, Duisburg, Germany
{milad.mirbabaie, julian.marx, stefan.stieglitz} @uni-due.de

Abstract. Digitization has led to increased social media utilization among companies to connect with their customers. We know that particularly CEOs, as the representing face of a company, can exert great influence to build corporate reputation. While reputation management in general has been researched extensively, we know little about the dimensions of CEO reputation management in social media. This paper deals with the distinction of organizational and personal branding in Twitter, and moreover, aims to determine eligible dimensions for CEO reputation management, based on the widely accepted Reputation Quotient. Therefore, we collected 3,604 social media postings of companies and their respective CEOs from Twitter. Through statistical and content analyses, we determined two supplementary dimensions for CEO reputation. *Shared Interests* and *Personal Logging* add private aspects to the spectrum of CEO reputation management, which have the capacity to foster consumer engagement.

1 Introduction

In recent years, social media has become an indispensable tool for brand communication. Compared to traditional marketing channels, social media provides a cost-effective platform for companies to promote products and interact with consumers [1], [2]. Since the digitization has progressed, a company is no longer judged solely on the basis of its products and quality of services, but also in terms of its communication and interaction with consumers. Customers want to speak up, provide feedback, ask questions and receive supplementary product information [3]. In addition to organizational brand presentation, top managers such as chief executive officers (CEOs) use social media pages to provide a platform for interaction and exchange [4]. CEOs, as the public face of a company, may involve private aspects in their posting

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

routine, and thus be perceived as more accessible and authentic [5]. As a result, not only boundaries between personal and professional social media use blur, but companies may also capitalize on the influence that personal brands exert on consumers [6]. While research acknowledges the impact of CEO personal branding on the reputation of the organization [7–9], little is known about how to conceptualize CEO reputation management in social media. Despite the consensus on the potential impact of a strong CEO brand page, few companies pursue it as part of their communication strategy.

Our study aims to address this issue by investigating the role of a CEOs Twitter presence alongside the corporate branding and motivate practitioners to intensify their efforts to employ a strong CEO branding in order to complement their reputation management in social media. The dimensions that matter, on this account, are the ones that occur when organizational communication is carried out through the individual channel of a CEO. On this basis, our paper centers around following research questions:

RQ1: *How do communication strategies of CEO and corporate branding differ in Twitter communication?*
RQ2: *What dimensions does CEO branding in social media add to corporate reputation management?*

Findings based on the above research questions would significantly enhance our understanding of CEO reputation management in social media. The contribution of this paper is primarily of practical nature, i.e. an improved utilization of CEO personal branding to build up a reputation that is detached from the organizational brand and is, for exactly this reason, valuable to the organization. At the same time, however, our study attempts to conceptualize CEO reputation management with consideration of Twitter-specific capacities such as retweet and follower mechanics. To address both research questions, we tracked social media data from Twitter over a timespan of eight weeks, resulting in a collection of 3,604 tweets that were expressed by leading firms within the IT industry and their respective CEOs. Our research methodology encompasses statistical analyses to determine how well tweets were perceived and content analyses to advance toward a better understanding of CEO reputation management on Twitter from a qualitative perspective. In order develop a predictive model for CEO reputation, which can be tested, this study first targets to establish a conceptual basis by means of an explorative approach. This offers promising opportunities for supplementary quantitative research on this matter. From a practical point of view, communication and IT strategists, and CEOs of large and medium-sized enterprises benefit from this study. Aligning the textual dimensions of CEO communication with capacities of social media is crucial for effective reputation management.

The paper is structured as follows. In a primary step, we review previous literature and form a theoretical background to this study. Subsequently, we outline our research design including methods and data analysis measure. We then present our findings and theorize relevant outcomes toward a concept of CEO reputation management in social media. Finally, we conclude our study with a summary, implications, limitations, and suggest further research prospects.

2 Related Work

With the prevalence of social media for brand communication, online reputation management as a relevant factor of influence for firm value and performance came into scholarly focus [10–12]. In comparison to traditional computer-mediated communication, social media use impacts organizational communication processes as they “afford behaviors that were difficult or impossible to achieve in combination before these new technologies entered the workplace” [13, p. 143].

Since corporate reputation is based on various pillars regarding the perceptions of stakeholders, companies unanimously try to govern associations with their organization toward establishing a favorable image [12], [14–17].

One of the main drivers for organizations to invest in online activities and engaging with consumers is the positive impact on corporate reputation [10]. Since consumers prefer companies with a positive reputation, the efficient use of social media platforms can promote customer loyalty and retention [12]. Furthermore, it may sustain a company's performance to consequently translate into higher market value [17–19]. Even in times of a crisis, a beneficial reputation can protect a company from negative consequences [21].

Through social media, however, corporate reputation has become increasingly determined by outside forces. Social media coverage is less manageable through public relations due to the empowerment of the consumer to publicly evaluate a company’s reputation and influence others [22]. Some scholars have observed the challenge for companies to appear as trusted actors on social media that have the capability to actively manage their reputation [10]. One way to tackle this issue is to split the inflows of corporate reputation on separate shoulders and complement a firm’s communication strategy with individual branding of high-ranking executives. CEOs, in particular, have the ability to personalize the organization, and at best, be a trusted actor. Not to mention that a strong CEO brand helps to establish positive relations with a variety of stakeholders [23], [24].

The association with a positively perceived public face may reflect upon the organization as a whole [25]. Literature, in this context, picked up the notion of ‘social CEOs’, which characterizes executives as socially acclaimed mediators who bring their organization closer to their customers [26]. CEOs, too, face affordances of social media platforms and applications that respond to their psychological needs [27]. As a matter of fact, they are perceived as the incarnation of corporate identity by an different groups of stakeholders [25]. Therefore, it is imperative for organizations to systematically incorporate CEO reputation in communication processes.

Existing literature provides evidence for examining reputation management on the basis of Twitter data. For instance, a study by Capriotti and Ruesja [4] analyzed the presence, activity, and interaction of CEOs on Twitter and found that the reputation of a company’s CEO affects and may even define the image of a company. In addition, CEOs may also positively affect their own career [7]. However, common practices of CEOs on Twitter oftentimes do not align with the character of the medium, e.g. engaging in one-sided conversations on a two-way platform [28]. Thus, considerable potential remains untapped when it comes to develop effective social media strategies for a CEOs reputation management. Moreover, Weng and Chen [29] conducted a study on the impact of CEO and corporate reputation on financial performance to compare the two. Both corporate and CEO reputation entail separate effects on the financial performance, but CEO reputation is considered as more relevant. Even if corporate reputation is observed as poor, the reputation of the respective CEO may still exert a positive impact on the financial performance.

Literature in this context does not comprise a sufficient framework that is applicable to CEO reputation management in social media. Therefore, in this study, we turn to fundamental work on corporate reputation management to be able to conceptualize our findings on CEO reputation management.

3 The Reputation Quotient

As a measurement concept to determine reputation and to differentiate between single dimensions of it, Fombrun et al. [30] introduced the Reputation Quotient (RQ). It has been acknowledged as a well-accepted basis for quantitative measurements regarding organizational reputation [31], [32]. Numerous studies have been conducted to apply and improve the RQ in practice, even in cross-cultural settings [31], [33]. Thus, we endorse this stream of research and employ the RQ as an eligible classification scheme to identify social media users' perceptions about the reputation of a company. To support this study, the suggested dimensions of corporate reputation serve as a template to be synchronized with CEO reputation. This allows to determine whether CEO reputation management can be assessed through existing reputational dimensions, or if additional dimensions are required for a conceptualization of CEO reputation management. As shown in figure 1, the RQ subdivides corporate reputation into six dimensions: *Emotional Appeal*, *Products and Services*, *Vision and Leadership*, *Workplace Environment*, *Social and Environmental Responsibility,* and *Financial Performance*.

The dimensions were established as a result of interviewing focus groups by means of a reputation survey. Hence, the dimensions reflect how a company is perceived from various angles. Benchmarking studies can provide important contributions here by analyzing which companies were able to achieve which reputation values with the help of which measures. This may include extended variants of the RQ detached from the measurement procedure of the initial RQ study [34]. To serve as a benchmark for our study, we employ the existing RQ dimensions to determine how corporate reputation management can proactively be addressed, i.e. tailoring social media content to match relevant dimensions.

Including *Emotional Appeal* in a communication strategy may result in positive feelings and respect for the company and eventually increase trust. Covering *Products and Services* is rather oriented toward marketing and holds the capacity to lead consumers to perceiving an organization as innovative, expecting high product quality, or to express identification with those products and services. *Vision and Leadership* conveys the corporate mission as well as a goal-oriented execution of a company's activities. Moreover, proficient management and the impression of an organization to be a popular workplace is part of the *Workplace Environment* dimension. *Social/Environmental Responsibility* aims to reflect a firm's commitment to good causes and responsibility towards environment and society. Finally, *Financial Performance* indicates an organization to be profitable, and to be capable to outperform competitors. Therefore, it is expected to continue to grow in the future and please shareholders [32].

The dimensions suggested by the RQ have been applied successfully for research in social media settings based on messages regarding corporate reputation [12], [35]. The RQ might serve as a useful baseline as CEO reputation, to a large extent, aligns with corporate reputation [24], [36]. However, as the taxonomy of the RQ was developed in a distinct context, it remains unclear if it seamlessly applies to CEO reputation management. We evaluate the RQ's usefulness in this matter by assessing its efficacy in classifying a random sample of CEO communication. According to the guidelines of [37] for taxonomy development, we define the professional leitmotif to be the meta-characteristic of each tweet. To evaluate the usefulness of the RQ dimensions, we square the data provided by our content analysis with the characteristics of each RQ dimension, and if necessary, expand the RQ typology to get closer to a general taxonomy for CEO reputation.

4 Research Design

4.1 Data Collection and Preprocessing

To obtain relevant data, we collected publicly accessible social media postings from Twitter. Due to its velocity and publicness [38], [39], Twitter serves as an eligible data source for this research endeavor. We arrayed a preliminary sample of firms from a pool of the *"Top 50 Global Technology Companies"* published by Fortune Magazine [40], which is based on overall market share. Moreover, we limited our selection of firms to the US market due to a high affinity for professional Twitter usage in the United States. We further established the criteria that each company and its respective CEO had to be active (≥5 original tweets per month) on Twitter prior to the tracking. Gathering data of both the company and the CEO allows a direct comparison of prevailing dimensions of reputation management. In order to evaluate CEO reputation management, we need the social media presence of the corporate brand to serve as a benchmark. Our tracking encompassed the activity of following accounts: @twitter, @amazon, @google, @apple, @microsoft, @intel, @tesla, @xbox, @jack, @JeffBezos, @satyanadella, @sundarpichai, @tim_cook, @bkrunner, @elonmusk, @XboxP3.

By means of a self-developed Java crawler and the open source library Twitter4J, we captured a total of sixty-one days of Twitter communication from April 25th, 2018 (0:00 UTC) to June 24th, 2018 (23:59 UTC). The crawler was set to only gather data provided with English language settings. We identified the official Twitter accounts of our company and CEO pairs and tracked all their Twitter activities. Extracted data was stored in a MySQL database for further preprocessing. We finally exported tables of the complete sample and used Tableau and Microsoft Excel to perform our analyses.

4.2 Statistical Analysis

In order to get a deeper sense of our dataset, we provide basic statistical metrics, which are primarily Twitter-specific. This includes the retrieval of metrics such as the follower count of the authors, but also key figures of single postings such as the retweet and favorite count of each posting [41–43]. Moreover, we calculate different ratios to ensure the comparability of the research subjects. To evaluate each dimension with regard to its impact on reputation management, we need to consider the preconditions of each account. Literature suggests that the follower count of Twitter users indicates its popularity, and therefore its potential reach [44]. Furthermore, we know that the number of retweets are suggestive of a messages' influence [43]. Hence, we consider a relational index of retweets per thousand followers ($R = \frac{r}{fw \times 0{,}001}$) or favorites per follower ($F = \frac{f}{fw \times 0{,}001}$). These values point to an assertion how tweets addressing certain RQ dimensions are perceived within the Twitter community.

4.3 Content Analysis

To develop a typology of CEO communication in social media we utilize inductive category formation based on the method of qualitative content analysis by Mayring [45]. Here, we reduce Twitter messages to their main point and sort them into categories. The coding process is illustrated in figure 1.

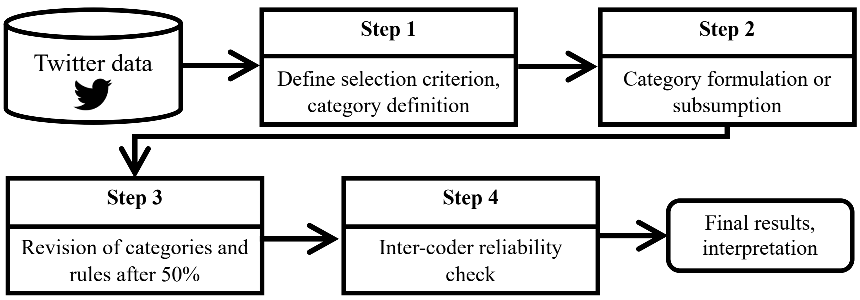

Figure 1 Category development and sample coding procedure, based on [38].

We define both text-based content as well as supplementary audiovisual content of tweets and retweets as the selection criteria. Our initial set of categories consists of the reputational dimensions provided by the RQ (step 1). In case conveyed messages are not covered by the RQ dimensions, e.g. "Wow the sky in Boston right now is crazy. Orange!", we create an additional category. In this case, the message and added photograph qualify the message to be allocated to the new category 'personal logging' (step 2). After coding 50% of the data line by line, we revise the set of categories to make sure it covers the whole spectrum of message types (step 3). The entire sample is set to be manually coded by each author to ensure inter-coder reliability (step 4). Using Krippedorff's alpha, a score of .827 was calculated. Our coding can be rated as reliable as $\alpha \geq .800$ [46]. We examine the sample in its entirety to discover commonalities and topical patterns. This will serve as a basis to answer our second research question and to theorize our findings with regard to CEO reputation management.

5 Results

Our final sample consists of eight companies and their corresponding CEO: *Twitter/Jack Dorsey, Amazon.com/Jeff Bezos, Intel/Brian Krzanich, Google/Sundar Pichai, Microsoft/Satya Nadella, Tesla/Elon Musk, Apple/Tim Cook, and Xbox/Phil Spencer.* Within the 8-week period of our data tracking, those accounts authored a total of 8,628 tweets. Figure 2 illustrates how those tweets spread among tracked accounts and how often they retweeted others.

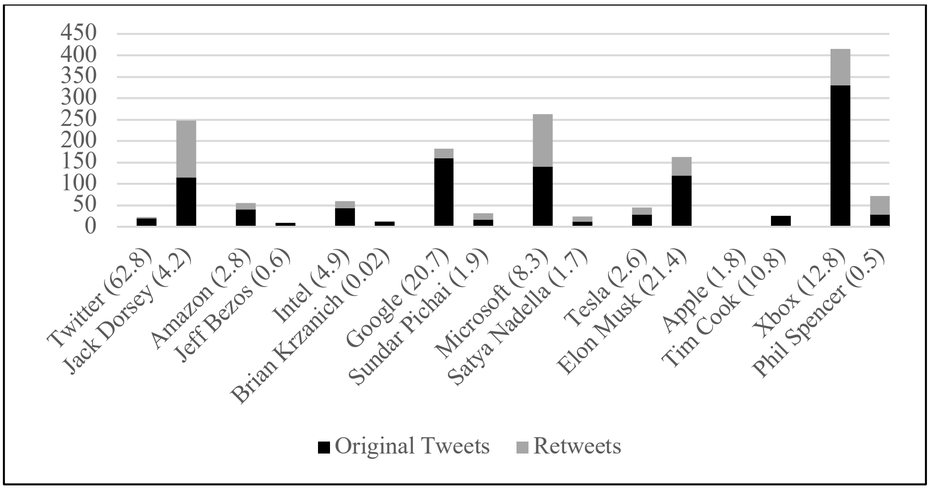

Figure 2 Tweet activity and follower count (in parentheses), April 25th 2018 - June 24th 2018

The data includes 1,101 original postings, 526 retweets, and 7,001 @mentions. The latter directly address a specific user but do not show up in the timeline of both communicator's followers. The large number of mentions primarily stem from @Xbox (4,137) and @Google (1,981). We were not able to capture tweets from the @apple account as it is solely use for nonrecurring advertising. Except for Twitter, CEOs author significantly less tweets compared to their corporate brand account. Those relations align with follower counts, as all investigated corporate brands have larger fan bases than their respective CEO.

Coding all original tweets and retweets resulted in a diverse distribution of addressed RQ dimensions. Figure 3 shows the spectrum of each account in relative proportions.

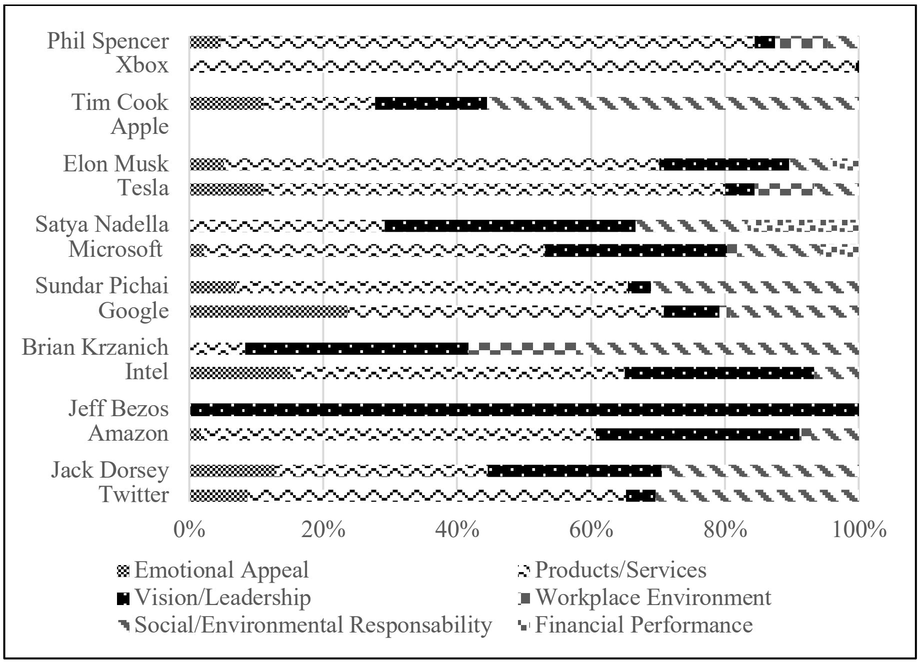

Figure 3 Spectrum of addressed RQ dimensions per company/CEO pair

Among the corporate brands, advertising products and services tends to be the predominant dimension. For CEOs, however, this dimension seems less relevant. While CEOs, too, advertise products and services to some extent, they rather focus on authoring tweets addressing vision and leadership and Social/Environmental Responsibility. Each tweet was exclusively allocated to one category. We ended up with 208 CEO authored tweets that did not fit the description of the initial six categories provided by the RQ dimensions. Consequently, we formulated additional categories to subsume those messages. Table 1 lists the total figures of tweets and retweets being categorized.

Table 1 Coding results (absolute figures) per dimension

	EA	*PS*	*VL*	*WE*	*SE*	*FP*	*SI*	*PL*
Companies	66	748	130	13	87	0		
CEOs	30	175	77	8	78	7	107	101

In a second pass of coding this subsample, we observed that those tweets were exclusively linked to the personality of the CEO. The first subgroup of messages (107) contained *Shared Interests* of the CEO that were of private nature. For example, Jeff Bezos authored a tweet containing a pop culture reference to remember an author who recently passed away. In a second example, Sundar Pichai expressed his expectations for the upcoming FIFA World Cup, naming a few teams he favored. The according tweets are represented in figure 4.

Figure 4 Tweet examples of the Shared Interest dimension

As a second group of messages (107), we identified postings that contained information about personal experiences and/or statements of the CEO. Following the popular term of blogging (and vlogging), we grouped those tweets under the notion of *Personal Logging*. It is important to notice that those tweets are authored from an ego-perspective. This excludes media or PR reports about the CEO. Jack Dorsey, for instance, shared his view from a rooftop in Boston. On Mother's Day, Jeff Bezos shared rather intimate thoughts about his mother, accompanied with a picture of her. The respective tweets are represented in figure 5.

Figure 5 Tweet examples of the Personal Logging dimension

In order to assess above dimensions with regard to their impact on CEO reputation management, we calculated relational indices. Follower counts were retrieved at the beginning of the tracking, and therefore, treated as an invariable value. Figure 6 depicts an overview of such measurements for better clarity.

For the R index (retweets per thousand followers), we calculated the mean value of retweets received for the sum of all original tweets and retweets posted or forwarded by each user. The F index (favorites per thousand followers), the retweets were excluded, as only original tweets collect favorites. We used abbreviations for better readability *(EA=Emotional Appeal, PS=Products/Services, VL=Vision/Leadership, WE=Workplace Environment, SE=Social/Environmental Responsibility, FP=Financial Performance, SI=Shared Interest, PL=Personal Logging)*, and listed our results in table 2.

Table 2 RQ dimension engagement (R=retweets per thousand followers; F=favorites per thousand followers)

CEO	*Follower Count*		*EA*	*PS*	*VL*	*WE*	*SE*	*FP*	*SI*	*PL*
Jack	4,212,972	R	1.95	0.03	0.38	0.01	1.2	0	1.6	0.02
Dorsey		F	0.07	0.13	0.2	0	0.26	0	0.1	0.23
Jeff	590,217	R	0	0	5.24	0	0	0	0.59	2.25
Bezos		F	0	0	18.11	0	0	0	4.39	20.92
Brian	20,778	R	0	1.88	2.11	1.17	0.92	0	0	0
Krzanich		F	0	4.14	5.04	4.93	4	0	0	0
Sundar	1,899,332	R	0.1	0.16	1.86	0	0.51	0	0.1	0
Pichai		F	0.74	1.39	5.41	0	3.64	0	2.39	0
Satya	1,717,000	R	0	0.18	0.13	0	0.34	0.8	0	0
Nadella		F	0	1.2	0.67	0	1.77	3.63	0	0
Elon	21,422,347	R	0.15	0.16	0.47	0	0.15	0.49	0.05	0.35
Musk		F	3.37	2.60	3.10	0	1.49	2.42	0.64	2,74
Tim	10,821,989	R	0.05	0.20	0.74	0	0.14	0	0.03	0.06
Cook		F	0.45	0.89	2.33	0	0.75	0	0.36	0.45
Phil	588,243	R	0.98	1.08	4.29	0.10	0	0.19	0.40	1.26
Spencer		F	0	2.27	2.18	1.04	0.84	0	3.23	8.64

The above findings suggest that the *Vision/Leadership* is prominently being addressed by the CEOs considered in our sample. At the same time, those postings provoked more engagement compared to the other dimensions. *Products/Services* and *Social/Environmental Responsibility* are part of the CEOs communication strategy in 4 out of 5 cases. We can further derive from this examination that Twitter users are more likely to add a tweet to their favorites rather than retweeting it. It further varies how much engagement CEOs receive from their following. For instance, Jeff Bezos received 5.24 retweets per thousand followers when addressing VL, whereas Jack Dorsey received only 0.38 retweets from his visionary statements.

We further observe that the supplementary dimensions of CEO reputation management are more often addressed than primary dimensions, e.g. the financial performance of their company. Considering SI and PL, Jack Dorsey received mediocre to little feedback when addressing personal issues. Jeff Bezos, however, received 20.92 favorites per thousand followers when taking his followers along his personal life. This was the highest score among all values.

6 Discussion

6.1 Distinguishing CEO and Corporate Branding (Research Question 1)

Our initial approach was to find similarities and contrasts of a corporation's communication strategy and the social media presence of its highest representative. In our sample, we found corporate brand pages to fall back on larger followings than their CEO-pendants. Moreover, the publishing activity of corporate brand pages is significantly higher than the one of CEO brand pages. Corporate brand pages may be used to supplement a firm's customer-service (Google, Amazon), which is apparent through intensive use of @mentions. This adds a much more conversational tone to the customer-brand relationship and, in this case, adapts to the character of Twitter.

Nevertheless, the corporate brandings are furnished with much more diligence in terms of content creation and publishing schedule. CEOs, in contrast, publish in a more sporadic and ad-hoc manner. In our study, we observed different strategies how CEOs may complement their corporate brand pages. In most cases, the CEOs followed similar agendas, e.g. tweeting and retweeting about *Products/Services* or the *Social/Environmental Responsibility* of their firm (e.g. Sundar Pichai, Satya Nadella). In other cases, the CEOs communication strategy supplemented their firm's efforts by focusing on different dimensions such as Vision/Leadership (Jeff Bezos, Brian Krzanich) or the Workplace Environment (Brian Kraznich). Measured against their follower base, the latter strategy provoked comparatively high engagement.

Our study displays that reputation management in social media is primarily employed to reach the customer base [12], [14]. Other stakeholder groups are rather neglected, as only Microsoft published tweets concerning the financial performance of their corporation. This situates social media in a unique position as they have the tendency to be channels for immediate action upon the customer's perception of the firm. This means increased empowerment to affect corporate reputation, but also higher volatility in how a company's reputation can change over time [14]. Hence, studies on reputation management in social media may find different dimensions of reputation management to be emphasized than, for instance, the financial performance of a company [32].

From a theoretical perspective, found the RQ dimensions to be eligible tools of classification when it comes to corporate reputation management [30]. However, in order to cover the entire spectrum of a CEOs reputation management, additional dimensions were required to mirror the capacities social media has to offer for CEO branding.

6.2 Supplementary Dimensions for CEO Reputation Management (Research Question 2)

Content analysis measures of social media postings attached to a corporate brand revealed that Fombrun's work including the RQ dimensions are doubtlessly applicable to the shape and form of contemporary online reputation management [16], [17], [30]. At the same time, this predicates that companies tend to not break new ground on a regular basis, but rather transfer established strategies onto new channels. CEOs, however, face the opportunity to meet with customers on a fundamentally different level of communication. five out of eight sampled CEOs portrayed themselves as fathers, husbands, and sports fanatics in front of their audience [5], [26]. Taking personal branding to such levels is a controversial choice to make. It blurs boundaries between private and professional life and leaves a person no choice but to be unhidden on a constant basis.

Despite these concerns, personal branding has become a commercial model of significant magnitude. Our study reveals that CEOs with exemplary roles in the IT industry cautiously discover personal branding elements as part of their image building in social media. Due to the inseparability of CEO and corporate reputation, theories dealing with reputation management require to widen their scope to incorporate the social mutation of CEOs. We argue that CEOs better meet the capacities of social media, as well as psychological needs of customers and themselves when communicating individually on social media [27]. This particularly holds for communication that addresses personal dimensions. Parasocial relationships between customers and CEOs may strengthen not only the CEO's reputation [25],[26], but at the same time, be carried over to the organizational brand.

Our results emphasize blurring boundaries between private and professional competences for CEOs, evoked through the ubiquity of social media and an amended brand-customer relationship. Nevertheless, personal branding may add significant value to the communication strategy of a CEO and result in a competitive advantage due to enhanced reputation. A supplementary individual communication strategy through the CEO brand holds the potential to increase overall engagement in Twitter. However, incorporating personal dimensions in professional brand communication should meet psychological needs of a CEO, who might set individual boundaries of self-disclosure.

Accordingly, we propose to append personal dimensions to our understanding of CEO reputation management. This first explorative investigation spawned *Shared Interests* and *Personal Logging* as relevant dimensions of CEO reputation management in social media, as shown in figure 6.

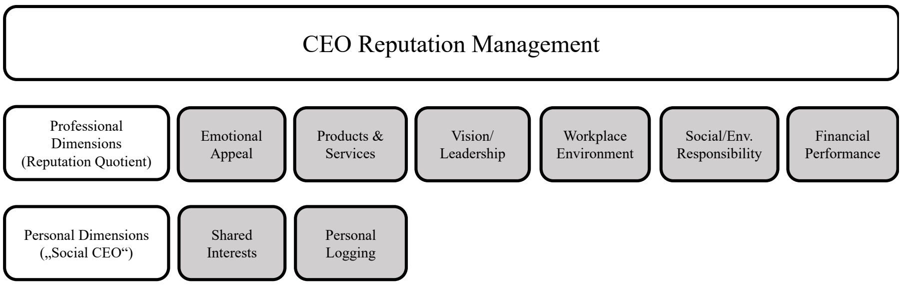

Figure 6 Dimensions of CEO Reputation in social media

The humanization of a corporate brand only works to a certain extend. Even though IT-firms push those boundaries through recent technological advancements such as social bots or conversational agents, an ever-present CEO has significant impact on the public image of a company. While fundamental work of [30] decently covers what we know as corporate reputation, extending the RQ dimensions to consider contemporary challenges and opportunities of CEO reputation management seems to be the next logical step. Hence, we need to allow for the individual characters of high executives to systemize their efforts in order to contribute to their personal and corporate brand, and consequently, to better serve their customer base.

7 Conclusion and Further Research

The study aims to impart new impetus to the landscape of research on reputation management. With regards to the ubiquitous role of social media, we award a new role to CEOs in terms of representing the fortunes of a company in a more accessible manner. By turning to [30] and their Reputation Quotient, we undertook efforts to adopt this set of dimensions to the specifications of CEO reputation management in social media. Through data collection by means of a self-developed java crawler and the official Twitter API, we were able to perform statistical and content analysis measures on a dataset of 8,628 tweets. The analysis of our sample, containing of corporate brands and their corresponding CEOs from the IT sector, revealed different RQ dimensions to be part of each communication strategy. Whereas corporate brands focus on promoting *Products/Services* and expressing their *Social/Environmental Responsibility*, CEOs authored *Vision/Leadership* statements more frequently. Moreover, we identified two additional dimensions, *Shared Interests* and *Personal Logging*, to complement the RQ and make it applicable to CEO reputation management.

Present findings add to existing knowledge by suggesting two personal dimensions of brand communication derived from the use case of CEO communication via Twitter. Furthermore, the study on hand is capable of contributing to science as personal dimensions prepare the ground to make the research quotient accessible for CEO reputation. We have identified novel dimensions that clearly distinguish personal brands from organizational brands. While our findings allow sufficient conceptualization, our study makes a first move toward theorizing the social capital of managers as an ether for reputation. Addressing the interaction with social media as exogenous information and communication tools is a research area of serious concern. Identified dimensions might not only help steering social media affordances more towards organizational needs. Platforms begin to integrate dashboard and analytics applications to meet the requirements of professional use. However, there is no such thing as an IT-based solution addressing reputational dimensions.

Our study comes with limitations as our findings rest upon a small sample of CEO and corporate brand pairs. Moreover, a snapshot of 8 weeks might not cover all facets of CEO reputation management performed on Twitter, especially for CEOs who author less frequently. We are aware that manual coding as part of qualitative research methods underlie the subjective assessment of all authors involved.

To strengthen our findings, more empirical research is required. We intent to extent the examination of this matter to a wider spectrum of social media platforms (e.g. LinkedIn, Facebook, Instagram) and industries to create a more heterogeneous data sample. Moreover, scholars researching this issue may consider falling back on a long-term data foundation and include critical phases of reputation management with increased volatility such as corporate crises. This includes cross-cultural examinations outside of the US-market. In order to build upon social media capacities that incorporate reputational dimensions, we suggest developing software prototypes that translate social media metrics to reputational scores, e.g. through automated sentiment analyses. This would allow organizations and CEOs to keep track of distinct levels of reputation and adjust communication strategies accordingly.

{cnitschke,williams,schubert}@uni-koblenz.de

Abstract. Enterprise Collaboration Systems (ECS) are emerging as the de facto technology platform for the digital workplace. This paper presents findings from an in-depth, multiorganisational study that examines the drivers and barriers of ECS-enabled change from two perspectives: i) the company initiating and driving the project and ii) key practitioners responsible for delivering the change. Data is collected from ECS using companies via a survey and face-to-face workshops, analysed using qualitative content analysis methods to identify categories of change and then synthesised to provide a rich classification and visualisation of the drivers, barriers, motivations and pain points (DBMP) to ECS-enabled change. This is followed by a discussion of the similarities and differences between drivers and barriers from both personal and company perspectives. The paper concludes by exploring the potential of the research and visualisation methods used in this work to provide the foundation for the longitudinal study of ECS-enabled change.

Keywords: Enterprise Collaboration System (ECS); Enterprise Social Software (ESS); ECS-Enabled Change; Drivers; Barriers.

1 Introduction

The transformation of work and new ways of working are essential for organisational success in the digital era [1]. Based on the success of social media platforms in everyday life [2], socially-enabled Enterprise Collaboration Systems (ECS) have emerged to extend traditional groupware (e.g. email, shared calendar) through the integration of social software features (e.g. wikis, blogs, social profiles) and provide large-scale integrated platforms to connect people, work practices, activities and structures [3], [4]. ECS have become the de facto IT platform at the heart of the digital workplace [5] and are generating significant interest for both researchers and practitioners [6].

Recent research has identified that initiatives for the introduction of ECS are being driven by company-specific objectives, including, for example, improved innovation management, better collaboration between employees, improved knowledge transfer and improved search for experts [7], [8]. However, individual organisations have differing drivers for introducing an ECS platform and are also experiencing a variety of barriers to system adoption and use, including for example cultural changes, reliance on other systems [9], [10] and poor formalisation of ECS communication protocols

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

[11]. Current research into the drivers and barriers of ECS projects typically draws from cross-sectional case studies conducted at a single point in time [10]. Both quantitative and qualitative research methods have been used to examine the adoption of ECS and enterprise social software (ESS) to identify and investigate ECS/ESS adoption drivers and barriers [12–19]. Nielsen and Razmerita [20] found that while ECS have the potential to support a variety of objectives, their adoption is affected by factors including individual (e.g. technical skills), organisational (e.g. management support) and technical factors (e.g. usability). By studying uncertainties as barriers for knowledge sharing in ECS, Trier et al. [18] place emphasis on the individual perceptions impacting and constituting barriers to ECS adoption, such as uncertainties regarding the purpose of the collaboration platform. While not making a distinction between ECS adoption barriers from a personal and a company perspective, Forstner and Nedbal [19] identified five problem areas: project management, technology, culture, top/middle management and employees. They also argue that organisations need to identify problems with the adoption of ESS at an early project stage and address them through project management. Similarly, Diehl et al. [2, p. 247] state that "cultural challenges can be anticipated and should be managed ex ante, not ad hoc." However, in line with the evolving and sociotechnical nature of ECS, the drivers and barriers organisations and their employees experience are emerging over time as they make sense of ECS and embed them into their digital workplace.

While current research provides insights into the importance of studying ECS adoption drivers and barriers, we see the need to establish appropriate means for capturing and investigating these drivers and barriers and building the foundation for studying the ways that they change over time. In their study on ECS adoption, Greeven and Williams [10] show that ECS adoption challenges and barriers are multifaceted and exemplify the complexity of ECS projects which organisations and the involved stakeholders are facing over time. In this paper, we build on our previous research and literature reviews on ECS adoption [8-10] and present the findings from an in-depth, multiorganisational empirical study that identifies drivers and barriers to ECS-enabled change from both the viewpoint of the company initiating the project and key practitioners involved in the everyday implementation and management of the project. Our goal is to extend existing work and lay the foundation for a long-term, longitudinal view of ECS-enabled change by following the introduction and use of ECS platforms over time.

2 Research Design and Data Analysis

This study is part of IndustryConnect, a long-term university-industry research program in the field of collaboration technologies and the design of the digital workplace [21]. IndustryConnect brings a team of researchers from a German University together with key practitioners from 31 German/Swiss companies. The organisations participating in the study are leaders in the introduction and use of ECS and have implemented IBM Connections, currently the largest, most integrated ECS platform [5]; all are committed to participating in interactive research to examine ECS-enabled change in their organisations. The IndustryConnect member companies are typically medium- and large-sized (1,000-300,000 employees) representing a range of industry sectors including: manufacturing, transport/logistics, retailing, government services and financial services. The key practitioners are all employees with responsibility for the introduction and use of the ECS in their organisation and represent a range of professional backgrounds including: information technology, information/ knowledge management, internal communications, organisational processes and business development.

The aim of this study is to identify and understand the drivers (D), barriers (B), motivations (M) and pain points (P) to ECS-enabled change and the adoption and ongoing development of ECS in organisations. Our objective is to examine ECS-enabled change from two perspectives:

i) Company perspective. The focus is on the company context and the broader reasons for initiating and driving the ECS project. From the company perspective we identify: *drivers (D)*, reasons why the company originally initiated the ECS project (e.g. expressed in strategy documents or strategic plans); and *barriers* (B), challenges/problems encountered that are constraining the ECS project and making the achievement of the company's ECS-enabled change objectives more difficult, and

ii) Personal perspective. The focus is on the everyday motivations and challenges of ECS-enabled change from the perspective of the key practitioners responsible for delivering the change. This perspective is shaped by individual experiences and the everyday activity in the organisation [22]. From the personal perspective we identify: *motivations (M),* reasons the ECS project is being supported or pushed forward by the individual practitioner and *pain points (P),* current challenges, problems, issues in the ECS project that the individual practitioner experiences in his/her daily work on the project and making the achievement of ECS-enabled change objectives more difficult.

The research study design is structured into four phases as shown in Figure 1 and discussed below.

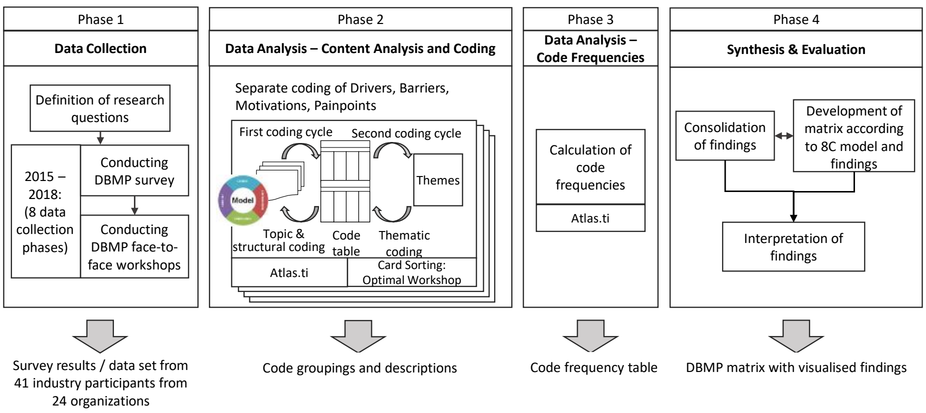

Figure 1. Research design phases

Phase 1: Data Collection. Primary data about drivers, barriers, motivations and pain points (DBMP) related to ECS introduction and use were collected between 2015 and 2018 from 41 practitioners representing 24 companies from the IndustryConnect program. Data was first collected via an online questionnaire comprised of four questions addressing both the company perspective ("What are the original *drivers* for your company initiating the ECS project?", "What are the key *barriers* encountered by your company constraining the ECS project?") and the personal perspective ("What are your current personal *motivations* for supporting the ECS project or pushing it forward?", "What are your personal *pain points* in the ECS project you experience in your daily work on the project?") of key practitioners involved in the respective ECS-enabled change projects. After completing the questionnaire respondents presented their DBMP in one of a series of face-to-face workshops. The objective of the workshop presentation is for each respondent to elaborate on their answers, clarify meanings and for the researchers to gather further examples. The presentations and discussions were digitally recorded and transcribed for analysis.

Phase 2: Data Analysis – Content Analysis and Coding. The drivers, barriers, motivations and pain points (DBMP) identified by each respondent were listed and coded. Using content analysis methods and following Saldaña [23] the data was coded through two iterative coding cycles using the qualitative data analysis tool ATLAS.ti. In the first coding cycle, topic and structural coding was applied to provide four basic code tables for the DBMP. Guided by the elements of the 8C model [24], the codes in the individual tables were then structured into two categories: i) functional DBMP codes relating to the ECS platform, its functionality and performance and ii) business DBMP codes relating to the organisation and its corporate objectives.

In the second coding cycle the card sorting method for thematic coding was applied [25]. To ensure research quality and reliability three researchers worked independently on the coding and reviewed the codes in joint workshops to clarify the emerging DBMP categories and to achieve a high level of intercoder reliability. Following the coding process, tables containing DBMP code groupings and code descriptions were created.

Phase 3: Data Analysis – Code Frequencies. Code frequencies, that is the total number of occurrences of each code, were calculated in ATLAS.ti and the code frequency table was created. The code frequency table provides an additional means for examining similarities and differences between drivers, barriers, motivations and pain points for different practitioners and companies.

Phase 4: Synthesis and Evaluation. In the final phase of the study the findings were synthesised and consolidated. The DBMP matrix (Figure 2) was developed to display the consolidated findings in a visual form. These consolidated results were presented to the study participants in a review workshop. The DBMP matrix itself was also evaluated as a method for visualising and consolidating the drivers, barriers, motivations and pain points data and as a method for presenting the data to the participants. The feedback from the participants was positive and the matrix provoked constructive discussions between the researchers and the study respondents.

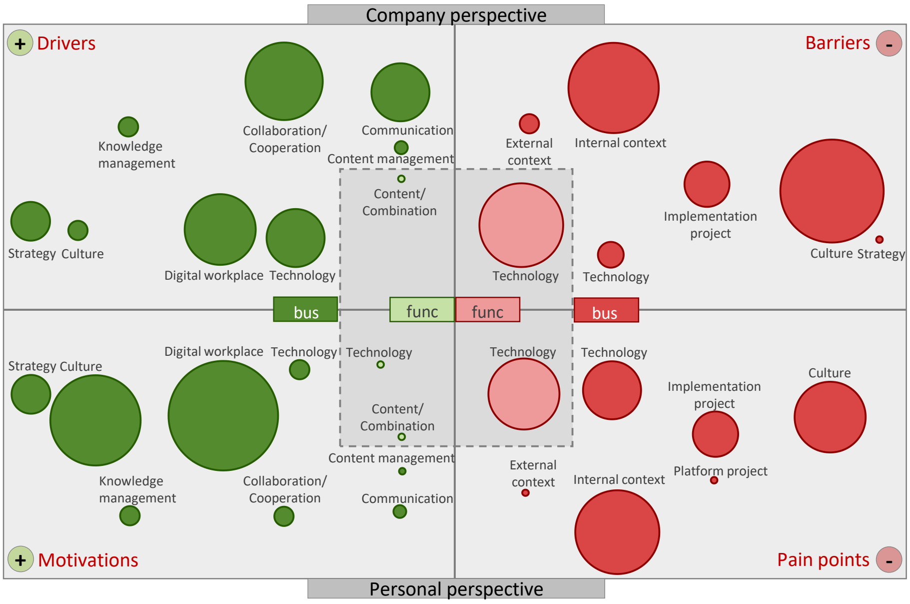

Figure 2. Drivers, barriers, motivations and pain points of ECS-enabled change

3 Findings and Discussion

The derived DBMP categories were visualised in a 2x2 matrix (Figure 2). The top two quadrants represent the company view, the bottom two quadrants the personal view; the quadrants on the left show the issues driving the project forward (*drivers* and *motivations*, green) and the quadrants on the right show the issues constraining the project (*barriers* and *pain points*, red). In total, 108 different DBMP codes were identified in the final coding iteration. The identified DBMP codes and categories were separated into *functional* (light green / light red at the centre of Figure 2) and *business* (dark green / dark red in Figure 2). The size of the bubbles represents the sum of the frequencies of the codes within a category. To enhance readability, bubbles of similar categories are placed next to each other (e.g. content management and communication, that can be found in the 8C model [24], or internal and external context). Furthermore, the matrix lines work roughly as mirror axes to improve comparability between the single quadrants and between functional and business DBMP within one quadrant.

Table 1. Drivers/Motivations: category descriptions and frequencies

Category		*Description*	*D*	*M*
Collaboration / Cooperation	bus	Relate to new or changing collaboration and cooperation practices and processes for business improvement	12	3
Communication	bus	Relate to new or changing communication practices and processes for business improvement.	9	2
Content Management	bus	Relate to new or changing content management practices and processes for business improvement.	2	1
Knowledge Management	bus	Relate to new or changing knowledge management practices and processes for business improvement.	3	3
Digital Workplace	bus	Relate to an integrated collaboration platform and what it is expected to enable regarding the support of organisational members and their work.	11	17
Technology	bus	Relate to the improved management and usage of IT within the corporate context and desired changes to business IT (architecture) solutions and concepts.	9	3
Strategy	bus	Relate to corporate strategy/ strategic objectives.	6	6
Culture	bus	Relate to the corporate culture, where cultural changes need to be enabled through the introduction of new technology and work practices and/or are needed for the successful embedding of new technology and work practices into the work environment.	3	14
Content / Combination	func	Relate to content creation, use, and management functionally supported by the collaboration platform.	1	1
Technology	func	Relate to expected or perceived positive characteristics and affordances of the collaboration platform itself and its functionality, e.g. ease of use or integration capability.	x	1

A similar set of categories emerged for the drivers (D) and motivations (M), and for the barriers (B) and pain points (P). Table 1 and Table 2 show the descriptions of the business (bus) and functional (func) categories identified for the four quadrants (DBMP) and the associated frequencies of the code categories. A cross is used in the tables when a category is not present in the respective DBMP quadrant. Each category description is comprehensive to cover a wide range of different DBMP codes. For example, the barriers and pain points category *implementation project* covers ten codes: *lack of systematics in the introduction*, *neglect of the head quarter*, *missing business link*, *poor transparency*, *low awareness level*, *poor training*, *missing binding rules*, *different target visions*, *missing use cases*, and *poor project management*.

Table 2. Barriers/Pain points: category descriptions and frequencies

Category		*Description*	*B*	*P*
External context	bus	Relate to actors and influences from outside the company that are restricting, constraining or otherwise negatively impacting the ECS project and its development (e.g. laws, regulations, customers, vendors, market developments).	3	1
Internal context	bus	Relate to actors and influences from inside the company that are restricting, constraining or otherwise negatively impacting the ECS project and its development (e.g. poor management support of the ECS project, work council, company structures, missing resources).	14	13
Implementation project	bus	Relate to the ECS implementation project itself and corresponding implementation strategy design decisions.	7	7
Platform management	bus	Relate to the ways the collaboration platform is managed and the consequences thereof.	x	1
Technology	bus	Relate to the management and usage of IT within the corporate context and unsatisfactory business IT (architecture) solutions and concepts.	4	9
Strategy	bus	Relate to the embedding/alignment of the collaboration platform into/with the corporate strategy.	1	x
Culture	bus	Relate to corporate culture, where cultural changes are needed for the successful embedding of new technology and work practices into the work environment.	16	11
Technology	func	Relate to perceived deficiencies in the collaboration platform itself and its functionality and usability, e.g. security, missing functionality, external access.	13	11

As can be taken from Table 1 and Table 2, there are differences between the personal and the company view in terms of the total number of mentions within a category. In the following sections we describe and discuss each of the four quadrants with illustrative examples of associated codes.

3.1 Drivers

Eight business driver categories and one functional driver category were identified as shown in Table 1. Each driver category contains a set of driver codes, for example, the driver category *collaboration/cooperation* contains driver codes such as: *increase of inter-site collaboration* or *support of international collaboration*.

The frequency of occurrence of the single driver codes indicates a stronger focus on business drivers and less on functional-oriented drivers for the introduction of an ECS. Since the drivers represent the company perspective, it is not surprising that there are more business-oriented driver codes and categories reflecting overall corporate objectives and visions, such as globalisation, business performance, productivity improvement, or support of organisational changes [26], [27]. The analysis reveals that ECS drivers may be i) opportunity-driven (e.g. support of international communication, improvement of cross-divisional collaboration, sharing of information) or ii) problem-driven (e.g. usage of external social media applications, communication hierarchy, reduction of e-mails).

Table 3. Driver examples

Quote	*Driver code*
"A global collaboration tool for all employees to bring colleagues from around the world closer together, in a flexible, forward-looking network culture" (Service Owner (IT), Automotive Parts Manufacturer 05)	D: bus: collaboration/cooperation: global collaboration tool; D: bus: digital workplace: networking
"The communication hierarchy did not fit; turn hierarchies upside down" (Head of IT, Security/Infrastructure, Clothing Manufacturer/Retail 02)	D: bus: communication: communication hierarchy
"Support cross-border collaboration" (Head of Communications/Knowledge, Consumer Electronics Manufacturer 02)	D: bus: collaboration/cooperation: support of international collaboration

In general, the main focus of drivers is on business achievements and improvements. In particular, organisations are striving to enable and improve collaboration and communication between employees as well as becoming a digital workplace and having the right technology in place to achieve this. The collaboration platform itself and its functionality and performance are of less concern as drivers of change. Table 3 shows examples of typical drivers expressed by the study participants.

3.2 Barriers

Six categories of business barrier and one functional barrier category were identified (Table 2). As with the drivers, each barrier category contains a set of barrier codes. For example, the barrier category *implementation project* contains barrier codes such as *missing binding rules* and *poor transparency*. The barrier code frequencies reveal that the biggest groups of responses relate to the business categories *internal context* and *culture* and to the functional category *technology*. Internal context largely refers to people who constrain the project (e.g. managers not supporting the project or the works council demanding specific requirements regarding personally identifiable information being captured in the ECS) and is seen as particularly problematic. Culturally, change management and the development of a new mindset is perceived as challenging. Functional barriers pointing to weaknesses in the collaboration platform (e.g. in terms of usability) and functional limitations (e.g. insufficient analytics measurement capabilities) were identified as major barriers to the ECS-enabled change projects.

Table 4. Barrier examples

Quote	*Barrier code*
"Knowledge is seen as property from the employees' point of view. Knowledge is not shared because this [new] attitude is not rooted yet. Also, this has something to do with the notion of performance. The employee thinks ‚If I advance something, I will be in the favour of my boss'" (Specialist, Collaboration, Steel Manufacturer 01)	B: bus: culture: corporate culture that makes collaboration difficult
"Financial and human resources" (Project Manager, Information Architecture, Logistics Services 01*)*	B: bus: internal context: missing resources
"The ECS is far too extensive, security and privacy requirements destroy the usability of the product. The app is not at all user-friendly." (Head of Corporate Portals, Air Transportation 01)	B: func: technology: system complexity; B: func: technology: usability

Barriers relate primarily to business issues, however, in contrast to the drivers, functional barriers are also of importance. The identified codes and categories show that some barriers only became visible in ECS use; they were unanticipated and organisations only recognized them through using the platform. For example, a missing killer app or system complexity that only becomes visible when the system is in use (Table 4). Functional deficiencies of the collaboration platform make achieving expected ECS benefits and outcomes, e.g. improved communication, more difficult.

3.3 Motivations

The motivation categories identified in the data analysis are similar to the driver categories, however they represent the personal view of the key practitioners and include different objectives. Eight business motivation categories and one functional motivation category were identified (Table 1). As with the drivers and barriers, each category contains a set of motivation codes. For example, for the motivation category *digital workplace* the motivation codes *creating transparency* and *establishing modern ways of working* were identified. These motivations focus on opportunities, such as designing the workplace of the future, establishing new ways of working, or promoting changes in the corporate culture.

Table 5. Motivation examples

Quote	*Motivation code*
"The opportunity to fundamentally make the daily work of 70.000 employees easier." (Senior Manager, HR, Logistics Services 02)	M: bus: digital workplace: make work easier
"I want to help shape change." (Senior Manager, Social Collaboration, Automotive Parts Manufacturer 02)	M: bus: culture: promote change/ change in corporate culture
"Future Work is my mission." (Manager Digital Transformation and Change, Automotive Parts Manufacturer 05)	M: bus: digital workplace: workplace of the future

The personal motivations in ECS projects are mainly in the business categories *culture* and *digital workplace*. The frequencies of the motivation codes and categories revealed the individual practitioners desire to be part of organisational change and the shaping and transforming of the company's culture and digital workplace. Functional motivations are seen as being of minor importance. The collaboration platform itself and its performance is of less importance; instead shaping the digital transformation is paramount. Table 5 provides examples of motivations where the active part and role of the individual participants in the ECS-enabled change projects becomes clear.

3.4 Pain Points

Five business pain point categories and one functional pain point category were identified (Table 2) where each category includes a set of pain point codes. For example, for the pain point category *culture* pain point codes of *change management* or *poor support for new mindset / ways of working* were identified. In line with the set of categories and the code frequencies, pain point categories (personal view) and barrier categories (company view) show highest similarity. As with the barrier categories, the categories *internal context* (business), *culture* (business), and *technology* (functional) are the most frequently cited categories, followed by *technology* (business). From the perspective of the key practitioners involved, the ECS project is constrained from inside the company due to missing resources and resistance from, for example, the works council as well as low level of digital competence. Culturally, acceptance and the lack of support for a new mindset and work practices is perceived as most challenging. Worth noting are the technology aspects that are being negatively perceived. This applies to both the corresponding business category, e.g. through multiple possible competing systems used by the organisation, and the corresponding functional category with issues of technology usability and system integration.

Table 6. Pain point examples

Quote	*Pain point code*
"Too many different tools and no single point of entry" (IT Manager, Collaboration/Knowledge, Technology Inspection Service)	P: bus: technology: variety of systems P: func: technology: missing single sign-on
"Binding rules on collaborative work [...] regulate a particularly strong group of Confluence users." (Project Manager Intranet, Retail Grocery 01)	P: bus: implementation project: missing binding rules; P: bus: technology: competing system
"Works council." (Project Manager, Automotive Parts Manufacturer 04)	P: bus: internal context: slow movement due to the works council
"System acceptance and the competition with Microsoft products" (Internal Consultant, Air Transportation 01)	P: bus: culture: acceptance; P: bus: technology: competing system
"Deficits in IBM Metrics: Development of analytics methods without existing documentation" (Specialist, Collaboration/ Statistics, Automotive Parts Manufacturer 02)	P: func: technology: deficits in metrics capability

As with the barriers, functional technology-related pain points become visible through ECS use. For example, practitioners noticed the significance of pain points such as a missing single sign-on feature when the ECS is being used alongside multiple other business software systems. The participants' responses in Table 6 show examples of individually perceived pain points in the ECS projects that make shaping the new workplace (which was one of the key motivations) more difficult.

3.5 Interpretation of Drivers, Barriers, Motivations and Pain Points

The visualisation of the DBMP (Figure 2) and the underlying data reveal both similarities and differences in the collected drivers, barriers, motivations and pain points.

While drivers and motivations for bringing the ECS projects forward are largely business-oriented, barriers and pain points clearly deal with functional issues related to the collaboration platform itself, including deficiencies in data analytics capabilities, external access, integration or usability.

From the study findings we also see a link between the position and role of the individual participants in the ECS project and the nature (functional or business) of the perceived pain points. As can be drawn from the example pain points (Table 6) the business-oriented pain points were largely identified by project managers and internal consultants, while the functional-oriented pain points were identified by IT managers and technology specialists. Overall, however, business-oriented DBMP are most prevalent. From a company perspective, the business-oriented drivers are about enabling and/or improving things, such as collaboration or the digital workplace, and place emphasis on ECS project outcomes. In contrast, business-oriented motivations showing the personal perspective focus on the path towards these outcomes, where having an active part in the transformation, particularly of the organisational culture and digital workplace, is key. Such obvious differences cannot be directly identified from the two quadrants on the right side of the matrix but are revealed in the coding tables. Both, business-oriented barriers and pain points specifically represent challenges from the internal context, for example through groups of people who obstruct or constrain the ECS project and the changing of culture. In addition, the business-oriented category *implementation project* has the same frequency for barriers and pain points. One reason for this is that that pain points personally perceived by the people responsible for the ECS project (e.g. project leaders and managers) are partly based on the ECS barriers prevailing inside the company, as these must be addressed by them in order to achieve ECS acceptance and satisfy their individual ECS project motivations.

Furthermore, there are some categories, e.g. *culture* or *technology* that can both be perceived as driving and constraining the ECS project. For example, while organisations and key actors in the ECS projects aim to bring about changes in the corporate culture and collaboration mindset by introducing a collaboration platform, the current cultural mindset and attitudes might also impede accepting and adopting new technologies and work practices.

4 Concluding Remarks

In this paper, we identify and analyse the drivers and barriers to the adoption of ECS. We conducted a survey with multiple ECS user organisations from different industries. Since ECS are largely being shaped by individual key practitioners in the organisations, who have different backgrounds, experiences with and expectations of collaboration systems, the *drivers* and *barriers* were studied from both a company perspective and a personal perspective. In order to differentiate between these views, we named the drivers and barriers from a personal perspective *motivations* and *pain points*. The drivers, barriers, motivations and pain points (DBMP) were collected, coded and their frequencies identified. This data is consolidated and visualized in the DBMP matrix, displaying the diverse DBMP categories and their relevance for ECS user organisations. This work extends previous work, for example [13], [16], [19] by representing multiple perspectives (company and personal) and providing a deeper and more nuanced classification of drivers and barriers.

While the current study does not yet consider the ways that DBMP change over the life of ECS projects it has delivered a clear set of DBMP anchor measures [28] that can be traced over time. The research approach and DBMP matrix provide a method for collecting and visualising DBMP and are now being used to capture DBMP from the same group of ECS using companies at regular points in time; enabling us to examine how they change (or not) over time. To achieve this requires a more animated visualisation of the DBMP matrix that incorporates the dimension of time.

From this study and further interviews and workshops with the current participants we have further identified that companies with similar drivers and motivations are designing the digital workplace differently [5] and are dealing with the same barriers and pain points in different ways. For example, the barrier and pain point of the works council being perceived as impeding the ECS project progress (by having specific requirements regarding personally identifiable information in the system or the inclusion of certain employee groups), is being addressed differently in different organisations. While some organisations involve and incorporate the works council in the ECS project, others attempt to exclude them or redirect attention away from seemingly problematic ECS functionality and procedures.

Building on this DBMP study, work is now underway to study how DBMP evolve and change over time as part of an organisation's digital transformation efforts. Our goal is to identify the organisational competencies and capabilities required to successfully achieve and manage ECS-enabled change. In particular, we are identifying key enablers and constraints to specific ECS outcomes in order to gain insights into how the ECS transformation process is being shaped. The achievement of expected and desired outcomes, e.g. faster innovation or removal of knowledge silos, requires the development of competencies and capabilities allowing for the management of ECS-enabled change and the successful embedding of ECS into the digital workplace.

Throughout the digital transformation process companies are encountering both expected and unanticipated enablers and constraints to desired ECS outcomes. For example, companies have benefitted from positive use cases that make the ECS more visible and encourage employees to be more accepting of social software. On the other hand, they are constrained by, for example, conflicting stakeholder interests and responding to new regulatory requirements. Existing research on IS capabilities has identified that capabilities are developed through action and interaction with technology and the embedding of emerging skills and competencies within the organisation [29–31]. Additionally, the emergence of capabilities requires a process of reflection and learning embedded in the specifics of the organisational context [32]. In order to successfully build a digital transformation capability, we see the need for organisations to i) reflect on and learn from the digital transformation process while identifying and developing the relevant competencies and resources, and to ii) anticipate future changes shaping the digital workplace while building the knowledge, skills and resources for enabling digital change. In this way and in contrast to prior research on the ECS introduction and adoption [15], [17–20], this research is studying ECS as evolving and sociotechnical systems and follows Dourish [33] by viewing the change context as being dynamically designed through ongoing interactions with the collaboration system.

The More the Merrier? The Effect of Size of Core Team Subgroups on Success of Open Source Projects

Leonard Przybilla [1], Maximilian Rahn[1], Manuel Wiesche[1], and Helmut Krcmar[1]

Abstract. Open source software (OSS) has become an important organizational form of building software. Given the desire to understand drivers of OSS project success and the known importance of social structure for team functioning, we investigate the effects of the relative size of contribution-based subgroups on community size of OSS projects. Drawing on extant research on OSS and faultline-based subgrouping, we investigate the relation with project community size of the relative size of subgroups based on reputation, issue focus, contribution extent and contribution persistence. While in several instances non-significant, results suggest a differential relation in which a large share of core members with high reputation, issue focus and persistent contributions positively relate to community size, whereas a large share of extensively contributing members in the core team is negatively related. Our findings are of value to research and practice by furthering the understanding of work in OSS projects.

Keywords: Open Source Software, Subgroups, Community Size, Team Governance.

1 Introduction

Open source and related concepts such as libre or free software development (in the following summarized as Open Source Software or OSS) have gained much traction in the beginning of the century [1] and continue to garner research attention recently [2].

Since most of the members of OSS projects contribute during their spare time and without monetary remuneration, the questions what motivates people to join, to contribute over longer periods of time and how such informal communities are managed have emerged as topics of research. Such issues are all the more relevant since despite overall success of OSS, a large majority of projects is defunct and not maintained [3]–leading to the issue how success in projects can be propelled.

OSS development is characterized as a virtual, distributed form of teamwork in which theoretically anyone can contribute [4]. This implies that developers are likely to differ on a number of attributes. OSS team members' motivations have been found

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

to be manifold–ranging from personal gain such as programming knowledge [1] or reputation [4] to philanthropic intentions [1]. Moreover, OSS team members embrace a common set of specific values and attitudes, which directly relate to work practices [5]. As may be expected from the clique-like description of OSS team interactions, the onboarding process of new members can be riddled with challenges [6].

The notion of positive effects of diversity in members on problem-solving [7] is only to some extent replicated in OSS [8], leading to the questions when and how diversity is conducive to outcomes. Based on characteristics shared by some members of a team and thus separating them from others, diversity can lead to so-called faultlines [7], which in turn may lead to perceivable subgroups [9]. Contingent on the specific reason for formation and configuration of faultlines and subgroups, the direction, i.e. enhancing or harmful, and strength of effects may differ [10, 11].

OSS teams as inherently open entities with a diverse set of members harbor much potential for faultlines and subgroups. Despite the critical importance of joint work in OSS, subgrouping and the resulting configuration as influential phenomena in general group research have, to the best of our knowledge, not received any research attention. We take a first step to addressing this void by investigating the following research question: Does the configuration of contribution-based subgroups in OSS teams relate to success as indicated by community size?

We first provide background information on extant research on OSS as well as faultlines and subgrouping before discussing specific implications in the context of OSS. We then introduce our hypotheses and the method used before reporting results of analysis and discussing implications. Lastly, we provide concluding remarks.

2 Background

In the following, we will briefly introduce extant research on OSS development and subgrouping before discussing the implications of subgroups in the context of OSS.

2.1 Work in Open Source Software Development

The success of OSS is astounding given its organizational challenges. Howison and Crowston (2014) report that organizing OSS is especially difficult for at least three reasons: Challenges presented by distributed work are exacerbated by relying on volunteers, which renders traditional incentive mechanisms ineffective. In addition, the work undertaken in OSS is complex with the associated difficulties [12]. Against the backdrop of previous research on the personality of developers [13], these assertions give rise to the questions which mechanisms help achieve valuable outcomes and why developers join and continue participating in OSS projects in the first place.

The motivations to join OSS projects are manifold. Given its characterization by voluntary contributions [1] and the ensuing absence of monetary remuneration, other causes such as personal motivations prevail. As private benefits, personal need for the developed functions, fun derived from working on the task and learning are key [1].

Membership in the community, the ability to gain reputation, and the possibility to receive job offers are also recurring themes [4]. The strong sense of community is mirrored in OSS participants sharing a common set of beliefs and values [5].

Assuming members assemble in a project, the issue of how work is organized arises. While OSS can be compared to several paradigms of work organization, unique differences are highlighted. Due to its inherently distributed nature, OSS can arguably be related to such teams, albeit results on governance may not be directly transferrable [12]. The voluntary and thus indeterminate nature is mirrored in elements that OSS development shares with agile projects [14]. More testament to the specific type of work accomplished in OSS is given by structural investigations. Typically, a relatively small core of developers contributes the majority of work, which is augmented by the smaller contributions of peripheral members [15]. Considering team composition, strong network ties of developers have been observed to bolster success [16]. For embeddedness of developers and projects, differential effects on success have been observed [17]. Moreover, the proficiency of projects at either developing new features or improving upon existing code has been observed to depend on the structure of collaboration [2].

The presence of a strong sense of community coupled with findings that a core of developers contributes differently than a periphery of developers gives rise to the question on how the configuration of the core relates to success in the larger community. To determine such possible effects, we propose to draw on faultline and subgroup theory.

2.2 Faultlines and Subgrouping

Diversity, i.e. differences in team members regarding attributes such as gender or functional background is found to be conducive to performance in teams by enabling the integration of diverse viewpoints [7]. In OSS, diversity of members has been found to improve some but not all outcomes [8].

Effects of diversity can be explained by so-called faultlines: Latent divisions among members based on characteristics shared by only some [7]. If perceived by members, faultlines are activated and lead to subgroups [18], i.e. several smaller entities within the overarching work teams [11]. For the purpose of this research, the term "subgroup" refers to activated faultlines and is rooted in faultline theory–notwithstanding its use in other contexts.

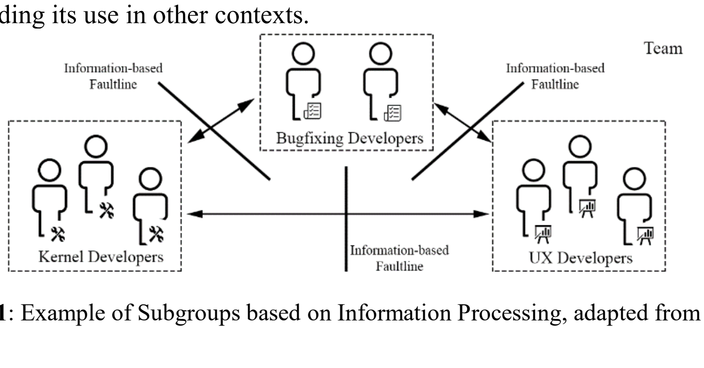

Figure 1: Example of Subgroups based on Information Processing, adapted from [19]

Faultlines and to a larger extent active subgroups have been found to affect team outcomes [9]. Recently, it has been proposed that the reason for subgroup formation may lead to different types of subgroups with different internal processes and thus different effects on group outcomes [11]. Identity-based subgroups due to e.g. differences in age are expected to trigger mostly negative processes, resource-based subgroups due to e.g. status differences harbor the potential for conflict but can boost efficiency, and information-based subgroups due to e.g. different expertise can engender team effectiveness by supporting information processing across groups. Given the need to coordinate knowledge in software development [20], the implications of information-based subgroups could be especially positive. Figure 1 exemplifies the emergence of subgroups based on information-triggered faultlines. The number of subgroups and their balance in terms of membership size, i.e. equally split versus imbalanced subgroups, also influence subgroup effects with e.g. an imbalanced configuration of geographically dispersed members leading to negative effects [10, 11]. Empirically, a complex interaction of subgroup formation, configuration and team outcomes has been observed [21]. In particular, software engineering practices may change subgrouping and its effects [19, 22].

2.3 Faultlines and Subgroups in Open Source Software

Considering the importance of commonly held values and community in OSS [5] and the observed effects of subgrouping raise the question whether harmful or positive effects of subgrouping occur in OSS. To this end, we provide an initial, non-exhaustive assessment of faultline types in OSS development.

By communicating through electronic means, members of OSS projects have limited possibilities to observe characteristics of their peers [8]. Faultlines based on *demographic attributes* may not be perceivable and thus irrelevant–unless members include demographic information in their public profiles. In fact, demographic attributes have not been found to be prominent among members [23].

Motivations to join OSS projects are manifold and thus harbor potential for splitting groups along identity-based faultlines. It could, however, be the case that like-minded individuals cluster in homogeneous groups. Motivations have been found to differ also based on project characteristics, i.e. size [24], which then would attract a specific type of developer. Since membership may not be fully determined by a single motivating factor and projects may cater to more than one need, e.g. enabling learning and at the same time providing opportunities to build reputation, motivation is likely to lead to identity diversity and thus faultlines in OSS projects.

Experience in OSS development in general and the specific project is expected to present an information-based faultline. Differences in professional experience are documented as faultlines [25], additionally in the context of OSS distinct differences in knowledge, which arguably is related to experience, are described [8].

Reputation as an individual's social status is important in the social fabric in OSS [26]. Reputation as the congruence of promised actions and actual behavior [27] is multi-faceted such that positive views in technical aspects can be coupled with negative social evaluations. Given this multidimensionality and basis for authority

[8], reputation is likely to differ for an individual between projects and for individuals within one project. These differences are expected to lead to a hierarchical structure and thus resource-based subgroup [11].

Differences in *activity type* are well-established differentiators in OSS projects and thus a likely faultline item. First, users and developers differ, where users mostly consume and at most make small contributions such as bug reports or minor changes, whereas developers contribute all major code advancements [8]. Within the set of developers, a hierarchy consisting of a core and more peripheral developers has been described: A set of core developers has a disproportionate share of contributions, which entails more influence and reputation, whereas a large number of peripheral developers contributes relatively little code [15].

The *extent and persistence of contributions* is another potential faultline. The overall amount of activity is expected to be an influential member characteristic. Abstracting from the specific contribution behavior, the core-periphery structure of OSS projects [15] is based on the extent of contributions. Activity is an antecedent to previously discussed characteristics such as experience and hierarchy. In addition, by contributing continually, members can build knowledge, which is a key criterion for advancing to more central roles [15]. Drawing on research into other open collaborative processes, roles are expected to be identifiable but flexible over time [28]. A subsequent reduction in activity may thus demote members from the core to peripheral contributors.

3 Hypotheses

We propose a set of hypotheses to investigate the correlation of the relative size of subgroups based on high reputation, issue focus, high contribution extent, and high contribution persistence and success of OSS projects as defined by community size.

3.1 Success in OSS

Success in OSS is not dependent on a single characteristic. The multi-faceted nature of OSS success is evident from the proposition of frameworks to assess success based on diverse indicators [29]. Following previous application [29], we use the size of the non-core OSS project community as an indicator of its external success since contributions of peripheral members are valuable to maintain the project [8]. The onboarding mechanism, i.e. to integrate new developers into the project has been described to be a difficult issue in OSS [6]: Community size is thus apt to indicate how well a project cannot only garner attention but recruit contributors, who potentially can advance to the core team. Based on the preceding discussion of characteristics prone to lead to faultlines and subgroups, we derive hypotheses on the relations of a selected subset of bases for subgrouping that are deemed relevant for community size.

3.2 Hypotheses on the Configuration of Subgroups in OSS Core

For the hypotheses on the relations of the relative size of subgroups defined by faultlines, we draw on findings concerning the stable yet dynamically changing roles in open collaboration [28]. Discussions on the type of potential subgroups and their related effects draw on the typology suggested in [11].

Reputation has been described as an individual's social status in OSS projects [26]. Drawing on extant research in subgrouping, differences in reputation can be related to hierarchical differentiation, which can lead to negative outcomes as resource-based subgroups [11]. At the same time, without perceptions of unfair distribution, a hierarchy can facilitate information processing and thus aid group performance [30]–which relates to potentially positive information-based subgroups. In the context of OSS, reputation has been found to increase trust and satisfaction in members [27, 31]. Considering virtual teams, trust in turn has been observed to increase participation and community activity [32]. Reputation may also facilitate the progression from observing user to contributor with decision power [8] through satisfaction, which leads to participation intentions [27]. In addition, since we focus on the size of the peripheral community as dependent variable, the presence of high-reputation individuals in the project core may signal credibility [27], which may help to attract new members.

H1: The relative size of the subgroup of high-reputation individuals in an OSS project will be positively correlated with community size.

Issue Focus: Different activity backgrounds lead to the potential of information-based subgroups, which can be positive [11]. A large share of issue-focused contributors, i.e. with most activity in creating and commenting on issues, is expected to foster community size. Reporting issues is a known pathway to transition from user to core contributor [33] since issue reports require less specific technical and project-related knowledge than code contributions. With commenting also being part of issue focus, a large share of issue-focused members implies many members may still be starting out as contributors or many people are helping others into the project by sharing knowledge through comments. Core members commenting on issues of newcomers is comparable to mentoring, which has been found to aid onboarding [34]. In addition, a large subgroup based on such behavior may send positive signals of a collaborative culture to outsiders and consequently make the project more attractive.

H2: The relative size of the subgroup of issue-focused individuals in an OSS project will be positively correlated with community size.

Contribution Extent: While rather general, the extent of contributions in projects is expected to foster success and to generate follow-up activity. Similar to reputation, past contributions in a project act as an outside signal of activity and maintenance–as opposed to a majority of OSS projects that are effectively abandoned [3]. Such signals may sway outsiders to become part of the peripheral network. Activity in and of itself is positive in OSS, which is witnessed by an emphasis on practical work in core beliefs [5]. The importance of activity for community building is mirrored in the finding that updates on activity are a key reason for following other members [35]. In addition, for acquiring new casual contributors, a large share of highly active contributors can make it easier for newcomers to identify who to turn to and ask questions and whose work to study to overcome issues related to a lack of replies found in onboarding [6]. In this sense, a large share of members in a high-activity subgroup may foster efficient processing as a knowledge-based subgroup [11].

H3: The relative size of the subgroup of extensively contributing individuals in an OSS project will be positively correlated with community size.

Contribution Persistence: Analogously to contribution extent, we expect a large share of persistent developers to aid community size. The presence of persistent contributors shows a project is actively developed and thus increases its attractiveness. Past activity may inform future activity [36] and thus benefit future contributions. In addition, persistent developers may be easier to identify and the likelihood of responses are increased, which can address the onboarding issue of receiving no reply from core members [6].

H4: The relative size of the subgroup of persistently contributing individuals in an OSS project will be positively correlated with community size.

Control Variables: To control for systematic differences in OSS projects, we include project age and the existence of previous releases as control variables. Project age is used to control for lifecycle aspects [37] and to capture related effects such as integration in the OSS community, access to resources and progress [38, 39]. As a binary control, the previous existence of releases is used to control for projects that while being actively developed do not declare official releases.

4 Method

4.1 Sampling

Data on OSS projects was obtained from GitHub Archive and a copy of the GHTorrent data on Google BigQuery. We included projects that had at least 100 pull requests or at least 500 commits and at least 2000 comments between January 1st 2014 and August 31st 2017, yielding 6037 projects of which we drew a 10% random sample. Controlling for name changes, the sample contained 580 projects. Since success is expected to be the result of collaboration we followed extant OSS research [37] and applied a lagged structure: Independent variables are collected from a six month timeframe in the middle of the project lifetime, community size in the following six months and control variables in the preceding six months. Sample size was reduced to 482 based on a sufficient level of activity in the reference period and the removal of two outliers showing an extreme level of activity not representative of the majority of projects.

4.2 Operationalization of Measures

Community size as a measure of external interest and thus success, see section 3.1, is operationalized as the extended development community [29] and implemented as the count measure of individuals associated with the project without being part of the project core. *Reputation of developers* is calculated as the prestige actor proximity index [40] by measuring how connected and how close an individual is to other members. This is a more elaborate approach than the one used by [26] to assess OSS reputation. Links between members are inferred by analyzing the sequence of users' comments, their quotes and direct references in discussions. The index increases with the number of reachable developers and if developers, which are directly or indirectly connected, get closer. *Contribution extent* is operationalized as an individual's share of overall project activity during the period of investigation, in terms of comments, issues, commits, and pull requests. This measure is inspired by previous constructions of developer-activity pairs in networks [2]. *Persistence* of an individual is operationalized as the share of periods with activity in all periods since the individual's first contribution. Following previous research classifying contribution types in OSS [2], *issue focus* shows the relative share of issue-related activity in an individual's contributions. It is operationalized as the ratio of the number of issue-related contributions to a project, e.g. issue reporting and commenting, compared to an individual's overall contributions to the project. We were, however, unable to reliably distinguish comments from issues to those to pull request, which may skew results.

Table 1 Operationalization of Measures

Measure	*Operationalization*	*Calculation*
Community size [Success]	Extended Development Community of p as sum of non-core members i_p^{nc}	$S_p = \sum i_p^{nc}$
Reputation	Connectedness and closeness of developer i to other developers j through comments, quotes, and direct references	$P_{ip} = \frac{I_i/(g_P - 1)}{\Sigma_j d(j,i)/I_i}$ I_i Number of nodes reachable from i g_P nodes in project p $d(j,i)$ distance of j to i
Contribution Extent	Share of i of overall activity in project p	$CE_{ip} = \frac{C_{ip}}{\Sigma_i C_{ip}}$ C_{ip} *Number of Contributions of i to p*
Contribution Persistence	Share of periods with activity since initial activity.	$CP_{ip} = \frac{A_{ip}}{S_{ip}}$ A_{ip} *# of periods with activity of I in p* S_{ip} *# of periods since first contribution of i to p*
Issue Focus	Share of issue-related activities in an individual's contributions	$R_{ip}^{issue\ focus} = \frac{C_{ip}^{issue}}{C_{ip}^{total}}$ C_{ip}^{issue} *# of issue-related contributions of i to p*

4.3 Analysis

For the independent faultline measures, we restricted analysis to the core project based on an activity threshold of twenty contributions. Since the count-based raw scores are prone to project-specific skews, values of faultline measures are normalized first. Drawing on previous findings concerning the specific effects of the relative size of subgroups [10], we operationalize the size of theoretically derived subgroups as the share of team members deviating more than half a standard deviation from the project median. Core members of projects can thus belong to either the high or low-value subgroup on the respective measure. This calculation is done for each independent variable. With the dependent variable being a count measure, Negative Binomial Regression (NBR) has been chosen as regression method.

5 Results

Table 2 Correlations of Variables

	High Reput.	Issue Focus	Contrib. Extent	Contrib. Persistence	Proj. Age	Comm. Size
High Reputation	1					
Issue Focus	-0.21***	1				
Contrib. Extent	-0.29***	0.29***	1			
Contrib. Persistence	-0.13***	0.16***	0.20***	1		
Project Age	-0.03	0.07	0.10**	0.26***	1	
Community Size	0.09*	0.00	-0.17***	0.10**	0.08*	1
Note:	*p<0.1; **p<0.05; ***p<0.01					

Correlations of variables–shown in Table 2–are relatively small with the maximum value being .29 in absolute terms. The direction of correlations is, however, worth mentioning: the share of members with high reputation is negatively correlated with all other measures, whereas all other correlations are positive. Table 3 details the regression models. The first model only includes the subgroup measures as independent variables, whereas the second and third one add the control variables project age and whether there have been releases in the project. The control variables do not change the direction of correlations but influence levels of significance. While we expected the attribution of members to subgroups to be meaningful for community size, the information content of the model is rather low judging from the pseudo R^2 values.

H1 regarding the effect of a large share of members with high reputation is partly supported: We observe a positive albeit insignificant and small relation.

H2 regarding the effects of a large share of members with a focus on issue activity is likewise partly supported with a small positive, albeit insignificant relation.

H3 regarding the effect of a large share of extensively contributing members is not supported with a highly significant and strong negative relation.

H4 regarding the effect of a large share of persistently contributing members is supported with a significant and strong positive relation.

Table 3 Results of Regression Models

6 Discussion

Based on the characterization of work in OSS projects and theory on faultlines and subgrouping, we investigated the relation of contribution-based subgroups and community size as a measure of success. While the applied regressions explain only a small share of variance, large sets of core members with high reputation, a focus on issues, and especially persistent contributions positively relate to community size. A large share of extensively contributing members is significantly negatively related.

As expected, a large share of high-reputation core members has a positive but small and after including controls insignificant relation with community size. With reputation being a key aspect of OSS culture [5], we expected the resulting differences in power, resource access and status to be attenuated by the culture of OSS work and thus to lead to a positive relation. Results suggest, however, that reputation may also in OSS projects lead to negative repercussions–possibly due to an identity- or resource-based subgroup. This relation may interact with the hypothesized positive effect. Operationalized as a social proximity measure, the positive finding is in line with previous work on the positive effect of internal cohesion for OSS success [37]. Structurally speaking, a larger share of developers with more direct access to other core members positively relate to community size. Drawing on previous research describing a positive effect of loosely coupled, decentralized developers for design as opposed to technical work [2], the expected signaling effect of high-reputation projects may draw in peripheral contributors–whereas the technical work of closely related core contributors may trigger feelings of inaptitude and thus present barriers to onboarding [6, 41]. Previous findings thus help interpret the only partly expected findings. In addition, reputation based on the distance of the social network may not be perceivable to outsiders and thus reduce the expected signaling effect. The current operationalization of reputation may overestimate values of members being in constant exchange with others without adding value to the project. Investigating other metrics, e.g. formal collaborator status, thus seems worthwhile.

The positive relation between a larger share of members focusing on issue activity and community size is relatively small and insignificant. With a grain of salt, this result may be interpreted as slight proof of the proposition that issue-focused core members foster community size as defacto mentors helping to overcome onboarding issues [34]. Moreover, supporting others as a core value in OSS [5] could propel membership. This line of reasoning has, however, to be questioned since the correlation between the share of high-reputation and issue-focused individuals is slightly negative. The small effect size may be due to our specific threshold values for considering members part of the project core as it could have included too many contributors and thus left no room for outside community. In addition, as stated before, the operationalization of issue focus suffers from the inability to classify some comments. Effects may be more reliably tested if the content of contributions was to be analyzed in more detail: In particular, the community building effect may be identifiable if responses to activity by non-core members were studied in particular.

The relations of contribution extent and persistence are somewhat surprising: Persistence is–as expected–significantly positively related, while extent is significantly negatively related. The correlation between the two measures is weak, which implies they capture distinct contribution types. Persistence might not only be the sum of contributions over time but may signal activity, future maintenance, and thus value in contributions to outsiders. It might also imply technical proficiency and learning forming part of the OSS culture [5]. Seeing sense in one's contributions can be related to the intrinsic motivational factors as key drivers of OSS membership [1, 4]. Persistence might thus signal a project is worthy of contributions. Extensive contributions on the other hand are operationalized by the overall activity of individuals. A large share of extensively contributing core members might create the impression of a closed circle and thus deter contributions–relating to the finding that newcomers face barriers in where to start contributing [6]. In addition, the negative correlation of contribution measures and high reputation is noteworthy since it may imply that contribution quality by high-reputation individuals is distinct from quantity.

This research provides initial evidence that the relative size of subgroups in OSS projects may have differential effects based on underlying faultlines. Findings on positive relations add to existing research on the onboarding of new members [6, 34] by outlining potential levers for action. It seems plausible that persistence and issue-related work can act as mentoring and thus as means to help newcomers get started [34]. For OSS practitioners, analyzing and possibly steering the observed relations may be helpful for increasing community size and thus potential human capital in their projects. Results also add to the discussion on the effects of balanced versus imbalanced configurations of subgroups [10, 11]. Our findings indicate that a larger share of members as an imbalanced configuration may have positive outcomes. Results further add to research on the differential effects of subgroups depending on their reason for formation and typology [11, 21].

7 Limitations and Future Research

This research is only a first step towards understanding the configurational properties of OSS members based on faultline and subgroup theory. There are several limitations, which in part may also explain the low pseudo R^2 values. A significant set of limitations arises from the choice of sampling and model specification. First of, the filtering criteria for including projects may have skewed results. In addition, the choice and operationalization of variables affect results. As faultline and subgroup measures, the entire breadth of characteristics studied in group research and psychology are conceivable. While carefully developed, operationalizations may not capture the phenomenon under study as expected. As an example, the operationalization of success as community size is just one option considering propositions to operationalize OSS success in multiple dimensions [29]. Furthermore, the inability to classify some comments may have skewed results. We strongly encourage further research using additional variables and testing the applicability of other operationalizations. Data has been collected during a limited timeframe using a lagged structure, which may have reduced explanatory power, especially if the timeframe studied was not representative for longer running projects. To inch closer to causal inferences, other methodologies such as experiments or mixed method approaches may be beneficial.

The distinction between core members and community poses two issues. Firstly, the threshold of attribution of members to either group may skew results. The operationalization may conflict with the observed fluid nature of OSS teams [23]. Secondly, we have studied relations of the share of members in the core team on the size and the extended community. This implies that all effects are indirect across the boundary of the core team, which may have caused some unexpected results.

Addressing these limitations and investigating additional aspects are promising avenues for future research. The effects of faultlines and subgrouping in virtual, loosely coupled groups warrants further exploration. In addition, investigating the effects of subgroups on outside individuals seems promising. Moreover, it may be worthwhile to investigate interaction effects between the proposed subgroups. As an example, the share of members with a combination of high reputation and issue focus would further the investigation of the proposed onboarding mechanism provided by these factors.

8 Conclusion

Open Source development has become an established organizational way of building software. Performance effects of faultlines and subgroups are commonly discussed in team research. While most subgrouping is described to be detrimental for team outcomes, more recent works have proposed to consider different basis for subgrouping and their configuration. We have investigated the faultline-based subgroup concept in OSS projects by first identifying characteristics that may trigger faultlines and subgroups. This assertion is the basis for the empirical investigation of the relations of community size and the relative share of core members belonging to subgroups characterized by high levels of reputation, focus on issues, and extent as well as persistence of activity. We find significant relations with the size of the extended project community by contribution persistence and extent and positive albeit insignificant relations of a large share of members with high reputation and issue focus. Our results add to extant research on subgrouping and their configurational properties. In addition, they provide an additional step towards understanding how success as community size of OSS projects can be fostered.

{tim.rietz,ivo.benke,alexander.maedche}@kit.edu

Abstract. Information technology is rapidly changing the way how people collaborate in enterprises. Chatbots integrated into enterprise collaboration systems can strengthen collaboration culture and help reduce work overload. In light of a growing usage of chatbots in enterprise collaboration systems, we examine the influence of anthropomorphic and functional chatbot design features on user acceptance. We conducted a survey with professionals familiar with interacting with chatbots in a work environment. The results show a significant effect of anthropomorphic design features on perceived usefulness, with a strength four times the size of the effect of functional chatbot features. We suggest that researchers and practitioners alike dedicate priorities to anthropomorphic design features with the same magnitude as common for functional design features in chatbot design and research.

Keywords: Acceptance, Anthropomorphism, Chatbot, Collaboration, Work

1 Introduction

Recently, the usage of chatbots for improving collaboration in the workplace has seen increasing interest [10]. Chatbots create new opportunities in digital work, potentially boosting collaboration culture [25]. Additionally, they have the potential of positively influencing the balance between the time allocated to work and private activities through digital interventions [5] and reducing work overload through supporting task management [45]. Major collaboration platforms in and outside the workplace include chatbots, such as Facebook, Slack, WhatsApp and Telegram. Slack has established itself as a successful platform used by thousands of companies, due to its capabilities for group collaboration and native integration of various productivity tools. Collaboration is commonly defined as making a joint effort toward a group goal, where joint effort encompasses acts of shared creation and/or discovery [3]. Collaboration systems used in the working context are referred to as enterprise collaboration systems, with Slack as a prime example. Airbnb, Autodesk, IBM and many others [40] frequently use the collaboration features of Slack and the possibility to access over 1000 chatbots developed by professionals and freelancers alike [34], alongside Slack's

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

natively integrated chatbot 'Slackbot'. As chatbots in enterprise collaboration systems are expected to become a substantial element of the modern workplace, there is a need to better understand the impact of chatbot design on user acceptance.

We observe a lack of user acceptance studies discussing overall chatbot design features in collaborative environments. In the face of limited resources, developers are required to make trade-off decisions regarding two essential aspects when designing chatbots: form vs. function. Traditionally, engineering-oriented disciplines tend to pay more attention to the functional dimension and dedicate less resources to the form dimension [7]. Form describes the relationship between design parameters and is primarily perceived as an aesthetic expression [36]. Due to its hedonic nature, form has a strong link to social presence of a bot and has been shown to positively affect perceived enjoyment and ease-of-use [17, 37]. This paper investigates the influence of anthropomorphic and functional chatbot design features in enterprise collaboration systems on user acceptance, on the basis of importance and frequency of usage of design features in Slack by practitioners. We formulate the following research question:

"How do anthropomorphic and functional chatbot design features in enterprise collaboration systems influence user acceptance of chatbots?"

In order to answer the research question, we follow a survey-based research approach and specifically investigate user acceptance of chatbots in the context of the enterprise collaboration system Slack. We contribute to the chatbot design body of knowledge by investigating how different design features influence user acceptance. At the same time, we provide a contribution for practitioners involved with chatbots in collaboration environments by providing input for the form vs. function trade-off decision in chatbot design.

2 Theoretical Background

2.1 Chatbots in Collaboration Systems

Chatbots are applicable for a large variety of situations, such as supporting collaborative learning [43], but are simpler in development and interaction compared to complex intelligent agents. Design decisions have to be made with regards to the 'chatting behavior' of the agent. Various configurations of chatbots are used in research and practice, such as agents that react dynamically to changing environments [51] or aid only on invocation (e.g. Slackbots /remind me functionality). Furthermore, seemingly small details of their conversational behavior, such as social cues, have a significant influence on the agents' effect on users [50]. Social cues are applied as an anthropomorphic feature of an agent, resulting in increased social presence [1]. In the example of MentorChat, a web-based agent for collaborative learning support, collaboration between individuals was enhanced by triggering discussions between students [43]. Furthermore, studies have shown that collaboration in a professional context suffers from a lack of group leaders, and that conversational agents can act as digital replacement for these roles [9].

2.2 Form and Function of Chatbots

Design science literature describes design features as concrete ways of integrating design principles into artifacts [28]. In the context of this paper, we use the term *design feature* as name for a group of functionalities that chatbots may provide. We refer to these individual functions as *items*. Chatbot design draws from two dimensions: form and function, the two fundamental components of design across domains [44], which definitions are displayed in table 1. Despite arguments for considering additional concepts in design [23], form and function are extensively considered as complete in forming the design dimensions [9].

Table 1. Literature definitions of the form and function design dimension

Design Dim.	*Definitions in Literature*	*Source*
Form	[…] while form refers to certain customer interface characteristics and is often addressed from the perspective of visual aesthetics.	[2]
	We define form as structural product characteristics that provide the architecture through which functional product features are delivered. Product form embodies the hedonic component of design.	[44]
	The form of the object as a whole can then be represented as the collection of components and a description of the interaction among components.	[36]
	[…] alternatively, design has been equated to product form, focusing on its esthetic characteristics. This approach has generally found that these attributes are related to hedonic value.	[23]
Function	Function refers to certain product function characteristics and their perceived performance […]	[2]
	Product function refers to product specifications and standard architectures - essentially the utilitarian aspect of product design. Functional design is defined by the factors, benefits, characteristics, and features that are combined to provide utility.	[44]
	[…] functional requirements which describe performance. There are many designs which satisfy any one set of functional requirements, therefore there cannot be a unique relationship between the function and the form of a product.	[36]

Form. The form of a product or service on the other hand refers to the arrangement of individual design components [36]. It is primarily perceived as an aesthetic expression [9] and can be interpreted as a user’s perception of non-utilitarian aspects. Form features mostly are hedonic in nature and characterized through pleasure derived from the appearance of a product / service [33]. Historically, form features of design are investigated in marketing and product development literature [25], and comprise a multitude of elements, such as usage of lines, curves, proportions and symmetry. In the domain of websites and software, research regularly focuses on visual aesthetics when discussing form features [24]. In the design of chatbots however, another form feature becomes a relevant research topic: anthropomorphic presentation of the virtual agent [38], (cf. chapter 4.2). Anthropomorphism is considered part of the form design dimension, as its items change the visual presentation of an agent and the interaction between components. Although the most commonly used variant of anthropomorphic virtual agents are embodied conversational agents [8], chatbots as well can incorporate anthropomorphic features. Despite a chatbot being limited in the range of applicable visual cues to appear more human-like, it may still rely on language that is enriched by emotional semantics or expression of emotions through emojis [42].

Function. The function of a product or service refers to parameters related to its general performance [36]. Historically, the function is dominated by principles from engineering [9]. The focus lies on providing utilitarian value, through addressing the practical needs of users. These can appear in simple functionalities, such as being able to communicate with an agent in natural language, or in more complex desires, e.g. safety or maintainability. Therefore, improving functional design features of a product/service pays consideration to how objects can be arranged in a way for users to interact with them efficiently and comfortably [44].

2.3 User Acceptance of Chatbots

We rely on a variation of the technology acceptance model (TAM) to investigate the impact of chatbot design features. Instead of utilizing the original TAM from Davis (1989), or its extensions, e.g. TAM2 [49], we decided for a model that includes perceived enjoyment (PE) as a core antecedent of behavioral intention [17]. The focus on chatbots in a work context stresses the interplay of hedonic and utilitarian aspects of a system [17]. Utilizing chatbots for improving company-internal collaboration might still be perceived as a novel application by employees [32]. This may introduce an hedonic component into work processes, potentially contributing to user acceptance of information systems (IS) normally perceived as utilitarian [17]. Besides PE, we do not include further concepts into our TAM evaluation, such as social presence or trust, as it is not in the scope of our evaluation. The study is intended to use a lean research model with a limited number of concepts. We are aware of concerns with the TAM methodology regarding its generalizability [4], the inclusion of factors external from the technology, or the models capabilities for predicting IT adoption [26]. Consequently, we evaluated the applicability of TAM as basis of the proposed research model against other common models used in IS research, such as UTAUT [47] or Task-Technology Fit [13]. The simplicity of the model, a broad range of research on its primary constructs alongside the inclusion of PE provides us with an appropriate model for this initial assessment. The traditional measures PEoU, focusing on the degree of peoples believe that using an IS is free of effort, and PU, focusing on the expected increase in job performance through using an IS [48], allow us to explore the utilitarian antecedents of behavioral intention. PE, the degree to which fun can be derived from using the IS, on the other hand explores the hedonic antecedents of it [17].

3 Research Model

Anthropomorphic form features influence users' perceptions of social presence, which in turn has been shown to positively affect PE [1, 33]. We expect the same relationship to be demonstrated in the context of chatbots in Slack. Furthermore, previous studies on TAM showed the close linkage between PEoU and hedonic values [17, 37]. As the form feature of design primarily induces hedonic value, we expect a positive relation between anthropomorphic chatbot design features and PE and PEoU.

H1: Anthropomorphic chatbot design features positively influence the perceived enjoyment of chatbots in enterprise collaboration systems.

H2: Anthropomorphic chatbot design features positively influence the perceived ease-of-use of chatbots in enterprise collaboration systems.

As we observe work context, the conceptual distinction between hedonic and utilitarian concepts may blur, since hedonic systems would more naturally occur in home environments [17]. As such, we expect to observe effects of the anthropomorphic design feature on PU.

H3: Anthropomorphic chatbot design features positively influence perceived usefulness of chatbots in enterprise collaboration systems.

A product design study identified PEoU as the most cited benefit (40%) of the utilitarian design [23]. Another study, investigating the role of function in utilitarian design of mobile data services, found a significant effect of function on user satisfaction, positively affecting PEoU and PU [2]. Thus, we formulate the following hypothesis for the effect of function features on TAM constructs:

H4: Functional chatbot design features positively influence perceived ease-of-use of chatbots in enterprise collaboration systems.

H5: Functional chatbot design features positively influence perceived usefulness of chatbots in enterprise collaboration systems.

Finally, in accordance with H1, hedonic and utilitarian concepts may blur at work and so we expect to observe effects of functional design features on PE.

H6: Functional chatbot design features positively influence perceived enjoyment of chatbots in enterprise collaboration systems.

Additionally, we investigate the effects of selected control variables – age, gender, experience (with Slack, with Slackbots, general developing experience, and chatbot developing experience in Slack) and education level of the participants. Figure 1 depicts the resulting research model.

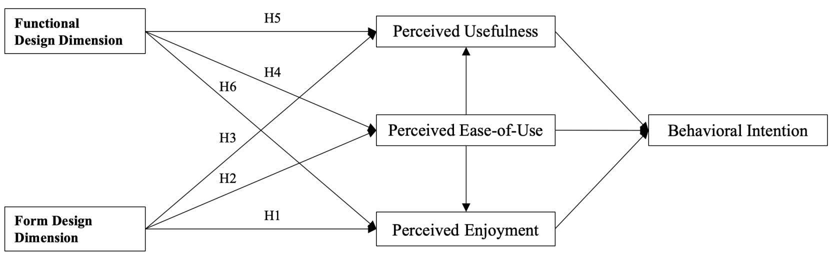

Figure 1. Research Model

4 Empirical study

4.1 Context: Enterprise Collaboration System Slack

As the experiment investigates design features of chatbots, the form of communication is text-based and the common technology for interacting with chatbots is instant messaging. Because we explicitly want to explore the effect of different design features on technology acceptance in a work context, we chose Slack as platform for our study. Slack is widely used in international enterprises and therefore provides a suitable solution for conducting a study. Slack has integrated a default chatbot, called "Slackbot". This default bot is approachable within every conversation. It can be enhanced by individually implemented commands. This function makes Slack particular interesting for this experiment. Besides its application in the work context, the natural integration of self-deployed chatbots by providing an interface API is necessary for providing custom designed solutions.

4.2 Selected Chatbot Design Features of Function and Form in Slack

Relevant design features are selected through a multi-stage process. Initially, a list of possible interactions, functionalities and behaviors available to bots in Slack is extracted from the Slack API documentation [41]. From the complete set of bot capabilities in Slack, we select five distinct groups of capabilities, whose effect on behavioral beliefs we attempt to measure. The five groups refer to design features of chatbots in Slack, that are commonly observable in bot implementations. The features are categorized according to the definitions of design features and its dimensions provided in table 1. Design features where pre-tested for importance and completeness with eight doctoral candidates familiar with using Slack in a work context and interacting with chatbots. During the pre-test the participants were confronted with the feature instantiations and the questionnaire. Their feedback was collected, evaluated and merged in order to develop the final survey. The following features are used as instantiations of the **functional dimension**:

Invocation. Usually, there are two ways of engaging in a conversation with a chatbot: either it is invoked by a command or it reacts by activating autonomously. In Slack, the user may activate the 'reminder' functionality of a chatbot by invoking the /remind command. At the same time, when pasting links into a conversation, e.g. from Google drive, the Slackbot will recognize the link and autonomously suggest a specific reaction to every subsequent link.

Intention-type. When interacting with a chatbot, the interaction can revolve around two intentions, seeking information or delegating a task [45]. A user may ask the bot for an update on the weather or to write an apology message to another user. More advanced chatbots may also provide a combination of both tasks, such as Google Assistant making a reservation with a service provider while sending information back to the user [27].

Question-type. The more sophisticated the interaction with a chatbot becomes, the more natural and simpler may the conversation feel. However, a sophisticated interaction increases the bot's complexity [18]. In order to keep complexity low, a chatbot will ask closed questions (such as Yes/No questions). This form of interaction allows the chatbot to dictate the flow of the conversation. Open questions on the other hand allow the user to communicate in a natural, unrestricted way.

Reaction-type. Finally, chatbots have various strategies of handling failure. When a bot struggles to understand or act on a command, it may react with an error notification and ask the user to retry or provide additional information. Other fallback mechanisms may include forwarding a user query to a common search machine or asking for more information. This behavior could be characterized as an attempt of the chatbot to satisfy the user in a fallback scenario by relying on outside sources and providing links [39].

The following feature is used to instantiate the **form dimension**:

Anthropomorphism. In presenting the bot to its users, a common approach is the humanization of the conversational agent, especially present in embodied conversational agents. For chatbots, the possibilities for making the bot appear as a human-like actor are limited. Common approaches are the inclusion of social cues in conversations, such as including short pauses before giving an answer [23], or making the bot include emojis in their conversational behavior [42]. The underlying idea of making agents more human-like stems from the CASA paradigm – computers are social actors [31, 35]. The paradigm states that social attributes are ascribed to computer technology during interaction, similar to another human, and was proven with sets of studies testing e.g. mindless responses in detail and the depth of social responses to computer's personality [31]. This can result in the development of social and emotional bonds with the agent [22] Social presence was identified as an antecedent of behavioral intention through affecting the PE of users [20]. Furthermore, the principle serves as a possible explanation for the observation that group allow agents to take on social roles, such as group leader, and viewing a machine as an embodied entity by referring to the agent as "him" and not "it" [8]. In Slack, chatbots can have a user profile, providing the same information as the profile of a human user. For explanatory reasons this aspect of anthropomorphic design features is displayed in figure 2.

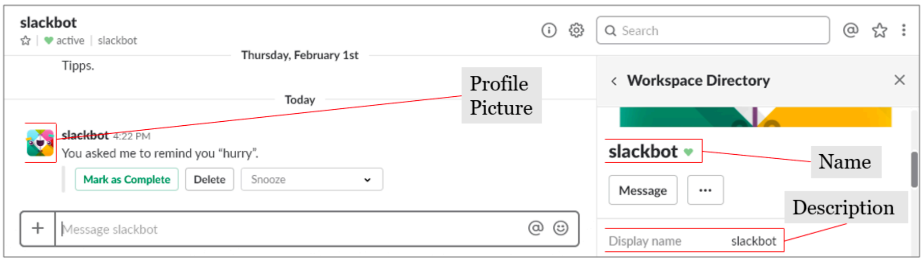

Figure 2: Picture and Name of Chatbot as Example of Anthropomorphic Design Feature

4.3 Procedure & Participants

This study is conducted as a confirmatory survey study. The study is set up using Limesurvey, a web application for creating and distributing research surveys. The survey language is English. At the end of the survey, participants have the opportunity to participate in a lottery for the chance of receiving rewards. For the purpose of eliminating survey replies not completed truthfully, we included two reverse coded and two trap questions. Trap questions ask participants to select specific answers to ensure reading the questions properly. For the evaluation procedure, the finalized survey is sent out to enterprises using Slack by posting the survey with an introduction text into relevant Slack workspaces. For this purpose, we have access to Slack workspaces of three international companies in the area of consulting, eCommerce & fashion and IT industry. Additionally, Slack has invitation only workspaces for professional chatbots, where the survey is distributed as well. We record a total of 71 answers. From those answers, 14 are not fully completed out or failed to provide the appropriate answer to included trap questions and therefore are excluded. In consequence the study sample contains 57 participants (N=57), whereby 48 are male (84,3%) and 9 are female (15,7%).

4.4 Measurement Approach

The structural model consists of two parts, the hedonic TAM and function and form dimensions. The constructs of TAM are derived from [17]. All items of TAM are measured on a seven-point Likert scale ranging from "Highly disagree" to "Highly agree". The question and answer forms are individually composed according to [46]. The design dimensions of chatbots in Slack are measured utilizing the design features introduced in section 4.2. Each feature is represented by two or more items, representing specific instantiations of the feature. To assess the influence of each item, the questionnaire applies a two-question characteristic, measuring importance and frequency of usage for each item. Both Importance and Frequency of usage are measured on a seven-point Likert scale. The measurement scales are derived from [46]. The two question characteristic is adopted from [30], who applied the design to study the relationship between features of a game and we-intentions. We adopt a reflective path model, suggesting that both importance and frequency of usage are a sample of the possible indicators for the respective latent construct. For the calculation of the two latent constructs, functional and form design dimension, we additively combined the two characteristics, importance and frequency of usage, for each item. We controlled for age, gender, education and experience. Experience is measured on four levels: Slack experience, chatbot experience, chatbot experience in Slack and general coding and development experience, on a seven-point Likert scale ranging from "Not at all experienced" to "Extremely experienced", as derived from [46]. An exemplary set of questions is depicted in table 2.

Table 2. Exemplary question set for one item from the Invocation design feature

Measurement characteristic	*Question*
Importance	How important is it to you, that the chatbot can be tagged in conversations like human users?
Frequency of usage	How often do you invoke the chatbot via a user command to perform some action?

5 Results

To evaluate the collected survey data, we apply partial least squares (PLS), a structural equation modelling (SEM) technique [7]. Specifically, we use the tool SmartPLS 3.2.7. As we try to explore relationships and the proposed research model, traditional common factor based PLS-SEM is chosen over component-based SEM [12, 14]. This approach is particular suitable for our model, as it is applicable for smaller sample sizes [14]. Moreover, we apply the bootstrapping method to calculate the significances of path coefficients.

5.1 Measurement Model

In a first step, we evaluate the measurement model. We apply a reflective instead of a formative modeling approach as the measurement items are representatives of the latent variable rather than a composition [14]. To assure the quality of our data, we determine the items' loadings and assure indicator reliability and validity (see table 3). All items of the measurement model load above 0.6 on their construct, which is an sign for indicator reliability [6]. Composite reliability (CR) is chosen to overcome limitations of Cronbach's α for measuring internal consistency. It reveals values at least between 0.7 and 0.8 for five out of six, a reliable indicator for an adequate confirmatory model and values higher than 0.8 for four of six constructs, indicating a good fit for confirmatory research for these constructs [14]. However, Cronbach's α for PE indicates almost no inter-item correlation, while CR for PE indicates correlation, but only at levels adequate for exploratory research [14]. The convergent validity was measured by average variance extracted (AVE). Except for one (AVE = 0.471), AVE shows values for all constructs higher than 0.5, which is sufficient [14]. However, as this represents only a small discrepancy from the accepted value for this one value, it is a minor limitation of the model but the analysis can be continued and is still valid [15]. Further, we assess discriminant validity by running the Fornell-Larcker criterion, confirming that the square root of the AVE exceeds the respective constructs correlation with other variables in the model [11].

Table 3. Reliability Measures of the Measurement Model

Latent Variable	*α*	*CR*	*AVE*	*Fornell-Larcker Criterion*					
				FuDD	*BI*	*FoDD*	*PEoU*	*PE*	*PU*
Functional Design Dimension (FuDD)	0.675	0.823	0.608	**0.780**					
Behavioral Intention (BI)	0.944	0.964	0.899	0.578	**0.948**				
Form Design Dimension (FoDD)	0.786	0.842	0.437	0.444	0.341	**0.661**			
Perceived Ease of Use (PEoU)	0.677	0.797	0.505	0.471	0.630	0.432	**0.711**		
Perceived Enjoyment (PE)	-0.094	0.617	0.639	0.488	0.535	0.255	0.662	**0.799**	
Perceived Usefulness (PU)	0.950	0.960	0.802	0.720	0.598	0.410	0.630	0.669	**0.895**

5.2 Structural Model

After evaluating the measurement model validity, we assess the structural model according to [17]. Figure 2 shows the structural model with the results of the PLS bootstrapping analysis with 5000 samples displaying the coefficient of determination (R2) for all endogenous constructs. The figure contains path coefficients, significance levels and effect sizes (f^2) of the paths.

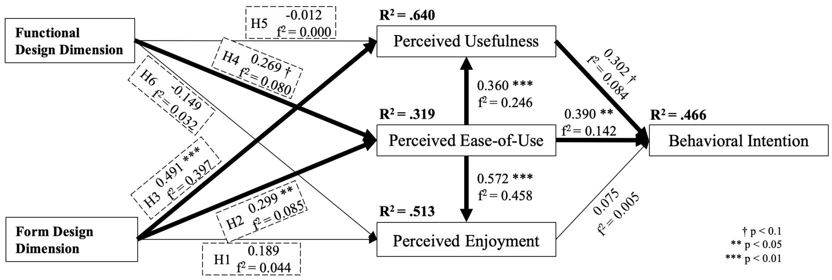

Figure 3. Structural Equation Model

We report significance on the following significance levels: $p < 0.01$, $p < 0.05$, $p < 0.1$. We explicitly allow for significances at the 10% level, as this study aims to identify promising correlations for future research to explore with more detailed and strict criteria, rather than minimizing false positives. For H1 our evaluation shows a significant effect of functional → PEoU ($p < 0.1$, $f^2 = 0.08$). H2 and H6 are not supported by the results as there is no significance measurable, whereas H4 and H5 are supported by the evaluation with significance at level $p < 0.05$ and $p < 0.01$, respectively. H3 is rejected as well, showing no significance. The constructs PU, PEoU and PE have positive loadings on BI. The paths from PEoU → PU and PEoU → PE also show a significant effect. Besides the path PE → BI, all of them are significant at least at the $p < 0.05$ level while only one is at the level of $p < 0.1$. The three outgoing paths from the anthropomorphic design features have a positive effect while the path to PU has a very strong path coefficient. The path to PEoU loads weaker. The effect size of anthropomorphic → PEoU (H4) counts for $f^2 = 0.085$, the value for anthropomorphic → PU (H5) for $f^2 = 0.397$. It can be concluded, that most of the paths have effect sizes $> f^2 = 0.02$, which at least accounts for small effects [16]. Only for PE → BI, the effect size is neglectable ($f^2 = 0.02$). The coefficient of determination for all constructs was medium up to high [7], with values between 0.319 and 0.64. Additionally, we test for the moderating effects of experience with developing, chatbots and Slack, but do not identify any significant effects.

6 Discussion

In contradiction to our initial hypothesis, anthropomorphic design features show no significant effect on PE. This rejects H3 and contradicts the assumption that form features have direct effect on the hedonic character of the acceptance of chatbots. Originating from the point of view that higher anthropomorphism is leading to higher perceived enjoyment of the user, this result is especially valuable. Drawing implications from this, it shows that a stronger humanization of chatbots does not necessarily result in higher user enjoyment. Additionally, no effects of significance involving PE, other than PEoU on PE, were observed in the study. A significant relationship between PE and BI, observed by previous studies (29), did not occur. Alongside the insignificant effects of form and function design features on PE, this may hint at the questionnaire failing to capture PE of participants. Cronbach's α for PE indicates no inter-item correlation, while CR appears at the lower end of the acceptable range. Consequently, the underlying construct items might not have measured the construct appropriately. On the other hand, the results may also be interpreted as PE not being a relevant factor to influence users' behavioral intentions, stressing the importance of the utilitarian character of chatbots in work environments. Taking a deeper look, all the more interesting are the further results of the anthropomorphic design features. They show the most significant effect of outgoing paths to PU. In addition, the path loading is strongest, and effect size is highest ($f^2 = 0.397$) of all evaluated paths. This means that the effect of anthropomorphic design features on PU is the strongest across all results. The finding is supporting H5. This result comes together with a significant path loading from anthropomorphic design features to PEoU, which supports H4. Although the effect is not as strong as to PU, it still is significant with a positive path loading and effect size considered as meaningful ($f^2 = 0.085$). Comparing the two paths - anthropomorphic design features → PU and → PEoU, we see the former one has almost twice the loading and effect size, showing a strong prominence of effect on PU.

Accompanying these results and contrasting them to the first discussion point mentioned above spawns a valuable implication. Instead of influencing the hedonic share of technology acceptance, anthropomorphic design features have the strongest and most significant effect on utilitarian aspects of chatbot acceptance. This was contrary to the initial assumption about humanization of chatbots and may therefore be seen as the main contribution of this research work. Further elaborating this idea, it means that Slack users accept a anthropomorphic chatbot more for utilitarian reasons than for joy and hedonic perception. As possible explanation, we call on the argument of context influence raised by van der Heijden [29]. It imposes that work environments are mainly associated with utilitarian values. The influence of anthropomorphic design features, which are assumed to be hedonic, seem to be controversial in this context. Our results suggest that they impact the utilitarian character of acceptance which goes hand in hand with the implication of [29], suggesting that hedonic features add acceptance to utilitarian systems and thereby usefulness, especially in the working context. Furthermore, we may theorize that user satisfaction is increased when interacting with chatbots that utilize anthropomorphic design features, thus benefiting PU and PEoU, similar to the effects that Botzenhardt et al. observed for functional design features [2].

Looking at the functional features of design characteristics, the only significant connection is pointing at PEoU. This supports H1. Therefore, we can report a positive effect of functional features on the ease-of-use of the chatbots technology and see the support of utilitarian aspects by functions in the design of a chatbot. On the other hand, H2 was not supported. This is interesting as well, suggesting that functional features may make usage easier but not necessarily make the chatbot more useful. Overall, we still document much higher loading, significance and effect size on the outgoing paths from anthropomorphic features than functional ones. Moreover, it is worth mentioning that H6 is rejected as well, stating no confirmative effect on PE. Mirroring the hypothesis about functional features (H1, H2, H6), our results at least suggest, that they are more likely to contribute to utilitarian aspects than to hedonic aspects, as we cannot confirm any significant relationships with PE.

Finally, aggregating our findings, they stress the importance of anthropomorphism in order to increase acceptance. This is valuable for both researchers and practitioners, giving a clear guideline for chatbot design and research. Observing this implication, it poses the questions if more anthropomorphism directly leads to higher acceptance. For answering this question, we want to mention the phenomenon of "uncanny valley" [29]. It compares human likeness of an entity with human affinity to this entity and states that the relationship is increasing, but only until reaching a specific point, the uncanny valley. Simultaneously, the raised equation is finally likely to fail, as humans are feeling rather unfamiliar when a technical system reaches this specific point of anthropomorphism.

6.1 Implications

"The aesthetics of your product speaks out for you just as much as the functionality, because if the functionality is no longer unique, guess what steps in? The beauty." [21]

We urge researchers and practitioners alike to pay attention to the importance of anthropomorphism for chatbot adoption. The results of this study show strong and significant effects on the utilitarian aspects of acceptance of the users. Moreover, taking up on findings on chatbots, they possibly serve as leaders in groups, the results gain even more significance as replacing a human being might demand for serving different social and hedonic facets. The importance of functional features goes without saying and the relevance of function features for PEoU could be demonstrated for the Slack in the work context. However, function and form features need to go hand in hand to achieve the best possible outcome. While function and form serve separate causes in the design of an agent, both are relevant for behavioral intentions of users. Tailoring both features to the individual task of a chatbot can significantly improve its acceptance amongst users.

6.2 Limitations

Some limitations apply to this study. The selected design characteristics for function may be perceived not as functionalities provided by a chatbot, but rather as characteristics of the agent's interaction with a user. As such, they may provide both utilitarian and non-utilitarian value. Furthermore, a specific chatbot task may affect the perception of function and form features. However, the selected function characteristics are present in chatbots fulfilling a large spectrum of tasks and purposes. Choosing distinct functions for this study might limit the findings of this study to specific fields of application. Regardless of these considerations, we suggest the evaluation of our results with chatbots dedicated to discrete tasks and purposes.

The study is framed as especially focused on the workplace. We assume this focus reveals different aspects than it does in private life. Though, there might be concerns that the tool Slack as well induce private mindset into the survey's results. We did not especially check for this in the questionnaire as we think it would not have fully covered the limitation. Regardless of these considerations, we suggest the evaluation of our results with chatbots dedicated to discrete tasks and purposes. Furthermore, we did not evaluate potential effects of the participants' PEoU, PU and PE on the design features proposed. As such, we cannot exclude reverse effects. Finally, despite applying PLS-SEM as evaluation method due to the small sample size, and adhering to the rule of thumb of 10 participants per [14], repeating the evaluation with a larger sample size may be advised to further solidify the results.

7 Conclusion

With this study, we evaluate the impact of anthropomorphic and functional chatbot design features on user acceptance in Slack, an enterprise collaboration system. We conduct an online survey, asking users of the common collaboration and messaging tool Slack about function and form features of chatbots. Contrary to our hypotheses formulated against the backdrop of previous studies on conversational agents, we identify anthropomorphism to have a highly significant effect on PU. The effect size of anthropomorphism on PU was four times the size of other significant effects identified. On these bases, we reject our initial hypothesis which predicted a strongly positive effect of form features on PE. These findings highlight the importance of form features, in the form of anthropomorphism, in achieving a high PU and consequently strengthening the BI of users. The results have implications for developers of chatbots in collaborative work environments. We urge researchers and practitioners alike to dedicate resources to form features in the same magnitude as dedicated to function features during chatbot development. At the same time, we encourage further research on the effect of function and form features of design in the context of specific chatbot tasks or specific collaboration environments, as well as other collaboration setups.

Abstract. Little is known about how digital work shapes the exchange of performance feedback, even though today's digital and global world demands for more continuous feedback than annual reviews. This research investigates a feedback app in a naturalistic context within a globally leading financial service corporation (InsurCorp). Drawing on malleability and voluntary participation, the app offers possibilities to send and request feedback between employees. Rich contextual insights from a multinational pilot study with 568 users are gained by triangulating qualitative data from 21 semi-structured interviews and 69 feedback app user reviews with usage data. Anchored in the theory of affordances, we provide insights on use practices and find that the app affords operational-level feedback exchange on specific subjects, while general feedback on sensitive topics is preferably exchanged in person. To understand actualization facilitators and barriers, we take a social-technical systems perspective to elaborate contextual factors that influence the individual's actualization decision.

Keywords: Performance Feedback, Digital Work, Affordance Theory.

1 Introduction

Exchanging performance-related feedback on work is key to ensure individual and organizational progress [1, 2]. Scholars and practitioners agree that the ongoing digitalization is changing the nature of work [3–5]. Accordingly, the question arises how the rise of digital work is shaping the exchange of performance feedback [3, 4, 6].

First, traditional performance management processes such as once-a-year goal settings, performance reviews and 360-degree feedback are losing their appropriateness for the twenty-first century. They are typically long, lack in visible outcomes and are less valuable than conversations that take place in the moment of performance [7, 8]. Accordingly, besides assessing the performance from a retro-perspective, there is a shift towards individualized real-time feedback that guides future action and facilitates improvement, training and development [8, 9]. Second, in today's digital and globalized world, virtual, distributed and remote work settings demand for digital work tools [10, 11]. In fact, the majority of knowledge workers relies on digital technologies

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

[3, 4, 6], e.g., 83 percent of employees in Germany use digital technologies at work [12]. Accordingly, novel digital technologies not only offer opportunities for knowledge workers to perform work, but also to exchange feedback [8].

Prior research shows how motivation and productivity can be improved through altering the likelihood of receiving feedback [13], providing computer-generated feedback [14–16], providing real-time feedback on specific behavior [17], and embedding feedback features into task-specific collaboration environments [18]. However, there is a lack of research that investigates novel digital work tools dedicated to facilitating performance feedback exchange between employees. Accordingly, calls for research emphasize the need to examine the use of technology for performance management [8] and to investigate digital work tools that support knowledge workers in their digital work environments [3, 11].

Against this backdrop, we adopt a case study research strategy to investigate a digital feedback app and its use in the context of a pilot project in a naturalistic workplace setting at the global financial service provider InsurCorp. While the action possibilities offered by the feedback app may be perceived as enabling as well as inhibiting to employees (i.e., perception of affordances and constraints), employees continuously decide how to realize value from using the app (i.e., actualization). Therefore, we pose the following research question: *How is the perception and actualization of affordances and constraints from feedback apps affected by employees' individual use practices and organizational context factors?*

To do so, we apply a sociomaterial perspective to adopt "a relational middle ground between technological determinism and social constructivism" [19, p.2].

2 Theoretical Background

2.1 Performance Feedback in the Context of Digital Work

Sending and receiving feedback has become a key activity of knowledge workers to exchange information that relates to their performance and understanding [20, 21].

Traditional Performance Feedback. In this research, we focus on a particular form of feedback, that is, performance feedback. Drawing on prior research, we consider performance feedback as "dynamic communication process occurring between two individuals that convey information regarding the receiver's performance in the accomplishment of work-related tasks" [1, p.260]. Thereby, literature distinguishes formal and informal feedback. The former denotes official and top-down enforced events (e.g., yearly goal setting, performance appraisal and 360-degree reviews) [9], whereas the latter describes feedback events that take place independent of formal mechanisms during day-to-day work [22]. Opposed to formal events, informal events often have the advantage of being more timely and contingent on the situation of performance [1, 22]. This is important, because effective feedback is said to be timely (e.g., reducing feedback cycles), specific (e.g., related to a specific event/subject), relevant for the performer (e.g., enabling to request feedback), accurate, and easy to understand [23]. Accordingly, work usually involves both formal and informal feedback exchange through feedback seeking and giving [22].

Digital Work Context. Work is increasingly characterized as digital work, i.e., "[an] effort to create digital goods or that makes substantial use of digital tools" [6, p.283]. Consequently, the possibilities to assess performance and exchange feedback digitally are rising. On the one hand, the work of blue-collar as well as white-collar workers can be recorded and analyzed [14]. This enables the provisioning of computer-generated feedback, which is often preferred and more trusted by employees as it directs employees' attention to the task leading to higher performance [14–16]. Similarly, the availability of performance information enables the provision of real-time feedback while engaging in a particular behavior, thereby reducing salience bias and causing greater behavioral shifts than aggregated feedback [17]. In fact, changing the likelihood of receiving feedback improves productivity [13]. On the other hand, and aside from computer-generated feedback, feedback exchange between employees occurs digitally, i.e., computer-mediated feedback [15]. Rather than on platform-based digital work tools with embedded task-specific feedback mechanisms [11, 18], we focus on digital work tools that offer possibilities for employees to provide and seek feedback [7, 8, 24]. This is particularly relevant for understanding others' subjective judgments, e.g., for managers to assess their effectiveness [10]. A particular type of instantiation of such work tools are feedback apps, e.g., used by Amazon, Deloitte, GE, and IBM [7, 24].

Feedback App. We regard feedback apps as *digital work tools dedicated to providing employees with possibilities to exchange feedback in their day-to-day work* [8]. Similarly, social software creates interaction potentials for employees to exchange information [25, 26]. Conceptualizing feedback apps as social software emphasizes two key characteristics that inform our research. First, it is malleable and flexible, and hence, open to various yet unforeseen use contexts [27, 28]. In fact, malleability and flexibility are crucial for digital work design, because "human workers have individual, diverging, and continuously changing needs" according which digital solutions need to be adopted [3, p.2]. Second, it relies on voluntary participation and emphasizes bottom-up engagement instead of top down enforcement [29].

2.2 A Sociomaterial Perspective

Digital artifacts such as feedback apps entail forms of physical and digital materiality, which are relevant to users and endure across time and place [30]. However, to obtain meaning and effects from technological structures requires their enrollment in practices embedded in institutional contexts [31], e.g., in shared routines and hierarchies [28, 30]. Even though structure may endure across some time and place, neither technological nor social structures are fully stabilized and can change [28]. In fact, they are interdependent in that "(1) all materiality is social in that it was created through social processes and it is interpreted and used in social contexts and (2) that all social action is possible because of some materiality" [30, p.10]. A sociomaterial perspective acknowledges this interdependency by adopts a relational perspective.

Theory of Affordances as Theoretical Lens. Grounding this research in the affordance theory puts the emphasis on the perceived possibilities that objects offer to humans in a certain context [32]. Proposed in the domain of ecological psychology, the theory is widely adopted in IS research [19, 33, 34]. Its relational nature proves to be useful as it theorizes both, the human and the technical aspects of IS. This guides our research to mutually investigate the properties of the IT artifact (i.e., a feedback app), and the goals and capabilities of the users (i.e., employees within InsurCorp). Thereby, three conceptual distinctions shape the present research: *affordance emergence*, *perception* and *actualization* [19]. First, *affordance emergence* describes goal-oriented action potentials that arise from the relation between a specified user and a specific IT artifact [34]. Affordances are real so that – in our case - the possibility to request feedback with an app exists whether or not a user perceives or exploits it [32]. Second, *affordance perception* represents the recognition of action potentials. They may or may not be (mis-)perceived by a user. Both depends on factors such as available information [35]. Action possibilities offered by an IT artifact are not always enabling but may also be constraining depending on the user's goals and capabilities [28, 36]. This may trigger changes in technologies or in routines, which in turn, may lead to changed perceptions of affordances and constraints [28]. For instance, the same artifact that once was perceived as enabling by a user, may suddenly be perceived as constraining, because the goals have changed, or the use of the IT artifact showed that the goals cannot be achieved [28]. Third, *affordance actualization* describes the realization of actions potentials which, in turn, leads to effects. Technology simultaneously liberates and controls human action and is, thus, both constraining and affording to a certain extent; what dominates not only depends on the user, but also on the institutional context in which the user is situated and the technology is embedded [36]. Consequently, not only the emergence and perception, but also the actualization decision varies across contexts and depends on factors such as expected outcomes and perceived efforts required [35]. An artifact may provide employees with possibilities to fulfill their goals and they may perceive them, however, still they may decide to not actualize them. Employees compare affordances of artifacts with similar affordances, which other artifacts offer [37]. Hence, the actualization of affordances by individual employees not only depends on their goals and the artifact's materiality, but also on the organizational context in which an employee is situated and performs its daily work [30, 31, 33, 35–39].

Actualization as Socio-Technical Phenomena. Prior research relies on socio-technical systems (STS) theory to elaborate the sociotechnical conditions of affordance emergence and perception [40] as well as organizational changes required to actualize organizational-level affordances [41]. Both, the investigated feedback app artifact and employees are embedded in an organizational work context. Accordingly, we draw on STS theory [42, 43] and build on prior work [41, 44] to inform our investigation of the actualization process, because the alignment of the four STS components facilitates technology use, while gaps in alignment impede technology use [44]. STS theory understands organizations as systems of actors, structures, tasks, and technologies [42, 43]. Specifically, actors comprise people with qualifications [43]. Structures refer to systems of communication, authority, and work flow [43]. Tasks represent the "raison d'être: the production of goods and services, including the large numbers of different but operationally meaningful subtasks" [43, p.1144]. At last, technologies describe available means for problem-solving such as computers [43]. In summary, studying the actualization of affordances at individual level requires a broad recognition of the socio-technical context that may stimulate the actualization in varies ways [39].

3 Research Design

3.1 Case Setting

Striving to contribute towards theory development on performance feedback in the context of digital work, we inductively gain rich empirical data [45, 46] from a case study to investigate the phenomenon of interest in its real-world context [47]. Namely, a pilot project introducing a feedback app into a global financial services corporation.

Social Setting. The pilot comprises 568 participants situated in a naturalistic work environment at InsurCorp, which employs between 100 and 150 thousand employees and operates globally in the fields of insurance and asset management. There are three key stakeholders. First, InsurCorp's technology provider in Germany runs the pilot and has the vision to transform InsurCorp into a digital group. Second, the global human resources (HR) entity finances the pilot. Accordingly, the project team consists of a project manager, a product owner, and an intern of the first two stakeholders. Third, different operational entities introduce the app. The recruitment process started by consciously selecting entities based on location and specialization. InsurCorp Germany, France and Morocco were selected as national companies running the core business. InsurCorp Technology in Germany and Singapore were selected to include technology-oriented companies. Investment Management, Communication and Corporate Responsibility, and Global HR were selected due to their international orientation. Next, the HR responsible of each entity invited employees to participate on a voluntary basis considering both executives and non-executives as well as males and females from various job roles and departments.

Technological Setting. The introduced artifact is a customized app dedicated to the exchange of feedback (see Figure 1). It has two main features: sending and requesting written feedback or points. Each feedback must follow the structure "I like, I wish" and is non-anonymous. All personal feedbacks are listed in an inbox and the app shows a ranking based on the quantity of exchanged feedbacks. The app is not available in the company app store but is a separate mobile web app accessible via URL. However, it is accessible from everywhere. Due to works council agreements and the limited number of licenses, registration is compulsory and follows a manual workflow.

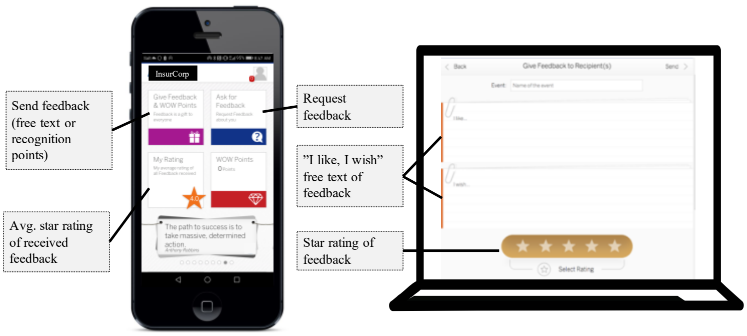

Figure 1. Screenshots of the feedback app on a mobile (left) and desktop (right) device.

3.2 Data Collection and Analysis

Data Collection. We obtained in-depth qualitative data from four sources of evidence and quantitative usage data from one additional source (Table 1) [47]. This suits well to address the sociomaterial and contextual research questions and given the restrictions of the works council. Similar to the recruitment of pilot participants, the interviewee recruitment process started by seeking names of pilot users from the HR responsible person of the individual entities. The goal was to cover executives and non-executives as well as heavy and light users (that used the app at least once) from varies functional and cultural backgrounds (see Table 1 and Table 2). To further disclose the interview process, all interviews were conducted either in German or English depending on the native tongue of the interviewee to increase the expressiveness of their statements. The interview guide follows well-established guidelines [48] and is grounded in the affordance theory. We started with questions to get to know the interviewees. Next, we focused on daily routines and work practices, since they "often oppose top-down specified production processes, and studying these processes creates a deeper understanding of individual needs" [3, p.4]. Accordingly, we continued with open-ended questions to prompt how and why the feedback app is used (or not) in everyday work. Further questions probed action possibilities and constraints as well as how these perceptions are influenced by the organizational context. Then, we shifted from today's use to changes over time and future use potentials. The interview guide was discussed within the project team and pre-tested in the first two interviews by analyzing the data and by requesting feedback using the app. The interviewees assessed the process with 4.5 out of 5 stars: "I liked the questionnaire as it allowed for some deeper evaluation of the use and potential of the tool. I think this is the correct way to collect feedback about the app at this stage. You also managed to create a pleasant trustful atmosphere which makes it easy to speak openly".

Table 1. Multiple sources of evidence

Data source	*List of details and descriptive statistics*
1. Qualitative semi-structured interviews	21 interviews with pilot participants (#1 to #21); 62% females / 38% males; 47.7% heavy users / 52.3% light users; 38% executives / 62% non-executives; Jul.-Dec. 2017; between 18 and 51 min. transcribed recordings.
2. Feedback app user reviews	69 reviews as answers to feedback requests using the feedback app (#FR); Aug. 2017 to Dec. 2017; 48% females / 52% males; avg. of 119 characters "I like" & 145 characters "I wish" statements; avg. of 3.82 of 5 stars.
3. Status meetings	Weekly WebEx calls within the project team; from Jul. 2017 to Mar. 2018; between 30 and 60 minutes.
4. Verification of results within InsurCorp	Discussion of results with the project team (face-to-face and WebEx), the manager responsible for people sourcing and development (face-to-face), the OE managers (WebEx), and with InsurCorp consulting (WebEx).
5. Quantitative usage data	Usage data (e.g., number of sessions, number of exchanged feedbacks, distribution of feedback ratings); Restricted by the works council to aggregated and transactional data (i.e., no feedback content).

Data Analysis. Following guidelines for qualitative research [46, 47, 49], data was iteratively collected and analyzed until a coherent picture emerged. We triangulated our sources of evidence in MAXQDA 12 [47] by adopting open, axial and selective coding [46]. The unit of analysis are individual employees within their organizational context, thus, analyzing individual affordances and constraints, while applying replication logic across operational entities [47]. During open coding, codes were assigned inductively to condense the transcripts. Our axial coding procedure was based on the theoretical lens to code (1) properties of the app, (2) properties of pilot users (i.e., goals, capabilities and context), and (3) (mis-)perceived and (non-)actualized affordances as well as constraints. During selective coding, we sharpened the connections between the affordances and constraints as well as the relations of the organizational context to the emerge-perception-actualization process. Drawing on related research [30, 40, 41], we extended the coding structure with the dimensions of socio-technical systems [42, 43] to elaborate factors of the organizational context in which an individual is situated.

Then, we triangulated our qualitative insights with quantitative data. First, over six months, 6,2% of users engaged in 26 to 50 sessions, while 45,9% of users only had one session. Second, feedback exchange decreased over time. Given the first month is 100%, the number of exchanged feedbacks decreased in the subsequent months: 65%, 23%, 22%, 5% and 4%. Third, the distribution of ratings associated with feedback is as follows: 5 stars (58%), 4 stars (33%), 3 stars (6%) 2 stars (2%), 1 star (1%).

Table 2. Characteristics and number of interview partners per operational entity and location

Entities	*Locations*	*Job roles (interview duration and type)*
Technology Provider (6)	Germany (2), Singapore (4)	#1 Head of Central Function Platforms (34 min, f2f) #11 Intern (37min, phone) #6 Human Resources Services (18min, phone) #7 Asia Core Systems (46min, phone) #8 Asia Core Systems (39min, phone) #14 Head of Tech. Prov. Singapore (27min, phone)
Investment Management Alpha (4)	Germany (3), Hong Kong (1)	#2 Employee Experience (51min, f2f) #3 HR Systems Consultant (47min, f2f) #4 Head of HR Digital (45min, phone) #5 HR Solutions Specialist (14 min, phone)
Investment Management Beta (3)	Germany (3)	#9 Head of Fixed Income (27min, phone) #19 Chief Investment Officer (37min, f2f) #21 Asset Liability Manager (49min, phone)
Global HR (2)	Germany (2)	#10 Processes - HR Transformation (23min, phone) #20 Head of People Sourcing & Dev. (38min, phone)
Insurance Morocco (3)	Morocco (3)	#12 Head of Dev. & Engagement (36 min, phone), #13 Portfolio Manager (28min, phone) #15 Audit Intern (RB, 25min, phone)
Communication (3)	Germany (3)	#16 Jun. Communication Manager (26min, phone) #17 Internal Communications Officer (35min, f2f) #18 Project Manager (40min, f2f)

4 Results

4.1 Affordances and Constraints of the Feedback App

Due to its malleability, the feedback app is open for wide variety of feedback. In practice, however, we identify common use practices in the form of four use scenarios and five use trajectories that explain how employees perceive and actualize the feedback app as a digital work tool to exchange feedback on concrete and operational activities, i.e. the first-order affordance.

Use Scenarios. First, the feedback app is used for *onetime activities*. For example, “I saw a presentation that I found particularly good, then I tried the app” (#7). Furthermore, the app was used to request feedback after meetings: “We did a lot of stuff around, we had a team offsite, I asked them [the participants] for their opinion on that.” (#2). Aside from group meetings, the app is used for one-on-one meetings: “I simply sent the people a request to give feedback or after giving a presentation to my boss” (#7). Second, use scenarios include *recurring activities*. For example, “we have a weekly call for [team name]. So, I asked ‘how do you like the weekly call?’ [and] ‘is it useful at all?’” (#3). Third, feedback is exchanged upon *phase changes* such as delivering projects, completing milestones, or finishing the first week at work. For instance, “when we delivered a project, then, of the four or five people working together, I would give some feedback to each of them” (#2). Fourth, the app is used to acknowledge *desired behavior*. “When something has been quite amazing, […], you say ‘that was good. that's quite nice’. You just want to give a little pat on the back.” (#17). Lastly, it was used to say thanks, e.g., “[to my manager for being] very calm and supportive and really helping me to be constructive” (#2).

Use Trajectories. Our results reveal how employees take up five trajectories of use. The first two use scenarios are rather typical (cf., Path 1-2 in Figure 2), while the three additional trajectories show how employees continuously navigate between physical and digital spaces to perform work and exchange feedback (cf., Path 3-5 in Figure 2).

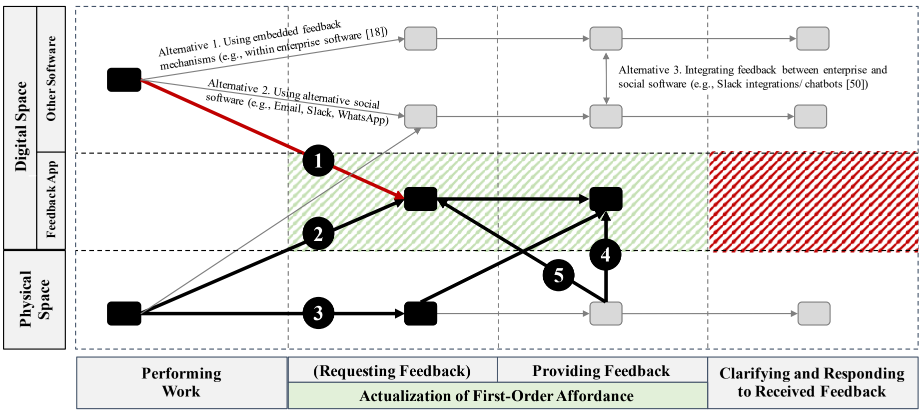

Figure 2. Trajectories (black) of actualization (green), alternatives (gray) and constraints (red)

First, employees exchange feedback on digitally performed work (e.g., a WebEx call). *Second*, the app is used for offline performed work (e.g., presentations) by either requesting feedback from colleagues or providing unsolicited feedback. *Third*, employees refer to the feedback app in conversations: “I don’t think I have done it [i.e., requesting feedback] by sending it from the app, but I rather asked them directly. More when we are in the dialogue… like you put in an additional sentence… is there any feedback feel free to use the feedback app” (#2). Accordingly, the app is not used until a colleague decides to actually send feedback. *Fourth*, even if feedback is exchanged in person, additional feedback may be exchanged afterwards. For instance, “yesterday we had a meeting with all the team leaders and there were some who had a comment or an idea after the meeting, […], you can do that via the feedback app.” (#1). *Fifth*, employees assess if they make progress on the feedback they received in person: “I had received feedback in different one-on-one discussions that I was trying to action, […], and so I asked some of them if I was moving the needle at all on that.” (#3).

First-order Constraints. *First*, constraints emerged from lacking integrations of the feedback app with other enterprise software (e.g., WebEx, Outlook). Employees perceived high media change efforts compared to alternative means to exchange feedback (see Figure 2), while the richness of the mediated feedback was limiting for some employees: “Can the app record snippets of a WebEx presentation?” (#FR). *Second*, employees perceived constraints from the limited possibilities to see who is registered and the impossibility to send feedback to non-registered co-worker. One employee explained: “I haven't used the app very much so far, since it is not very transparent who of my colleagues has signed up for the pilot phase” (#FR). It was argued that “if we could send feedback to someone that is not registered, it would push him/her to register” (#FR). *Third,* some employees expected to send anonymous feedback: “I thought this was anonymous and it doesn't seem like it is and that's a deal breaker.” (#17). *Fourth*, employees perceived constraints in clarifying and responding to feedback (see the red rectangle in Figure 2): “I would actually like to have more of an interaction on the feedback that I give… like a feedback on the feedback I’m giving… or […] that I’m receiving. […]. And when I receive a feedback where there is something positive and there is something constructive for improvement… then […] I want to answer to that” (#2).

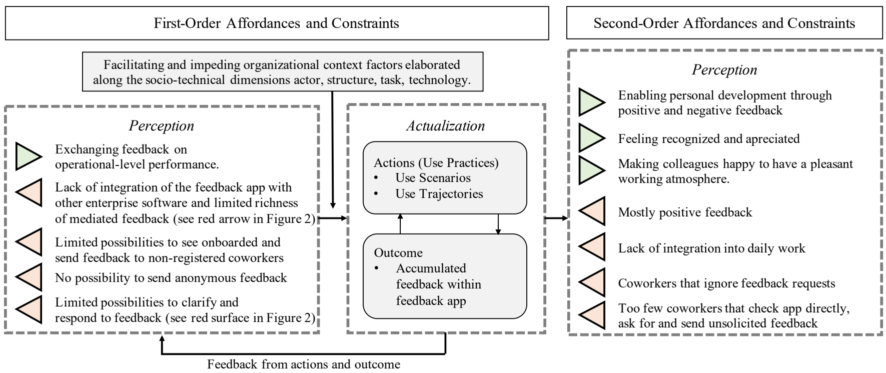

Figure 3. First-order and second-order affordances (green) and constraints (red)

Second-order Affordances and Constraints. Actualizing the first-order affordance to exchange operational-level performance feedback enables the emergence of second-order affordances and constraints (see Figure 3). Given the accumulated operational-level feedback as outcome of the first-order affordance, employees see potentials to for personal development by identifying weaknesses and strengths through positive and negative feedback: "it can actually give me more stuff to work on. To see what are my weaknesses and my strengths and how to improve overall" (#FR). As such, the app serves as "feedback account" to collect feedback in one place. In turn, constraints emerge from the way coworkers actualize the first-order affordance. Most notably, employees mention an emphasis on positive feedback: "Using the app, I realized most feedback remains personal and the app will be biased to only positive comments" (#FR). This is consistent with the rather high star rankings associated with the feedback. Interestingly, only some employees find this constraining, while others are satisfied and compare it to social media: "I do not write on anyone's Facebook wall 'I dislike your beach picture'. […] You can tell if your contributions are good in that if you get likes for it, it's probably good […, and otherwise] it was probably only average" (#21). However, employees consistently reported to feel happy and recognized when they received feedback: "It's a simple thing but receiving points or positive feedback really makes your day even better" (#FR). And sending feedback enables employees to maintain a pleasant working atmosphere that fosters motivation and a feeling of belonging together: "it just makes people feel good when you make them happy, and then it is more pleasant to work together" (#1).

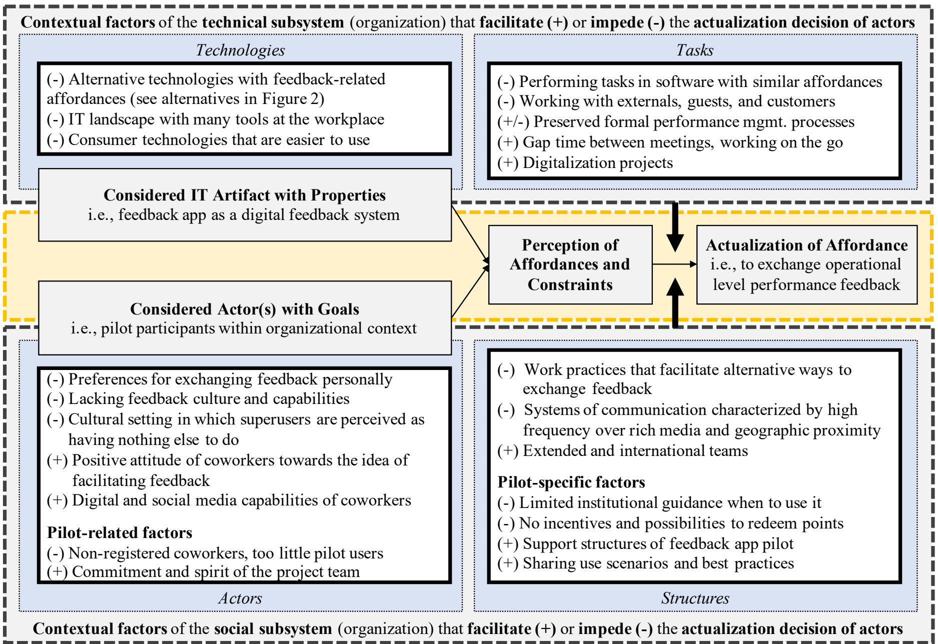

Figure 4. Facilitating and inhibiting context factors of the technical and social subsystem

4.2 Socio-Technical Context Factors that Facilitate and Impede Actualization

Still, employees may or may not realize the perceived possibilities to exchange feedback. In fact, the number of exchanged feedbacks decreased over time. Our results suggest that understanding individual's actualization decision requires considering their sociotechnical context, which comprises facilitating (+) and impeding (-) factors.

Technical Subsystem. The feedback app is part of a larger technical subsystem. Employees use it in the context of other technologies at work. A fragmented IT landscape with too many tools impedes actualization: "I wish NOT to work with an additional tool" (#FR). This goes along with alternative technologies that offer similar affordances, e.g., an employee stated that "for me it's actually equivalent to email. But not much better" (#9). Comparisons also include consumer technologies: "when you WhatsApp call people and it appears 'rate the quality of your call', you just click a star and then it [the feedback on the call] goes away" (#17). The technological context, in turn, goes along with the task environment. Performing tasks in software that offers feedback-related affordances inhibits employees' willingness to exchange operational-level performance feedback with the feedback app (see alternatives in Figure 2). Furthermore, working with externals, guests and customers is an inhibiting factor. For example, an auditor points out: "I used it only once, because I wasn't in the company. I am doing inspections, so I go around Morocco" (#15). Consequently, individuals expressed their need to "use it with guests/customers, because this feedback counts the most" (#7). Embedding the pilot in a task environment in which formal performance management processes are preserved was perceived as facilitating and inhibiting. On the one hand, it is additional work: "I would find it ideal if the feedback app is developed so that it replaces the 360-degree feedback. [...]. I cannot have five different processes" (#9). On the other hand, employees argued for keeping it separate from the formal processes to keep it casual, fun and engaging as well as prevent dishonest use. Further observations include facilitating factors, e.g., when working "on-the-go or if you have gap time between meetings" (#1). It was emphasized that the app "should necessarily be seen together with other digitalization topics that we are talking about here at [organizational entity], for example digital e-learning" (#21). In such contexts, people's efforts need to be recognized and incentivized to bring projects forward.

Social Subsystem. Employees are part of a wider social subsystem. We find work practices that facilitate alternative ways to exchange feedback and inhibit the need to use the feedback app. For example, closing meetings with face-to-face feedback rounds was mentioned as "ending ritual of meetings" (#1). Thus, limiting actualization to situations in which additional feedback is provided afterwards (see Path 4 in Figure 2). Also, daily Scrum stand-up meetings offer an alternative to exchange timely feedback. Further, working frequently with coworkers over rich media is identified as inhibiting, while extended and international team structures are facilitators: "of course I use it a lot more when I'm in [inter-regional meeting]. […]. They come in, present, go out, and fly back to Paris, Milano, and so on […] then you write that together in the evening, on your way home, if you sit on the train" (#19). This is increasingly relevant, because „when we are developing into [the direction of] virtual teams with less rigid hierarchies and work with different teams across projects, we just need it" (#21). In addition to prevailing structures, the pilot project entails inhibiting and facilitating context factors. For example, collecting feedback and points without incentives and possibilities to redeem these points was mentioned as inhibiting factor together with limited institutional guidance when to use the app: "I wish to have more guidance on when to give feedback. […, and on] how to understand the feedback app vs 360/ multi rater vs other regular feedback" (#FR). Sharing identified use scenarios and best practices was perceived to mitigate this factor. Also, actor-related context factors of the pilot further inhibited the actualization. Many users where surrounded by non-registered coworkers, and hence, felt that there are too little pilot users: "as the group is small, it's hard to not be too repetitive and/or biased towards the group who participates" (#FR). Further, being surrounded by actors that prefer to exchange feedback personally limits its usefulness. While general feedback on sensitive and controversial topics was preferably exchanged in person, employees' preferences varied for concrete and operational-level feedback. Coworkers with a positive attitude towards the idea of facilitating feedback and digital and social media capabilities foster the actualization.

5 Discussion and Conclusions

5.1 Discussion of Implications

Implications for Theory on Digital Work, Social Software, and Feedback. We address calls for research on digital work [3, 11] by elaborating how employees in digital work environments still navigate back and forth between various digital and physical spaces to perform work and exchange feedback. Our results reveal that the feedback app, in contrast to traditional feedback systems, is immediately perceived as digital work tool for operational-level performance feedback. As such, there are similarities to alternate systems that offer similar affordances. Namely operational feedback may be exchanged in general purpose social software (e.g., email, Slack), task-specific systems with embedded feedback mechanisms [18], and through integrating enterprise systems in social software that facilitates social interactions and feedback exchange [50]. While the feedback app is perceived as enabling personal development and growth, this second-order affordance requires employees to use the feedback app as central hub to accumulate feedback in one place. Therefore, future research should investigate how performance feedback can be integrated across systems (e.g., feedback app and enterprise systems) and sources (e.g., computer-mediated and computer-generated). Further, the feedback app introduces a novel type of enterprise social software aside from general-purpose social software such as social networks. Prior research on social software for specific purposes is scarce, hence, we provide unique contextual insights on social software tailored to the exchange of performance feedback. These findings are equally relevant for performance management literature, since they respond to calls for research to better investigate informal day-to-day feedback [51] and to examine the use of technology in managing performance [8].

Implications for Affordance Theory. Existing research draws on socio-technical systems theory to elaborate affordance emergence and perception [40] as well as the actualization of organizational-level affordances [41]. We extend prior research [40, 41] by elaborating how socio-technical context factors affect the actualization process of individuals situated in organizational work environments. We contribute to existing actualization models [35, 37] since the identified factors provide a concrete explanation of how perceptions of expected value and effort are affected by the socio-technical context and why affordances may not be actualized even though they are perceived.

Implications for Practice. Practitioners that introduce feedback apps, should mitigate the identified constraints and inhibiting socio-technical context factors, while enhancing facilitating factors. Designers of feedback apps should consider the use scenarios and trajectories by supporting these practices and preventing the identified constraints as well as inhibiting context factors. For example, feedback apps should integrate well into software in which digital work is performed and should address the need of employees to switch between physical and digital spaces.

5.2 Conclusion and Limitations

Investigating the feedback app within a pilot project at InsurCorp enabled us to elaborate affordances and constraints perceived and actualized in a naturalistic case setting as well as to present facilitating and impeding socio-technical context factors.

Nevertheless, our results must be viewed in the light of its limitations. The qualitative and interpretive nature of this research prevents exhaustiveness. The selected pilot participants and interviewees possibly share behavioral and perceptional traits that may not be representative. Even though we minimized selection bias by considering employees from diverse operational entities, locations and job roles, they all belong to the same large financial services group. Finally, changes of the technical and social structures as well as data analyses in this domain are restricted by the works council. Future research in other organizational contexts and countries is needed.

The Effect of Marker-less Augmented Reality on Task and Learning Performance

Peter Sommerauer, Oliver Müller, Leonard Maxim, and Niels Østman

IT University of Copenhagen, Department Business IT, Copenhagen, Denmark
{psom,olmy,leom,nies}@itu.dk

Abstract. Augmented Reality (AR) technologies have evolved rapidly over the last years, particularly with regard to user interfaces, input devices, and cameras used in mobile devices for object and gesture recognition. While early AR systems relied on pre-defined trigger images or QR code markers, modern AR applications leverage machine learning techniques to identify objects in their physical environments. So far, only few empirical studies have investigated AR's potential for supporting learning and task assistance using such marker-less AR. In order to address this research gap, we implemented an AR application (app) with the aim to analyze the effectiveness of marker-less AR applied in a mundane setting which can be used for on-the-job training and more formal educational settings. The results of our laboratory experiment show that while participants working with AR needed significantly more time to fulfill the given task, the participants who were supported by AR learned significantly more.

Keywords: Augmented Reality, Learning, Mobile Application

1 Introduction

Augmented Reality (AR) is known as a technology which augments the real environment with relevant digital information [3]. Such information can be superimposed on recognized objects using smartphones, tablets or AR goggles as user interfaces between the real and the virtual world. Additionally, AR allows a full 3D view of virtual objects and enables users to interact with them.

AR's potential has been shown in many use cases and in various settings, such as informal and formal learning environments, workplaces, museums and natural environments [2, 4, 5, 6, 10, 12, 21, 22, 24, 25]. In most settings which have been studied so far, trigger images or QR codes have been used for identifying objects in order to superimpose digital information on them [4]. Only few applications exist that use so-called marker-less AR [4]. Marker-less AR works in a way that the real environment itself and real objects therein are recognized by the app, which then augments digital information and adds functionality to the digitally enriched objects and environments [25], without any pre-defined trigger images or QR codes.

In this study we investigate the application and effectiveness of marker-less AR to support both the execution of a specific task in a mundane setting and the learning about

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

the underlying domain by executing the task (i.e., learning-by-doing). In particular, we intend to answer the following research questions:

- RQ1: How can marker-less AR be implemented in a real-world environment?
- RQ2: How does marker-less AR affect task and learning performance?

In the pursuit of answering our research questions, we developed a marker-less AR app, which enables the user to learn the names of objects from the real environment. We created a fictional learning situation with a given task and compared the results from two groups, one using an AR-based tool, the other using a traditional paper-based tool (Note that a direct comparison between marker-less and marker-based AR is not the aim of this study). Hence, our laboratory experiment uses a static group design with an experimental group and a control group. With this design we intent to investigate the differences in task and learning performance of the two groups by measuring task performance (i.e., time required for completing the task) and learning performance (i.e., answering a post-test questionnaire with questions about the task).

The remainder of this paper is structured as follows: To prepare the background, we first present related work and provide theoretical background on marker-less AR and its implementation. As our study was motivated by investigating task performance and learning performance, we also present associated performance metrics that are derived from learning theories. We then outline the app development process along with the embedding of a number of theory-ingrained design principles, followed by an introduction of the used dataset for image recognition and the setup and execution of our experiment. Next, we provide detailed insights into our data analysis, which prepares for the discussion of our results. Finally, we conclude with a brief summary and directions for future research.

2 Background

Our research background focuses on synthesizing the findings of published systematic literature reviews on AR learning and empirical studies about marker-less AR from the last decade. In order to identify relevant related work, we analyzed the most cited literature reviews on AR for education.

Most extant studies do not focus on using AR in real-life environments, but investigate its use for supporting a narrow and well-defined task in a controlled setting. Hence, it is not surprising that virtually all existing studies focus on the application of marker-based AR, which is easy to implement in a controlled laboratory setting, and that only few studies have investigated the use of marker-less AR so far [4, 5, 21, 26]. Moreover, marker-less AR is one key aspect discussed for implementing hybrid tracking for ubiquitous AR [5, 21, 25, 26].

What most studies have also in common is that they emphasize the need of further research on the features, use, advantages, and limitations of AR in educational settings [2, 4, 6, 10]. Reported advantages of AR in educational settings include learning gains, higher motivation, facilitated interaction, better collaboration, lower cost, better user experiences, just-in-time information, enabling of situated learning and student-centered approaches, increase of students' attention, enjoyment, exploration, increased capacity for innovation, creation of positive attitudes, more awareness, anticipation, and authenticity [2, 3, 4, 5, 6, 10, 11, 12, 21, 22, 24, 25, 26]. In contrast, repeatedly reported limitations of AR in education include the observation that AR apps are mostly designed for only one specific knowledge field [4], that teachers cannot create new learning content [2, 4, 10, 22], that there are difficulties maintaining superimposed information, that learners pay too much attention to the virtual information, that evaluation focused on short-term instead of long-term learning [4], and that AR can be perceived as an intrusive technology [4, 21, 26]. Still, most studies found positive evidence for the effectiveness of AR in education, for example, in the form of enhanced learning performance, higher learning motivation, improved perceived enjoyment, decreased cost, as well as adding creating positive attitudes towards education and fostering students' commitment [2, 3, 4, 5, 6, 10, 11, 12, 21, 22, 24, 25, 26].

In Bacca et al.'s review of AR for education, the authors report about 19 studies that use marker-based AR, 4 studies with marker-less AR, and 7 studies covering location-based AR [4]. They discuss challenges around the improvement of recognition algorithms (e.g., for human forms) in the process of achieving more immersive and not intrusive AR learning experiences. Furthermore, they recommend vocational educational training (VET) classes as target groups for future studies.

In their literature survey of AR, Billinghurst et al. [5] additionally focus on technology for user activity tracking considering input and interaction. They provided first design guidelines and interface patterns for AR development tools, starting with considering physical objects, virtual content and interaction metaphors and their connection. Additionally, they suggest future research directions as user tracking, user interaction, AR displays, and social acceptance of AR.

Dunleavy & Dede provide insights in AR teaching and learning, focusing on AR utilizing mobile, context-aware technologies (e.g. smartphones, tablets), thus enabling AR users interacting with digital information which is embedded within physical environments and in both, formal and informal learning environments [12]. They additionally investigate affordances and limitations for AR related to teaching, learning and instructional design and see AR as primarily aligned with situated and constructivist learning theory, stating, that AR positions learners within a real-world physical and social context while guiding, scaffolding and facilitating participatory and metacognitive learning processes (e.g. authentic inquiry, active observation, peer coaching, reciprocal teaching). Since AR legitimate users in peripheral participation with multiple modes of representation, they distinguish between location-aware and vision-based AR. In this context, AR has some limitations regarding student cognitive overload and managing level of complexity, which is a key instructional issue. Therefore, they recommend to decrease cognitive load by creating a simplified experience structure initially and increasing complexity as the experience progresses, thus scaffolding each experience explicitly at every step to achieve the desired experience or learning.

When Radu states that the educational community remains unclear regarding the educational usefulness of AR and regarding contexts in which this technology is more effective than other educational mediums, he refers to 26 publications comparing student learning with AR vs. non-AR apps [22]. Radu observed some negative consequences, such as attention tunneling, usability difficulties, ineffective classroom integration, and learner differences. His table of factors influencing learning in AR covers content representation, multiple representations that appear at appropriate time and space, learners are physically enacting educational concepts, attention is directed to relevant content, learners are interacting with 3D simulations, interaction and collaboration are natural.

Still, the benefits of AR in educational environments and the value of AR apps applied in educational environments has not yet been investigated in its entirety [8]. The different directions of AR apps differ regarding their potential benefits. In their systematic literature review to synthesize a set of 25 publications, Diegmann et al. [10] identified 14 different benefits clustered in six different groups. They considered dimensions like state of mind (e.g. increased motivation, increased attention, increased concentration, increased satisfaction), teaching concepts (e.g. student-centered learning, collaborative learning), presentation (e.g. increased details, information accessibility, interactivity), learning type (e.g. improved learning curve, increased creativity), content understanding (e.g. improved development of spatial abilities, memory), and reduction of costs [10]. They then mapped the benefits to five directions of AR in educational environments (discovery-based learning, objects modeling, AR books, skills training, AR gaming) and indicated that specific directions of AR apps are more likely to lead to certain benefits, such as increased motivation. Especially, they emphasize that future research is needed to investigate the causality between benefits and directions of AR.

In their review of AR in education from 2011 to 2016, Chen et al. focused on research which includes the uses, advantages, features, and effectiveness of AR in educational settings [6]. They recommended to undertake more studies considering the difference of cognitive process and psychological immersion between AR and reality settings, individual interaction, sense of identity, adaptive application in AR, AR classroom design and evaluation research, teacher's role model in AR educational setting, design and implementation of AR learning resources in K-12.

The literature review by Akçayır & G. Akçayır focuses on current advantages and challenges of? AR education. Although AR promotes enhanced learning achievement, they experienced a discrepancy for AR in terms of cognitive load and/or cognitive overload, and AR ease of use vs. challenges for AR app usability [2]. Since research studies report both, they advise AR developers to develop and consequently implement empirically proven design principles, focusing on AR use and educational outcomes, and AR apps designed for diverse populations (e.g. kids, students, lifelong learners). They emphasize the need to investigate students' satisfaction, motivation, interaction, and commitment, and provide insights from research and development comprising explanations of development processes and factors being considered in design.

Dunleavy, Dede, and Mitchell document in their review covering AR simulations for teaching and learning, how teachers and students describe and comprehend ways of participation in AR simulation, to aid or hinder teaching and learning [11]. By means of qualitative case studies across two middle schools they demonstrate that AR supports multi user environments and immersive collaborative simulation.

For professional education and training, Palmarini et al. focused on the state of the art of AR apps applied in maintenance [21]. Based on 30 primary studies between 1997-2017, they unveil most relevant technical limitations for AR and propose results indicating a high fragmentation among hardware, software and AR solutions which lead to a high complexity for selecting and developing AR systems, thus identifying areas where AR technology still lacks maturity (e.g. marker-less AR).

Further limitations for AR which are still present today were depicted by Zhou et al. for tracking techniques, interaction techniques, user interfaces, and AR displays, especially for head mounted displays (HMD) [26]. Although the development of AR hardware became more sophisticated in the past decade, the major technical issues are not sufficiently dissolved and need to be overcome, like low sensitivity trigger to recognition [2].

3 Methodology

In our study we followed the advice from Dunleavy & Dede (i.e., decreasing cognitive load by creating a simplified experience structure) [12], Diegmann et al. (i.e., causality between benefits of AR) [10], Chen et al. (i.e., AR classroom design and evaluation research, design and implementation of AR learning resources) [6], Palmarini (i.e., use of marker-less AR) [21]. In order to develop an AR app for both school and professional education (VET), we applied design principles from Billinghurst et al. (i.e., real physical objects/virtual elements to be displayed, linking interaction metaphor) [5] and Sommerauer & Müller (i.e., design elements derived from learning theories) [24].

For the evaluation of the effect of marker-less AR applied in a learning scenario we chose to design a controlled laboratory experiment to compare the support of AR with traditional, paper-based material inside a classroom. In this, we aimed to ensure that no or hardly any differences in information equivalence [16] could affect the results of our study. Finally, our research design aimed to support and control exactly those research design elements which were the key subject of investigation.

With the experiment we examined the usability of AR, its effectiveness and the potential for teaching and learning. The evaluation covered measures for perceived usefulness, perceived learning and students' motivation as well as objective performance in terms of time to completion for the task and number of mistakes made in a recall and retention test administered as a post-test. In addition, we employed the Systems Usability Scale (SUS) [23] to evaluate the usability of the applied AR system.

In our app development, we considered design elements from Billinghurst et al., who proposed to focus on physical objects, virtual content, the interaction metaphor, and their connections [5]. Additionally, we applied the conceptual framework by Sommerauer & Müller [24], which is inspired by Anderson's work on how learning can be enhanced using emerging technologies and applying learning theories [1]. At the heart of this framework are one or more learning sequences, each consisting of one or more connected learning activities. At the center of a single learning activity stands the learning content. This content should be designed according to different learning theories, indicated by the different concentric layers surrounding the learning content.

At the first layer, it is proposed to apply the 12 design principles of the cognitive theory of multimedia learning (CTML) [18]. In the second layer, design elements from mobile learning (e.g., Herrington et al. [13]) shall be considered for application design. Finally, it is proposed to implement design elements from game-based learning (e.g. leaderboard, mission) [14], simulations (e.g., storytelling, drama), experiential learning theory (e.g., diverging, assimilating) [15], and situated learning [19]. Additionally, collaborative learning elements can be introduced at the learning stage, where multiple learning activities are combined into a learning sequence [24].

We instantiated the above described conceptual framework by developing an AR learning app prototype. It supports the task of learning names related to physical objects used in a particular professional domain – in our case, the florist industry. More specifically, the app combines machine learning techniques for image recognition and machine translation to identify objects that are in the focus of the mobile phone camera in real-time and superimpose information such as the object's name in different languages onto the object. As a training application, the app can be used in any workplace environment and the trainee can select between exploration mode or quiz mode. In both, the user needs to focus the particular object using the device's camera (e.g. smartphone, tablet, any head-mounted device). Once the object is recognized, the app provides a selection of labels, comprising the three most likely names of the object using a percentage scale and colors. In quiz-mode, the app shows the most likely label and two randomly selected labels and the trainee has to pick the correct one. Figure 1 shows screenshots of the application and show the explore and quiz modes.

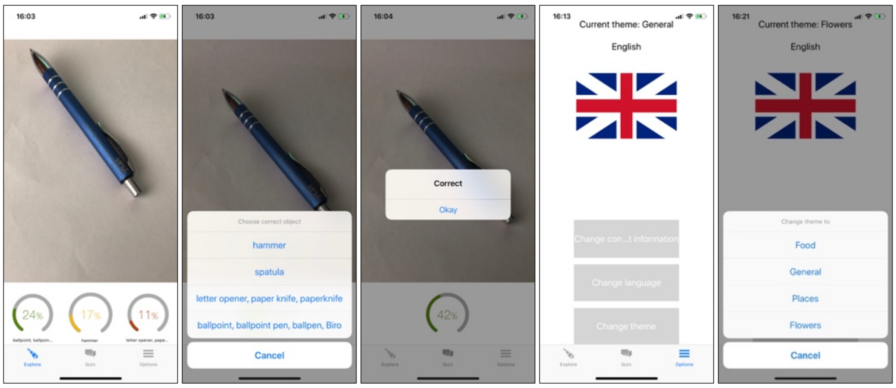

Figure 1. App in explore mode, quiz mode and selection of language and theme

The app design integrates design elements from CTML (i.e., the multimedia principle, the spatial contiguity principle, the temporal contiguity principle, and the signaling principle) with elements from the theory of mobile learning (i.e., users can use the app across space and time) and game-based elements). From a technical perspective, the app is based on Apple's ARKit framework[1] for implementing mobile

[1] https://developer.apple.com/arkit/

AR experiences, Google's MobileNets model[2], a convolutional neural network for efficient image recognition on mobile phones, and the Google Translate API[3] for automated translation of texts into multiple languages.

As a foundation for our flower identification app we used the flowers dataset by Nilsback & Zisserman [20], implemented as a selectable theme in our app. The flowers dataset consists of 8,189 images of flowers commonly occurring in the United Kingdom. The images are divided into 103 classes and each class consists of between 40 and 250 images. The images are scaled so that the smallest dimension is 500 pixels. The flowers are identified by different features describing different properties, e.g., color (HSV values of pixels), histogram of gradient orientations (HOG) [8], and distinctive image features (SIFT) [17] on foreground region and foreground boundary. In prior studies the recognition accuracy was measures at 72.8 percent.

The instructional design for the learning situation applied in the experiment contained elements from cognitive and constructivist learning theories. While the learning content was prepared based on CTML principles, elements of constructivist theory were implemented in the learning activity, such as, task orientation, mobile learning, and situated learning, by sending learners on missions including storytelling.

The laboratory experiment was based on a sequential quantitative method research [7] applying a static group design. The aim of the experiment was to identify differences in the application of AR vs. traditional learning. While the experiment group was supplied with mobile devices (iPhone 8+ and X) running the AR app, the control group received a traditional, paper-based tool (catalogue) to fulfil their task. Both groups received the same instructions and were required to fulfil the same task. At the end of the experiment both groups received a post-test questionnaire covering the same topics and questions. The questionnaire contained three sections. The first covered aspects for perceived usefulness, perceived learning, and students' motivation. The second part was a multiple-choice test asking for the names of five flowers shown as pictures. For each, participants could choose between three given names. The number of correctly identified flowers was used as an objective measure for learning performance. The third section of the questionnaire contained ten questions from the System Usability Scale (SUS), which was only available for the group using AR in the experiment.

4 Experimental Setup

The laboratory experiment followed a static group design comprising an experimental group and a control group. With this design we intended to investigate the differences in task and learning performance of two groups: one supported by an AR tool and one using traditional tools (i.e. a catalogue). Following similar studies [2, 3, 4, 5, 6, 11, 12, 22, 24] and in line with our research questions, we used the item "time for task completion" as a measure for task performance and "No. of correctly identified flowers" from the questionnaire after the treatment as an indicator for learning performance. Figure 2 gives an overview of the randomized field experiment.

		Group 2			paper based catalogue							

Figure 2. Overview of the randomized field experiment

We prepared two flower meadow, each consisting of 100 fake flowers composed of four different flower pictures per flower species and covering a selection of 25 different flower species from the flower dataset. The pictures were printed on paper and mounted on skewers. On the back side, the fake flowers were numbered according to an internal reference list to allow internal identification without the need for labels.

As a traditional tool for supporting participants in the experiment, we prepared a flowers catalogue covering exactly the 25 different flower species from the flower meadows. The flower pictures in the catalogue were different from those in the flower meadow and the catalogue was ordered alphabetically.

The questionnaire in the first section used a Likert scale containing five values from strongly disagree (1) to strongly agree (5) and covering eight questions:

- Perceived Usefulness:
  A. The AR app / catalogue was helpful to fulfil the task.
- Perceived Learning:
  B. With this activity I have learned something.
  C. I have learned about flowers.
  D. I can put together a bouquet on my own.
- Motivation: What do you think about the experiment and its setup?
  E. The introductory story was motivating.
  F. The task was simple and understandable.
  G. It was exciting to fulfill the task.
  H. The activity was entertaining.

Both rooms for the experiment where prepared in the same way. We set up the flower meadow with the fake flowers sticking in carton boxes and grouped by flower type. The carton boxes were placed on three tables in the center of the room. There was enough space to walk around the tables and to reach the flowers easily.

The main task for the participants was to collect six flowers from the meadow, which were named in form of a word-cloud on the instruction sheet in an envelope. We prepared five envelopes and the selection of the flower names for the word-cloud was done by a randomization process. Such, we used a webtool (www.randomizer.org) to collect 5 sets of 6 unique numbers per set within the range from 1 to 25. To arouse student attention and motivation, we narrated a story to send them on a mission, thus following design principles from game-based learning and simulation: “You fell in love with another person and have learned that you can break the ice between you and your crush with a smoothly arranged bouquet of flowers. Since you are absolutely unfamiliar with how to create a convincing flower bouquet, you ran a data analysis on your partner’s Facebook account and received a list of preferred flowers presented in the word-cloud below”. The mission to accomplish was formulated in the way, that “You know that love is like a little bird which flies away after some time and since you have just this one chance to score, give your best and collect the flowers as listed in the word cloud from the “self-service shop” as accurately and as fast as you can!”.

While the AR group could use a prepared iPhone (we used four iPhone 8+ and one iPhone X) to complete their mission, the control group (non-AR group) was provided with the aforementioned flowers catalogue. As noted earlier, we used different pictures for the catalogue and the production of the fake flowers.

The experimental process was designed in a way that after listening to the initial instruction participants were assigned an envelope with further instructions, the story, the mission, and either an iPhone or a flowers catalogue. Then the researcher started a timer and the students needed to collect the flowers as fast as possible. Afterwards, they came back to the researcher who recorded the collected flower numbers and asked students to complete the questionnaire. Since the students received a participant number, this number was noted on the questionnaire for later analysis. Once the participants completed all tasks, the fake flowers were put back to the flower meadows and the room was prepared for the next group.

5 Implementation

We invited 71 students from a Masters course in Information Technology at a technical university in northern Europe to participate in the experiment, but only 44 attended. The students were already divided into working groups from their course and we assigned them to sessions with a maximum of ten students per session and a duration of approximately 15 minutes. Participating students received a voucher from the university’s coffee shop as a reward right after the experiment.

The experiment started with a short introduction to welcome and thank the students for their participation. The participants were given some motivational instructions and were told to not chat with each other during the experiment or tell others about the experiment afterwards to not influence other students attending later. To split the group into the AR group (participants interacting with AR app during the experiment) and non-AR group (control group working with catalogue instead of AR app), students were told to choose between one of the two rooms by having equal numbered groups.

Participants could choose one of the five envelopes and when they started reading the instructions, a timer was set. After collecting the flowers, the students had to move to the research assistant and hand over their flower bouquet and all provided materials. To document the selected flowers and the required time to completion for the task, participants received a number to record their results for analysis. They then received the questionnaire to be answered on their own, marked with their participants number. After the students completed the questionnaire, they could leave the experiment.

Both experiment groups were treated in the same way, except of having different tools (AR app and paper catalogue) to fulfill the main task. There were no a priori time restrictions given, but students in the AR group were asked to terminate the collecting of flowers after 15 minutes.

6 Data Analysis

A participants' data record contained participant ID, group (AR, non-AR), gender (female, male), envelope number, IDs of the collected flowers, time to task completion, and the answers to the questions of the post-test questionnaire. In a first analysis, we assessed the number of correct flowers collected and the answers from the questionnaire. Overall, 18 female and 27 male students took part in the experiment, where 20 were assigned to the AR group and 25 the non-AR group.

In the AR group, 6 female and 14 male participants required from 510 to 1200 seconds to complete the given task (median 858.5 seconds, mean 864 seconds). They collected between 2 and 6 correct flowers from the given bouquet (median 4, mean 4.45). In terms of learning performance, the number of correct named flowers in their post-test questionnaire reached from 0 to 5 (median 2, mean 2.55).

In the non-AR group, 12 female and 13 male participants needed between 68 and 330 seconds to complete the task (median 171 seconds, mean 182.24 seconds). They collected 0 to 6 correct flowers from the given bouquet (median 5, mean 5.16) and the number of correctly named flowers in the post-test questionnaire reached from 0 to 5 (median 2, mean 1.96). Between the two groups there was no difference in the distribution of envelopes, which was tested by performing a Kolmogorov Smirnov test.

Next, we ran an exploratory correlation analysis between all relevant pairs of variables in our dataset (Table 1). We found statistically significant correlations between group assignment and time to completion (mean of AR/non-AR: 864sec/182sec), perceived usefulness (QA) (mean of AR/non-AR: 3.65/4.40), and one of the questions related to perceived learning (QC) (mean of AR/non-AR: 3.4/2.8). Interestingly, we also found a significant correlation between gender and the number of correctly collected flowers (mean of female/male: 5.33/4.52, $p<0.01$), and perceived usefulness (mean of female/male: 4.50/3.77, $p<0.01$).

As our pseudo random assignment of students to groups did not produce an even distribution of males and females between the AR and non-AR group and because the correlation analysis indicated that gender is correlated with some of our dependent variables of interest, we decided to use regression models to test the main hypotheses of our experiment, namely that AR has a positive impact on (perceived) task performance and (perceived) learning performance. The advantage of a regression model over t-tests or ANOVA is in the ability to model the influence of multiple independent variables (in our case group and gender) on one dependent variable. Table 2 summarizes the results of this analysis.

Table 2. Regression results

According to the regression results, participants in the AR group did not perform significantly better in terms of correctly identifying flowers than participants in the paper catalogue group. With regard to time needed to complete the task, participants in AR group even performed significantly worse than participants in the paper catalogue group. Hence, we did not find any empirical evidence that the AR app increased participants' objective task performance in terms of task accuracy and task time. Consistent with this finding, participants in the AR group evaluated the perceived usefulness of their tool (i.e. the AR app) significantly worse than participants in the non-AR group working with the paper catalogue.

However, when looking at objective learning performance, measured by the number of questions answered correctly in the post-test questionnaire, we found that participants in the AR group performed significantly better. This finding provides empirical support for the effectiveness of AR as a tool to enhance students' objective learning performance. With regard to perceived learning (measured by the average scores of questions B-D), we did not find a significant difference between the groups.

7 Discussion

In our experiment students achieved an observably better learning performance when using the AR flower identification app instead of a comparable paper catalogue, a result that is similar to prior research results comparing AR-based training to traditional paper-based training methods [4, 12, 22]. Therefore, and to answer RQ2, we conclude that AR can support students' learning performance. However, it may also be that the learning performance for the AR group was influenced by their longer task completion times, thus students were more engaged with the learning content and more motivated [2]. This can either be seen as a potential confounding factor which has to be controlled for in future studies (e.g. by predefining the available time for conducting a task), or as a positive side effect of using AR for teaching and learning [4, 5, 6, 12, 24, 25]. One could argue that when using AR students voluntarily spend more time with the learning materials, as compared to using traditional paper-based tools.

Considering participants' behavior during the experimental task, we noted that students in the AR group acted differently than those in the non-AR group. While participants in the AR group needed to investigate the flowers sequentially (because the app can only identify one object at a time) and thus examined nearly all flowers from the meadow, participants in the non-AR group selected a flower's name from the task description, searched for the name in the catalogue, and then located the flower by scanning the flower meadow with their eyes and matching the picture from the catalogue with the pictures on the meadow. On the one hand, this resulted in much shorter task times, as the human eye can focus on multiple objects at the same time (or at least can change focus much more quickly than AR technology), in comparison to the participants in the AR group who additionally had to perform the task of hand-eye coordination when using the app. On the other hand, when filling out the post-test questionnaire students realized that they had not inspected all flowers from the meadow and catalogue in sufficient detail in order to answer the questions correctly (the flowers students had to name in the post-test were different from those they had to collect).

A further observation related to the above point was that as participants in the AR group were forced by the app's functionality to look at each flower and since the app showed the three most likely names for identifying a flower and the elated confidence levels, students required more attempts to select the correct flower. We are convinced that this was a main driver behind the longer time needed to complete the task. Additionally, students from the AR group confirmed that it is more fun to look at the flowers with the app instead of just learning from a book.

It is remarkable that while the perceived learning of the AR group is not significantly higher compared to the non-AR group, their objective learning performance was significantly higher. The better objective learning performance may be explained by the different ways participants approached the task in the two groups. While students in the non-AR group focused on finding the flower picture for the given flower name and selecting a similar flower from the meadow, students in the AR group pointed their smartphone upon every single flower in the meadow to see its name. A single flower was represented multiple times in the flower meadow and students from the AR group visualized a particular flower more often. This finding corresponds to results from other studies, where AR is more effective than using traditional media [2, 4, 6, 10, 22, 24].

Since the paper catalogue prepared for the experiment was ordered alphabetically and only contained few pages covering the presented 25 flowers, students in the non-AR group had an advantage when matching flower names between the task description and catalogue. This could be a major limitation in our study in regard to the results for participants task performance times compared with participants from the AR group. Using a flower identification book with hundreds of pages ordered by species instead of alphabetically would have been more realistic for our comparison and would probably have led to different results, at least in terms of task completion times. However, this observation indicates that the prepared catalogue was designed to support task completion.

Our app is technically able to identify up to 60 pictures per second, comparing it with several thousands of pictures from the database. Thus, the setup of the experiment with only a handful of flowers did not challenge the full potential of the app, which is a further limitation in terms of system performance in comparison of traditional tools with AR based tools. Nonetheless, with our study we could contribute to the discussion about improvement of AR recognition and marker-less AR [4]. For future research and practical application, the AR app can be utilized in any other learning environment just by exchanging the underlying image recognition machine learning model. This represents a cost-efficient alternative to integrate AR into classroom trainings [22].

8 Conclusion

With the app development and its application in the experiment we could answer our RQ 1 and demonstrate how marker-less AR can be implemented for education in a real-world environment. Thus, we followed recommendations for further research in the directions of implementing AR in real-life settings [6] and applying image-based tracking [5] and marker-less AR [4, 21, 26] for ubiquitous learning [2]. Moreover, with our study we investigated how marker-less AR affects task and learning performance in a mundane setting, for example in our simulation of a florist’s job. Our results showed that from a learning aspect, students using the AR app performed better when it comes to recalling the learning content, similar to prior studies [2, 6, 10, 24]. Although students in both groups achieved the same level of accuracy in fulfilling the given task, those students in the AR group needed more time. Since the experimental setup unintentionally supported the control group in faster task completion time, which points towards the finding that tasks processed with AR need to be designed differently.

Relying on the predefined dataset and machine learning model from Nilsback & Zisserman [20] was an efficient decision and guaranteed a consistent recognition rate for each object in the experiment. However, participants had some troubles with finding the correct focus for the fake flowers because of reflections, shadows and different illumination caused by the changing daylight which is also mentioned in prior studies and therefore a limitation which should be investigated in future research [2, 11, 21].

Students from the non-AR group benefited from the reduced catalogue to accomplish their mission. Since the AR app is able to recognize up to 60 pictures in a second from a dataset containing 8,189 pictures, the comparison of both tools in the experiment and for the given task, to search and identify a flower by its given name, was not really fair. However, with our study we demonstrate a content application of AR in association with its benefits and directions, particularly its scalability in a mundane situation.

Conducting an experiment just with students is not always satisfying. However, in our larger research program this was only a first test to demonstrate the use of the marker-less AR app and to collect and analyze first empirical data to investigate its effectiveness. In fact, we are beyond this now and are currently testing the app with a target group of low-threshold skilled employees.

From the aspect of using marker-less AR in educational settings we have ascertained that the recognition sometimes lacks due to optical influences, which is still a common issue for AR applications [2, 4, 5, 12, 21, 24, 25, 26]. Hence, future technological development should focus on recognition algorithms and the preparation of large and validated datasets in order to support the implementation of marker-less AR in education and in various real-life situations. Furthermore, the application of object detection instead of image recognition inside AR applications provides potential for new findings about how full 3D support for such AR apps assists learning and a better understanding. First results from our continuing research already confirm that object detection facilitates the recognition of a series of objects in one single viewpoint.

Abstract. The private use of the Internet via desktop and smartphones during working time, also known as cyberloafing, has become a common practice at many workplaces. While critical voices expect performance losses through such behavior, their opponents perceive of the interruptions created by cyberloafing as an opportunity to recover and continue working with increased productivity afterwards. Given the growing body of research on Internet-related employees' opportunism, this paper presents a systematic literature review of 69 studies to identify the factors behind cyberloafing. The classification includes personality traits as well as antecedents related to the job, organization and personal life. The paper concludes with a clear picture of the kind of circumstances which tend to increase cyberloafing and which factors statistically do not seem to have any impact on the abuse of Internet during working time.

Keywords: Cyberloafing, Cyberslacing, Not-work-related computing, Internet addiction.

1 Introduction

Today, most organizations are connected to the Internet to support their routines: to complete electronic payments, to communicate with customers by providing online support, to research new product ideas, to craft and monitor their own brand on Social Media or to collaborate on projects with people all over the world. Despite many ways to boost business efficiency, in many cases the Internet at workplaces is also used by employees for private matters [1-2]. This unproductive use of the Internet during working time is often referred to as cyberloafing, cyberslacking or non-work-related computing. These terms are used as synonyms to signify the abuse of the Internet during working time [3]. Almost 90% of employees misuse the company's Internet access to send and receive private e-mails or visiting news websites [4]. Also shopping (65%), visiting sport websites (60%) and booking vacations (50%) are reasons for employees to go online during work [4]. Furthermore, browsing through Social Media is quite

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

popular and justified by taking mental breaks (34%), connecting with friends and family (27%) and supporting professional connections (24%) [5].

People spend more than one hour per day during eight hours of working time on the Internet [6-7]. As a result, employees continuously interrupt their work which has been found to be more disruptive than external factors [8]. Moreover, for companies the private use of the Internet by employees during working time results in higher expenses [9]. The costs of cyberloafing are at an estimated 85 billion dollars per year for all US companies [7].

Since the boundary between private and business life is continuously more blurry for many people [10], the issue of cyberloafing gains more and more relevance. Employees often require more flexibility at their jobs [11]. On the one hand, people with flexible working conditions, meaning their work is not fixed to certain hours or locations, show higher levels of engagement, stronger organizational commitment and higher job satisfaction [12]. On the other hand, this flexibility implies the use of the Internet for private issues at workplaces.

So far, companies' reactions to cyberloafing are ambiguous. While some companies ban private use of the Internet during working time (e.g. FedEx) [13], others have not taken any actions.

Considering the complexity attached to the concept of cyberloafing, the antecedents of this behavior must be better understood. This study aims to summarize the main factors that drive cyberloafing by conducting a systematic literature review. In terms of research contribution, our paper provides an initial attempt to synthesize existing research findings on the phenomenon. For industry leaders, our work offers a holistic view hinting at how to manage employees in the digital age.

2 Review Method

The literature review follows the guidelines from von Brocke et al. [14] and Webster et al. [15]. Studies were searched using the keyword "cyberloafing" on different scientific databases: Google Scholar (1520); JSTOR (33); ScienceDirect (80); ProQuest (123); InfoTrac (23); ACM Digital Library (2); IEEE Xplore (5); Taylor and Francis (35); Emerald (31) and SAGE journals (24). Synonyms like "cyberslacking" and "non-work-related computing" were also considered during the search process, however no additional unique results were yielded.

After reviewing the titles and abstracts, a total of 231 papers were identified and analyzed in more detail. Out of these, only peer-reviewed papers published in English and with a clear focus on the empirical study of cyberloafing were selected. Since browsing Social Media websites is one of the main reasons for taking a mental break at work [5], the publications' timeframe was set to 2003-2017. This starting point corresponds with the emergence of Social Media websites such as LinkedIn and MySpace, founded in 2002 and 2003 respectively. The selected 145 papers then underwent a full-text review. Finally, a total of 69 studies that investigated the antecedents of cyberloafing were selected as a baseline for further analysis. All studies in the final sample were published between 2004 and 2017 and employ quantitative surveys as the main method. Employees from both private and public sectors took part in the studies. Geographically, the majority of samples originate in the US (50%), Asia (33%) and Turkey (15%). This could be explained by the fact that the work-life balance in these regions is very low, as OECD studies show [16]. Methodologically, 26 studies (37%) apply hierarchical regression for data analysis, and 44 studies adopted different empirical methods such as multiple regression analysis. The results of the analysis are summarized in the following chapter.

3 Results

3.1 Theoretical foundations

Nearly one half of the studies in our sample have a strong theoretical background. In particular, theory of planned behavior, general deterrence theory and social learning theory often serve as conceptual foundation to discover drivers of cyberloafing (Table 1). In some cases, more than one theory was applied. In 26% of the studies the research framework is not rooted in a particular theory and the hypotheses are mainly formed on the basis of past research.

Table 1. Overview of approached theories

N=69	*PBT*	*GDT*	*SLT*	*RCT*	*ET*	*TAT*	*SET*	*BT*	*RT*	*Other*	*No theory*
Number of papers	15 (22%)	12 (17%)	7 (10%)	6 (9%)	5 (7%)	5 (7%)	3 (4%)	3 (4%)	3 (4%)	14 (20%)	18 (26%)

Note: PBT = Planned behavior theory; GDT = General deterrence theory; SLT = Social learning theory; RCT = Rational choice theory; ET = Equity theory; TAT = Trait activation theory; SET = Social exchange theory; BT = Bonder theory; RT = Role theory

The theory of planned behavior states that subjective norms, attitude towards behavior, and perceived behavioral control lead to a deviancy like cyberloafing [17]. In contrast, social learning theory assumes that learning is a cognitive process which happens through the observation of existing norms in groups as well as through rewarding actions or punishing their consequences [18]. In the context of cyberloafing, this means that existing company norms and policies influence employees' behavior. In line with this, general deterrence theory claims individuals can be detained from undesirable acts by using countermeasures like strong disincentives and sanctions [19].

Among others, rational choice theory [20], equity theory [21], trait activation theory [22], social exchange theory [23], border theory [24-25] and role theory [26] were adopted to explain causes of cyberloafing.

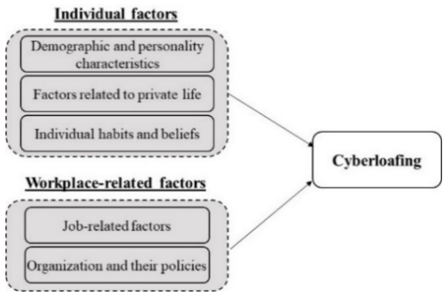

Figure 1. Summary of the antecedents of cyberloafing

Our systematic literature review uncovers several antecedents that underlie individual cyberloafing, as tested and shown by prior research. Considering 83 different original factors, we categorize dominant antecedents into two groups: individual factors and workplace-related factors.

3.2 Individual factors

With regard to individual factors of cyberloafing we distinguish between (1) the demographic and personality characteristics of employees, (2) factors related to their private life, as well as (3) their beliefs and habits with regard to cyberloafing.

Demographic and personality characteristics

Using Internet access for personal purposes while pretending to do legitimate work is linked to a number of different demographic characteristics and personality traits, as presented in Table 2.

Table 2. Demographic and personality characteristics as antecedents of cyberloafing

Demographic and personality characteristics	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Gender (0=male; 1=female)		[4], [28-37]	[6], [38-50]
Age	[28]	[4], [31], [33-34], [36], [41], [43], [46], [51]	[6], [29], [37-38], [42], [44-45], [50], [52-53]
Relationship status (single=1, other=0)	[30], [38]	[54]	
Education	[38-39], [53]	[6], [36], [42], [46], [54], [55]	
Internet skills and computer experiences	[6], [39]	[4], [36], [43-44]	[41]

Demographic and personality characteristics	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Big five personality traits			
- Openness		[38], [45], [56]	
- Conscientiousness		[51], [56], [57]	[38], [45-46], [52], [58], [59]
- Extraversion	[32], [38], [45], [47], [61]	[56]	
- Agreeableness		[38], [45], [51], [56], [57]	[59]
- Neuroticism	[38], [57]	[47], [57]	
Emotional intelligence and honesty		[51], [62]	[36], [45-46], [56], [63], [66]
Self-regulation		[58]	[35], [51], [62]

Previous studies deliver ample evidence that younger [6], [29], [37-38], [42], [44-45], [50], [52-53] and more extroverted people [32], [38], [45], [47], [61], males [6], [38-50], and experienced Internet users [6], [39] tend to cyberloaf more during their working time. Further, a number of studies show that singles are apt to completing job-unrelated tasks at their workplaces [30], [38]. A potential reason for singles to cyberloaf is the search for potential spouses on social networking sites [65]. Additionally, some studies show that high education level [38-39], [53] can be positively related to cyberloafing.

In contrast, high emotional intelligence [36], [45-46], [56], [63], [66], honesty [56], [63], [66], self-regulation [35], [51], [62], conscientiousness [38], [45-46], [52], [58], [59] and agreeableness [59] are personal characteristics which are negatively related to cyberloafing and thus rather contribute to compliant behavior at the workplace.

Factors related to private life

A number of studies manifest that factors related to employees' private life can be linked to cyberloafing (Table 3). For instance, a number of studies show people with many private obligations are apt to engaging in job-unrelated tasks at their workplaces [66-68]. A potential reason might be that people with a high level of private demand tend to use the Internet during working time to organize private matters [65]. Furthermore, previous research ties interruptions during sleep and exhaustion to cyberloafing behavior [47], [69]. One explanation is that sleep interruptions during the night could reduce the intrinsic motivation to work, which in turn leads to more cyberloafing [69].

Table 3. Factors related to private life as antecedents of cyberloafing

Factors related to private life	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Bed time and exhaustion	[47], [69]		
Private demands hours	[66-68]	[70-71]	

Individual habits and beliefs

Interestingly, some employees show a positive attitude towards cyberslacking and perceive of Internet breaks to be useful [4], [61], [72-73] and appropriate [27], [41], [65-66], [70], [72], [74]. Moreover, the power of habituation effect is revealed: those who have integrated cyberloafing into their working routine [27], [33], [35-36], [40], [41-43], [49], [51], [72], [75] practice it more often. In line with social learning theory [18] and theory of planned behavior [17], this witnesses the importance of preventing measures at the initial stage to be able to avert occasional undesirable actions from establishing. The results for individual habits and beliefs as antecedents for cyberloafing are presented in Table 4.

Table 4. Individual habits and beliefs as antecedents of cyberloafing

Individual habits and beliefs	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Personal habits of cyberloafing	[27], [33], [35-36], [40], [41-43], [49], [51], [72], [75]	[4], [29], [31]	
Self-efficacy		[33], [54], [58], [62]	
Normative beliefs and subjective norms	[27], [41], [65-66], [70], [72], [74]	[4], [61]	
Perceived usefulness of cyberloafing	[4], [61], [72-73]		
Procrastination	[76], [65-66]	[57-58]	

3.3 Workplace-related factors

Workplace-related factors of cyberloafing combine reasons attributed to (1) the nature of the job itself, including characteristics the employee doing it, as well as (2) the factors related to the organization and its policies.

Job-related factors

As a subcategory, job-related factors rooted in the nature of the position itself and the function of an employee designated for it are identified from previous work (Table 5).

Table 5. Job-related factors as antecedents of cyberloafing

Job-related factors	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Tenure		[33], [43-44], [51], [77]	
Organizational position	[30], [38], [42], [46], [54-55], [66]	[36], [51], [67]	
Salary/income	[34], [42]	[6], [28], [51], [77]	
Stress and number of working hours	[43], [68], [78-79]	[32], [42], [47], [55], [64]	
Proximity of supervisor	[33], [55]	[38], [67]	[37]
Boredom	[6], [51], [64], [71]		
Meaningfulness of work		[45]	[33], [38], [42], [66-67], [77]
Creativity of work	[6], [66], [80]		
Internet work utility	[6], [42]		
Job satisfaction	[27], [33], [81]	[6], [32], [36], [42], [47], [55], [80]	[41]
Withdrawal behaviors	[80], [82-83]	[30]	

We find that employees in high positions [30], [38], [42], [46], [54-55], [66], with higher income [34], [42] and higher levels of stress [43], [68], [78-79] tend to cyberloaf on the Internet more. In light of cyberloafing as an opportunity to refresh oneself during work, there may be higher need for mental breaks through cyberloafing in jobs that require creativity [6], [66], [80]. Furthermore, studies show that boredom at work [6], [51], [64], [71], the ability to use the Internet to improve the job [6], [42] and the ability to hide cyberloafing at work [83] can provoke cyberloafing. Consequently, those who perceive of their work to be meaningful will engage in cyberloafing significantly less [33], [38], [42], [66-67], [77].

Yet, the links between the level of job satisfaction and cyberloafing behavior remain unclear. Some studies suggest that people tend to cyberloaf [27], [33], [81], if they are satisfied with their jobs. This could be explained also as people which can use the Internet for private matters during working hours are more satisfied with their work. Others disagree this positive correlation and believe employees only substitute their disliked labor with other activities including surfing the Internet [41].

Organizations and their policies

Another cluster of factors contains organizational features, norms and policies (Table 6).

Table 6. Organizational factors as antecedents of cyberloafing

Organizational factors	*Significant positive relationship to cyberloafing*	*No significant relationship to cyberloafing*	*Significant negative relationship to cyberloafing*
Organizational size		[77]	[29], [41], [55]
Norms	[4], [33], [63], [74], [80], [82-83]		
Monitoring and external control		[4], [37], [41], [77]	[29], [31], [36], [44], [52], [73], [84]
Internet usage policies		[41], [55]	[36], [38], [42], [45], [52], [66], [85]
Sanctions		[44], [73]	[27], [37], [43], [63], [85]
Internet access	[38]	[67]	
Organizational justice		[31], [35], [42], [46], [86-87]	[50], [59], [88-89]
Performance appraisal and career advancement		[54]	[90]

It is evident from the research that open access to social network sites [38] and norms which allow Internet use for all purposes [4], [33], [63], [74], [80], [82-83] are significantly associated with cyberloafing.

Furthermore, the bigger the organization [29], [41], [55] and the more thoroughly the monitoring of employees [29], [31], [36], [44], [52], [73], [84], the less likely the Internet is abused during working time. In addition, Internet usage policies [36], [38],

[42], [45], [52], [66], [85] and potential sanctions [27], [37], [43], [63], [85] prevent staff to deviate from actual tasks. These findings are in line with general deterrence theory [19] claiming that awareness of sanctions may decrease a punishable behavior. Furthermore, employees are likely to reduce their opportunistic behavior if they observe peers being penalized [27]. Finally, objective performance ratings, wider perspectives of career opportunities [90] and high levels of organizational justice [50], [59], [88-89] are shown to restrain cyberloafing.

4 Discussion

The aim of this systematic literature review was to investigate the current state of research on the factors behind cyberloafing. A total of 69 papers were analyzed to explore factors associated with this behavior. Our review suggests that theory of planned behavior and general deterrence theory are the most frequently applied theoretical concepts for studying the phenomenon. While theory of planned behavior is mainly focused on determinants from employees' side, like subjective norms, individual attitude, and perceived behavioral control leading to cyberloafing, general deterrence theory is taking the employer perspective with studies centered around preventing measures, policies and sanctions as the main restraining mechanisms. To provide a better overview of factors associated with cyberloafing, two groups of determinants were proposed: individual and workplace-related determinants.

The cluster of individual factors associates cyberslacking with individual characteristics and skills, including gender, age, personality traits, computer skills, sleep quality, relationship status as well as personal attitudes towards cyberloafing. The analysis suggests that younger [6], [29], [37-38], [42], [44-45], [50], [52-53], extraverted people [32], [38], [45], [47], [60] with good computer skills [6], [39] are more likely to abuse access to the Internet for non-work related matters. The second group contains workplace-related determinants like the employee's position within the company, salary and job satisfaction as well as organizational policies on Internet abuse during work time. Employees in higher positions [30], [38], [42], [46], [66], [54-55], their education [38-39], [53], income [34], [42] and levels of stress [43], [68], [81-82] correlate with a higher rate of cyberloafing. Restriction of Internet access [36], [38], [42], [45], [52], [66], [85] and sanctions [27], [37], [43], [63], [85] for non-compliant behavior are shown to be significant measures against cyberloafing.

The literature review illustrates the complexity and multifaceted nature of the cyberloafing phenomenon. On one hand, the given collection of antecedents delineates a typical employee who is inclined to factors which can be (at least partially) influenced by their employer through the number of working hours or the physical proximity between employee and supervisor. On the other hand, our analysis reveals a number of non-workplace-related factors which companies can control less and only influence to a limited extent. Our results are in line with the social trend of work-life-blending [93], which means that the boundaries between work and life are increasingly softened which has employees mix their professional and private interests. Especially employees who need to spend much time at work [43], [68], [78-79] use cyberloafing as a way to follow up on private matters during working time [29]. Furthermore, our findings identify that young people [6], [29], [37-38], [42], [44-45], [50], [52-53] and employees of small companies [29], [41], [55] tend to cyberloaf more. These results are also conform to work-life-blending trends. Especially young people (the so-called Generation Y) and employees of start-up companies do not draw clear lines between work and private life [94].

Although organizations have an interest in reducing cyberloafing, as the employees' productivity could be influenced in a negative way [95], we have found enough confounding evidence that the breaks taken to cyberloaf are helpful in providing inspiration for creative work [6], [66], [80], increasing job satisfaction [27], [33], [81] and reducing work-related stress [92].

Our results further imply that the antecedents of cyberloafing have many different business specificities, and the strategies of handling cyberslacing depend heavily on the corporate culture and governance of the respective company.

5 Conclusion, limitations and future research

Cyberloafing at the workplace has become common in the digital age. Summarizing extant research, this paper provides a structured review of current literature on cyberloafing with a special focus on its antecedents. However, empirical results remain scattered. This paper addresses this gap by conducting a systematic literature review and providing a comprehensive summary of existing findings on the factors behind cyberloafing. Furthermore, this study extends IS research by presenting a number of practical implications for corporations, their management and employees. We reveal an array of conflictual findings that exist in the literature, which calls for a more thorough exploration into the reasons of these diverging insights.

The current study is subject to a number of limitations. First, the papers included in our sample were found through keyword search, followed by a subsequent exclusion. Second, we acknowledge possible interdependences of factors in our classification which is mainly attributed to the heterogeneity of the studies summarized. For example, age could be a confounding variable in the correlation between a) computer skills and cyberloafing and b) relationships status and cyberloafing. This is because younger generations have better digital literacy and are not likely to have founded own families yet. Therefore, our framework compiles and recaps previous research without delivering a strong causal model. Third, we treated cyberloafing as a unified construct without analyzing its multiple facets like type of activity or time of occurrence. Recognizing these limitations, our research serves as point of departure for future investigations in this area. For instance, future research could take into account the organizational culture and the corresponding work-life-blending, industry type (e.g. construction vs. IT sector), type of tasks (e.g. creative vs. routine jobs) and types of employment (full time, part time, casual, fixed term, apprentices and trainees). Moreover, intercultural comparisons between Western and Eastern countries would be interesting.

Abstract. Internal crowd work has emerged as a new form of digital gainful employment that changes the nature of work. However, the possible effects of internal crowd work on the individual level have been largely neglected. In this paper, we therefore present our research in progress which is concerned with the effects of work characteristics in internal crowd work that have impact on the individual's empowerment and satisfaction. Thus, we developed our research model and conducted an online survey amongst 118 internal crowd workers of a Swiss bank who were asked to test new software. Our expected contribution will increase the understanding of internal crowd work and provide important insights for organizations to (re-) design work on internal IT-platforms.

Keywords: Crowdsourcing, Internal Crowd Work, Empowerment, Work Characteristics.

1 Introduction

Companies increasingly use IT-platforms to reach out to employees, speed up collaborative work and support ideation within the organization [1]. As a new form of collaboration, internal crowd work reflects an IT-enabled group activity based on an open call for participation in an enterprise [2]. While external crowd work is performed with individuals from outside the company boundaries, in internal settings, the own employees act as an internal crowd to leverage the collective intelligence as part of their working time [3]. Internal crowd work has seen a substantial uptake in practice and has attracted a first wave of research papers and dedicated studies [2]. There is abundant research that exhibits the potentials of internal crowd work for organizations, such as fast access to internal knowledge [2, 4]. However, the perspective of employees – the individuals who act as internal crowd workers – has been largely neglected. Although few studies addressed the motivations of individuals working in the crowd, there is a gap in understanding experiences and perceptions of internal crowd workers [5]. While prior studies focus on efficiency and performance dimensions, systematic analysis regarding the intended or unintended ethical consequences of these new work structures

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

have been mostly absent [5]. Therefore, it is essential to better understand internal crowd work as a new type of digital work out of an employee's perspective. One well-established construct that is associated with the individual perception of work is empowerment which enhances work satisfaction [6]. Since prior studies shows that employees working in collaborative environments tend to be more satisfied [7], we believe similar effects to be present in internal crowd work. However, while satisfaction in crowd work has so far been examined mainly as a motivational construct [e.g., 8], we thus analyze the crowd workers' perceptions with regard to work itself to reconceptualize the phenomenon [9]. Thus, this survey seeks to fill the outlined research gaps by addressing the following research question: *How does empowerment affect the employees' satisfaction with internal crowd work?*

2 Theoretical Background

As theoretical lens of our paper, we apply the self-determination theory (SDT) that evolved from research on intrinsic as well as extrinsic motivations and expanded to include research on work organizations [10]. In general, SDT suggests that both individuals' performance and their well-being are affected by the type of motivation they have for their job activities [10]. There are several concepts of SDT that have been extended to work characteristics literature as important aspects of individuals' work [11]. In particular, work characteristics provide several core objective features (e.g., task, variety, task significance, feedback, or task complexity) associated with any job and further drive psychological states such as self-determination [12]. In this context, Seibert et al. [13] found work characteristics to be contextual antecedents of empowerment. In general, the psychological construct of empowerment examines individual experiences and intrinsic motivational aspects of the employee [14]. In particular, the subjective and individual interaction of the employees with the given work structures is investigated [15]. Against this background, the organizational structures (i.e., work characteristics) influence the individual interpretations of psychological empowerment.

3 Research Model and Hypothesis Development

Drawing on SDT [10], we unravel the mechanisms of how work characteristics affect satisfaction in internal crowd work. We assume psychological empowerment to be a mediator and thus to act as a mechanism through which the work characteristics influence satisfaction. On the one hand, internal crowd work initiatives provide a range of different tasks to be performed. On the other hand, due to the platforms automated evaluation and review processes, crowd workers receive direct feedback on their performance. Further, internal crowd work reflects an opportunity for employees to collaboratively work on more complex projects. Thus, we focused on *task variety*, *feedback from task*, and *problem solving* as work characteristics that are grounded in the very nature of internal crowd work. We expect employees who perceive high task variety, feedback from task and problem solving due to their participation to feel more empowered and further satisfied. In our case, we developed our research model in the context of an internal crowd work project of a Swiss bank. The bank is currently developing new software and usually integrates their employees in the testing of its internal applications. In sum, figure 1 depicts our research model.

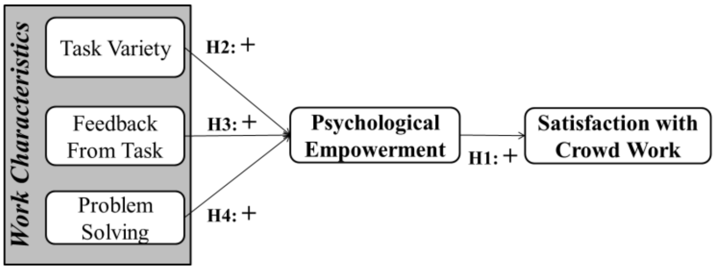

Figure 1. Research model

Previous research [12-15] has shown, that psychological empowerment can be regarded as mediating variable between structural work characteristics and job satisfaction. In this study, we assume similar effects since the voluntary testing of special internal software or applications enhance a feeling of self-determination and thus empower the employees. In turn, the employees might feel more satisfied due to their newly acquired freedom in task performance. Hence, we assume:

H1) *A crowd workers' psychological empowerment positively influences the satisfaction.*

As already mentioned, work characteristics seem to be associated with psychological empowerment [13]. Thus, we first introduce task variety that refers to the degree to which a job requires workers to perform a wide range of tasks [11]. Jobs of high task variety are more likely to empower subordinates since they break the chains of monotony [16]. In our case, the employees choose between various testing tasks (e.g., integration tests, interface tests, or security tests) that increase self-determination in daily work and foster satisfaction. Hence, we expect:

H2) *The positive effect of task variety on satisfaction is mediated by empowerment.*

The second essential characteristic is feedback from task that reflects the degree to which jobs provide direct and clear information about the effectiveness of task performance [17]. In this study, the employees receive direct feedback after the submission of their bug reports via the internal IT-platform. Thus, they are immediately informed about their testing performance and are better able to plan necessary next steps themselves. As a result, they are even more satisfied, which is why we suggest:

H3) *The positive effect of feedback from task on satisfaction is mediated by empowerment.*

Third, problem solving refers to the degree to which a job requires unique ideas or solutions and reflects the more active cognitive processing requirements of a job [18]. Jobs with high problem-solving requirements provide a chance for employees to perform in challenging, novel situations in which they are able to demonstrate their sense of competence [19]. In internal crowd work, the testing requires specific expert knowledge of employees [20]. In our study, the internal testers were asked to find all kinds of bugs within the new software. Since no best solution is specified in advance, the employees independently conduct explorative analysis. This procedure gives meaning to the testing tasks and thereby empower the employees. As a result, solving challenging tests might further increase employee's satisfaction. Thus, we assume:

H4) *The positive effect of problem solving on satisfaction is mediated by empowerment.*

4 Research Method

We conducted an IT-based survey to collect data from internal crowd workers within a Swiss bank. In sum, a total of 118 internal crowd workers provided a completed questionnaire (response rate: 46.8%). We used well-established and valid items for the measurement of work characteristics [11], psychological empowerment [14], and satisfaction [21]. To minimize extreme response and acquiescence biases, we include items with both positive and negative wording [22, 23]. We have already applied exploratory and confirmatory factor analysis to confirm validity and reliability of our measures. The measure of sampling adequacy was 0.78, indicating excellent applicability of exploratory factor analysis. We extracted 5 clearly interpretable factors. Since the values for composite reliabilities and the average variance explained surpassed the value of 0.5, convergent validity could be assumed [24]. As part of further analysis, we assume a mediation effect that describes when and under what conditions an effect occurs. Thus, we will perform ordinary least squares (OLS) regressions with a nonparametric bootstrapping approach to compute bias-corrected confidence intervals for testing our hypothesis [25, 26]. This allows us to investigate our research model while ruling out alternative models [27].

5 Expected Contributions

To our knowledge, this study is the first to investigate the nature of internal crowd work from an individual's perspective and therefore provides two main contributions. First, we gain information for a better understanding of internal crowd work [5, 28]. According to Rivard [9], we conceptually clarify the construct of psychological empowerment by examining its antecedents and effects on satisfaction, based on the individual perceptions of employees. Second, in line with prior research on SDT [10, 29], we unravel different work characteristics (i.e., *task variety, feedback from task,* and *problem solving*) as predictors of empowerment in internal crowd work. Thus, we illustrate that organizations can empower and even enhance satisfaction among their workforce by implementing internal crowd work. In sum, we believe that the employees might feel more self-determined and free in daily work due to their participation.

Abstract. The sale of blockchain-based digital tokens as a novel funding mechanism, referred to as initial coin offerings (ICO), has grown exponentially, resulting in $12bn raised globally during the first half of 2018. Due to the novelty of the phenomenon, the concept is not yet entirely understood. Existing research provides first insights into ICO endeavors and design only. To date, comprehensive and in-depth analyses of ICO design archetypes to better understand prevailing ICO characteristics are missing. We bridge this gap by enriching an existing ICO taxonomy and applying a cluster analysis to identify predominant ICO archetypes. As a result, we identify five ICO design archetypes: the average ICO, the liberal ICO, the visionary ICO, the compliant ICO, and the native ICO. We thereby contribute to a comprehensive and in-depth understanding of the ICO phenomenon and its implications. Further, we offer practitioners tangible design suggestions for future ICOs.

Keywords: Blockchain, initial coin offering, ICO, cluster analysis, design archetypes

1 Introduction

Emerging digital technologies challenge existing business structures and invoke innovation [1, 2]. As one example, blockchain forces organizations to rethink and innovate their business models. Thus, while the technology's potential is not yet entirely assessed and understood, we observe increasing interest in its vast use cases from both practitioners and academics [3, 4]. In the past years, a use case in the financial service industry is attracting high attention: sales of blockchain-based digital tokens as a novel funding mechanism, referred to as initial coin offerings (ICOs) [5-9]. Despite regulatory uncertainty [10-12], ICO fundraising has grown exponentially throughout 2017 (343 ICOs) and 2018 (394 ICOs in six months) [13]. Indeed, for the first half of 2018, the Wall Street Journal reports $12bn raised in the global ICO market [14].

Due to the novelty of the phenomenon, the concept of ICOs is not yet entirely understood [5], and a number of questions - especially related to regulation - need to be

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

answered in practice and academia. With regard to the ICO's inherent idea of providing open, global, and decentralized access to funding, regulation becomes very difficult [12]. Regulators and many governmental institutions have just started to take action in the so far mostly unregulated ICO market [7]. The regulation approaches, however, are neither homogeneous, nor follow an integrated global strategy. Thus, the actions range from banning ICOs to taking no action or focusing on specific ICOs only [15]. One major problem is the heterogeneity of ICOs, although there were first approaches of standardization [16]. Additionally, recent research indicates that the ICO success heavily depends on its design parameters [9, 12, 17, 18]. Therefore, in-depth analysis of ICO design variations is necessary to better understand the phenomenon and react appropriately from an economic, societal, or regulatory side.

In particular, Information Systems (IS) research and specifically sociotechnical research needs to address this information technology driven phenomenon and provide a systematic understanding, as there is a need to investigate implications of the technology [19]. Classifying the extremely heterogeneous ICOs into predominant, lucid archetypes, analyzing them, and thereby getting a systematic understanding of the emergent phenomenon contributes to the current body of knowledge. Further, it allows to establish a common understanding of ICO designs, related consequences, and the application for investors and ventures. Yet, scientific research in the young research domain of ICOs is still scarce [5, 12, 18]. Boreiko and Sahdev [9] provide an overview of the evolution of ICOs. Chanson, Risius and Wortmann [5] compare ICOs to traditional crowdfunding mechanisms and Fridgen, Regner, Schweizer and Urbach [7] propose a taxonomy to classify ICO characteristics. They furthermore suggest four possible ICO archetypes as a basis for future research. However, in the rapidly evolving ICO landscape, enhancing the taxonomy [7] by adding additional cases might reveal necessary amendments to the taxonomy and further archetypes that occurred after November 2017. Although these research projects represent first important steps into the emerging domain, to date, a comprehensive and in-depth analysis of ICO archetypes is missing. Therefore, the goal of our research project is to bridge the existing gap by empirically investigating and analyzing ICO archetypes and evaluating ICOs in a structured manner. Therefore, we define the following research question: *Which quantitatively derived and qualitatively interpreted ICO design archetypes do exist, and which design parameters do differentiate them?*

To answer this question, we conduct a cluster analysis upon the refined ICO taxonomy of Fridgen, Regner, Schweizer and Urbach [7], to initiate the next step in ICO research. Compared to this existing study, we find more reliable results by increasing the clustering performance. We conduct a two-stage clustering approach, which yields in more accurate results, as the final clusters do not depend on a random selection of initial cluster centroids. [20-22]. By doing so, we aim to make a twofold contribution: First, we propose empirically based archetypes obtained from a sound clustering methodology providing a comprehensive understanding of the ICO phenomenon and of related implications for individuals as well as economic or regulatory organizations. Second, we aim to allow practitioners to conclude on concrete design suggestions for potential future ICOs with regard to the consequences arising from specific design decisions.

2 Research Method

In this section, we give an overview on our overall research approach, and resume with a detailed introduction of our cluster analysis. To identify meaningful archetypes of ICOs, we perform a cluster analysis, in line with IS literature and the exploratory research setting [23-25]. A cluster analysis is a statistical technique with the aim to group entities of similar kind into respective clusters. The variation within groups is minimized, whereas the variance between groups is maximized [20, 21]. In general, cluster analyses are applicable to describe generic archetypes of entities [21, 26]. In IS research, according to an analysis of 55 IS articles, researchers chose this method regularly to classify observations of specific objects of interest [27].

The cluster analysis follows three basic steps: First, we select the clustering variables. In chapter 3, after giving a general overview on blockchain, ICO, and design archetypes, we therefore review existing research on ICO classification, including the ICO design taxonomy of Fridgen, Regner, Schweizer and Urbach [7]. Second, we determine the appropriate cluster algorithm. Finally, we apply statistical methods to confirm the reliability as well as the validity of the results. We report the application of the hereinafter described research method in chapter 4. The qualitative interpretation of the archetypes and the conclusion follow in the remaining two chapters, 5 and 6.

Variables: The selection of clustering variables represents a fundamental step in cluster analysis because it highly affects the outcome [28]. Following a deductive approach [29], the chosen variables need to be closely linked to extant theory [22]. For this purpose, choosing a taxonomy's dimensions is a commonly applied approach [23]. Therefore, we use the 23 dimensions of the taxonomy from Fridgen, Regner, Schweizer and Urbach [7] as distinctive variables. Some researchers propose to perform a factor analysis as a pre-process and use the resulting factor scores for the clustering [28, 30]. However, literature does not recommend this approach if the data is not suitable for factor analysis due to dropping factors may then result in suboptimal clusters [22]. Furthermore, using factors hampers the interpretability of cluster outcomes [31, 32].

A*lgorithm:* After the selection of the cluster variables, we select an appropriate clustering algorithm. The application of hierarchical or non-hierarchical algorithms is well-recognized. However, both algorithms have various limitations when applied in an isolated way [22]. Hierarchical methods (e.g., Ward's algorithm) are highly sensitive to outliers [21, 33]. Non-hierarchical procedures require pre-specifying a number of clusters, which is difficult in an exploratory study field [27]. Therefore, instead of choosing one method, researchers developed two-stage clustering to improve the clustering performance and to receive more accurate results - combining the advantages of both methods [20, 22, 28, 34]. As this represents the expert consensus among IS researchers [27], we adopt this two-stage clustering process.

Validation: As a basis for valid clusters, Hair, Black, Babin and Anderson [21] suggest finding significant differences between the selected variables for the developed clusters. Thus, we use cross tabulation analysis to identify which variables significantly contribute to the differentiation of ICO archetypes [26]. Subsequently, we conduct post-hoc tests to compare single clusters.

Data sample: To provide a comprehensive perspective on ICOs in this paper, we collect a data sample consisting of 84 ICOs with each 23 categorical data points along the taxonomy's dimensions. For this purpose, and due to the lack of an exhaustive ICO database, we create an ICO longlist through the lists published by token information providers that are perceived as most reliable in the blockchain community, such as ICObench [35], Coindesk [13], and SmithAndCrown [36]. Our sample includes ICOs from different industries and from all over the world in the period spanning from January 2013 to July 2018. As ICOs are rarely restricted to national borders and even intermix existing industries, it is very difficult to quote reliable information on the geographical origin and industry assignment.

3 Foundations

3.1 Blockchain, Initial Coin Offerings, and Design Archetypes

Blockchain is a decentral data structure that allows to store transactions immutably, chronologically, and transparently in distributed networks. Recently, a blockchain use case called ICO has become a popular alternative financing method for organizations [6, 7, 9, 11, 37]. This phenomenon emerges due to the rise of the second generation of blockchain and the establishment of smart contracts. Smart contracts are referred to as computer programs that allow to implement business logic tamper-proof in blockchains [38]. This enables the development and execution of programs that invoke secure transactions between two or more parties with no need of knowing and trusting each other [3, 33]. As smart contracts are also able to control digital assets, they enable the issuance and distribution of digital tokens that reside on top of blockchains [39]. This mechanism to create and transfer tokens is the fundamental part of any ICO. The funds raised during an ICO typically finance blockchain-related projects [40]. In this way, an ICO represents an alternative to crowdfunding in venture financing [8]. A substantial difference to crowdfunding, however, is the tradability of tokens on secondary markets. Tokens do not necessarily entail ownership of a firm but can fulfil various functions [9]. For instance, they might act as a digital share in a project or grant access to a blockchain enabled platform [41].

Since the surge of the ICO phenomenon in 2017, there has been increasing academic attention spent to analyzing various aspects of ICOs. Empirically, Adhami, Giudici and Martinazzi [17] analyze the success determinants of ICOs, gathering financial data and looking at theoretically obtained input variables. Amsden and Schweizer [12] as well as Fisch [18] propose a different definition of success including also the token's listing status. Based on these studies, Boreiko and Sahdev [9] propose a further definition of success, distinguishing between top ICOs, average ICOs, and failed ICOs. Li and Mann [11] focus on how an ICO increases social welfare and discuss governance mechanisms of an ICO thereby proposing guidance to regulators.

Furthermore, first research steps to explore the underlying classification of ICOs have been made by Fridgen, Regner, Schweizer and Urbach [7]. They applied a structured in-depth analysis of ICOs to develop a taxonomy incorporating 23 dimensions. In their research outlook, they are already able to identify four basic ICO archetypes. However, as their study is limited to k-means clustering, their results strongly depend on the selection of initial cluster centroids [20-22]. Additionally, as the cluster analysis deals with the special case of categorical data, a more powerful distance measure should replace Euclidean distances [42]. Finally, as their focus is the development of a taxonomy, their cluster analysis remains a descriptive only first step towards the differentiation of ICO archetypes. Since recent research indicates that ICO design parameters significantly influence ICO success [9, 12, 17, 18], it is of vital importance to understand and analyze predominant ICO archetypes. Soh and Markus [43] and Trice and Beyer [44] argue that the empirical identification and evaluation of archetypes is a suitable method to create understanding about multifold and complex new phenomena. Existing research indicates that a selected meta-characteristic can classify and evaluate ICOs, however, these classifications in current research draw on a rather conceptual basis [7]. Thus, building upon empirically validated design parameters and applying an in-depth two-stage cluster analysis, our study represents an important step towards a better understanding of ICOs.

3.2 ICO Classification

Since blockchain is a dynamic and a very young research area, design parameters of ICOs are continuously evolving. Therefore, we undertake a critical reflection on the taxonomy of Fridgen, Regner, Schweizer and Urbach [7]. We find its meta-characteristic *Design parameters and characteristics of ICOs* applicable for our study as it comprehensively covers both, the purpose of the taxonomy as well as the purpose of the archetypes we aim to investigate. However, it generally is a valid limitation of taxonomies that additional cases can possibly not be classified within the existing dimensions. This is why Nickerson, Varshney and Muntermann [45] require a useful taxonomy to be extendible when new types of objects appear. The restriction that taxonomies are collectively exhaustive implies that a taxonomy is not final but needs to be extended incrementally by including additional dimensions and characteristics in the course of time. Thus, we follow the advice of Nickerson, Varshney and Muntermann [45], and revise the taxonomy of Fridgen, Regner, Schweizer and Urbach [7]. From the conceptual perspective, we deduct the dimensions on the basis of related literature and of semi-structured interviews with ICO practitioners. From the empirical perspective, we iteratively examine our data sample of 84 ICO cases and classify them into the taxonomy. We find that some new characteristics and dimensions appeared in the ICO environment, and thereby add or adapt dimensions and characteristics when necessary to cover all ICO cases. As a result, we suggest enriching the model by adding further characteristics to two existing dimensions and by re-defining the characteristics of three dimensions. Table 1 shows the final overarching dimensions forming our theoretical framework.

Token purpose: To the current four token purposes, we add the two novel types *Equity security token* and *Non-equity security token*. Applying SEC regulation, a token represents a security if they meet all elements of the Howey test [46]. These include that the token embodies (i) an investment of money, (ii) in a common enterprise, (iii) with an expectation of profits [47]. An equity security token bears a dividend to the token holder, see for example the TAAS token. A non-equity security token behaves like a security but represents a loan for a specified time, and the founders are able to buy back the token, see for example the ZRCoin [48].

Team lockup period: Following IPO and Venture Capital literature, we apply the more common term *lockup* instead of vesting for the dimension, referring to the time window during which owners are not allowed to redeem their tokens [49].

Pre-sale before ICO: We add the characteristic *multiple* to the dimension, since the analysis of ICO cases reveals that some ICOs follow both, a private and public pre-sale.

Auction mechanism: Empirically, we observe the Dutch auction mechanism as the only implemented one so far, however different manifestations are possible. We therefore change this dimension's characteristics into *no* and *yes* thereby subsuming all kinds of theoretical auction mechanisms.

Funding cap: The analysis of ICO cases reveals that a specified soft cap does not necessarily trigger a remaining time limit of the ICO. It generally represents a minimum funding goal the team aims to raise in order to create a minimum viable product. Sometimes, analogous to the all-or-nothing mechanism in crowdfunding [50], if the ICO fails to reach the soft cap, the issuer returns all funds.

4 Cluster Analysis and Identification of ICO Archetypes

In this chapter, we apply the aforementioned research method and provide the quantitative results of the cluster analysis. We collect a data sample consisting of 84 ICOs with each 23 categorical data points along the taxonomy's dimensions. Since we select the taxonomy's dimensions as cluster variables, we need to avoid overweighting underlying constructs. This is an issue if the clustering variables are significantly correlated [22]. Therefore, we conduct a multiple correspondence analysis (MCA), which is as an extension of a principal component analysis for categorical data [51]. We obtain low eigenvalues of the resulting factors. This indicates that we should keep the initial 23 dimensions as clustering variables.

According to the chosen two-stage clustering process, the clustering algorithm starts with the hierarchical analysis. We apply Ward's method, which is the most commonly applied algorithm among the hierarchical methods [27] due to the production of reliable cluster results [23, 24, 52]. For the distance measure between categorical data points, literature recommends using the Jaccard, the Simple Matching, and the Dice coefficient [31, 53]. We test different measures and find that all produce highly similar results [23]. We then inspect the dendrogram and the scree-plot to determine the appropriate number of clusters [20]. This step reveals that five clusters represent the optimal number of clusters as any additional cluster would not significantly lower the total within cluster sum of squares. Additionally, we compute the average silhouette width and the gap statistic [54]. They both confirm the five-cluster solution. Next, we conduct non-hierarchical clustering with the results from the Ward's method as input to pre-specify the number of clusters. Among IS studies, researchers widely use the k-means approach with Euclidean distance measure [27]. However, research indicates that k-means is not the optimal approach to process categorical data since Euclidean distances are not meaningful on a discrete sample space [55]. Huang [56] therefore proposes a non-hierarchical clustering algorithm called k-modes, using a simple dissimilarity measure and substituting the means of the clusters with modes [33, 55]. The application of the k-modes algorithm to the dataset results in our five final clusters. Subsequently, we apply Pearson's χ^2 and Cramer's V, measures for the strength of a relationship, to analyze global differences across all clusters in the categorical data points [23, 24]. To compare single cluster differences, we use Pearson's χ^2 with correction for alpha inflation (Bonferonni style).

Table 2 provides an overview of the cluster analysis results. The results indicate the significant contribution of the taxonomy's ICO design dimensions chosen as cluster variables to the differentiation of ICO archetypes. The Chi-square reports significant values for most cluster variables, and the Cramer's V reports medium to strong association. The exceptions reflect some sales terms variables, i.e. the funding currency and the fixing of the price, closely related to the auction mechanism, as well as two time-related sales terms. Analysis reveals that the information gained from these variables is low, and there is low variation among clusters. We also conduct the clustering without these variables and received nearly identical results. Thus, in order to not lose information, we keep the variables in the taxonomy [45], as we perceive them as important dimensions in the overall characterization of ICOs.

Table 2. Results of cluster analysis

5 Analysis and Implications of ICO Archetypes

The cluster analysis grouped five distinct entities of similar kind with regard to the respective ICO's design characteristics, minimizing the variance within the groups. Due to the initial hierarchical clustering approach, which does not require to pre-specify a number of clusters, our analysis yields in a different number of clusters compared to the archetypes from Fridgen, Regner, Schweizer and Urbach [7]. Additionally, since our dataset also includes novel forms of ICOs, our five clusters differentiate more particularly with regard to the token terms including the token purpose. Each of these clusters thereby form a unique archetype which we investigate in the following.

Archetype 1: The average ICO. This ICO archetype represents the largest cluster. We perceive its characteristics as the most typical ones since it resembles the patterns of a traditional crowdfunding campaign. Based on top of an existing blockchain, the issuer raises a capped amount of funding. Capping the amount possibly avoids being perceived greedy and may mitigate the risk of regulatory attention [57]. A private pre-sale allows the issuer to raise money prior to the regular sale. The team can then focus on developing the product early, whereas the early investors benefit from a discount. This archetype implements a usage token providing access to a service or platform and does not transfer voting rights or company shares to the token holders. It therefore tends to target investors who are interested in the actual use case, i.e. the access to a service or platform provided, rather than e.g. investment returns.

Archetype 2: The liberal ICO. This archetype shows comparably less governance from issuers with regard to sales terms and issuer terms. It tries to maximize the target group of prospective buyers, since it does not require prior registration. Furthermore, it does not impose geographic restrictions nor restrict the access to accredited investors. Additionally, this archetype does not offer any pre-sale and there is no purchase amount limit. This indicates that the tokens are sold on a first-come, first-served basis without favoring wealthy or institutional investors. Thereby, we consider that this archetype corresponds the most to the truly global and inclusive blockchain idea [37]. This archetype partially includes those ICOs planning multiple funding rounds instead of a single round only. In venture capital, funding traditionally takes place in multiple rounds, one consequence is that the issuing team remains incentivized [58]. This is why blockchain experts also believe that an iterative funding approach could be the future of ICOs [59].

Archetype 3: The visionary ICO. In many of its design parameters, this ICO archetype offers several value propositions. The issuer grants voting rights to its investors which can thereby participate in the initiative's development. Additionally, the archetype sets lockup periods for the token share allocated to the issuer. These lockups prevent the team from selling their tokens directly after the closing of the ICO, which stabilizes the post-ICO token price [60]. Further, this archetype specifies both, a soft and a hard cap for the ICO. The announcement of a clear funding target range conveys the message that the issuer intends to raise an amount aligned with the expected costs of network development [57]. In many cases, the whitepaper specifies that all funds are returned to investors if the ICO fails to reach the soft cap [12]. This procedure reduces the investor's risks and indicates that the team links its funding tightly to the development costs. Thus, we conclude that this ICO archetype goes beyond being just a funding mechanism, but targets at investors that truly believe in the business model and its long-term success.

Archetype 4: The compliant ICO. The prevailing pattern in this archetype represents the regulatory orientation of the ICO design. By burning the unsold tokens post-ICO, the issuer keeps the percentages in token allocation between issuer and investors stable. Usually, the token burning benefits the token holders, since it decreases the total number of available tokens, and, consequently, may increase the value of each individual token [61]. However, a controlled appreciation of the token value may attract regulatory attention, since then the token could be considered as a security [62]. Another peculiarity of this archetype is the structuring of the issuing legal entity as foundation. Recently, there has been a trend in the ICO universe to divide the corporate structure into two separate entities, where a foundation runs the ICO, and another entity runs the business operations [10]. This enables the legal separation of the liabilities associated with the ICO. With regard to the sales terms, the issuer has more information and control over the investors as they need to register before they can purchase tokens. Additionally, pre-defined purchase limits restrict the token sale. Limiting the maximum purchase amount can enhance a wider distribution of the tokens, thereby preventing a token concentration of a single investor. A concentrated token share distribution could raise regulatory issues regarding secondary market trading. Thereby, we conclude that the design of this ICO archetype, more than others, takes into account the current regulatory uncertainty and seeks to comply with potential upcoming ICO regulation.

Archetype 5: The native ICO. Differences regarding the technical token terms predominantly characterize this archetype. In particular, the token implementation level represents a striking characteristic of this archetype. Whereas many tokens use the ERC20 token standard from the Ethereum blockchain, this archetype, however, distributes tokens that are native to their own blockchain. These tokens are often referred to as protocol tokens. They may be used as simple currency or might have other use cases, such as a stake to participate in a network. Often, the developers aim to create novel use cases based on these tokens. These innovative features appear to aim at overcoming challenges of existing blockchain solutions such as scalability [39]. Another unique characteristic in this cluster is the uncapped supply of tokens, so all investors are able to buy as many tokens as they desire. We conclude that this archetype comes with interesting specificities especially for blockchain enthusiasts.

Summarizing, we learn that the five archetypes differ from each other with regard to value propositions, target groups, and existing challenges. From an ICO issuer perspective, a key task constitutes the definition of a clear value proposition. This ultimately translates into the respective target group of investors. For example, designing an ICO similar to archetype 3, the visionary ICO, might also attract investors interested and engaged in the further development of the network. Many ICOs incorporate a liberal design, i.e. archetype 2, corresponding to the fundamental idea of the blockchain technology. Implementing a liberal ICO design, however, one might end up having investors exploiting the non-existing restrictions (e.g. money laundering purposes). From an investor perspective, it is of vital importance to know what the objectives of the ICO issuer are to better understand the token prize development. Being interested in the long-term vision, it might make sense to look out for ICOs with designs similar to the archetypes 1 and 3, the average and the visionary ICO. If an investor primarily seeks a promising financial return, investing into compliant ICOs as archetype 4 might be the right way. In that case, the ICO might attract higher regulatory attention due to the token burning that leads to a potential reduction of the investor's risk. Taking the amount of cases within each cluster into account, we observe that most ICOs currently do not consider regulatory issues. This may be due to the novelty of the phenomenon. Partly, the global nature of blockchain applications may make it difficult to consider the regulatory variety across countries. ICO issuers might therefore decide to ignore any regulatory aspects so far. This picture, however, is likely to change since the ICO phenomenon is attracting more attention recently, especially from the regulatory side.

6 Conclusion and Outlook

ICO as a novel funding mechanism represents a promising example of a blockchain use case that recently draws attention in both, research and practice. Although first research projects analyzed specific aspects of the emerging phenomenon, we poorly understand the implications of ICOs yet. Thus, in this research paper, we bridged this research gap and investigated ICOs with regard to their design parameters and focused on the identification as well as qualitative analysis of predominant archetypes. To do so, we first enriched the established taxonomy for ICO design [7] to account for recent developments in the fast evolving blockchain domain. Second, we used the taxonomy's 23 dimensions as clustering variables and conducted a cluster analysis on 84 ICO cases. As a result, we proposed five ICO archetypes which illustrate different combinations and dominant aspects within the ICO design parameters. Further, we examined these clusters and presented a qualitative interpretation for each archetype.

Before emphasizing our contributions to both research and practice, we acknowledge some limitations as well as highlight promising starting points for future research. First, we limited our sampling procedure to ICOs with exhaustive data available to allow for comprehensive structuring according to the taxonomy's dimensions. Second, we used a convenient data sample, which represents a representative share of the total ICO market only. Third, this paper only addresses ICO design parameters, rather than other ICO aspects, which have been examined in traditional crowdfunding literature, such as the business model and industry or the quality of marketing. These aspects should be subject to further research that might help to better understand the ICO phenomenon. Fourth, the ICO market is highly dynamic and most ICO issuers are startups. Thereby, token sale models are constantly evolving, leading to dynamic emergences of novel ICO design patterns. However, we strongly believe that our empirically obtained archetypes comprehensively describe the current ICO market. Finally, it also remains for future research to investigate how the fast developments of blockchain technology influences the future of ICOs.

The theoretical contributions of our research address the research gap in three ways: First, we provide a systematic and comprehensive overview on predominant ICO designs. We suggest five ICO archetypes with different value propositions, target groups, and challenges. The better fitting clustering method and the qualitative discussion and interpretation of the archetypes allow to abstract from single peculiarities of specific ICOs and enable thereby generalizable propositions. We therefore systemize the findings generated by Fridgen, Regner, Schweizer and Urbach [7]. Second, the archetypes extend existing ICO classifications by various aspects and allow for generalizable findings, instead of taking into account single characteristics. Third, we lay the foundation for further research in the area of ICOs. Since the archetypes are theoretically grounded on an existing taxonomy and empirically verified, they provide a more systematic and in-depth perspective on the phenomenon. This will help synthesize research on ICOs and identity promising research avenues.

Besides our theoretical contributions, our research provides practitioners with various backgrounds and perspectives on the ICO phenomenon. First, the classification into predominant archetypes may provide structured guidance for ventures that plan to conduct an ICO. Second, from an investor point of view, the archetypes can lead to more informed and grounded investment decisions. Third, for traditional financial intermediaries, including early stage venture capitalists or crowdfunding platforms, the enriched taxonomy and archetypes may help to characterize potential competitors. Fourth, our approach to structure the heterogeneous ICO market through design archetypes allows to reduce complexity, which may help regulators to perform regulatory tasks more effectively. This ultimately reduces the uncertainty in the market for all participants.

Abstract. In recent years organizations have started utilizing big data and advanced analytics not just to support decision-making to raise process efficiencies, but also to engage in new data-driven services. These data-driven services complement the current product and service portfolio and create additional value for customers. In order to capture the value created, organizations need to design sustainable revenue models consisting of a revenue (how) and pricing (how much) mechanism. In order to develop a deeper understanding of one part of the decision-making process on revenue models, we apply a qualitative study and analyze the results through the lens of rational choice theory. Based on the interviews, we derived four factors – service characteristics, provider interests, customer interests, and market factors - influencing the design. By this, we contribute to the general understanding of the design of revenue models and enable further investigation into this field of research.

Keywords: Big Data, Business Model, Revenue Model, Revenue Mechanism

1 Introduction

Every organization is concerned by the dawning era of big data analytics [1]. They are pushed to make use of data analytics to stay innovative and ahead of competitors [2]. Organizations mostly leverage data analytics to support their decision-making and improve process efficiencies, e.g. by continuously monitoring market trends to better allocate their sales force across different business units. However, in order to stay competitive in an ever servitizing economy, companies may use data analytics to create new products and services [3]. This can be achieved by either wrapping the product or service with data analytics [4] or by introducing entirely new data-driven business models [5]. Rolls-Royce, for example, has gone down the path of reinventing its service portfolio by enriching the use of a physical product – jet engines - with data analytics. By providing detailed product usage data (e.g. fuel consumption, temperatures, altitude), its customers can drive efficiencies in product usage [6].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Data-driven services are characterized by relying on data as their key resource and analytics to provide value to the customer. To take advantage of the value creation opportunities of these data-driven services, companies must design a suitable revenue model as part of their overarching business model [7–9] (cf. Figure 1). A process that is found to be a major challenge for organizations that approach datatization [10]. The question of how to design revenue models has already been challenging in the context of servitization and has not yet been answered conclusively [11]. Initial studies shed light on the availability and usage of revenue models for data-driven services in general [e.g. 11, 12]. Companies still need to decide which model is appropriate for their particular data-driven service. We want to investigate this decision-making process to approach this rather underappreciated field in research. In this explorative study we first investigate the decision-making process to build a better understanding of the factors influencing the choice of a revenue model. By that we aim to contribute to the general understanding of revenue models in the context of data-driven services. In particular, we contribute factors that represent an influence on the decision-making process for revenue mechanisms and we demonstrate that rational choice theory can be leveraged to explain our observations.

We initially focus on the analysis of data-driven services due to the current interest and demand in the market. In contrast to other services (e.g. air travel, maintenance services), data-driven services are characterized by being scalable through IT infrastructure and the fact that data, as a key resource, can be reused simultaneously at no additional cost [14]. Our research is guided by the overarching research question:

"What are the factors influencing the decision-making process for a revenue mechanism for data-driven services in a B2B environment?"

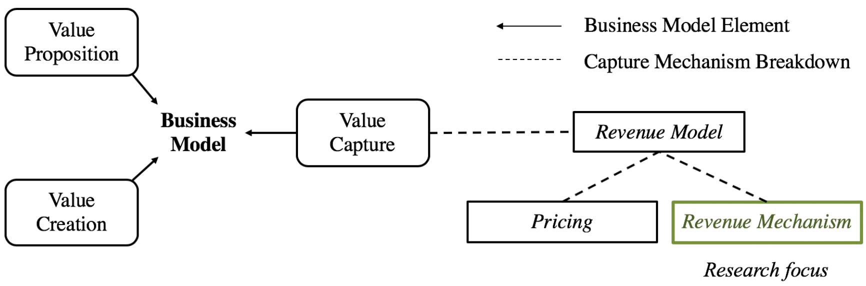

Figure 1. Research focus

We conducted interviews with 14 experts that were involved in the design of revenue models for data-driven services. By applying a qualitative content analysis and looking at the results through the lens of rational choice theory, we derived and analyzed four factors influencing the decision-making of the revenue mechanism for a data-driven service.

The remainder of the paper is structured as follows: section 2 introduces data-driven offerings and elaborates on the current state of research on revenue models. Section 3 illustrates how we collected data and the means of analyzing it. The results of our interview study are being presented in section 4. The paper closes with a brief summary, discussion, study limitations and managerial implications in section 5.

2 Related Work

In this section, we give a brief introduction to data-driven offerings and revenue models. Furthermore, we show that there is a need to develop an understanding of the factors that influence the choice of a revenue model.

2.1 Data-Driven Offerings

With the ever-increasing amount of data being generated, many organizations have realized that there is value hidden within this data. Often, data is generated as a byproduct of other activities e.g. through the use of sensors that connect the digital and physical world [15, 16]. An increasing amount of enterprises are making use of that data by developing new data-driven services or shifting their entire business model to be more data-driven. For instance, machine manufacturers start collecting real-time product usage data in order to move from reactive to predictive maintenance activities to reduce the costs of downtime [17].

Exploring the field of big data and its applications, e.g. for developing data-driven offerings, is not new. For instance, Manyika et al. [16] provide a broad overview on how the use of big data and services impact innovation, competition, and productivity. Chen et al. [15] explore ways in which insights derived from the use of big data can have an impact on different domains while highlighting the importance of the evolution of business intelligence and analytics over the past decades. Hartmann et al. [5] develop a taxonomy of data-driven business models and argue that the effective use of big data, e.g. by offering purely data-driven services, could lead to a competitive advantage. In their recent work, Wixom and Ross [4] propose three ways for enterprises to monetize their data: internal improvements, wrapping, and selling. They argue that besides deriving internal efficiencies, organizations can engage in becoming an information business by using data analytics to offer stand-alone services (selling) or to enhance the value of an existing core product or service through analytics (wrapping).

As organizations start developing new data-driven offerings, the question on how to capture the value of such offerings emerges and organizations are still struggling with answering it [10]. Revenue models describe the mechanism to capture this value and function as a critical component of the overall business model of the organization [18].

2.2 Revenue Models for Data-Driven Offerings

Literature on revenue models offers a multitude of perspectives on what they are: “revenue streams” [19] “pricing mechanisms” [20] and “payment model” [21] are some of the most common ones. While some of them have a customer view (e.g. payment model), others focus on the way the service provider captures an offering’s value (e.g.

revenue streams). Eventually, the meaning of a revenue model boils down to being a mechanism to capture the value of a good or service [8]. The definition of a sustainable revenue model is crucial for the viability of a business. Therefore, scholars agree that the revenue model is a critical component of the overall business model [7, 18, 22, 23].

The revenue model describes an overall architecture, which essentially consists of two key elements: revenue mechanism and price setting [8]. While price setting deals with how much to charge for a service or product, the revenue mechanism targets the question how to charge. The process of pricing a new product or service usually follows one of three approaches: cost-based, competition-based or value-based pricing. Since pricing is a complex field of research by itself, our study focuses on the decision-making process of revenue mechanisms. A study conducted by Schüritz et al. [12] provides an initial overview of the revenue mechanisms most commonly used by organizations offering data-driven services: in the availability-based model, also called subscription model, customers pay a service fee for a particular time period in which the service is being made available – independent of how much the offering is essentially used during that period [24, 25]. In contrast, a usage-based revenue mechanism only allows the provider to earn revenue when the service is actually used by the customer. This requires the definition of a unit of measure for the service to be charged [26]. Another model is so-called performance-based; in this case, the compensation of the provider is dependent on outcome generated for the customer [27, 28]. Also, multi-sided revenue mechanisms exist; they involve two or more interdependent customer groups. Google Adverts is a popular example of this model since it acts as a 'hub' that connects an advertiser and an end customer indirectly.

Data-driven services may also be used as a free add-on to an existing product or service. In such cases, the organization has chosen an indirect payoff model since the service is paid for by the revenue stream generated through the core offering itself.

Previous studies, such as the one conducted by Schüritz et al. [12], have shown that organizations have deployed various revenue mechanisms. However, little is known about the decision-making process that lets an organization select a revenue mechanism and reject others. A recent study conducted by Sprenger et al. [13] sheds a light on this topic by exploring the evolutionary changes of revenue mechanisms for digital offerings to support managerial decisions. The scholars suggest that the choice of the most suitable revenue mechanism depends on (1) the type of digital offering, (2) the stage of evolution and (3) six additional constrains. However, most research conducted on the topic of revenue models for digital businesses focuses on pricing decisions [29] or explores the trade-off between free vs. paid approaches for digital content [30].

While the work conducted by Schüritz et al. [12] and Sprenger et al. [13] sheds some light on revenue mechanisms for data-driven services in general, no conclusive work has been done to understand the decision-making process on revenue mechanisms.

Picking a revenue mechanism is a decision made on an organizational level. Nevertheless, it always comes down to an individual or group of individuals deciding. The process of determining which options are available, then choosing the most preferred one is widely discussed in rational choice theory. Individuals aim to maximize their utility (u), which can be understood as the organization's objective such as profit or revenue maximization. Since employees are incentivized to contribute to the firm's objective, e.g. through bonus payments, they adopt this view in the decision-making process. Choosing among alternatives A = {a1, a2,…,aj} is further guided by personal preferences and constrains, which may help us in understanding how decisions are made [31].

3 Research Design

To get a better understanding of the factors that influence the choice of a particular revenue mechanism for data-driven services, we follow a rigorous qualitative research process that is based on a set of interviews. Despite the fact that this study leverages procedures strongly associated with the grounded theory methodology (GTM) (e.g. open and axial coding), it omits elements such as memoing and theoretical sampling [32]. Therefore, we consider our approach for data collection and analysis a qualitative content analysis based on Krippendorff [33] and Bengtsson [34].

3.1 Data Sources

In order to understand how providers of data-driven services have designed their revenue model, we needed to collect data that gives us precise information on all the influencing factors, which were considered during the decision-making process.

In a first step, we collected data of publicly available cases from service providers that offer data-driven services in a B2B context (e.g. through websites, customer references, and news articles). Our working assumption is that the results of this study may differ when looking at B2B vs. B2B services. For this reason and limitations in resources available, we initially focus on one type only. The identified use cases served as a pre-study to inform next steps of our research. In particular, we were able to define more specific criteria for the sampling of interviewees and for the development of tailored questionnaires. Since the data collected through the case analysis did not provide enough detail to derive reasons why particular revenue models have been chosen, we decided to collect data by conducting a series of interviews with representatives of service providers that offer data-driven services and that were involved in the decision-making process.

Our prior collection of service providers of data-driven services served as sample frame for our interview study. All of these companies have already implemented data-driven services and have gone through the decision-making process of selecting a revenue mechanism. For the sampling of the interviewees, we followed a criterion-i purposeful sampling approach [35]. The criteria were defined that only representatives, who were directly involved in the decision-making process are subject of interest for interviews. We therefore focused on approaching the product managers and heads of service for the particular data-driven service via LinkedIn. The expected small number of respondents were either themselves available for an interview or forwarded our request to a colleague with better insight in the design of the revenue model. This approach has yielded a total of 14 interviews, which have been conducted in the time frame between August 2016 and June 2017. The interviewees hold various positions within their organizations such as product manager, head of service and head of innovation. The focused data-driven services are offered by global leaders in the fields of manufacturing, IT services, logistics and telecommunications. An overview of the interviewed organizations partners is given in Table 1.

Table 1. Overview of interviewed companies

Company	*Revenue (2017 in bn €)*	*Employees*	*Countries active*	*Number of interviews*
Manufacturing I	3,8	11.000	50	1
Manufacturing II	84,3	370.000	>150	1
Manufacturing III	0,8	3.500	40	1
Manufacturing IV	78,1	400.000	60	1
Manufacturing V	4,2	19.000	60	1
Manufacturing VI	3,6	13.500	70	1
Manufacturing VII	43,0	160.000	79	1
Manufacturing VIII	8,7	61.000	>100	1
Teleco	52,0	130.000	24	2
IT Services	1,0	7.000	7	2
Logistics[1]	164,3	290.000	>150	2

In order to create an open discussion situation in which the interviewee is willing to discuss the topic, a semi-structured interview approach is chosen. The questions asked during the interviews covered four themes: motivation to introduce a data-driven service, service type offered, revenue mechanism selection, and pricing strategy. While all of the sections contributed to the results of the study, the focus lay on the third one: revenue mechanism. Interviewees were asked why they selected a particular model and why others were rejected. The interviews took place in two phases: the first set of eight interviews were used to explore the inquiry and inform phase two, allowing for a set of more in-depth questions. In the subsequent set of interviews, the same questions as in phase one were asked and, additionally, some assumptions derived from the initial interviews were explored. Most of the interviews have been conducted over the phone with few exceptions where in-person meetings were made possible. Interviews have been transcribed except for one case in which the interviewee preferred the researcher to take notes.

3.2 Data Analysis

The 14 interviews are analyzed using qualitative content analysis. In this particular case, two coding cycles are conducted: to account for the explorative nature of topic, we pick an open coding approach for the first iteration, followed by axial coding [36]. The software MAXQDA is used to support this work.

[1] Figures refer to the parent company of the organization interviewed

In the first iteration, we start with no pre-defined list of codes. The transcribed interviews are labelled according to our research objective, identifying all factors that are influencing the choice of the revenue mechanism. Initially, 32 different codes are identified by the researchers. In a subsequent step, codes are grouped into categories and subcategories by two researchers in a workshop. The outcome of the coding of the first eight interviews serves as an input for the next interview set.

For the second iteration, we choose an axial coding approach. This step ensures that the codes identified in the first iteration are reassembled and that categories and sub-categories relate to each other accordingly [37]. Glaser [38] stresses the importance of this step since it requires sharpening the code for achieving its best fit. The final number of interviews we conducted was driven by our sampling criteria and by the availability of the interviewees during that time. Furthermore, we did see a saturation in the data in the final interviews.

Finally, to verify the results, we ask two independent researchers to code all interviews again based on the coding structure derived from the second coding cycle. To ensure objectivity and validity of the results, we calculate the intercoder reliability as an indicator of measurement consistency. An 85% mapping of the coded segments ensures a high confidence level in the results. Discrepancies between the researchers are discussed until an agreement is reached.

4 Influencing Factors

Designing a revenue model is a critical part of releasing new offerings to market as it describes the process of capturing the value of the offering. In some cases, the revenue model may even decide if the offering becomes a success [7]. Therefore, the decision for a particular revenue model is of high importance. Based on our interviews, we understand that there are two key decisions the provider has to make: how (revenue mechanism) and how much (price) to charge the customer. Unlike for the design of a product or service, we could not see formal processes or methods in the organization to decide on a revenue model, but we identified a series of factors that influence the decision-making process. When looking at an organization as a decision-making unit, the factors can be regarded through the lens of the rational choice theory (RCT) as preferences and constrains that inform the decision-making process. RCT postulates that the agent (an individual or organization) aims to maximizing the outcome of a rational decision while having the choice among multiple alternatives. The maximization of the net benefit, or utility, is driven by the benefit and costs as well as the level of risk that arises [31]. While the service provider eventually is the one to make the decision on the shaping of the revenue mechanism, decision-making on the customer side (i.e. purchase vs. non-purchase of a service) also needs to be taken into account. This means that both, the provider and the customer, intend to maximize their utility. In the following, we draw parallels between the decision factors identified and notions of RCT.

We have identified four groups of factors: service characteristics, provider interests, customer interests, and market factors. The revenue mechanism is chosen for a specific data-driven service, which is driven by certain characteristics. We can see that these specific characteristics itself have an influence on the choice of the revenue mechanism. Further, both provider and customer have individual interests and preferences regarding the revenue mechanisms that influence the choice. Finally, provider and customer interact in the context of an industry or market, which may have an influence on the selection of the revenue mechanism as well.

4.1 Service Characteristics

Data-driven services are such that rely on data as their key resource and analytics to provide value to customers. The offered services, however, may substantially differ from each other: for instance, there are heavy equipment manufacturers that start providing monthly usage reports to the operator of the machines for predictive maintenance purposes or a mobile phone network operator that provides targeted advertising services based on customer movement data. The nature of these offerings in itself can differ substantially and have an influence on the selection of the revenue mechanism. We identified two characteristics that play a role in the decision-making process: the usage pattern and the level of integration with a core product or service.

The usage pattern describes the frequency the customer actually uses the offering, which is often defined by the service itself. For instance, an alarm service of machinery that has to continuously monitor and process data in order to detect abnormalities. Hence, the data-driven service is provided continuously and adds value not just at a certain point in time. The choice of the revenue mechanism should therefore reflect that value for the customer is created on a continuous basis. The product manager in manufacturing company IV emphasizes this point using a different example: "(…) for a dashboard service, a pay-per-use model does not make sense since looking at the dashboard once represents a use. But this is not how a dashboard works. Dashboards show changes over time and need to analyze data continuously." In scenarios where the value of a service is usually derived from using it occasionally, e.g. generating a quarterly report on energy consumption from a utility provider, other revenue mechanisms may be more appropriate to use (e.g. usage-based).

Further, the integration with the core offering influences the choice of the revenue mechanism; i.e. the extent to which the data-driven feature is integrated with a core product or service. Data-driven offerings may be provided as a stand-alone service such as a navigation app on the smartphone or integrated with a core product or service such as system status monitoring for an elevator. A high level of integration between the data-driven service and the core offering makes it often difficult to distinguish the value created through the data-driven service from the one created through the core product or service. In such cases, services are often not charged separately and more likely to be charged indirectly through the revenue stream of the core product or service. With a decrease in the level of integration between the core offering and the data-driven service, there is an increase in the likelihood that an additional and therefore separate revenue mechanism for the data-driven service is chosen by the provider.

4.2 Provider and Customer Interests

Undisputedly, the provider of a product or service has an interest in capturing the value created by their offerings - not just to cover the costs but to create a sustainable business model with attractive profits. On the other side, customers that benefit from the offering and see how value is created for them are willing to pay for it. Therefore, the interests and preferences of the provider and the customer have an influence on the selection of the revenue mechanism. There are four dimensions – economical, relationship, capability, and common practices – within this group of factors that influence the choice of the preferred revenue. Economic objectives describe how financial targets that the provider and the customer deem relevant to their business strategy can influence the selection of a revenue mechanism. The relationship perspective between the two parties focuses on the level of trust and therefore supports or inhibits the implementation of certain mechanisms. Based on technical and knowledge capabilities, particular revenue mechanisms are enabled or prevented. Further, common practices outline habits and preference of the provider and customer for a revenue mechanism design.

Economical. While overarching financial objectives of organizations include the maximization of profits or revenues, operational targets can influence the selection of the revenue mechanism for data-driven services. Depending on how the management team sets these targets, certain models are more advantageous to implement than others. A project manager from an IT service company stresses the challenge in this: “Yes, we have also thought about it [a usage fee model], but we noticed that [with this model] we would place ourselves in a less favorable position (…) because of the usage behavior (…).” Financial objectives among our company sample vary broadly - even within one industry. Some organizations have a strong focus on ensuring that they have a quick and reliable return on investment since the setup of data-driven services often requires substantial upfront investments. For example, a product manager in manufacturing company II notes: “(…) I have to think from the perspective of a supplier. I must get a return on my investment. And for that reason, it is not important for me, if he [the customer] looks at the dashboard one time or one hundred times.” Consequently, the provider choses a mechanism where it can achieve a short-term return on investment. Furthermore, the ability of organizations to plan future cash flows with certainty is significant; organizations therefore oftentimes prefer mechanisms that have a fixed payment schedule (i.e. subscription model): “(…) a recurring payment is always attractive, simply because we have more predictable revenues, this holds true for the customer as well as for you, you have a continuous revenue stream, too. This way, both sides, provider and also user can plan the whole thing in a better way.” (Business Development Manager – Telco Industry). Providers need to ensure that running costs (e.g. server infrastructure) are covered; this is especially relevant for data-driven services that require to be available around the clock. Examples include the availability of a dashboard or an alert service. Subscription models are an example of a revenue mechanism that allows the provider to cover these running costs with a high level of certainty while e.g. usage-based models could lead to a gap in the revenue stream since they are less predictable.

Customers prone to risk avoidance may have an increased need for spending money in a very conscious way; i.e. customers only want to pay for the service when it is needed. A usage-based model is an example of a mechanism that supports this objective. Consequently, we can infer that the level of risk averseness of the provider and the customer alike define a personal preference in the decision process and therefore impact the order of preferred choices.

Relationship. The way the provider and customer regard and behave towards each other defines their business relationship. It is in the interest of the provider to build a long-lasting relationship in order to maximize the customer's lifetime value. The level of trust between the business partners is one factor that influences the strength of the relationship. Building trust into the provider to deliver the service in quality comes over time and sometimes requires the provider to give away a service for free at first before being able to charge for it. A product manager in manufacturing company I notes: "(…) we have done it in a way where, after installing the heavy equipment machinery, we offered it [the service] for free for two years and then started charging for it". The quality of the relationship, hence, enables or inhibits the use of certain revenue mechanisms. For example, a performance-based revenue mechanism can only be applied if there is a high level of trust: "(…) as long as I cannot prevent, on a technical level, that nobody can manipulate [results], in their favor, then such models [performance-based] are only possible with mutual trust" (Product Manager – Manufacturing Company VI).

The examples show that the state of the relationship between the partners has an impact on the choice of the revenue mechanism and therefore acts as a constraint in the process. Providers can treat customers fairly and build a trusted relationship to ensure ongoing revenue streams or follow a strategy to extract the maximum amount of revenue and profit from the client while accepting that it may not return for re-purchase.

Capabilities. The complexity of a revenue mechanism and its initial definition, implementation and monitoring can vary broadly. Simple mechanisms, such as a subscription, are often better received and understood by the customer compared to more complex constructs (e.g. performance-based). Furthermore, a lack of availability of knowledge and tools to implement the more complex models further limits the selection of revenue mechanisms available. Therefore, the existing capabilities on provider as well as customer side enable, limit or restrict the implementation of revenue mechanisms. The head of technology of an IT services company describes these limiting constraints in the choice process: "We didn't have an advanced or automated billing system to do usage-based or performance-based billing, so we just charged customers based on a simple monthly subscription in the contract agreement – which was simple for everyone to understand, and also simple to implement."

Data-driven services offered by the provider support one or multiple business processes on the client side. In order to setup more complex revenue mechanisms (e.g. performance-based), the client has to have a good understanding of how the service interacts with its processes and impacts business outcomes. If this is not given, more simple revenue mechanisms should be applied (e.g. subscription model).

Common Practice. We identified three levels where habits and common practices influence the choice of the revenue mechanism: individual, organizational and industry. On an individual level, we can observe that personal preferences of the person in charge of making strategic revenue model decisions plays a role. The person may transfer personal experience into the business environment and require a service to be offered in conjunction with a particular revenue mechanism.

Within an organization, there is a tendency to apply the same revenue mechanism for new data-driven services as has been done for existing ones. On the one hand, capabilities and processes for the implementation of existing revenue mechanisms are likely to be already in place and, therefore, a smooth implementation can be ensured. The introduction of a new model, on the other hand, oftentimes requires the definition and implementation of new processes, which may create additional risk of failure both for the provider and the customer. Hence, similar to the economical perspective, the level of risk avoidance and therefore a personal preference is a driving factor for the choice of a revenue mechanism.

On an industry level, customers expect the availability of certain mechanisms as a consequence of being common practices. For example, customers may expect a service to be offered for free when an expensive piece of heavy equipment machinery is purchased. An interviewee from manufacturing company III explains: "(…) it's sometimes difficult to point out to the customer that he should pay so much for this [the service], because says, 'if I buy such an expensive machine from you, then it [the service] should be included'" (Head of Innovation/Strategy - Manufacturing). This describes a scenario where the service is bundled with a core product – described as "wrapping" by Wixom & Ross [4].

The shift of common practices and therefore the preference of customers within an industry can also require the provider to introduce new and unproven revenue mechanisms. For example, the customers' intent to shift the risk of service fulfilment and success towards the provider. An example of a revenue mechanism that helps achieve this objective is the performance-based one since the provider only gets paid in case of proven success. Failure of a provider to offer a revenue mechanism that enables the shift of risk towards the provider side may inhibit the sale of the service.

Despite the fact that the provider is the one to make the final decision on the revenue mechanism design, customer preferences need to be considered by the provider. Failure to do so may result in customers choosing the offering of a competitor or not making a purchase decision at all, which, in turn, impacts the net benefit of the provider.

4.3 Market Factors

While provider and customer are most directly involved in the value creation and value capture of the data-driven service, they do not interact in a vacuum. There can be additional players involved that have an influence on the selection of the revenue mechanism. The behavior of competitors can urge the provider to offer one revenue mechanism over another. Further, the collaboration with partners in an ecosystem may require the provider to align its revenue model design with that of other players.

Therefore, market factors are to be considered a constraint in the decision of the agent and, according to RCT, limit the number of choices available to maximize utility.

Competitors. While it is often difficult to compare data-driven services between providers due to their unique and new character, bidding situations sometimes allow to observe what competitors offer. In addition, some revenue mechanisms may be more frequently used than others. An interviewee describes this as: "This is common in this industry" (Head of Innovation/Strategy – Manufacturing Company III). Being able to offer a revenue mechanism that is not common (e.g. performance-based) in a particular setting or industry may be recognized as a competitive advantage since special capabilities are often needed for the implementation.

Partners. Oftentimes, providers of data-driven services do not have the internal capabilities to develop and run a service on their own (e.g. hosting & connectivity services) and hence are required to collaborate with sub-providers. Therefore, the provider is urged to pick a revenue mechanism that ensures a continuous cash flow (e.g. subscription model) to cover ongoing obligations towards its own partners. The product manager of manufacturing company I describes this using an analogy: "(…) like the landlord of a building has to decide which costs to absorb and which to pass on to the tenants [to remain solvent]."

Many services nowadays are sold through 3rd party platforms (e.g. Apple Store, Google Play Store). These platforms may constrain the revenue mechanisms that are allowed to be used through contracts with the provider of the data-driven service. In addition, offering bundles offerings with a sales partner may further constrain the choices since the strategy needs to be aligned with other parties' expectations.

5 Conclusion

In summary, our research explored the factors that influence the selection of a revenue mechanism for data-driven B2B services. In order to do so, we conducted 14 expert interviews and analyzed them by applying open and axial coding. This led to the identification of four influencing factors: service characteristics, provider interests, customer interests, and market factors. Provider and customer interests as well as market factors are further broken down into subcategories to account for the specifics of each influencing criterion.

Each of these factors influence the provider when designing a revenue mechanism. The particular shaping of some factors even enable, hinder or promote certain revenue mechanisms (e.g. the lack of technical capabilities or knowledge to define a unit of measure inhibits the implementation of usage- or performance-based models). The choice of a revenue mechanism requires the provider to synthesize all available information and to decide on the best strategy for the situation at hand.

Our contribution with this paper is two-fold: on the one hand, we derive factors that influence the decision-making process for revenue mechanisms for data-driven services, and, on the other, we point out a set of initial schemes on the direction that each factor may influence a decision for or against a particular mechanism. With this, we contribute to the general understanding of revenue models and lay the foundation for more elaborate research in the field that could eventually help identifying the appropriate revenue model for a data-driven service.

5.1 Discussion

Looking at the influencing factors derived from the interviews through the lens of rational choice theory shows that a major part of the results (provider and customer interests, market factors) can be explained by either personal preference of the decision-making unit – informed by their attitude towards risk - or a constraint. However, not all results can be linked to RCT: service characteristics shape a category of their own and therefore stand out from the rest. These insights extend the knowledge in the field of revenue model research for data-driven services and contribute to developing a better understanding of decision-making for such services. It shows that the characteristics of the service being offered has a particular impact on the revenue mechanism. Thus, there is an opportunity to identifying the most appropriate revenue model for a particular service. Our study extends extant literature in the field of data-driven service research and provides the basis for more research in this space.

5.2 Managerial Implications

The implications of this study for practice are relevant in such that the design of the value capturing mechanism, which the revenue mechanism is a part of, has an influence on whether an offering becomes a success for the organization or not. Our results show that the selection of the revenue mechanism is a complex and critical endeavor due to the number and variety of factors that need to be considered. We have shown that some of the factors not only call for the use of a particular revenue mechanism, but that they can also preclude their use. Organizations should be aware that not only their own interests, but an entire ecosystem of influencing factors play a role when designing an overarching revenue model for data-driven services.

5.3 Limitations and Future Research

Despite applying a high level of rigor, our analysis is not without limitations. The services analyzed in the context of this study all apply to business-to-business transactions. We encourage to repeat this study taking also B2C services into account and to compare the results. Furthermore, our sample was limited to a total of four industries. Extending the study to additional industries would allow verifying the results in a broader context.

We encourage future research on the topic of revenue mechanisms for data-driven services. From our point of view, there are several areas that would benefit from further research. For once, our study focused on the identification of influencing factors for the selection of revenue mechanisms, however, future research could further explore the importance of each of these factors; i.e. to conduct a quantitative study on the subject.

A further avenue to explore is to develop an understanding if the factors identified also hold true in the context of B2C offerings since we focused B2B offerings in this study.

Abstract. Data have become a key ingredient for ICT-enabled business models. Nevertheless, there is great uncertainty among scholars and practitioners alike about how to leverage data as an essential innovation resource. This raises the question of how to design data roles to innovate business models. To answer this question and to facilitate a deeper, cause-effect-relation understanding of the interdependencies between data roles and business models, system dynamics was chosen as the approach of analysis. Within a multiple case study of five business model cases with multiple embedded units per case, the study shows that there are four recurring basic data role patterns e.g. 'incremental improvement' or 'initial data boost' and two data role characteristic patterns, describing how data roles unfold within business models e.g. 'change in self-reinforcement' pattern. Overall, the patterns help to visualize and articulate data usage in business models and therefore contribute to the ongoing endeavor of innovating business models.

Keywords: Business Model Innovation, Big Data, System Dynamics, Data Role Patterns

1 Introduction

In the course of increasing digitalization, information and communication technology (ICT) has become both an enabler and constraint for new business models (BMs) [1]. ICT-enabled and dynamic business processes require a constant adapting and reshaping of BMs to cope with the continuously changing business environment across all industries [2, 3]. As a key ingredient or even ignitor for ICT-enabled innovating of BMs, 'digital data' have increasingly gained importance [4, 5]. This paper aims at facilitating a deeper understanding of how data innovate BMs, and shows the impacts of data on BMs. For this purpose, the paper examines the design of data roles, which are resulting from the usage of data to achieve an overarching business goal, e.g. efficiency gains through process transparency using IT systems, in order to innovate BMs. The term 'data roles' describes on a cause-effect-relation basis the task and underlying concrete impact of data on the elements of a business model (BM). Going one step further, the study enriches information systems (IS) research, with outlining

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

the reciprocal relationship between IT-capabilities, the choice of data roles, and the interlink to BM configurations. Thus, the paper positions itself at the vertex of IS and business model innovation (BMI) research, because so far literature largely and particularly discusses how to make data consistent with business strategy [6], reflects the opportunities of leveraging data to innovate existing BMs, outlines how to build completely new BMs [7] or internet-based BMs [8], and addresses constructing and implementing data related adaptions and amplifications to existing BMs [4, 9, 10]. However, in order to be able to build completely new 'data-based' BMs [11], an awareness on how to design data roles to innovate BMs with consideration of data impacts on the BM is required. The failure of building these completely new BMs may be ascribed to a lack of knowledge regarding BMs and the concatenating management of digital data as an essential resource to innovate BMs. This is not a surprise due to the specific and partly fuzzy characteristics of data which make data as a resource difficult to manage [12, 13]. Because of these complex data characteristics, it is not sufficient to give way to simplifications and generalizations [14, 15] at the endeavor to understand the role of data to innovate BMs. Moreover, to grasp non-linear, cause-effect-relations between data roles and BMs, a novel data-focused perspective on BMs is required. To meet these requirements and to provide managers and scholars an advanced understanding of the dynamic data roles behind the static BM story, illustrated as target images in a BM (data) canvas [16–18], a dynamic and conceptual representation method is premised. System dynamics - a computer-aided approach to enhance analysis and decision making for complex systems [19] - turns out to be a suitable approach for this, due to it's potential of simplified and consistent representations of BMs, including quantified considerations of feedback loops and delays between the individual BM elements [20]. In case of our study, the interrelations and feedbacks between data roles and BMs are focused. With use of the system dynamics approach the study seeks to answer the following research question: ***How could data roles be designed to innovate business models?***

2 Theoretical Background

2.1 Innovating Business Models

According to Shafer et al. (2005) [21] the study's central subject of matter – BMs – are defined as 'the firm's logic of creating value'. Although many authors conceptualized a holistic view on the logic of a firm's value creation by outlining consolidated components of a BM, a common understanding is not overarchingly achieved [22]. Examining the most cited publications on this topic one may conclude that there is common understanding among the following three components within the BM definition [11]: value proposition, value creation and value capturing [10, 23–28]. Gassmann et al. (2014) [17] breaks these three components down to four fundamental BM questions: "Who is my target customer?", "What is offered to the target customer?", "How to build and distribute the value proposition?" and "Why is the BM financially viable; what value is generated?" As the hackathon artefacts A1 and A4 of the empirical field (see figure 1) are based on the BM definition of Gassmann et al.

(2014), the BM understanding of this study is oriented on the conceptualization of the BM components: How (value creation), what (value proposition), value (value capturing) and who (key customer). Since the emergence of the internet economy the topic of innovating BMs has gained much popularity [29], and BMI can be seen as a subordinate BM research stream. With the opportunities of the internet and the accompanying ICT, firms obtained a broad armamentarium to completely change the rules of competitive environment [30] by approaching the customers with entirely new, data-based BMs [31]. However, innovating BMs remains an ambiguous concept. Thus, different research streams consider BMI either as a process (e.g., search, experiment, transformation), while another stream see BMI as a output. [32]. As our research is based on a hackathon where 171 students innovated BMs by initiating and ideating new BMs based on the firm profiles, capabilities and existing BMs, we understand BMI as a process. This is in line with the research question *"How could data roles be designed to innovate business models?"*, which also provides support for the ideation process of innovating BMs. Furthermore, system dynamics as a dynamic BM experimentation, modelling and simulation approach also understands innovating BMs as a process. In comparison, most conventional approaches fall short grasping the dynamics of BMs over time. They depict innovation as a static image or a 'snapshot' of a BM at a certain point in time, i.e. when it functions as wished. But a BM - especially a data-based BM [2] - is by no means a purely static concept. It must constantly be innovated and adapted to changing internal and external forces [25] in order to protect the recently implemented BM against imitations [10, 28], or react [32] to strategic discontinuities or global competition [33]. However, especially long-established firms, struggle with constantly innovating BMs due to the complexity of inherent IT-systems and - infrastructure or path dependency such as legacy systems and products [10]. Therefore, innovating BMs is often lengthy, risky or costly, or at worst, all three of the before mentioned challenges [34]. These challenges can be overcome and BMs can be made manageable by adopting an effectual attitude toward BM modelling and experimentation [35]. Chesbrough (2010) states: *"[Model] experiments will fail, but [if] they inform new approaches and understanding, this is to be expected - even encouraged"* (Chesbrough, 2010 p. 362). Also, Osterwalder et al. (2005) [36] claim that *"simulating and testing business models is a manager's dream"* (Osterwalder, 2005 p. 16). In other words, to overcome the above mentioned 'deadlock' for established companies and to keep pace with the dynamically changing ICT-enabled business environment, new data-related approaches for innovating BMs must be developed. BM simulation, more precisely the system dynamics approach, appears to be a suitable and necessary means to innovate BMs.

2.2 System Dynamics

System dynamics is a simulation and experimentation approach for enhancing analysis and decision-making on complex and dynamic systems [20]. System dynamics was initially developed by J. W. Forrester in 1968 [37] as a methodology developed from several scientific approaches including system theory, information science and cybernetics [38]. System dynamics is considering all elements of a system as actively influencing the behaviour of the system through interdependencies and mutual interactions of elements, so-called feedbacks. The cyclic consequences inside a system are represented by causal-loop diagrams (CLDs). A CLD shows a sequence of events (actions, information, objects, people) successively causing another event until the first mentioned event is caused again. These feedback loops can either be self-reinforcing and dominating the system over time due to exponential growth effects, or self-correcting and balancing a system due to corrective and attenuating effects [39]. The CLD visualization of several reinforcing or balancing, non-linear, multi loop conditions help people to remove cognitive barriers for understanding the complexity of a system. For managing highly interrelated, complex systems such as BMs, system dynamics uses computer-aided modelling and simulation tools like Powersim or Vensim. These computational simulation tools help managers to quantify flows (information, goods, people or financial means) inside BMs, and therefore, provide managers and scholars the opportunity to test and gauge their decisions and to learn about the consequences of their actions in complex corporate and industry contexts of their BMs [20, 37]. Understanding, testing and gauging BM decisions is especially important during the ideation phase of innovating BMs where managers generate new BM ideas by overcoming the current BM logic through reflecting novel, non-trivial changes in the way the BM elements are interrelated [32]. System dynamics has been applied to various BM domains like transportation [38], economic and ecological sustainability [40] or the revolutionary and evolutionary market strategies at the automotive security equipment sector [41].

3 Research Design

3.1 Case Study Design

To explore how data roles could be designed to innovate BMs an exploratory multiple case study was carried out. The case study method aims at retrospectively comprehend complex issues of a contemporary phenomenon within a real-life setting. Furthermore, the case study method is useful when literature and theoretical knowledge do not fully delineate the issue of research with appropriate certainty and clearness [42]. We see these aspects of a multiple case study as given in our study, since the case units of the case study were carried out in the context of an industry-initiated and -derived student hackathon with real-life oriented design decisions in the hackathon process to increase the significance for industry. Additionally, the process was accompanied and supervised by a total of three industry partners. The empirical field of the multiple case study was a hackathon, a collaborative event where 33 student teams ideated BMs for the mobility sector. These 33 teams were split to five different cases, which represented the five essential actors in the mobility sector. Each actor had different pre-settings through company history, firm resources and capabilities, existing BMs and financial KPIs. These actors were: an automotive OEM, mobility fleet operator, digital mobility aggregator, public transportation company and a new automotive rebel OEM. These five mobility actors were represented multiple times as embedded units per case.

3.2 Hackathon Design

Hackathon Approach

A hackathon is a marathon coding event in which a group of predominately computer programmers or IT-designers are intensively involved in developing a software prototype for a specific application, or applying a technology prototype for a specific purpose over a short period of time [43–45]. In this study, software developments or technology applications (the pure coding) were in the background. The objective of the hackathon was to let student teams compete against each other in a partially defined competitive environment with the task to come up with innovative data-based BMs Hence, to quickly and interactively generate and test BMs for real-life problems in a simulation environment [44, 45] - in our case the manifestation of future mobility.

A hackathon can be carried out with different target groups according to the statement of problem and the desired prototype output [46]. For this hackathon, student teams represent a scientifically significant and suitable hackathon execution group for two main reasons: Firstly, they are unbiased and open minded regarding new, disruptive ideas because of no long-term organizational affiliation. Therefore, more distinguishable results can be expected than with a purely industry hackathon. Secondly, to meet the needs of future customers by means of new innovative BMs, it is essential to include today's students in the innovation process of these BMs.

Future Mobility Hackathon

The Future Mobility Hackathon was a collaborative project between two university institutions of Switzerland and a German car manufacturer to foster creativity and a spirit of innovation among students while leveraging the power of system dynamics, and to support the practice partner to gain an advanced understand of future mobility needs. A total of 171 participants from both university institutions worked in teams to ideate, model and analyse innovative but also viable BMs for the mobility sector. The hackathon was conducted on a total of four dates during October and November of the year 2017. Throughout the hackathon the teams developed a series of six BM artefacts to go from an innovative idea and target image of the BM, based on the BM definition concept of Gassmann et al. (2014) [17] (BM magic triangle) to graphical illustrations and evaluation models for the dynamics of the BM (CLDs). The hackathon concept was fitted by industry-derived design decisions like different pre-settings of the hackathon players e.g. firm history, resources and capabilities, and university program-related design decisions like the release of the hackathon competition evaluation criteria at the beginning of the event to ensure the industry significance and to support the students in two ways: reducing the complexity of innovating BMs, and increase the students' identity with the object of study and therefore their creativity in the innovation process.

3.3 Data Selection and Collection

As stated above, five different hackathon BM cases, each with multiple embedded units (in total 33 teams) were examined in the multiple case study according to the case study method of Yin (2012) [42], which can be divided into 3 main phases: 1) define and design, 2) prepare, collect and analyse, and 3) analyse and conclude. In the first phase the data selection was carried out. Impartially of the team performance in the hackathon, the authors selected all generated artefacts (6 artefacts per team; 33 teams in total) throughout the hackathon process. The data collection (case study method phase 2) took place based on several data sources (see figure 1): sketched and computer-aided artefacts (A1-A6) ranging from a rough description of the target image of the BM by means of the BM magic triangle [17], over differently sophisticated CLDs of the BMs (which show the dynamics of the teams' ideated BMs) to the BM pitch presentations in the final competition round. The artefacts (A1-A6) were collected through submissions at the end of each hackathon competition phase. During the hackathon phases where the teams actively ideated, conceptualized and adjusted their artefacts, qualitative team observations were carried out by 6 hackathon supervisors. The focus of these team observations was on the team debates regarding data inside the artefacts and on the team's notion about how data roles could be designed to innovate BMs. These qualitative team observations were an important part of the data collection to give the authors a deeper understanding of data roles in BMs and to find out if there were conflicting views on the usage and role of data. Figure 1 explains for each phase of the hackathon the outcomes of the hackathon, which way they were collected (submission, team observations, or semi-structured interviews) and their input for the case study.

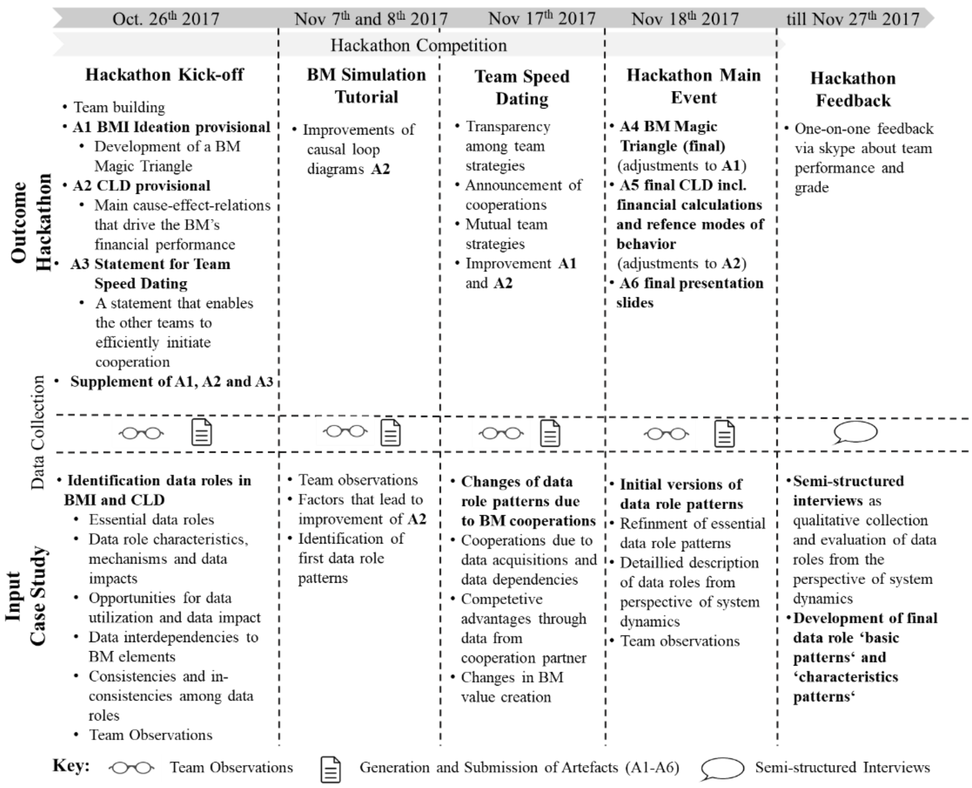

Figure 1. Data collection of the case study

Based on the findings from the analysis of the artefacts as well as the team observations, semi-structured interviews [47] were conducted with 24 of 33 hackathon teams in the aftermath of the hackathon. Since the interviews were not mandatory for the students, not all student teams agreed to be interviewed. The aim of the semi-structured interviews was firstly to uncover personal experiences, knowledge and attitudes of the hackathon participants regarding the design of data roles to innovate BMs. Secondly, the semi-structured interviews aimed at validating and enriching data from the preceding analyses of the hackathon artefacts and team observations to better explain data roles in BMs in order to obtain more objective findings as a valid foundation for further research. The 24 interviews were conducted based on a questionnaire, consisting of five open-ended questions. The questions were arranged in a way that at first the interviewees were free to state and explain the roles of data in their BM as they thought of them, how important they consider these data roles to innovate BMs, and on how they designed and realized them in their artefacts. These questions were followed by more specific questions in which the interviewees had to find and explain data roles, their characteristics and impacts on BM elements inside their CLD artefacts.

3.4 Data Analysis

We started our analysis for *the design of data roles to innovate BMs* with reflecting the BM magic triangle artefacts A1 and A4 in order to understand the BM target images and why data were used within BMs to get a first sentiment on data roles (see figure 2 step 1). To enhance the quality of this step of analysis and to check if there were conflicting views on the usage and role of data within the team, or if we might have misunderstood the artefacts, we cross-checked them with the qualitative team observations. In case that the teams have expanded their BMs by collaborating with other teams, we also analysed the artefacts A3, because collaborations may have an impact on the use of data. In step 2 we analysed the CLD artefacts A2 and A5 to understand the BM dynamics, reasons for data usage and positions of data as well as their impacts on the BMs. Moreover, we analysed the dynamics and consequences of data impacts (data loops) on BMs. In step 3 we extracted the identified data loops and cross-checked their validity, objectivity and reliability with the data loops inside and outside the cases. Again, we cross-checked the data loops with qualitative team observations and afterwards we validated and enriched our findings with data from semi-structured interviews. Based on step 1-3 we developed the six abstracted and generalized data role patterns that describe how data roles could be designed to innovate BMs (step 4). Figure 2 shows the 4-step analysis that identified the data role patterns.
Using the example of the illustrated 'the more the more' data role pattern at figure 2, we will briefly explain how to read our findings (data role patterns). The circle, called 'loop', represents the core mechanism of a BM. The general rule of system dynamics states that any intervention of an event triggers effects that eventually refer back and cause the same event again. This coherent relation is illustrated through circles (loops) based on several individual 'events'. The data-affected loops can be self-reinforcing, represented by a plus with a circular arrow around it or balancing, represented by a minus with a circular arrow around it. For matters of reading comprehension, the

authors recommend reading the abstracted and generalized data role patterns, in the direction of the data impact (data impact direction is highlighted by bold arrows). In case of the above stated loop this means: The more useable data (e.g. infrastructure, vehicle, road environment) is generated through a higher utilization rate of shared autonomous driving cars, the more [higher] data quality can be ensured. More [higher] quality improves the relative level of competition and thereby attracts more customers, which lead to a higher use of the service, and thus to a higher data generation, with which the quality of the shared autonomous driving service can be improved again. The loop is self-reinforcing.

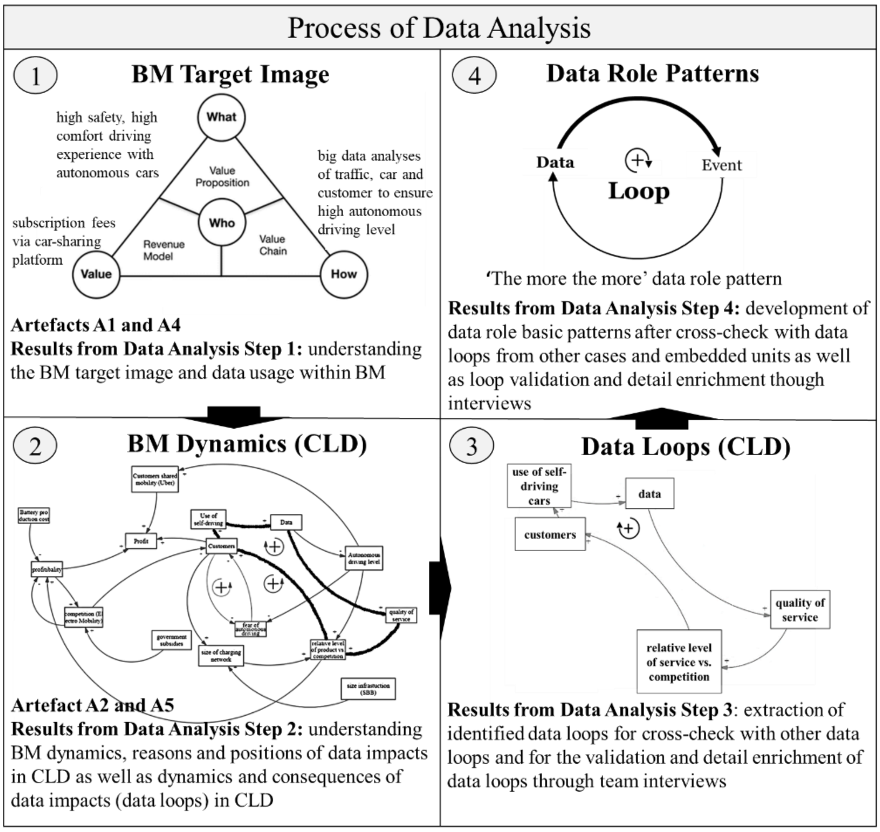

Figure 2. Process of data analysis

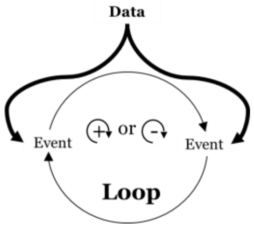
4 Findings

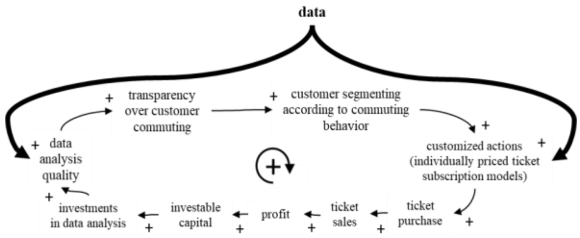
This chapter outlines the six key findings of the multiple case study. According to the research question "*How could data roles be designed to innovate business models?*" the authors identified the following recurring six data role patterns. These are: **'incremental improvement'** (**KF1**), **'initial data boost'** (**KF2**), **'business enabling'** (**KF3**) and **'the more the more'** (**KF4**). As all five cases of the case study with their multiple embedded units compose of these four data role patterns, they are called ‘data role basic patterns’. Moreover, the study identified certain, complex characteristics of these patterns, describing the combination of the four ‘data role basic patterns’ (**‘mix and match’** (**KFa**), and the dynamics and thus implicit change in the mode of action of the patterns (**‘change in self-reinforcement’** (**KFb**). These patterns are called ‘data role characteristic’ patterns. The following tables (table 1 & 2) represent the key findings of the study with brief descriptions of their data role mechanisms, revised snippets of the original CLDs and the corresponding abstracted and generalized graphical data role patterns.

Table 1: Data role basic patterns

Key Finding 1: ‘Incremental improvement’ data role pattern



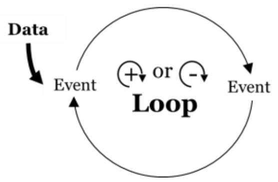
KF1 (#21)



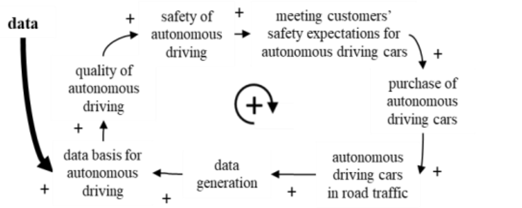
Description: Data are used to incrementally enhance the way a BM creates, captures or proposes value through data impact on one or more events of an existing BM loop. Data only induce incremental business improvements like enhanced transparency for customized actions. However, the traditional BM is only partially innovated.

Example: *Individually priced tickets: If a customer uses an app or the computer to book the daily subway ride from home to work, the transportation company knows through data analysis that the customer commutes daily, and thus can offer the customer an individually priced subscription. The BM is just incrementally improved and not fundamentally reinvented.*

Key Finding 2: ‘Initial data boost’ data role pattern



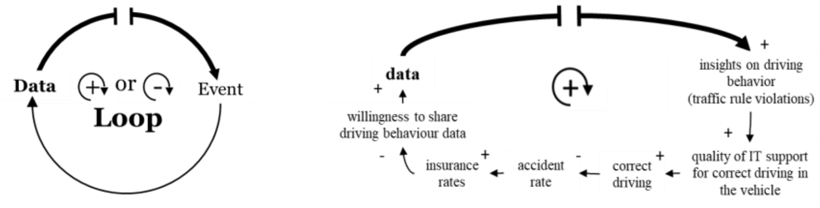
KF2 (#14)



Description: Through an initial, intense data-boost the events of the core mechanisms of a BM will be enriched with the necessary critical amount of data. Once the critical data amount is reached the functioning of the essential loops is initiated and the BM starts operating.

Example: *Safety of autonomous driving cars: If customers are willing to use autonomous cars in case that they are safer than non-autonomous cars, an initial high data volume (data boost) is necessary to ensure customers' minimum safety expectations of the service. Once the certain safety expectations have been met, the safety of the service doesn’t need further significant increases.*

Key Finding 3: 'Business enabling' data role pattern

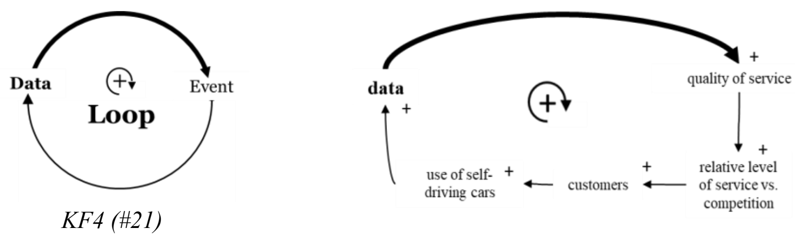


KF3 (#21)

Description: Data enact as business enabling because the BM is only made possible by the utilization of data, e.g. through data insights. Compared to the 'initial data boost' data role pattern, at this data role pattern, the core mechanisms of the BM have a constant, equally intense impact and dependency on data.

Example: *<u>Pay how you use insurance rates</u>: Instead of annual vehicle insurance rates, customers pay proportionally based on their driving behaviour. Traffic rule violations are displayed directly in the vehicle to educate the driver. Unsustainable and vehicle-damaging driving is penalized by higher rates; correct driving is rewarded with lower unsurance rate. The accident risks for the insurance companies decline. Thus, they can offer cheaper rates. Cheaper rates increase the customes' willingness to share driving behaviour data. The loop is self-reinforcing.*

Key Finding 4: 'The more the more' data role pattern



KF4 (#21)

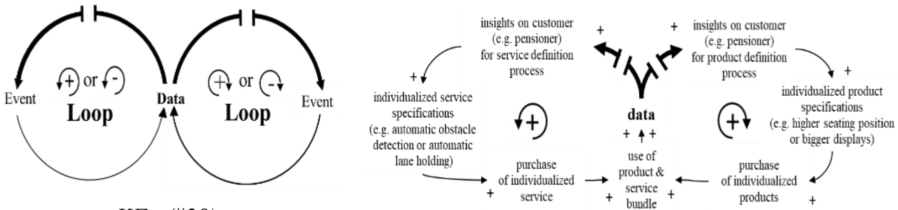
Description: BMs can have a 'the more the more' data role pattern e.g. regarding the quality of the offered service (value proposition) if 1) the quality of the service is directly improved by the quality of the database, and 2) the quality of database is improved by the amount of available data. 'The more the more' data role patterns are self-reinforcing.

Example: *<u>Service quality of autonomous driving</u>: The more an autonomous driving service is used, the more data are generated. With more data the algorithms for autonomous driving are getting better, and thus the quality of the service is getting better. The better the quality of the service, the higher the relative level of competition. Therefore, more customers use the service, and subsequently the loop reinforces again.*

As stated above, the study also identified two patterns which describe the characteristics of the four 'data role basic patterns'. These so-called 'data role characteristic patterns' (see table 2) are '**mix and match'** (**KFa)**, and '**change in self-reinforcement'** (**KFb**).

Table 2. Data role characteristic patterns

Key Finding 5: 'Mix and Match' data role characteristic pattern

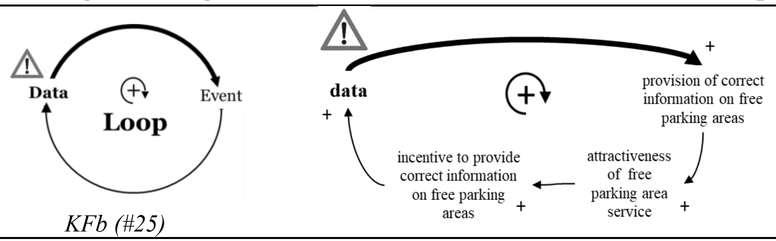


KFa (#28)

Description: On prominent characteristic of the four basic data role patterns is that they can be combined with each other in any form and number. In the exemplary graphical illustration two 'business enabling' data role patterns are arranged around data as the central point of both loops. Because of the centricity of data (two loops), data have an enormous impact on two complementary core mechanisms within BMs through simultaneous direct effects, and thus significantly determine the dynamics of a BM.

Example: *Individual cars with individual mobility services: Based on customer insights (e.g. customer is a pensioner) the firm can individually design cars according to customer preferences e.g. higher seating position and larger displays. Also based on customer data, the firm can offer complementary mobility services for the individually designed cars like lane holding assistants. Thus, the firm uses data to enable two different but complementary BMs, building an individual mobility environment for the customer.*

Key Finding 6: 'Change in self-reinforcement' data role characteristic pattern



KFb (#25)

Description: The pattern describes a possible dynamic behavior of a self-reinforcing data role over time. With changing data attributes as volume or quality, the role of data can change abruptly in the way it is operating in reinforcing loops. Therefore, a business-fostering, self-reinforcing loop changes to a business-destructing, self-reinforcing loop. Consequently, data become an exponentially growing threat to the BM. This pattern is an enormous uncertainty factor for BMs, because once an input flow (e.g. data volume) changes, the exponentially increasing consequences are hard to handle.

Example: *App-based free parking area community service: A service where members tell each other about free parking areas in the city, is business-fostering, self-reinforcing until false data (e.g. by opportunism of residents in free parking streets) is distributed to the community network. False information leads to a lower attractiveness of the service, which reduces incentives for other users to make their known free parking areas available to the community. As a result, there is less correct information provided in the app and the attractiveness of the BM continues to decline exponentially (business-destructing loop).*

5 Discussion and Conclusion

The study aimed at facilitating a deeper understanding of how to leverage data as a new essential resource to innovate BMs. For this purpose, the paper examined - on the basis of an exploratory multiple case study [42] - the design of data roles to innovate BMs. Through the grounding on system dynamics [20] the identified data role patterns (KF1-KF4, KFa & KFb) provide an advanced understanding of the complex and dynamic data impacts and concrete interrelations with BMs. Moreover, the identified six data role patterns take the discussion of *"how to leverage data to innovate BMs"* one step further and provide generalized and consistent representations of how to design data roles for the viability of BMs. This distinguishes the study from previous contributions, which rather reflect the nature of data usage and the potential and importance of data for the core logic of a particular BM from a more static and conceptual level [7, 9, 48]. However, some may argue, that the patterns are relatively established knowledge, debating network effects, platform BM interdependencies or critical data masses for market strategies, but the authors are convinced that the paper is of novelty for the discussion of how to innovate BMs with data for three reasons: 1) visualization of data impacts, 2) possibility of data impact quantification, and 3) validation of known data roles in data-based BMs outside the realm of purely digital BMs. In detail:

Firstly, the data role patterns help to visualize complex, cause-effect-relations to contribute to an enhanced management articulation of data usage. Especially consequences of data usage to improve value creation, value capturing and value proposition via building a clear step by step chain of effects is of particular interest for scholars and managers alike. Therefore, the patterns help to overcome cognitive barriers at decision making both in highly volatile industries like emerging ‘blue oceans’ [49] and existing industries in transition such as mobility sector, health care, insurance, aviation or mechanical engineering. Secondly, applying system dynamics approach, managers, consultants and researchers are able to quantify data role impacts to test and gauge data usage to design the data roles best suited for the desired BM. Thirdly, the study explores that known cause-effect-relations of data roles from the realm of purely digital BMs, also apply at data-based BM in the industrial sector, where customer needs (e.g. mobility) are still realised by physical (non-digital) products like vehicles or trains. Hence, the findings contribute to an advanced understanding and management of designing data roles to innovate BMs impartially, be it a long-established industrial firm (e.g. an OEM, which integrate digital services in their current product offerings and IT-capabilities), a start-up /digital rebel (which builds BMs from scratch due to the utilization of data) or a highly digitalized incumbent firm (which expands its existing digital portfolio in new domains).

Also, the study has implications for scholars, because it provides a new, conceptual view (data role patterns) on a largely discussed issue [9-14] namely, how to leverage data to innovate BMs. Thus, the study builds i.a. on the research of Casadesus-Masanell and Ricart (2011) [50] on how to design a ‘winning BM’. Exposing causal insights on how to design data roles to innovate BMs, this study is giving a knowledge foundation on answering future research questions on how to design a winning ‘data-based’ BM. In accordance with the design decisions of the hackathon, the findings of this study are bounded. Therefore, further research projects should validate the identified patterns and search for additions and modifications under different settings of the empirical field. Due to the methodological approach of a multiple case study [42], qualitative data is collected and analysed. Future studies should carry out quantitative analyses to explore and quantify the intensity of data role impacts on BMs. Also, this study contributes to the ongoing research by setting out a first explanatory approach of how to design data-based BMs, considering data as a dynamic BM resource that is causally intertwined with the BM components value creation, value proposition and value capturing [11].

Analysing the data role patterns in light of resource-based view [51], i.e. understanding data as an existing or evolving resource, or a dynamic-capability [52] i.e. the management of data roles over time, may add considerable theoretical and conceptual insights, leading to fascinating and inspiring research questions and empirical approaches.

Business Model Innovation and Stakeholder: Exploring Mechanisms and Outcomes of Value Creation and Destruction

Sebastian Hermes[1], Markus Böhm[1], and Helmut Krcmar[1]

[1] Technical University of Munich, Department of Informatics, Munich, Germany
{sebastian.hermes, markus.boehm, krcmar}@in.tum.de

Abstract. Given the objective of the focal firm to generate value for stakeholders, this research aims at assessing mechanisms and outcomes for value creation and destruction between business model innovation (BMI) and stakeholders. To achieve this goal, we conduct a systematic literature review and apply grounded theory as coding scheme. Taking frequent mechanisms and outcomes into account, we construct a conceptual framework and pioneer theory building. As main result, we identify BMI creating economic return for third parties and product/service access for customers. Both outcomes are based on the mechanism of altering resources and processes. In contrast, analyzing stakeholder's main influence, we find management creating strategic orientation by providing know-how. Our research agenda emphasizes the design of BMI from an ecosystem perspective and the destructive consequences of BMI. While the ecosystem level of analysis provides new insights into the concept, investigating negative impacts contributes to a more holistic understanding of BMI.

Keywords: Business model innovation, stakeholder theory, literature review, grounded theory, theory building

1 Introduction

The concepts of business models (BMs) and, more recently, BMI have become of increasing interest for scholars in recent years [1-3]. While BMs usually relate to firm-level value creation and capture [4], BMI also scrutinizes the novelty in value proposition as well as the logical and structural reorganization of firms [5]. The present paper defines BMI as a "search for new business logics of the firm and new ways to create and capture value for its stakeholders" [6], because it emphasizes the importance of an ecosystem perspective. One of the approaches to BMI recommended by Chesbrough [7] is to orient the firm towards an open BM. The concept of openness in BMs is viewed as being both innovative and cost-effective [8], which stresses the virtue of value creation and value capture when cooperating with external stakeholders. In addition, Tankhiwale [9] identifies that pressures from external stakeholders and regulations are often the drivers of BMI. Further reasons to involve stakeholders in the innovation process stem from managing conflicting objectives between internal and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

external stakeholders [10, 11], sensing new business opportunities [1], aligning and internalizing inter-organizational cognitions [12], strengthening a focal value proposition [13], and sustaining competitive advantage and profitability. Thus, some authors suggest that the objective of the firm is to generate value in different ways for different stakeholder groups [14]. Focusing on stakeholder theory is therefore vital to understand the emergence and consequence of BMI. The stakeholder-oriented approach becomes also relevant in the age of digital transformation as organizational boundaries are dispersing and the processes of value creation and capture are evolving from bidirectional to multidirectional, from centralized to decentralized, and from closed to open. As a consequence, stakeholders can be involved by applying open innovation approaches like idea communities [15] or idea competitions [16], but also through merger and acquisitions, joint development agreements, or inter-organizational negotiations [12]. To date, limited attention has been given to the reciprocal relationship between BMI and stakeholders despite the acknowledged influence stakeholders can exert on an organization's BM [9] and despite the fact that firms are reacting to innovations instead of driving them [17]. More specifically, Foss and Saebi [3] as well as Aspara, Lamberg, Laukia and Tikkanen [12] identify the need to examine the initiatives exerted on BMI by stakeholders while Spieth, Schneckenberg and Ricart [1] perceive the integration of stakeholders into the BMI process requiring further investigation. However, such fundamental questions are currently not systematically outlined, addressed, and answered. We are therefore providing a starting point with the present paper, which aims to contribute to the development and refinement of BMI by using a stakeholder lens [2, 18]. We determine the need for a more comprehensive view and assessment of value creation and destruction in a focal firm's ecosystem during the BMI process. Hence, the paper investigates what outcomes of value creation and destruction occur during BMI and the intervention of specific stakeholder groups. The outcomes are analyzed from a BMI perspective on the one side and from a stakeholder perspective on the other side. In addition, we present latent mechanisms pursued by each entity to achieve either value creation or destruction. Revealing these mechanisms is particular important to better describe and explain how value was created or destroyed [19]. The purpose of this paper is therefore to review current literature on the reciprocal relationship between BMI and stakeholders, evaluate them, and outline avenues for future research. While reviewing, synthesizing, and structuring current literature, we are guided by the following three research questions:

1. *Which outcomes does BMI have for stakeholders?*
2. *Which outcomes do stakeholder interventions have for BMI?*
3. *Which mechanisms account for the outcomes?*

2 Related Work

2.1 Business Models and Business Model Innovation

Although a focus of attention, the concept of BMs is "a slippery construct to study" [6]. Several frameworks of BMs have been seen in the literature so far [20-23]. A consensus is evolving to conceptualizing BMs as a holistic description and architecture of how value is created, delivered, and captured [24-26]. Thus, emphasizing the importance of integrating the perspective of stakeholders [27]. While interest in BMs is several decades old, the notion of BMs as distinct object of innovation was initially discussed in 2003 by Mitchell and Coles [28]. According to Zott, Amit and Massa [2], BMI can be characterized as a new dimension of innovation setting itself apart from process, product, and organizational innovation. Hence, giving rise to novel approaches for incremental or radical innovation of entire value chains, enabling competitive advantage and superior performance [29]. Due to the lack of construct clarity in BMs [30], it is not surprising that similar conclusions have been made with regard to the definition of BMI. However, various literature reviews attempt to categorize BMI research in unique streams paving the way for granular construct agreement [1, 3, 18]. For instance, Schneider and Spieth [18] present three major research streams: Prerequisites of conducting BMI, elements and processes of BMI, and results achieved through BMI. Building on these findings, Foss and Saebi [3] systematically investigate concepts, processes, outcomes, and consequences of BMI. This paper contributes not only to the research gaps of examining antecedents, outcomes, and boundary conditions of BMI as discussed by Foss and Saebi [3], but also to the effects and enablers of BMI since organizations often innovate their BMs as a reaction to changes in their environment [18].

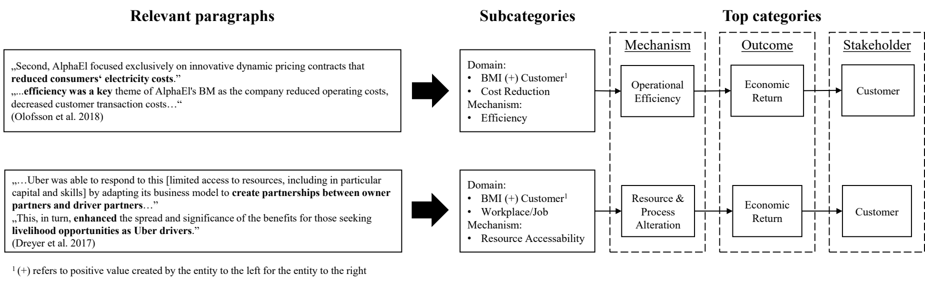
2.2 Stakeholder Theory in Business Model Research

According to Donaldson and Preston [31], stakeholder theory has turned into a major research stream in management literature. The concept is also widely recognized across different domains and becomes an increasingly important perspective for investigating BMs [32]. Freeman and Reed [33] define stakeholder as "any identifiable group or individual who can affect the achievement of an organization's objectives or who is affected by the achievement of the organization's objectives" and may be either primary (impacting the firm directly) or secondary (influencing the firm indirectly via primary stakeholders). Besides, stakeholders can be differentiated into internal and external stakeholders. While internal stakeholders include for example employees and top management teams, external stakeholders refer mainly to customers, users, suppliers, or universities [34]. Another well-established method to categorize stakeholders refers to arraying stakeholders on a power versus interest grid [35]. Freeman and Reed [33] argue that the responsibility for evaluating and mapping stakeholders lies at the top management level. Various researchers combining stakeholder theory and BMI agree on this perspective and regard the integration of stakeholders as a managerial task as well [36, 37]. Integrating customers is especially seen as a key activity for BMI. We infer from current literature that active stakeholder management is highly relevant to BMI research and that this implies developing strategies about when to integrate whom in which phase of BMI.

3 Design and Classification Paradigm of the Literature Review

Literature reviews are a well-known and rigorous approach to collect existing knowledge within an area of interest and to outline former research [38]. We found a descriptive review approach most appropriate for the present stage of this research [39]. We have therefore targeted three prominent online databases: Scopus, Web of Science, and EBSCOhost. Following the search terms of Foss and Saebi [3], we conducted title, keyword, and abstract searches across all three databases with the following query: (stakeholder OR partner* OR "Special interest groups" OR "Open Innovation") AND ("Business Model Innovation" OR "Business Model reinvention" OR "Business Model renewal" OR "Business Model dynamics" OR "Business Model transformation" OR "Business Model evolution") AND (effect* OR influenc* OR affect* OR impact*). The search identified a total of 101 articles. Following a staged selection process [40], the articles in the database were then scanned and filtered in two stages. The first stage involved removing duplicates as well as scanning titles and abstracts for apparently irrelevant articles. This stage of filtering excluded for example those articles that addressed the phenomena of new BMs instead of innovating an existing one or those articles that relied on the wording “partner” instead of describing the stakeholder they refer to in more detail. A total of 25 articles remained in the database. The second stage involved manually analyzing each article’s full text and including those articles that touched on the phases and components of BMI as well as distinct stakeholder specifications and precise value creation and destruction descriptions. By the end of this stage two articles were discarded, resulting in 23 remaining articles. In addition, we conducted a backward and forward search as recommended by Levy and Ellis [41]. We therefore reviewed all cited and citing papers of the 23 articles. We identified 10 additional articles, and therefore 33 peer-reviewed articles form the basis of the review in this paper. To systematically reveal and investigate academic insights on the reciprocal relationship of BMI and stakeholders, we developed a literature coding scheme. Figure 1 provides a small extract of the coding scheme.

Figure 1. Exemplary extract of the coding scheme



The extraction of insights was guided by the research questions raised earlier in this paper. In order to comply with our research aim, coding occurred on a textual level instead of categorizing the papers in general. Hence, an “open - axial - selective” approach informed by grounded theory [42] was adopted to identify the categories used for literature analysis. Such conventional and explorative content analysis has been recommended as a rigorous method for reviewing literature [43] and described as less confirmative than direct or summative approaches [44]. We assigned therefore specific subcategories to relevant paragraphs of each paper and then synthesized them into more generic top categories.

4 Descriptive Analysis

The 33 articles investigated account for a total of 319 subcategories. These split into 164 subcategories for mechanisms and 155 subcategories for outcomes. While the subcategories for the mechanisms converge into 13 top categories, 11 top categories emerge for the outcomes. The general focus has been on value creation and less on value destruction as destructive mechanisms and outcomes account for merely 79 subcategories altogether. It is noteworthy that the studies of Hienerth, Keinz and Lettl [45] and Olofsson, Hoveskog and Halila [46] make up the highest numbers of subcategories. While Olofsson, Hoveskog and Halila [46] explore BMI driven by sustainability issues at a social enterprise, Hienerth, Keinz and Lettl [45] focus on the implementation process of user-centric BMs. Both articles emphasize information and communication technology (ICT) as enabler and driver for digital transformation, which can act as antecedent for BMI [3]. However, BMI does not necessitates using ICT, in contrast, changing the logic of a firm can be achieved by different means [3]. The finding of ICT as trigger for digital BMs is also highlighted by most of the remaining articles [e.g. 47]. Moreover, the topic of sustainability appears to be another important unit of analysis as it is often mentioned as goal or purpose of BMI [e.g. 48]. The vast majority of articles have been published either in the areas of technology, innovation and entrepreneurship or in business administration literature. Around one fourth of articles stem from engineering and organization studies. The remaining articles are allocated to areas of sustainability, strategy, production, finance, and marketing. Interestingly, no article originates in information systems research despite the significance given to ICT and digital transformation in context of BMI. Further characteristics about the articles considered are illustrated in table 1.

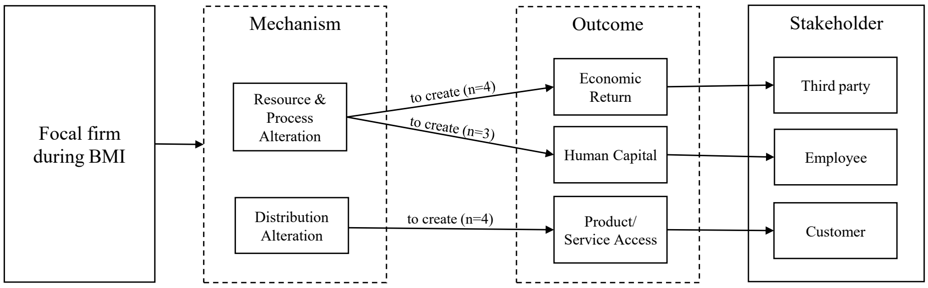
5 Towards a Conceptual Framework

We are now aiming to conceptualize the field, which might be a first attempt towards theory building [49]. Meredith [50] calls this a philosophical conceptualization, which in this case is based on reading the papers repeatedly. Since our goal is not only to describe the phenomenon accurately (outcome) but also to explain how it occurs (mechanism) and to whom (focal firm or stakeholder), we draw on the concept of context-mechanism-outcomes (CMO) pattern configuration. According to Linsley, Howard and Owen [19], "a CMO configuration is a proposition stating what it is about an initiative that works, for whom and in what circumstances." In this paper, context refers to BMI and stakeholder intervention while mechanisms and outcomes are investigated in order to develop an in-depth understanding about the reciprocal relationship between BMI and stakeholder intervention. Thus, we extracted according configurations only if the mechanism-outcome-stakeholder configuration had been identically mentioned by at least three articles. Doing so allows rigorous conceptual deduction of the cautiously proposed framework. The mechanisms and outcomes used to develop the framework stem from the synthesized top categories. The results are depicted in figure 2 and 3 and will be further explored in the next sections.

5.1 Business Model Innovation and Value Creation

As initial step, we identify the mechanisms used and the outcomes triggered by BMI to create value for particular stakeholder groups. On the one hand, we recognize how *altering resources and processes creates economic return for third parties.* Berti and Casprini [51] for example describe how an airport's processes changed towards offering extra-aviation activities. Thus, enabling shopping malls, parking providers, and restaurants to build flourishing businesses at the airport. On the other hand, we notice that *resource and process alteration also benefits employees in form of fostering their human capital*. While Aspara, Lamberg, Laukia and Tikkanen [12] stress how Nokia's business model transformation led to the selection of business that enhanced the development of corporate human resources, Carayannis, Sindakis and Walter [48] mention that the organizational transition towards servitization encouraged employees to adopt new skills and knowledge. Next, we present our findings about the *alteration of distribution channels and its positive influence on the customer's access to products and services*. By investigating how an original equipment manufacturer innovated its BM towards becoming an own brand and product developer, Carayannis, Sindakis and Walter [48] observed an expansion of direct sales from wholesalers to single retailers. Hence, allowing additional customers in the value chain to access its products. Ghezzi, Cavallaro, Rangone and Balocco [17] find a similar effect studying BMI in the context of mobile portals and their shift to application stores. In mobile portals, the customer's access is limited to the operator's portal. The portal represents the sole interface through which end customers obtain content and service offers. By engaging in the application creation and distribution paradigm, the focal firm permits higher openness and independence to third parties, providing users broader product and service choices. Moreover, the firm integrates application developers as a new customer group and transforms its business model into a two-sided market. Figure 2 illustrates the mechanisms used and outcomes triggered by BMI to create value for particular stakeholder groups.

Figure 2. Business model innovation and value creation for stakeholder



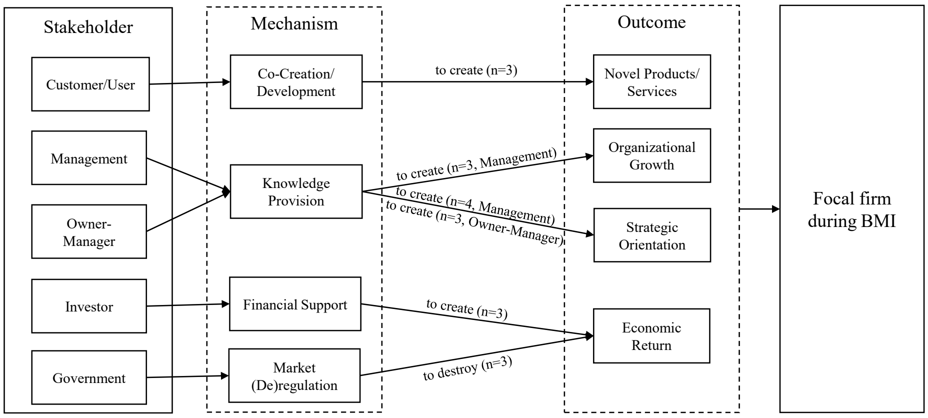
5.2 Stakeholder Intervention and Value Creation

This section describes how the mechanisms used and the outcomes triggered by different stakeholder groups enhance the BMI of the focal firm. First, we present our findings about the *beneficial effect of customers and users engaging in co-creation in new product or service development*. In their multiple case study, Hienerth, Keinz and Lettl [45] investigate the success factors of involving users in core business processes. Doing so, they report that the company LEGO engaged continuously with its users in co-creation resulting in the launch of the LEGO Factory platform - now called LEGO Ideas. The authors observed the same pattern at the company Coloplast, which integrates users in order to co-create new products with the development staff. Interestingly, the companies in both cases relied on IT tools to improve their co-creation processes since these IT tools facilitated large-scale user interaction and effective information collection. Accordingly, Kohler [52] delineates how various integrator platforms offer products that are co-created by the crowd ranging from t-shirts sold on Threadless to cards sold on Minted. In case of product platforms, the author identifies a similar co-creation procedure and refers to Apple's IOS and Google's Android ecosystem. Both companies allow users to develop and distribute their apps on top of their platforms. Hence, crowd members co-create new products or services with platform providers. Secondly, we discuss how *management's provision of knowledge creates organizational growth* for the focal firm during BMI. Abebe and Myint [53] identify that board members facilitate BMI adoption because they provide valuable information on changes in the external environment. Accordingly, management can positively contribute to firm performance by providing valuable and relevant external information. Similarly, Guo, Zhao and Tang [54] provide statistical support for the positive effect of top managers' human capital on BMI. More specifically, the authors show how combining top managers' managerial skills and managerial ties might enable the focal firm to capitalize on existing opportunities, whereas top managers' entrepreneurial skills can guide the focal firm to convert information and knowledge acquired through managerial ties into new business or product opportunities. Thirdly, we outline our findings on the *positive influence between managers' or owner-managers' provision of knowledge and the focal firm's strategic orientation*. In addition to enhancing organizational growth, Abebe and Myint [53] also show that larger boards can positively contribute to firm strategy since their extensive knowledge improves the quality of strategic decisions. Hence, management teams provide the human capital necessary to adopt new innovations in the marketplace. By analyzing Nokia's corporate BM transformation, Aspara, Lamberg, Laukia and Tikkanen [12] describe how top managers seek to retain or renew existing BM elements. While a corporate crisis led top managers to decide on changing Nokia's BM to a new, more legitimate corporate recipe, it was top management's knowledge about strategic fit and complementarity product that enabled the firm to reformulate its strategic positioning. Regarding owner-managers, Olofsson, Hoveskog and Halila [46] state that the social vision and the business experience of the founder were especially crucial factors contributing to the success of the focal firm. For example, the founder introduced new marketing ideas like environmentally certified electricity, which attracted new customers. Interestingly, once the founder resigned, the firm experienced a strategic identity crisis to some degree. Additionally, Velu and Jacob [55] argue that entrepreneurs that are also managers comprise a more holistic understanding of the business and more comprehensive insights about internal and external environments. Therefore, owner-managers enable the systemic and strategic change that BMI demands. Finally, we elaborate how *investors create economic return by providing financial support* to the focal firm engaging in BMI. While Berti and Casprini [51] describe that investors became an important source of revenues by acquiring company equity, Olofsson, Hoveskog and Halila [46] scantily state that the investor's financial support was critical to the success of the sustainability-driven firm investigated. Moreover, Demil and Lecocq [21] elucidate how one major investment enabled an English football club to build new infrastructure and improve personnel training. These developments permitted the football club to counter negative impacts resulting from legal rulings.

5.3 Stakeholder Intervention and Value Destruction

The following section depicts how *market regulations and deregulations implemented by the government destroy economic return*. In their search of dynamic consistency during BMI, Demil and Lecocq [21] illustrate how regulation reduced revenues and deregulation increased costs. The governmental regulation was grounded in the Taylor report and forced an English football club to reduce the capacity of its stadium by almost 50 percent. As a consequence, the club was facing the prospect of regular losses by the end of the 90s. In contrast, the Bosman ruling relaxed the existing transfer system and relieved football players from their preposterous contractual status. This deregulation facilitated competition for the best players between European clubs which raised both salaries and transfer fees. Similarly, Sosna, Trevinyo-Rodríguez and Velamuri [56] report that the deregulation of the Spanish dietary products market eased the government registration of products. Hence, the focal firm had to contend for shelf space against incumbents, who competed on brand strength and product range, and against new firms competing on price. Figure 3 illustrates how the mechanisms used and the outcomes triggered by different stakeholder groups create and destroy value for the focal firm engaging in BMI.

Figure 3. Stakeholder and value creation and destruction for the focal firm



6 Future Research

6.1 Designing Business Model Innovation from an Ecosystem Perspective

Our review revealed that all studies focused on BMI from a firm-centered, inside-out perspective, neglecting network relationships [10, 51, 57, 58]. Hence, future research can gain additional insights from applying an ecosystem perspective that goes beyond the dyadic stakeholder-firm relationship. Spanning organizational and bilateral borders does not only enhance our understanding of the consequences of BMI, but it also reveals a new context to which the purpose of BMI can be aligned to. Instead of striving to create value solely for the firm or different stakeholder groups, BMI can be designed to propose and create value for the entire ecosystem it operates in. We argue that adopting such a holistic approach alters the purpose of BMI towards more sustainable business practices. The underlying reasoning is two-folded. First, we draw on general equilibrium theory [59] and derive that value creation on the one side leads to value destruction on the other side of the ecosystem. However, as is typical for biological ecosystems, once one side of the ecosystem suffers it also affects the other side of the ecosystem. Destroying value in one part of the ecosystem will therefore sooner or later affect the firm initiating the value destruction in the first place. Secondly, we feel that the understanding of this circular independency leverages preventive activities. Thus, firms applying the ecosystem level of analysis to BMI will adopt more sustainable business practices. Theoretical contributions can be made in two ways. First, to the position-based view of the firm as the company adjusts its position in response to environmental and market forces following an outside-in perspective. Second, to the ecosystem concept as the company aligns its structure, processes, and activities towards proposal and creation of value for a multilateral set of stakeholders and ecosystem actors [13]. Building on the above reasoning, we propose to investigate the following research questions: Who to design BMI for and for which purpose(s)? When to integrate which kind of ecosystem actor to achieve the selected purpose(s)? How to design BMI to create and maintain sustainable business practices? How to govern sustainable business practices? How to incentivize direct and indirect stakeholder to participate in sustainable business practices? Studying these questions can provide practitioners with novel concepts on how to build sustainable business growth and enhance firm survival.

6.2 Exploring Value Destruction of Business Model Innovation

In our analysis of existing literature, we identified that the concept of value destruction as a consequence of BMI is being under-researched. Current research efforts do scratch the surface of value destruction, but hardly manage to investigate it in more detail. In cases where they do explore value destruction, it is solely in terms of how stakeholders affect BMI, but not the other way around. For example, Holm, Günzel and Ulhøi [47] mention how several cases of value destruction impede BMI. The cases range from complying with third-party standards due to cooperation with sales intermediaries to competing with users due to new ICT involving users in value creation and diffusion. However, they miss to explore the underlying mechanisms and impacts more thoroughly. In contrast, research on the government as destructive trigger for BMI has been widely investigated so far. For example, Demil and Lecocq [21] illustrate how governmental regulation reduced revenues and how deregulation increased costs during the phase of BMI. We argue that the concept of value destruction provides avenues for fruitful research, especially when investigating how BMI destroys value for the actors in the ecosystem. At present, research is concentrated on only one side of the coin, value creation, but neglects to explore value destruction as the other, as important side of the coin. Engaging with the proposed concept provides additional insights on the emergence, mechanisms and consequences of value destruction. Therefore, contributing to the other, the negative side of BMI. Following this concept helps not only to understand how BMI affects primary stakeholders, but also how it impairs secondary actors in the ecosystem. We feel that negative externalities in particular provide interesting phenomena to explore in future endeavors. Therefore, we are calling for exploration of the following research questions: How do customers, suppliers, complementors, competitors etc. inhibit firms from aligning their BMI with ecological, societal, and financial goals? How and to which degree do the negative externalities of BMI affect stakeholders that are not part of the firm's direct network? Evidence and motivation for negative externalities can be observed at Uber and Airbnb [60]. At Airbnb for example, hosts do not pay lodging taxes, therefore municipalities lose tax revenues and hotels suffer from unfair competition. Moreover, landlords find their long-term tenants turning into short-term landlords, unjustly enriching themselves and skirting rent stabilization laws. Another group of indirect stakeholders, neighborhoods, claim to be overrun by visitors bringing noise, trash and traffic. In sum, the negative externalities of Airbnb can decrease the amount of housing and increase renting prices [61]. Consequently, homes for residents who work within the city, participate at votes, build families, or simply have no other place to go, are being diminished. During the investigation of externalities, research should not only focus on case studies of constructive BMI; insights from destructive BMI can enhance the field and provide new perspectives. Patterns for the design and strategies for the governance of sustainable business development could emerge in multiple-case studies of constructive and destructive BMI and their impact on the economic ecosystem.

7 Limitation and Conclusion

Several limitations affect the results of our study. First, the literature search might not cover all relevant studies due to the choice of keywords. For example, alternative terms for the concept of stakeholder such as partner, competitor, employee, government etc. might yield further relevant articles. Second, the applied coding process simplifies the results of the studies to make them comparable. Similar subcategories were assigned to more generic top categories. In the course of this process, some insights might have been lost and may not be represented in our results. To conclude, we uncovered latent mechanisms and outcomes of value creation and destruction by applying an open, axial, and selective coding approach to synthesize implicit insights of the 33 articles identified by our keyword search. Abstracting from individual findings, we attempted to construct a conceptual framework relating prevalent mechanisms to specific outcomes and stakeholders, hence, clarifying the reciprocal relationship of BMI and stakeholders. We identified two relationships as main results on how BMI creates value for stakeholders. First, BMI creates economic returns for third parties by altering resources and processes. Second, BMI creates product/service access to customers by altering resources and processes as well. Reversing the direction of impact to stakeholders influencing BMI, the main result emerges from management creating strategic orientation for BMI by providing their knowledge. Last, we outlined potential avenues for future research. We recommend to study the design of BMI from an ecosystem perspective. The new level of analysis will provide further insights into the concept of BMs and is highly relevant in practice. Moreover, we think that future research needs to explore the destructive side of BMI. Investigating the negative consequences of BMI will contribute to a more holistic understanding of BMI. By reviewing existing literature and deriving issues for future research, our study contributes to information systems literature in several ways. First, we provide an overview on research related to the beneficial and destructive impacts between BMI and stakeholders. The overview highlights new insights that were previously incorporated implicitly in the literature. Second, we summarize mechanisms and outcomes related to value creation and destruction across all studies. In doing so, we identify and illustrate the key concepts currently being touched on by scholars in the field of BMI. Third, we expand existing theory on BMI by identifying and explaining those antecedents of BMI which Foss and Saebi [3] call stakeholder demands. Addressing their proposed gap number two, we provide insights about internal and external stakeholder demands and illustrate what Aspara, Lamberg, Laukia and Tikkanen [12] call "initiatives of other stakeholders than managers (or investors)." Moreover, we contribute to theory on outcomes of BMI by taking an ecosystem perspective. Instead of investigating what outcomes BMI has for the focal firm, we explain what outcomes BMI has for its stakeholders. Fourth, we derive specific issues for future research that are rooted in existing research but show how our understanding of BMI and its design can be enhanced. Finally, our study is relevant for practice by laying out which impacts practitioners need to consider when engaging in BMI. The issues we identified will prove to be useful in practice and will further advance the applicability of the scientific findings during BMI.

Abstract. A wide range of Internet of Things platform providers operate diverse business models to cater for the manifold requirements of the IoT. This paper contributes to a more precise understanding of IoT platforms as an essential building block of the IoT based on the characteristics of its business models. Even though research listing technological dimensions according to which IoT platforms differ, they have neither been systematically derived nor been linked to the business model concept. In turn, they lack descriptive power on the heterogeneous value creation mechanisms of the platform providers. Within our research, we first analyzed 195 IoT platforms and systemically developed a taxonomy allowing the characterization of IoT platform business models. Second, based on this taxonomy, we identified nine archetypes of IoT platform business models and illustrated typical combinations of business model characteristics. Equipped with such an understanding, practice and research can analyze existing IoT platforms more accurately.

Keywords: Internet of things, IoT platforms, Taxonomy, Business model, Archetypes

1 Introduction

There are 20 billion connected devices forecasted by 2020 [1]. For connecting all these heterogeneous physical products to the digital world, IoT platforms are essential. They act as a central backbone connecting the heterogeneous device landscape, different data sources, developers and end-users [2]. To give an illustrative case: The cloud company Amazon operates an IoT platform and provides the functionality to manage millions of devices. Other companies can build on these functions and develop IoT applications. For instance, Miovision, a company offering a variety of devices for measuring air quality and noise builds on Amazons platform to connect its physical devices and to develop applications that support cities in improving transport capacity, safety, efficiency and performance [3]. However, in order to take advantage of the economic opportunities more than 450 firms have entered the market for IoT platforms [4]. While all platforms are offered under an IoT related platform label, they vary considerably as they focus on different aspects of the IoT technology stack and correspondingly include diverse functionalities in their offerings, leading to different types of value creation [5].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

So far, academia has highlighted different technological characteristics of IoT platforms. Some researchers stress the integrative role of IoT platforms and describe them as an abstraction service for smart objects, i.e. a digital representation of physical objects equipped with sensors, actuators and communication technology is available on the platform [6, 7]. Thereby, the IoT platform can be operated on the cloud level and provide the functionalities in a platform as a service manner or in a local environment running on a gateway or other devices[6]. In addition, some researchers include the role of end-users and characterize platforms as interaction enablers between end-users and smart objects by providing the necessary infrastructure [2]. Later on, the understanding of IoT platforms as instantiation of a digital platform emerged, i.e., a software-based system that provides core functionality shared by the interoperating modules [5, 8]. These core functionalities include integration, management and monitoring of smart objects, that can be utilized to build applications for the IoT [6]. In sum, IoT platforms can be understood as a specific type of digital platforms that are (i) operated in a cloud or local environment, (ii) enable the interaction between smart objects and end users (iii) by providing a core functionality to third party developer to support the development of modular applications (iv) on the basis of an abstraction service that is integrating underlying infrastructure and different data sources.

To advance the understanding of the IoT, existing technological considerations must be complemented by a business perspective [9]. Against this backdrop, we argue that a business model-focused view on IoT platforms is necessary, as it provides just the right perspective for relating rather technological aspects (e.g., platform openness) to essential business decisions (e.g., pricing model), thereby making these interdependencies explicit and thus manageable as part of a systematic business model design process. Considering this need, the paper strives to answer the following two research questions: *(1) How can instances of IoT platform business models be characterized?, (2) What are the IoT platform business model archetypes that can be differentiated?* To do so, we briefly provide the necessary background to digital business model frameworks before we proceed in four phases: (1) We develop a representative database of IoT platform providers. (2) We carry out a systemic literature review to identify publications that introduce specific dimensions along IoT platforms. (3) We deconstruct the business model of platform providers into a classification scheme that serves as a taxonomy and thus, a theory for analysis [10]. (4) Lastly, we empirically identify business model archetypes from this taxonomy.

2 Digital Business Model Frameworks

The term business model describes how an organization creates, delivers, and captures value [9]. In literature, the concept mainly serves as a classification basis for emerging value drivers, as performance indicator, or as foundation for business model innovation [11]. Several authors have introduced business model frameworks that provide design options for specific business model components e.g., [9]. This component-based view on the business model concept i.e., a system comprising a set of interacting components, is dominating the current scientific discussion [11]. However even though

an intense scholarly discourse, there is no consensus on what a business model actually is, nor on what specific set of relevant components are included[1] [12].
With respect to our research questions, we focus on frameworks that were developed explicitly for digital business. This is necessary as IoT platforms (as well as many other platforms) rely heavily on digital technologies to create value and can therefore be considered digital business models [13]. We identified several specific business model frameworks describing the generic dimensions of digital business models, most importantly [14], [15] and [16]. In addition, other authors have also introduced business model taxonomies for specific digital domains. These approaches are more precise as they not only describe the component and dimensions of digital business models in a certain domain, but also specify the potential characteristics for each of these dimensions. Therefore, they are not only useful for analyzing existing business models but are also a powerful tool for business model innovation [17]. Therefore the first objective of this research is to develop a business model taxonomy for IoT platforms.

3 Methodology

In prior publications, the taxonomy development was conducted for two reasons: first, to provide the fine-grained approach to re-structure a comparatively young research domain (e.g. 17), and second, to set the ground to extract archetypes (e.g., 18). We included central elements from these studies in our four-phase research design.

3.1 Phase 1

In the first phase, we created a database of IoT platforms that were operational between May and June 2018 following three steps: first, we combined a variety of sources, starting from IoT platforms mentioned in the literature review (54 platforms), continuing with a tag search for "IoT platform" in the world's largest tech database CrunchBase (221 platforms), and finally adding the platforms of the leading IoT database Postscapes (123 platforms). By pooling the sources, we obtain 398 platforms. Second, we excluded providers who occurred more than once, went bankrupt, got acquired, ceased operation or offered no market-ready product. As a result, we have a reduced data set of 237 IoT platforms. Third, to have a consistent understanding of an IoT platform, we excluded platforms that did not follow the introduced understanding of an IoT platform (see introduction). The database contains all the leading platforms according to multiple market analyses (e.g., [1]). Further commercial reports indicated the presence of more than 450 IoT platforms [4]. However, we consider our database with 195 operating platforms as a sufficiently representative sample of the overall IoT platform market to identify the most relevant business model dimensions as well as archetypical combinations of these dimensions.

[1] For further theoretical details on the business model concept, see [12]

3.2 Phase 2

In the second phase, a systematic literature search and analyzes was carried out [19]. To identify all potentially relevant publications, we conducted a keyword search using the databases ScienceDirect, IEEE, AISEL and Google Scholar in the title, abstract and keywords by using the following search strings[2]: "IoT", "Internet of things", "platform", "middleware", "cloud", "classification", "types", "typology", "taxonomy", "business model" resulting in an initial sample of 327 publications.

Table 1. Literature based dimensions

Author	Conceptual dimensions	Literature-based taxonomy dimensions
[20]	• Core capabilities • Platform openness	Context awareness, Device management, Interoperation, Platform portability, Security and privacy
[21]	• Core capabilities, • Platform integration • Partner system • Degree of support	Access, Architecture, Data store, Documentation, External integration, Fault tolerant, Finality, Languages, Last update, License, Load balancing, Memory, Official Companies, Programming, Replication
[22]	• Core capabilities • Platform openness	Analytic tool, API/library, Connection type, Database type, Data formats, Energy efficiency, Messaging protocol, Notification/alert, Open Source/commercial, Platform resource requirements, Programming Language, Security, Software Development Tool, Storage Space, Visualization
[23]	• Platform integration • Degree of support	Device Management, Conversion Security, Decentralization, Enterprise integration, Event-Management, Filtering & enhancement, Information, Maintenance, Technology abstraction, Visualization
[2]	• Device support • Application sales channel • Partner system • Degree of support	Data ownership, Data processing and sharing, Developer support, Ecosystem formation, IoT marketplace, Support of heterogeneous devices
[24]	• Core capabilities • Device support • Degree of support	Availability, Developer Friendly, Plug and Play, Provision of Support, Real time data, Scalability, Security & Privacy Provisioning, Solution Type, Storage of data
[25]	• Core capabilities • Device support • Transaction based revenues	API protocols, Application, Cloud model type, Data analytics, Data visualization, Device configuration, Real time data capture capability, Usage costs / developer costs
[26]	• Core capabilities • Platform openness	Integration to Cloud, Mostly Used applications, Security, Supporting Protocols, Type of Analytics

To further systematize the review process we proceeded in three steps. First, we screened the abstract with regard to our research question (sample size 147). Second, we solely included publications in peer reviewed journals or conferences to ensure scientific rigor (sample size 96). Third, we conducted an in depth analyzes were each publication had to contain technical or other business model related dimensions that support the description of IoT platform business models (sample size 7). We than conducted a forward-backward, resulting in sample of eight publications (table 1).

In the next step, we systematically analyzed the literature corpus and identified three limitations: (1) The literature based dimensions are not systematically derived, but were rather developed ad-hoc, and lack details regarding the origin of each dimension and the associated characteristics, resulting in lack of transparency. (2) The presented dimensions were mostly developed in a technical context and not linked to the business model concept, thereby neglecting important components of a complete business model. Possibilities to capture value remain largely unexplored. (3) The introduced taxonomy dimensions are only sporadically evaluated on a representative real world sample of IoT Platforms. In addition, we have derived eight conceptual dimensions

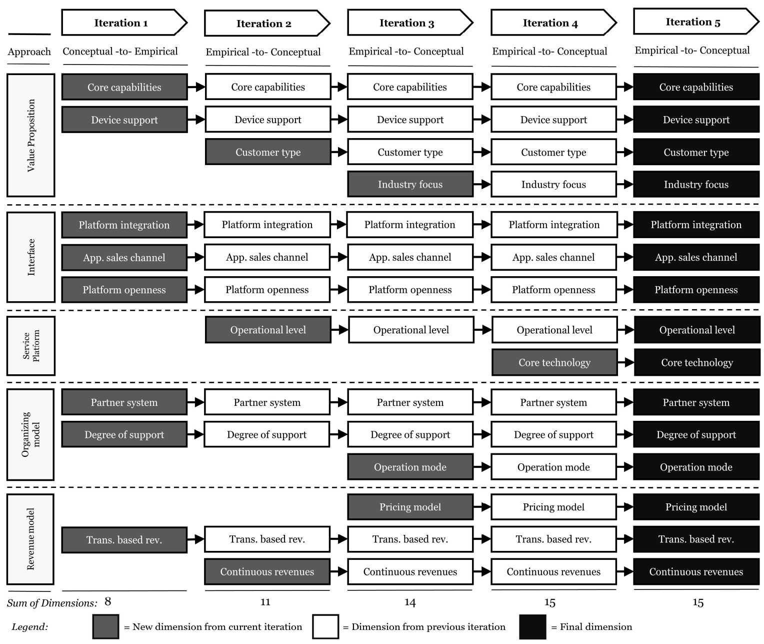
[2] Some contributions use platform [2], middleware [20] and cloud [21] interchangeable thus we included them in the key word search.

from the literature, which serve as a starting point for the taxonomy development and provide researchers with initial notions of how IoT platform business models differ.

3.3 Phase 3

In the third phase, a taxonomy of the IoT platform business models was systematically developed. The process was guided by the taxonomy development method of [27]. The method is rigorous, since the necessary steps and ending conditions are clearly defined and proven in numerous applications. In addition, the method enables the combination of already identified dimensions with new dimensions from the research of real objects.

Figure 1. IoT platform business model taxonomy development



In the first step of the process, we casted our meta-characteristic within the VISOR framework from [15], similar to [17], to assure that all relevant components of digital business models are covered. The VISOR framework is the most adequate one for decomposing the business model of IoT platform providers, as it emphasizes the importance of the customer interface, the central role of digital platforms, and the need to orchestrate complex digital ecosystems. The VISOR framework consists of five components: value proposition, interface, service platform, organizing model and revenue model. Second, our taxonomy development process is based on the eight objective and four subjective ending conditions proposed by [27]. Third, we ran through five iterations until all IoT platform providers from the database were classified and the ending conditions were met (figure 1). In the first iteration, we opted for a conceptual-to-empirical iteration and integrated the taxonomy dimensions identified during the literature review (table 1). For the second, third, fourth, and fifth iterations, we conducted empirical-to-conceptual cycles, leading to successful classification of all IoT platform providers in the data sample. To reduce the complexity of these cycles, we classified the providers according to their company size i.e., multinational companies (MCN), small and medium companies (SME), startups and project settings (e.g., open source projects). At this point, all providers from the database were classified, seven further dimensions were added (i.e., customer type, industry focus, operational level, core technology, operation mode, pricing model, continuous revenues) and all objective and subjective ending conditions were fulfilled, thereby ending the iterations.

3.4 Phase 4

In the fourth phase, we conducted a cluster analysis to empirically derive IoT platform business model archetypes from the taxonomy. Based on the work of [28], a two-step approach delivers the best results. They indicate that using Ward's method to identify the optimal number of clusters represents the first step. Therefore, the clusters must be further specified using an iterative partitioning procedure. In accordance with this recommendation, we first applied the Ward's clustering algorithm (all analyses were conducted in SPSS, version 22). The similarities between the two organizations (objects) were calculated by the number of identical characteristics along the taxonomy dimensions and measured as square Euclidean distance, which is suitable for binary data. These results indicate that five or nine cluster solutions would be most useful for a k-means in depth analyses.

We then applied the k-means method to the five and nine cluster solutions. In both cases, the algorithm ran through five iterations until no significant improvements were achieved in the last iteration. Subsequently, we evaluated the resulting clusters manually for their explanatory power. A closer look reveals that the five cluster solution is largely similar to the seven core capabilities of the IoT platforms neglecting some important differences between underlying business logics. The nine clusters, on the other hand, were more fine-grained and reflected some essential differences, particularly regarding value capture. In short, the nine-cluster solution has more explanatory power because it provides important distinguishing characteristics. Therefore, we will only explain the results of the nine-cluster solution in this article.

4 Results

4.1 Taxonomy

The resulting taxonomy contains 15 dimensions, each with two to seven different characteristics (table 2). Each of the 195 platform providers from the database are represented by exactly one characteristic per dimension. The taxonomy contains the most important dimensions according to which IoT platform providers differ i.e., business model components that are identical for all providers are not listed here [27].

Value Proposition

Core capabilities: What are the core capabilities offered for developers by the IoT platform? First of all, the capabilities of IoT platforms greatly vary. Where some platforms focus on things by providing operating systems to develop embedded software for smart devices, other platforms enable the connectivity of things by offering telecommunication hardware such as sim cards and the infrastructure to manage the connections (e.g., Ciscos Jasper Platform). Some others focus on the management of devices by allowing remote firmware updates and configuration management of the connected devices (e.g., Echelon). Another group of platforms offer cloud storage options for the incoming device data or running code (e.g., GroveStreams) whereas others mainly provide analytic capabilities including means to extract insights from the data (e.g., SenseIoT) or capabilities to develop and deploy IoT applications through a developer environment (e.g., Ayla). A last type of IoT platform provides multiple capabilities such as, application development environments and cloud storage to provide an all-in-one IoT platform approach (e.g., ThingWorx).

Table 2. Taxonomy of IoT platform business models

VISOR	Dimension	Characteristics of the dimensions						
Value proposition	Core capabilities	Embedded device operation	Connectivity enablement	Device management	Device data storage	Analytics	Application development	Multiple capabilities
	Device support	Selected 3rd party devices	Exclusively provider´s devices	Selected 3rd party devices and provider devices	Any device, if provider's standards are used			
	Customer type	Consumer	Business	Business and consumer				
	Industry focus	Single-industry platform	Cross-industry platform					
Interface	Platform integration	In enterprise system	In web services	In multiple diverse systems	No integration opportunities			
	Application sales channel	Marketplace functionality	External marketplace necessary					
	Platform openness	Fully proprietary	Hardware proprietary	Software proprietary	Open source			
Service platform	Operational level	Operated on device	Operated on cloud	Operated on device and cloud				
	Core technology	Telecommunications	Sensors and microcontroller	Cloud technologies	Other technologies			
Organizing model	Partner system	Open partner system	Proprietary partner system	No partner system				
	Degree of support	Non personal technical support	Personal technical support	Personal technical and business support				
	Operation mode	Operated by platform provider	Operation by 3rd party possible					
Revenue Model	Pricing model	Developer projects are free and enterprise projects are priced	Developer and enterprise projects are priced	Free for use				
	Transaction based revenues	Per connected device	Per API call	Traffic based	Combination of multiple sources	Per request	Free for use	
	Continuous revenues	Time based (monthly / yearly) minimum fees	Pure pay as you grow (no continuous fees)					

Device support: What are the devices supported by the platform? Some platform providers allow selected third-parties to connect their devices to the platform, whereas others exclusively support platform provider devices. Several platforms support all types of connected devices when the platform standards (libraries) are implemented on the device and the predefined API is used.

Customer type: What is the customer type of the platform? Even though a majority of the platform providers are focused on business customer types (e.g., General Electrics), some providers also address the platform (e.g., IFTTT) to the consumer segment. *Industry focus:* What is the operating industry of the platform? Some platforms are designed to operate in a single specific industry, e.g., home or manufacturing, whereas others are designed as a cross-industry platform.

Interface

Platform integration: Does the platform offer integration functionality for other systems? While some platforms offer a strong functionality to connect to enterprise software like ERP, CRM or SCM systems, other platforms provide integration frameworks to enable rapid connectivity to web services, e.g., like AWS.

Application sales channel: Does the platform offer a marketplace to publish IoT applications? Some providers offer a marketplace (e.g., Libelium) to support developers in publishing applications. On other platforms, the developers rely on external marketplaces e.g., Arktik (Samsung), Pega 7 (Pegasystems).

Platform openness: To what extent is the platform open for modifications? Some platform providers follow the open source approach, i.e., the platform code can be modified and is open to run on any third-party device (e.g., KAA IoT platform). In contrast, there are platforms that are hardware proprietary and run exclusively on specific devices (e.g., Siemens Mindsphere), or software proprietary, which means that they can operate on any device with no access to the platform code. Some platforms are also fully proprietary, meaning that developers cannot run the platform on third party devices or change the platform code (e.g., Ayla IoT platform).

Service Platform

Operational level: On what level is the platform operated? IoT platforms run on different operating levels. Some run on a central cloud and manage millions of devices (e.g., Grovestreams), whereas others can be operated on edge devices such as a local gateway or small single-board computers (e.g., Phao, Fosstrack). Furthermore, some other platforms have a flexible structure and can run on both levels (e.g., Nimbits).

Core technology: What core technology does the provider supply along with their platform? The core technology may include sensors and microcontrollers (e.g., Siemens, General Electrics), telecommunications technologies (e.g., Cisco, Huawei, Vodafone), cloud infrastructure (e.g., Amazon, Google), or other technologies.

Organizing Model

Partner system: How is the access to the partner system organized? Some providers operate a proprietary partner system which does not allow the direct participation of complementary providers. Other providers offer direct registration for the partner program, taking into account complementary competencies and services. Some providers do not operate a partner system at all.

Degree of support: What kind of support does the platform provider offer? Some platform providers offer non-personal technical support e.g., via documentations or an online forum, whereas others run personal technical support teams. Some providers give additional business support, for example, in finding an IoT business strategy.

Operation mode: Who operates the platform? Some providers exclusively operate the platform on their own, whereas others also allow operation by third parties, for instance, on the customer's infrastructure or an external cloud service provider.

Revenue Model

Pricing model: What pricing models does the platform provider follow? Platform providers mostly distinguish between restricted developer projects (e.g., including

limited connected devices) and professional enterprise projects (e.g., large scale projects). Some platform providers do not charge the developer projects and solely price enterprise projects whereas others charge both kinds of projects. A few providers offer their platforms free of charge (e.g., KAA, Node Red, Paho).
Transaction based revenues: What are the transaction based revenues received by the platform provider? Platform providers make revenues on different kinds of transactions: e.g., per connected device, per API call, or per generated traffic. Other providers combine different sources or calculate the price per specific request.
Continuous revenues: Is the platform provider receiving continuous revenues? Some platform providers charge a fixed fee regardless or in addition to the actual transactions (hybrid pricing). Others follow a pure “pay as you grow” approach and charge no minimum fees.

4.2 Archetypes

The analysis identified nine clusters, each cluster covers between 15 to 32 IoT platforms of the 195 data samples. The extracted clusters have different centers along the dimensions and characteristics of the IoT platform business model taxonomy. As the taxonomy is mutually exclusive and collectively exhaustive, the results can be presented as percentages (table 3). For instance, in the sixth Cluster, 94% of the platforms offer application development as a core capability for developers, whereas 6% of the IoT platforms provide analytic capabilities for incoming device data. In the following, we present the characteristics that differentiate the nine clusters.

Cluster 1 - Embedded Device Operation Platform: Platforms in the first cluster provide capabilities to develop and operate embedded software on devices. As devices are equipped with more sensors, data processing power and increased connectivity, developers must manage the emerging complexity. Embedded device platforms support developers in overcoming the underlying device complexity, as the platforms ensure the integration of diverse hardware components and provide the functionality to develop add-on applications on the basis of the platform’s core. RIOT OS, is a typical example for such an embedded device platform and represents an operating system (similar to Linux or Windows for the personal computer) that can be operated on any connected device. Other embedded device platforms in the first cluster are Amazon (FreeRots), Microsoft (Windows IoT) and Googles (Android Things).

Cluster 2 - Device Connectivity Enablement Platform: Platforms from the second cluster enable and manage the connectivity of devices via telecommunication technologies (e.g., sim cards, router and gateways). The Cisco Jasper platform, with 40 million connected devices is probably the largest provider of this cluster. The platform ensures that all devices used by developers are connected in a reliable and secure manner. It also provides the software environment for efficiently managing the connectivity to all devices that are equipped with a cisco global sim. The platform is addressed fully to large scale business customers and operates in several industries (e.g., smart security). Other representatives of the second cluster are Telekom (Cloud of Things), or Ericsson (Device Connection Platform).

Cluster 3 – Device Management Platform: The third cluster describes platform providers who ensure that the connected devices are working accurately on a device level by running patches, updates for software as well as changing embedded configurations. For example, the Helix Device Cloud operated by the technology provider Wind River (Intel subsidiary). The platform supports developers in device monitoring, bidirectional file transfer, remote access as well as in the detection and diagnosis of device problems mainly for devices included in Wind Rivers partner system (e.g., ARM, Intel). The Helix Device Cloud is focused on business customers who develop solutions in several industries (transportation, building automation, street lighting) and provides integration opportunities in existing ERP and CRM systems. Other well-known industrial platform providers in the third cluster are Sierra Wireless (AirVantage), Siemens (MindSphere) and Relayr.

Cluster 4 - Device Data Storage Platform: The fourth cluster consists of platform providers who deliver scalable cloud infrastructure for the storage of device data and operating codes to developers. The SenseIoT platform, launched in 2015 and a spinoff of Sense OS, offers a storage platform where any device can connect to, by using the SenseIoT API and store streamed device data. As storage platforms are designed in a universal manner, they address consumers as well as business customer and run in multiple industries (no restrictions). SenseIoT is a fully proprietary platform that is operated on a cloud level. SenseIoT, as it goes for the fourth cluster, is a pure "pay as you grow" provider. Other prominent providers offering cloud storage platforms include Sales Force (IoT Cloud) or Pentaho IoT.

Cluster 5 - Device Data Analytics Platform: The fifth cluster includes platforms that perform various device data analyses based on millions of incoming device data sets, from data clustering to machine learning up to predictive analysis. GroveStreams, a platform on which IoT analyses run, offers a range of tools for analyzing and visualizing IoT device data and operates a typical business model from this cluster. Similar to the fourth cluster (cloud storage platforms), Grovestreams allows any device to be connected to the platform, and allows developers to use it in multiple industries. Other representatives of the fifth cluster are Uptake, DataRPM or Cloudera.

Cluster 6 - Application Development Platform: The sixth cluster describes platform providers offering IoT application enablement through a software development kit to enable rapid development and deployment of IoT applications. These platforms offer a set of tools that incorporate language-independent support for programming-in-the-large tasks. The platform provider, Ayla Networks, operates the Ayla IoT platform that is a typical representative of the sixth cluster. The platform contains a variety of APIs that can be used to rapidly develop iOS and Android applications based on incoming device data. Ayla operates the platform and charges enterprises as well as developer projects per customer specific request. Other platforms belonging to the sixth cluster are DeviceHub, Arktik (Samsung) and Temboo.

Cluster 7 - Application Development, Market Place Platforms: The seventh cluster covers platforms that offer application development capabilities (similar to the sixth cluster) for developers. A typical business model from this cluster is operated by IFTTT. The platform is a free cloud service that allows application building on the basis of the if-this-then-that logic (IFTTT). For instance, if a user possesses an intelligent lighting system, it can be linked to the users' location. If the user leaves the house, the light switches itself off. And when the user gets back home, the lights turn on by themselves. IFTTTs support all devices if the platforms standards are used and is one of the few platform providers who offer, a market place functionality that allows developers to publish their if-this-then-that applications. Other examples of the seventh cluster are the more business focused IoT marketplaces of Libelium, PTC or Telus, where hardware components are also offered in addition to applications.

Table 3. Cross cluster analysis

Cluster 8: Application Development, Open Source Platforms: The eighth cluster also describes IoT application development platforms. However, in contrast to the sixth cluster, providers from this cluster typically offer an open source freeware IoT platform for developers. A well-known example and a typical platform of this cluster is Nimbits, launched in 2014. Nimbits supports developers in application building by providing an easy to use web server that connects things to each other. Based on the open source approach, Nimbits can be operated on any device (from a single-board computer to a cloud service) and hence, by third parties. Other freeware open source application development platforms in this cluster include KAA Project and DeviceHive.

Cluster 9 - Multi Capability Platforms: Platforms of the ninth cluster comprise multiple capabilities, such as an environment to rapidly build frontend applications (cluster 6), to manage devices (cluster 3) as well as to analyze incoming device data (cluster 5). A typical example of this all in one platform approach is ThingWorx that was acquired by PTC in 2013. ThingWorx supports all devices that use the provided code library and covers several businesses mainly in the industrial area. ThingWorx provides strong integration capabilities in existing enterprise systems (e.g., of SAP and web services as AWS). Furthermore, platforms from this cluster typically offer personal technical as well as business support, e.g., ThingWorx employs an "IoT university" to support developers in monetizing their IoT applications. Other platforms belonging to the ninth cluster are OceanConnect (Huawei), Bosch IoT Suite or Microsoft Azure IoT.

5 Discussion

5.1 Implications for Research and Practice

Our study is the first to focus on IoT platforms as an essential building block of IoT by using a business model lens and empirically deriving archetypes of an IoT platform business model. Thus, our taxonomy presents an overview of the phenomenon by combining the most important dimensions mentioned in existing research e.g., device support, application sales channel, or the degree of platform support [2, 21] with newly identified dimensions that are essential to structure and compare the business logics of IoT platforms (e.g., customer focus, core technology, and pricing model). By abstracting beyond the business model of individual platform providers, our taxonomy helps to identify different types of IoT business models based on their dimensions and characteristics. In addition, the taxonomy as well as the archetypes allow for a quick understanding of important differences, and assist researchers in anchoring their contributions more precisely within these types. The iterative taxonomy development process devised by [27] allows other researchers to extend the presented taxonomy when new IoT business models arise in the future. In short, our taxonomy and archetypes provide new insights into the design options of IoT platform business models and help systematize and synthesize previous fragmented research at the IoT.

Our archetypes provide findings regarding the issue of how different hardware (e.g., telco and device manufactures) and software firms (e.g., cloud providers) strategize in a platform environment [8]. As business model archetypes can conceptually be viewed as linkages between the business strategies of the platform providers and their

operational strategy implementation [12], our results contribute to the emerging body of work regarding digital business strategies [29]. For instance, hardware manufacturers (cluster 2, 9) and telecom operators (cluster 3, 9) have been implementing a bottom up strategy by positioning their IoT platforms on top of their existing device offerings. By launching their platforms, those firms extend their existing offering (telco hardware, sensors, and microcontrollers) and add another opportunity for digital value creation while simultaneously shifting away from a hardware-centric business model. In contrast, software based companies have been following a top down approach by providing platforms for analytics, storage and application enablement or combining a bottom up (embedded device platform) as well as bottom down (multi capability platform) approach. For instance, Microsoft and Amazon have been providing an embedded device platform (cluster 1) as well as multi capability platforms (cluster 9) and can therefore provide the capabilities to operate, connect and build applications on top of existing devices, without manufacturing any. Third, there are startups that mainly operate IoT platforms within single product strategy. Their IoT platforms typically emerge with a system centric approach, often focusing on a top down strategy that incorporates capabilities to develop applications or managing devices based on code library's which is a facilitator for building up scalable, extensible, heterogeneous systems (e.g., Thing Worx) often supported by acquisition or funding of incumbent firms (e.g., PTC). However, as the interconnection of people and things progresses and numerous companies exploit the economic potentials, our archetypes provide a fruitful starting point of how different actors strategize in the IoT platform ecosystem.
Our research also provides important contributions for managerial practice. First, our database, taxonomy and archetypes offer managers a comprehensive overview of the fast moving IoT platform market. Furthermore, the taxonomy and the archetypes facilitate a quick understanding of the most common business model configurations of IoT platform providers. Second, our taxonomy serves as a concrete tool for business model innovation as it allows the necessary abstraction needed to identify unoccupied business models, as reflected by combinations of characteristics currently not offered by competing firms. We acknowledge that the taxonomy serves as a tool for simulating creativity but is not the key to reveal the perfect business model.

5.2 Limitations and Future Research

Our study is not free of limitations. First, [27] describe a taxonomy as never truly perfect, but in the best case useful. We argue that our developed taxonomy is useful in dissecting the business models of IoT platform providers. It also helps researchers and practitioners to identify differences within a business model configuration. Additionally, it is necessary to note that there is no perfect number of clusters and they are at best useful for a specific purpose. Second, the results of our research are limited to the business model configuration of the IoT platform providers at the time of data collection. As the IoT platform market was almost non-existent a few years ago and changes quickly, the database and the classification of individual providers will therefore become obsolete soon. However, the taxonomy and the archetypes of the IoT platform business models reflect the constituent elements of these instances and make them relevant for a longer period. Third, as we build our taxonomy within the empirical to conceptual cycles on the database, our study is inherently limited to the IoT platform providers contained in our sample and the respective information given at the provider's website. Though our database is quite large, following a consistent understanding of the research object and containing leading platform providers, not every platform provider has been listed in our dataset, nor can the reliability of the stated information be ensured. Fourth, given absence of a standard description of IoT platforms, the provider's information is often distributed across the entire website, using an inconsistent terminology and forcing the researchers to derive the complete information. However, as the study progressed, researchers became more experienced in handling this information and deriving complete datasets.

Given the current dynamic of the IoT field, a need for deeper and future-oriented investigations in the field is evident. Thus, the archetypes and corresponding characteristics can serve as starting points for studies on the transformation of the identified business model archetypes (e.g., extending core capabilities). In addition, when linking the identified business model archetypes to financial figures, they support the analyses of IoT platform providers with regard to aspects such as the probability of long-term success or the funding received, or the acquisition patterns of individual archetypes vis-à-vis others. Furthermore, the consideration of platform operating costs (not covered by the VISOR framework) in a future analysis will result in a more comprehensive understanding of the identified archetypes. However, based on the generality of our approach, following the aim to fit different types of IoT platforms, we had to compromise on the level of granularity. Future research can elaborate on precise taxonomies, by focusing on specific archetypes of IoT platform providers.

Abstract.
In order to compete with radical digital ideas, more and more large companies are founding corporate incubators. These small and agile companies are designed to accelerate disruptive innovation and transfer it to the parent company. However, it is obvious that the design and work in these newly established units are often efficient and the return of ideas cannot be effectively realized. This paper has collected a list of 131, partly non-public, incubators and evaluated them according to classic design parameters for companies (e.g., location, industry, etc.). In addition, success factors for digital corporate incubators (such as the design of the innovation process) were collected for deriving success principles.

Keywords.
Corporate incubators, innovation management, start-up management, innovation lab, new business development

1 Introduction

A lot of "traditional" and established industries are facing quick changes with possibilities of digitalization [1]. It is accepted in literature and business practice, that disruptive innovation is hardly carried out in long-existing and large-sized companies, which often rely on fundamental approaches within their Research and Development (R&D) departments [2]. This leads to a common trend: With the help of special organizational units, internal entrepreneurs or external startups, established companies try to force digital innovation [3].

Many established companies (e.g. Siemens, Lufthansa, Bayer) have set up incubators, which operate mostly independent from other business units [4]. The term "corporate/business incubator" is frequently used for incubators, which are connected to a company [3]. Research on corporate incubators is a relatively new area and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

incubators in companies have not been categorized [5]. The effectiveness and results of business incubators are controversially discussed, and success factors are not defined or even known [6]. Often parent companies interfere too much [7] or give too little budget as well as wrong resources [8]. Successful examples show that even supposedly small factors such as the location or the legal form can have a major impact on success. The outcome of the innovation and venture creation process has high uncertainty and needs flexible management [9]. Incubators and accelerators are, especially in business and technology-driven countries, highly needed [10].

The motivation for this work-in-progress contribution is to answer the following research questions (RQ):

RQ1: What types of corporate incubators do currently exist worldwide?

RQ2: What are the environmental preconditions of successful incubators?

2 Methodology

A combination of approaches was used following the mixed methods by [11] to identify patterns in hidden research field data.

1. **Identification**: In the first step, the authors created a list of currently implemented corporate incubators using a general desk research. Available sources such as the Deutscher Aktienindex (DAX), published case studies, documented interviews, as well as book chapters, were used to collect and further investigate incubators. Another approach was interviewing managers of corporate companies at international fairs, and in personal meetings about their current activities. Fragmented lists of incubators (e.g., list by [8]) were consolidated. The generated list seems to be the currently largest dataset on corporate incubators available and will be part of the poster presentation.
2. **Coding**: All incubators identified were further analyzed by internet research. Metadata (e.g. name, parent company, etc.), as well as relevant parameters (e.g. preconditions as budget, location, number of employees), were documented. These factors result from a literature review on fragmented success factors of incubators in scientific databases.
3. **Analysis**: Since the extension of the dataset is an ongoing research of the authors, the dataset as well as the interviews conducted with many incubators, a qualitative content analysis based on [12] was performed so far.

3 Preliminary results

Some statistics on the dataset and derived success will shortly be introduced. The four different categories of incubators shown in Figure 1 are based on the work from [10] and [5] and was adapted with the results from performed interviews and statistics. The, in literature, used category names are combined with the knowledge of several interviews to *Independent*, *Corporate-integrated*, *Communal/State* and *Academical incubators*.

3.1 Relative Distribution

Based on the list of 131 collected incubators, statistical analyses were possible. For several areas of interest, clear industry trends are visible.

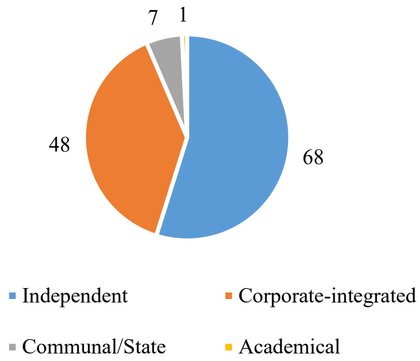

Figure 1. Incubator types

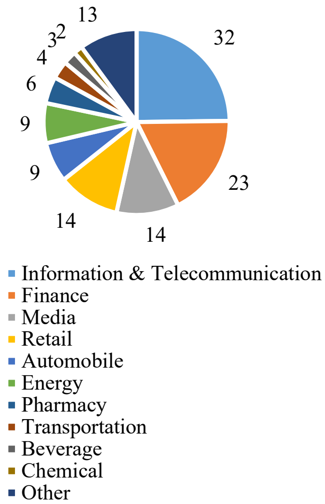

Figure 2. Industry fields of incubators

Figure 1 visualizes that most of the listed incubators are independently founded as separate company. Some are part of the formal parent organization (corporate-integrated). Only a small amount of analyzed incubators are communal/state (7) or academical (1) incubators. The high number of independent is an expected result as the research for incubators focused on corporate/business incubators. This is a reasonable result as communal/state driven incubators and academical incubators are not profit-oriented; they support local economics or regional institutes and cooperation with companies. Most incubators identified are in Germany and the USA. Within industries large companies establish incubators whose market offers are extensively digitized (Figure 2). Furthermore, incubators are found in those industries where significant changes are expected by radical technological progress.

3.2 Environmental preconditions of successful incubators

Besides the statistical analysis, four main design areas were identified during qualitative interviews based on [12], which can have a positive influence on corporate incubators, when they receive attention during the strategic setup. The interviews were performed with structured questionnaires and the answers were analyzed in the three steps *Clustering*, *Extraction* and *Aggregation* based on [13].

1. **Strategic focus**: Incubators need a clear strategic orientation in order to be able to prioritize and decide on a project. It was mentioned by managers of

incubators that existed more than 2 years have a lot of tasks from the existing parent company instead of focusing on entirely new business opportunities.

2. **Intervention phase**: To successfully focus on few but relevant and promising projects and business models, it is necessary to have criteria how possible projects are evaluated. Similarly, to principle 1 the most responsible managers of incubators mentioned in interviews that they had to establish an evaluation framework to validate and prioritize new ideas.
3. **Preferred exit-path**: For several interviewees, the spin-off exit path was especially the favourited exit-path for disruptive innovations in the 10% area. Especially for incubators from industrial companies, the exit path was mentioned in direct interviews as important.
4. **Corporate integration**: The transfer of projects into existing corporate structures needs proper configuration as problems can occur during the transfer. A success factor is to define the transfer into corporate departments with all stakeholders in the corporate structure. Some interviewees mentioned that the transfer must be defined during the initial configuration.

4 Implications for further research

This work in progress provides a comprehensive dataset on digital corporate incubators worldwide. The analysis of the success factors is in an initial stage and needs more work to be based on a broader information basis. As shown in 3.2 the invention phase is, of course, important for corporate incubators, but the exit path and the corporate integration is also of interest. The results and methods from this research in progress can serve as a general foundation for discussions with other participants of the research area at the conference. The generated list of incubators and examples that were evaluated more in detail can be used for further research with adaptions based on the discussion and remarks from the conference. The researched incubators have a strategical focus on corporate integration and independency as this is one key for medium- and long-term success. Regarding a low amount of white papers and industry studies more innovation labs are switching focus from corporate projects to company building.

Abstract. Many established companies currently face digitalization challenges. Part of their answer is often the creation of new digital business models based on new technologies, which do not necessarily replace the existing business model but act as additional source of economic value. Having two business models in parallel in the same company creates the opportunity of synergies between these business models. However, knowledge about the interaction between digital and non-digital business models remains scarce. This study, currently in progress, contributes to research by filling this gap and identifying synergies already taken by companies of various industries, leading to a better understanding of digital business models within established companies and their interaction with existing, traditional business models. For practitioners this study provides insights on how to benefit from parallel business models within a company and thus how to better face digitalization.

Keywords: Digital business model, business model, synergy, digitalization

1 Introduction

BMW created DriveNow as IT-enabled business model [1] offering car-sharing. However, BMW didn't terminate its existing business model of manufacturing cars and therefore has two different business models in the same company, one traditional and one digital. In fact, as new digital business models often go hand in hand with companies' answer to digitalization and as many companies have not yet faced digitalization challenges [2], even more new digital business models and co-existence between the new digital business model and the established business model can be expected [3].

While research attention in the past focused on conflicts, synergies and mechanisms on how to manage two non-digital business models in the same company [4, 5], these business models differ mostly through low-cost vs. premium products [6]. However, digital business model relate to value creation, delivery and capture through new digital technologies [7, 8] and the potential differentiation to traditional business models is large. So far researchers shed light on the interaction between digital and non-digital business models primarily through the differentiation of channels (offline vs. online) in

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

publishing and retailing [9, 10]. This leads to our research question: “What potential synergies exist between a new additional digital business model and the established business model?”

Through multiple interviews with managers from six companies from various industries, this paper identifies synergies between digital and established business models based on business model representation and the synergy theories of complementarities and resource relatedness [11-13].

The study at hand contributes to research by providing a better understanding of IT-enabled digital business models within established companies facing digitalization, answering the research call of Veit et al. [14]. Lastly, it supports practitioners to better manage and ensure the success of a new digital business model.

2 Theoretical Background

2.1 Digitalization

Digitalization can be described as the manifold sociotechnical phenomena and processes of adopting and using new digital technologies in broader individual, organizational, and societal contexts [15]. As of today this digitalization is a major challenge for many established companies from different sectors [2]. Hence, this topic is of importance for practitioners but is also recognized by IS scholars as it has reached top IS journals [16]. The focus is mostly on digital business strategies companies can employ to handle the digitalization [17, 18], often affecting changes in value creation with the use of new technologies leading to new digital business models.[19]

2.2 Business Model Representation

Many definitions for business models exist [20], the commonly accepted definition by Al-Debei et al.[14, 21] is: “The business model is an abstract representation […] of all core interrelated architectural, co-operational, and financial arrangements designed and developed by an organization [and] all core products and/or services the organization offers” (p.372). Furthermore, a digital business model is based on new technologies to create, deliver and capture value [7] e.g., video-on-demand services [14], departing from the differentiation of online vs. offline channels [10].

The business model representation from Steiniger et al. [22] (adapted from [7]) is used as he showed that its suitability to compare non-digital and digital business models without being too abstract. The nine components, grouped in four categories, of the business model representation are finally:

1. Product: Value Proposition
2. Customer Interface: Target customer, Distribution channel, Customer relationship
3. Infrastructure Management: Capability, Value configuration, Partnership
4. Financial aspects: Cost structure, Revenue Model

2.3 Synergies

The concept of synergy primarily comes out of the strategy and economics research [13]. The two types of synergies are super-additive value synergy and sub-additive cost synergy.

Super-additive value synergy is based on a complementary set of resources and can be described following the economic theory of complementarities as "doing more of one thing increases the returns to do more of another" [12]. Sub-additive cost synergy refers to the use of common resources across units and is therefore based on resource relatedness [11].

Similar to Radszuwill and Fridgen [23], the definitions of synergies can be adapted to the business model context with (a) and (b) being two business models:

- *Super-additive business model value synergy*: When the sharing of business model components between two or more business models leads to increased value compared to conducting the business models individually (Value(a+b) > Value(a)+Value(b)).
- *Sub-additive business model cost synergy*: When the sharing of business model components between two or more business model leads to lower costs compared to conducting the business models individually (Costs(a+b) < Costs(a)+Costs(b)).

3 Research methodology

This study follows the interpretive research principles of Klein and Myers [24] for qualitative, idiographic research using a multi-case approach [25-27]. We selected companies from various industries and size to allow for replicability. Only established companies having an additional digital business model for more than two years were chosen to ensure that they can sufficiently inform the research [28]. In each of the six cases two semi-structured interviews, based on an interview guideline, were conducted, on site or on phone, with two managers to discover different viewpoints and remove biases of interview partners [29, 30]. Additional documentation, publicly available or shared by interview partners served as secondary data source. Coding is done following the business model representation components as first order coding elements [31, 32]. Table 1 summarizes the cases and positions of interview partners.

Table 1. Selected cases and interview partners

Case ID	**Sector**	**Size** (number of employees)	**Interview partner**
1	High-tech	10,000 – 50,000	Head of Digital innovation unit
			Project manager within IT
2	Pharma-ceutical	> 50,000	Manager within digital innovation unit
			Team leader within IT
3	Automotive	> 50,000	Manager within digital innovation unit
			Team leader within IT

Case ID	Sector	**Size** (number of employees)	Interview partner
4	Utilities	10,000 – 50,000	Manager within digital innovation unit
			Team leader within IT
5	Logistics	< 10,000	Manager within digital innovation unit
			Chief Information Officer
6	Automotive	> 50,000	Head of Digital Innovation Unit
			Team leader within IT

4 First Results

Our initial research reveals potential synergies along several business model representation components and we focus in this section on case 1 only, to demonstrate first results. In case 1 the company built up a subscription-based platform, offering image recognition and analytics of images and data collected via medical technology of different manufacturers as new digital business model. Sales and maintenance of high-tech, e.g. medical technology underlie its traditional business model.

Super-additive business model value synergy: Through the new digital business model, the *value proposition* of the traditional business model is enhanced as existing products can be directly connected to the platform, thus offering higher value to similar costs. Also, in terms of *capabilities* the traditional business model benefits as knowledge about new capabilities of the digital business model such as cloud development or agile way of working are shared.

Sub-additive business model cost synergy: The development of the new digital business model is accelerated thanks to solid and reliable *distribution channels* within the traditional business model. In fact, existing channels (e.g., via industry fairs) were used to not only promote the traditional business model but also the new digital business model.

5 Discussion and Conclusion

This paper at hand can be seen as an initial examination of synergies between additional digital business models and established business models within companies. Despite being limited by the number of cases, first results indicate that the traditional business model benefits from super-additive synergies (e.g., complementary products) whereas the new digital business model is supported by sub-additive synergies (e.g., resource relatedness). Further analysis will create a more comprehensive overview of synergies, along all business model components, contributing to research and practice by a better understanding of new additional digital business models, grounded on synergy theory, and of companies' answer towards digitalization. Future research might focus on an in-depth quantitative analysis of the impact of business model synergies on the performance of a new digital business model.

Investigating Personalized Price Discrimination of Textile-, Electronics- and General Stores in German Online Retail

Tsagana Badmaeva[1], Joschka Andreas Hüllmann[1]

[1] WWU Münster, Interorganizational Systems Group, Münster, Germany
{t_badm01,huellmann}@uni-muenster.de

Abstract. Developers of pricing strategies in e-commerce businesses see a wide range of opportunities for deploying online price discrimination techniques given their ability to track consumers' online identity and behavior. In theory, an increasing use of personal data enables organizations to show every single consumer their own personalized price, which is determined by the consumer's characteristics, e.g. age, gender, surfing history, or location. This paper aims to explore the existence of online price discrimination activities within the German e-commerce market using a three-method approach. First, inquiring the online retailers via email and investigating their public documents; second, surveying students; and third, using a software crawler to simulate surfing activity. Our results do not provide any evidence of individualized price discrimination, which, we argue, is due to economic and political reasons, not technical reasons.

Keywords: online price discrimination, tracking, privacy, e-commerce, personalization.

1 Introduction

The German e-commerce market increases steadily as people are more comfortable and willing to purchase goods online[1]. At the same time, the trend for personalization in online retail is growing [1, 2]. We see prospects of e-commerce businesses to collect and evaluate personal data such as age, gender, location or device used in order to offer specific prices for each customer – called *personalized price discrimination*. However, the public is wary of this development and raises concerns about privacy, tracking and consumer protection. Institutions such as the OECD [3], the German Federal Ministry of Justice [4], consumer protection initiatives [5, 6], newspapers [7, 8], and the citizens question what effects data and algorithms have on consumers. For a debate on price discrimination, it is vital to uncover discriminatory practices in order to make interac-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

tions with online retailers transparent. Using personal data for setting prices is a sensitive issue, in particular in Germany [9], which could require political or legislative measures in the future [10].

Previous studies [6–8] explored personalized pricing practices of internationally operating e-commerce retailers, ranging from hotel-booking sites to general online retailers, by using software scrapers. However, the studies do not focus on the German market, while existing German studies prefer a manual approach to collect data and have small sample size [9–11]. We lack comprehensive information on the current status of personalized pricing in German online retail. To close this gap, we suggest triangulating results from manual data collection and automatic scraping.

In this paper, we explore the prevalence of personalized pricing activities performed by textile-, electronics- and general stores in the German online retail market. We selected the eleven biggest online retailers by revenue and investigated the presence of price discrimination practices in their shops by combining surveys, an automated crawler and a discourse analysis. Our study contributes an overview of the tracking ecosystem and reports on the existence of personalized pricing activities in German online retail. It provides survey items and a software crawler to identify such mechanisms. Our research does not detect any price discrimination practices for the selected online retail shops, which, we argue, results from economic and political reasons.

2 Background

2.1 Price Discrimination

Effective pricing strategies are key to increase demand, sales and profit [16]. One pricing strategy is price discrimination (or differential pricing). In general, price discrimination is defined as a variation of price cost ratio across units or groups of buyers [17]. In our context, we define price discrimination as follows: the producer sets varying prices, which includes discounts, for an identical product or service for different consumers based on the consumer's characteristics, the time or location of purchase, the amount of purchase, or other relevant information [14], [16–18]. The goal is that the consumer pays the highest amount that they are willing to pay, i.e. the marginal willingness to pay (WTP) [21]. Price discrimination requires information about consumers and the producer’s ability to estimate the consumer’s marginal WTP as accurately as possible [19]. In an ideal information environment, the producer can set the price to the consumer’s marginal WTP to extract the maximum consumer surplus and maximize his profit. Depending on the available information, three degrees of price discrimination are distinguished [17, 22]:

Third degree price discrimination describes different prices for segments of consumers and is the most common form of price discrimination. It requires sociodemographic information about the consumer [17]. Examples are student or senior citizen discounts or regional price variations. **Second degree price discrimination** is based on the *amount* or *quality* of a given product or service, usually including consumers’ self-selection of *amount* or *quality*, to mitigate the difficulty of distinguishing consumer types. Examples for *amount* are volume discounts and examples for *quality* are airfares, namely business and economy tariffs. **First degree price discrimination** requires the most information as each person gets a personalized price based on their characteristics [17]. With detailed information about the consumer, the producer can determine the maximum WTP and capture the maximum consumer surplus. Collecting enough information to implement first degree price discrimination is difficult. Nonetheless, large-scale data collection is a first step to enable first degree price discrimination. For example, Shiller [23] demonstrated a profitable first degree price discrimination model based on 5000 trackable consumer characteristics using behavioral and sociodemographic traits. Historically, this type of price discrimination is known from the used cars or insurance market or from the bazaar in one-to-one transactions. Now, it is possible to implement and automate it for all consumers online.

The degrees are not mutually exclusive [19]. Personalized price discrimination is based on the segments of third degree price discrimination, with the ultimate goal to achieve a first degree price discrimination. Alternatively, we can explain personalized price discrimination as an extreme case of third degree price discrimination with segments of size one.

2.2 Conditions and Implementation of Price Discrimination

Certain conditions must be met to implement price discrimination. A firm (1) needs some market power, or consumers buy elsewhere, (2) it needs to control the sale of the product or service to set the price and (3) the consumers' willingness to pay must differ from one another [17]. Sufficient information about consumers to distinguish them into segments must be available [24, 25]. The segments need to be actionable, substantial, accessible, measurable, profitable and stable and are distinguished by behavioral, psychographic, sociodemographic and geographic criteria (for more information see [23–25] [2]). Behavioral criteria include used channels, brand loyalty, buy volume, and previous purchases. Psychographic criteria include lifestyle, social identity and personality, for example, attitude towards risk, expectations of quality of products. Sociodemographic information includes gender, age, children, job, education, income. Geographical criteria are distinguished into macro (country, city) and micro (district, street). Based on data for each customer, segments can be inferred from quantitative statistical analysis such as cluster analysis or machine learning algorithms [26, 27].

The data is sourced internally or acquired externally. Internal data includes customer master data from CRM systems, i.e. data that a consumer enters on the website, for example, name, address, city, etc. Other data is based on the actions that customers perform, i.e. which articles they view, click, purchase, rate and review. Besides, the data includes technical information such as IP address, device, user-agent, or operating system. Prevalent shop software solutions offer the functionality to collect this data, and to use it for consumer segmentation as well as price discrimination. In addition to analyzing internal data, shop solutions offer integrations with external data sources.

[2] Market segmentation is a concept that goes beyond price discrimination.

External data sources originate either from third party analytics services or trackers[3], which capture users' online activities on the web [28] and may provide extended insights [29, 30], or from offline datasets, e.g. voter records, or vehicle owner data. There are multiple services available, for example, TruSignal, Adobe Customer Experience Cloud, Google Analytics 360, Bluekai, Lotame, and more. However, the market of these services is highly concentrated around a few big players, who accumulate data, which makes it valuable to acquire, but also sensitive to privacy issues [29–31].

2.3 Consumer Perspective

Growing consumers' awareness of aggressive tracking and the amount of gathered data lead to a discussion on the privacy and ethics of tracking and personalized prices. This is exacerbated by the fact, that the big players accumulate most of the data [32, 33], and the extent of data collection and sharing is concealed from consumers [30].

Since online retailers are not transparent about their pricing mechanisms, it is unknown if personalized pricing takes place at all, and what type of data significantly changes the segmentation of consumers and the resulting prices [15]. The growing data collection and the lack of transparency on what consequences particular information has, lead to privacy issues and may unsettle consumers [34]. There is an information asymmetry between the online retailers and the consumers [31]. Consumers can only believe the privacy statements, which are mandated since the EU-GDPR and given by online shops, as there are no (easy) neutral ways to check for personalized price discrimination [35]. For a debate on personalized price discrimination in Germany, it is crucial to provide empirical means to investigate the current extent of personalized price discrimination in online retail. Therefore, we contribute such means to assess the extent of personalized price discrimination, empirically, and report on our results.

3 Related Work

Previous studies have found little to none price discrimination in online retail. Despite checking 200 U.S. shops, Mikians et al. [12] found only few price differences caused by a combination of system, sociodemographic and behavioral criteria. Hannak et al. [11] explored U.S. shops and the tourism industry using Amazon Mechanical Turk and simulated user profiles. They found different prices on nine of sixteen e-commerce websites due to changes in system and behavioral criteria. Vissers et al. [36] and Hupperich et al. [13] investigated the tourism industry, both using simulated browser fingerprints and user profiles. Vissers et al. did not find any price discrimination, while Hupperich et al. find differences based on geographic criteria. For both studies, other criteria did not lead to any price changes. Schleusener and Hosell [4] and Kraemer et al. [14] focused on the German market using a manual approach. The former found

[3] Due to space limitations, we cut the technical description of third-party trackers and the tracking ecosystem. Instead, an explanation is provided in [38, 39].

price discrimination in the tourism industry, with system criteria being relevant. Interviews with professionals corroborated their results. Kraemer et al. [14] found price discrimination based on geographic and system criteria.

The findings of previous studies are inconclusive, as some results indicate price discrimination in the tourism industry, while other studies find no price discrimination at all. Furthermore, only two studies focus on the German online retail market, leaving it underexplored and requiring further research.

4 Research Design

To investigate the existence of price discrimination in the online retail market, we select the eleven biggest German online e-commerce retailers according to their annual revenue. They are the most relevant shops from a consumer rights perspective, i.e. more revenue means more involved consumers, and we choose textile, electronics and general stores, because they are less explored compared to the tourism industry. First, we analyze the discourse on price discrimination using public information on the selected shops, shop software vendors, tracking providers followed by contacting them. Second, we build a survey based on the found information, which captures personal user information. Test persons filled out the survey and use their personal devices to check prices in each shop, manually. Third, we use an automated software crawler, which simulates user activity and user profiles, to check the prices in each shop.

Table 1. Selected Online Shops (Revenue in Million EUR in 2015)[4]

Shop	*Revenue*	*Sector*	*Shop*	*Revenue*	*Sector*
amazon.de	7.790,60	General	tchibo.de	450,00	General
otto.de	2.300,00	General	conrad.de	433,20	General
zalando.de	1.031,80	Textile	alternate.de	376,70	General
notebooksbilliger.de	610,90	Electronic	hm.de	344,60	Textile
cyberport.de	491,30	Electronic	esprit.de	342,00	Textile
bonprix.de	484,70	Textile			

First, for the discourse analysis, we investigate the most prevalent trackers among the top 20 worldwide [33, 37] and observe the involved actors as well as their activities. We evaluate public documents on their websites in order to understand what, how and why they track the information of consumers in their services. Besides the trackers, we look at the three biggest standard shop software by market share in 2017 (Shopify, WooCommerce, Magento)[5]. We evaluate their websites for functionality related to tracking, consumer segmentation and price discrimination; and what consumer criteria the software makes use of. We also contact them directly, and assess available third

4 http://www.statista-research.com/wp-content/uploads/Infografik_Top-100-Onlineshops_D.pdf (last access 2018-10-09).

5 https://www.statista.com/statistics/710207/worldwide-e-commerce-platforms-market-share (last access 2018-10-09).
The market share has changed since we collected the data.

party addons for each shop software. According to the EU-GDPR, e-commerce companies have to disclose how they obtain, process and use personal citizens' information as well as the purposes of doing so. This implies that companies are to disclose whether they perform any kind of price discrimination activities using personal data of customers. Using this opportunity, we assess the privacy notices of each online shop and contact the data protection departments of each online shop. The question that we forwarded to the data protection departments is:

"*Due to the EU-GDPR, we would like to inquire, whether and in which way personal data influences the determination of visible prices, including potential discounts or vouchers (also via mail or email), in your online shop.*" (Translated from the original German statement).

Second, the three checked shop software packages provide the functionality to implement personalized price discrimination, but there is no information if any of the shops use this feature. Only the number of reviews hints that the features may be used, so we use the criteria collected from the discourse analysis to develop a survey. The survey consists of two parts. The first part is a list of 20 hyperlinks to products of the selected shops. The second part asks for behavioral and sociodemographic criteria as well as system attributes as seen in Table 3. We distributed the survey to four different student groups in Germany depicted in Table 2. The students checked the prices of the 20 selected products with their own devices, browser settings, and accounts and filled out the survey accordingly. Some students used proxies and VPNs, but the most common types of connection were University WiFi and mobile data. Due to logistical issues, we were unable to record the type of connection.

Table 2. Samples

Round	*Group*	*Size*
1st round	International students	12
	PhD students	14
2nd round	Bachelor students	13
3rd round	Bachelor students	22

Table 3. Survey Items

Survey Items	
Age	Manufacturer
Gender	Hobby
Device Type	Previous Visits
Operating System	Previous Purchases
Language	Social Media Logins
Apps	

Within the groups, at least 10 different participants checked each product's price. All checks were conducted in one session at the same time, to rule out prices changes over time. Between the groups, different products and shops were tested to increase the breadth of the study. The participants recorded all prices in EUR, which we later analyzed.

Third, due to the logistics of conducting a survey, we develop an automated software to triangulate our findings based on [12, 13]. The goal of the software is to simulate ordinary user activity for seven days, to build five online user profile and accumulate cookies. After seven days, it checks the prices using the five profiles.

Table 4. Crawler Profiles

Profile	*Keywords*
Profile1	Frankfurt Football
Profile2	Tennis Dortmund
Profile3	Horseriding München
Profile4	Cooking News
Profile5	Gucci Rolex

Table 5. Actions for Profile Simulation

Website	*Engagement Actions*
twitter	click and like
reddit	click, like and subscribe
facebook	click, view and like
google	click, scroll and wait
bild	click, scroll and wait
youtube	click, view and like

Each user profile is generated from two keywords (Table 4) that the crawler uses to engage on search, news and social media sites (Table 5), and is assigned a distinct proxy to simulate geographic location. The software is implemented in Python using Selenium with the Firefox driver and the source code is available on GitHub.

5 Findings

Discourse Results. The tracking ecosystem sees actors with varying primary activities, from data management platforms to marketing solutions, who track consumers' information. We found that most of them have dedicated services that perform tracking. The tracked data is distinguished into sociodemographic, behavioral and system criteria, sourced internally and externally. The purposes of tracking by the actors overlap. The criteria in Table 6 depicts what data the clients of the actors can acquire, not what data the firms behind the services collect and analyze.

Table 6. Players in Tracking and Targeted Analytics. Legend: Google Analytics 360[G], Facebook Analytics[F], Amazon Pinpoint[P], Adobe Target[T], Optimizely[O], SAP Hybris Marketing Cloud[H].

Main Service	Data Management Platform[G], Advertising[G,F,O], Marketing Solution[T,H]

We reached out to the three online shop vendors to inquire whether their software supports personalized price discrimination. Although it is not a core functionality of Shopify and WooCommerce, it is feasible through addons. For Shopify, multiple addons are available, for example, "Customer-Specific Pricing", "Storakle", or "Segment

Builder", while for WooCommerce, we only found "WP Statistics". Magento has advanced customer segmentation built-in, which can be enhanced by the addon "Prices per Customer". Magento also allows the integration of external data, for example, the import of offline purchase data.

We found that all of the observed online retailers authored a privacy declaration, in which they depict data use for targeted advertising, statistics and server operations, but not for pricing purposes. After inquiring about the use of price discrimination via email, the majority of the contacted online retailers (7) denied usage of discrimination activities towards customers based on their personal data, while Otto.de, Bonprix.de, hm.de and Amazon.de did not answer the mail at all. Tchibo.de and Esprit.de state that they select consumers for discounts and gifts based on personal data and previous purchases, i.e. they engage in indirect price discrimination based on ex post discounts.

Survey Results. Due to space limitations, we do not report all descriptive statistics in detail. We only report them for selected items and only the top three values: n=61, age (M=24.84; SD=4.5), gender[6] (64% male; 18% female), device type (34% Windows; 31% Android; 13% iOS), and language (62% German; 26% English; 12% other). Most selected hobbies are travelling (46%), technology (41%) and sports (20%) and most visited shops include Amazon.de (43%), Zalando.de (28%) and Notebooksbilliger.de (25%). Top installed apps are YouTube (56%), Facebook (46%) and Instagram (38%). The first round with 26 international and PhD students showed a few insignificant prices differences. For four distinct users, prices differed by 9.00 EUR, 2.00 EUR, 0.05 EUR and 0.09 EUR on Otto.de, Zalando.de and Cyberport.de (last two). For the biggest difference, 9.00 EUR and 2.00 EUR, we compared the survey characteristics of the users with differing prices. Although, both of them were using mobile devices, the model and language of those devices were distinct from the other test persons. The second round of tests, in which 13 bachelor students participated, showed two differences in prices at 0.05 EUR and 0.60 EUR for Tchibo.de and Alternate.de. The last round with 22 bachelor students found only one instance of price differentiation by 0.10 EUR on Amazon.de. Overall, we tested 93 prices of products. Due to insufficient cases of price differentiation – presumably caused by transcription errors – the results do not substantiate the existence of systematic online price discrimination in the observed online retailers.

Crawler Results. Utilizing the crawler, we scraped the prices of 865 products with each of the five profiles, totaling 4325 checks in 27 sessions. We crawled all prices within the sessions at the same time, while the different sessions took place throughout one month. The shops Notebooksbilliger.de, Hm.de and Conrad.de are missing in the results due to their bot protection. They recognized our crawler and prevented the page load and scraping of prices. To add another electronics store, we crawled Mediamarkt.de instead. Apart from software errors, when the website layout changed and the scraper failed to extract the correct price, we did not find a single difference in prices in the entire data set for any of the selected products and shops.

[6] Eleven participants did not fill out their gender.

6 Discussion

Our results are consistent with previous studies and show that personalized price discrimination is not widely used in online shops. Nevertheless, as evidenced by the practices of the tourism industry [4, 11, 13], the implementation of personalized price discrimination is generally feasible. The first key condition to implement it, is sufficient information on the consumers to distinguish them into segments [19, 24, 25]. Based on the current data collection means, enough information on the consumers is available to derive such segments and to implement third degree price discrimination [17, 22]. Schleusener and Hosell [4] hypothesize a reason for the lack of personalized price discrimination may be the lack of technical expertise by German online retailers. However, our results show that all standard software packages provide the means to collect internal data and offer integrations with external data providers. Furthermore, if the shops have the expertise to develop a custom shop software, then they have the expertise to implement consumer segmentation and price discrimination. Hence, we argue that the lack of expertise is not the reason for the non-deployment of price discrimination practices.

Instead of technical obstacles, the reasons may be economical. The data providers do not disclose any prices on their websites, but acquiring external data may be costly compared to the value it provides, so acquiring external data may not be profitable for online shops. Yet, this does not explain the lack of price discrimination using internal data. As stated in the second condition for price discrimination [17], the retailer needs market power, or consumers will switch to other shops, if the same products are offered elsewhere. This is exacerbated by readily available online search. Another reason may be that employing personalized price discrimination can hurt the brand [4], because changing prices can lower the perceived price fairness of consumers [16].

Online retailers acquiring and exchanging customer data with third parties (including outside of EU legislation), without knowledge by the consumers may bring about dissatisfaction [10]. German citizens, compared to other countries and cultures, are sensitive to privacy issues, in particular since the EU-GDPR is effective [9]. The threat of legal action by consumer protection initiatives, and potential repercussions due to mistreatment or theft of data, may bar online retailers from implementing personalized price discrimination. It may be too risky to lose the trust of consumers and their brand value over the comparatively small profits, delivered by personalized price discrimination practices.

We conclude that the reasons for the lack of price discrimination in Germany are not technical, rather it must be for economic and political reasons. The digitalization, paired with intransparency of data collection and usage, especially by international players, brings rapid changes and means that price discrimination can start to occur any time. Thus, it is imperative to monitor potential price discrimination continuously. In a bigger project, our software can be improved with better monitoring abilities to provide ongoing assessment of personalized price discrimination.

We also received anecdotal references from colleagues and consultants, which we were not able to corroborate. Contrary to our findings, three retail and e-commerce consultancies claimed that their clients are engaging in online price discrimination. We assume that either their clients have not rolled out any price discrimination yet, or they are in pre-testing, or they are not part of our selected shops, or our methods did not detect them.

7 Conclusion

In previous studies, German shops were not widely tested using surveys and automated scraping, and the ecosystem with its players was not systematically explored. Hence, our study makes a valuable contribution, as we investigate the prevalence of personalized price discrimination practices in the German e-commerce market through triangulation. By using three different methods, we reach a holistic picture of the ecosystem, its players and their use and exchange of data for the purpose of price discrimination. Contrary to our expectations, the results of our study do not substantiate that online retailers in Germany perform online price discrimination practices. In particular, the discourse analysis shows that the technical possibilities for price discrimination are widely available. Yet, both the survey and the crawler results show no evidence of price discrimination by the tested online shops. As discussed, we argue that this is due to political and economic reasons, not because of technical reasons.

The discourse analysis is limited to the official documentation, references and responses of the players. The survey and crawler are restricted by the sample size. Other limitations include the colocation of the survey participants and the usage of University Wi-Fi, since one of the characteristics that was proven to alter prices within consumers is the geographic location. Some participants made errors while transcribing prices. Several shops detected the crawler as a bot. We used free proxies, which might be blacklisted and negatively affect the price scraping, and the crawler directly accessed the product pages and did not traverse the shop websites. Nevertheless, our results match those observed in earlier studies. Future iterations of this experiment should be conducted with larger sample size and an improved crawler. The reasons for price discrimination can be further explored by conducting expert interviews.

Various institutions such as the OECD [3], the German Federal Ministry of Justice and Consumer Protection [4], consumer protection initiatives [5, 6], newspapers [7, 8], and most importantly, the German citizens and consumers recognized price discrimination as a major concern. Personalized price discrimination is a prime example of the algorithmization and digitalization of society and economy, and what effects data and algorithms may have on its people. Due to the digitalization and rapid changes of the online ecosystem, we encourage a continuous assessment of price discrimination practices in the future.

8 Acknowledgements

We thank Felix Murrenhoff, who programmed the original version of the crawler and collected data.

Abstract. The term Internet of Things (IoT) is widely used and discussed. However, there is still no scientifically generally valid definition and therefore no uniform understanding of the term in practice. To counteract this, we present a possibility to limit the term with the help of applications in the IoT environment. Specifically, we analyze the use of IoT along the value chain of companies by conducting a structured literature analysis.

Keywords: Internet of things, applications, use cases, value chain, retail

1 Introduction

The Internet of Things describes the digitization and internet-capable integration of physical objects into the networked society [1]. In addition, the term includes things that not only collect local information autonomously, but also learn from it, adapt it and use it to interact with the world around them [2-4]. The aim of such devices is to create added value through appropriate services. In this case, the notion of IoT goes back to Kevin Ashton and the Auto-ID Center at the MIT. They designed a company-wide radio frequency identification (RFID) infrastructure in 1999 [5].

Today, there is an increasing number of previously non-digital products (e.g. light bulbs, bikes and watches) being equipped with sensing technology, application logic, and a network connection. Generally referred to as product service systems (PSS), they are defined as a combination of products and services. While these services initially only extended the functionality of a product [6], such systems may have inverse roles nowadays, in which the product is only a vehicle of the service. Their emergence has led to numerous areas of application in sectors like energy, healthcare, or home automation, changing the nature of business models in these industries [3]. IoT is also omnipresent within companies in all areas such as production and logistics. Through 2020, an estimated 26 billion smart objects will be installed, generating a market size of approximately $7.1 trillion [7-9].

Although IoT is omnipresent and a widely discussed multidisciplinary topic in various fields such as computer science and telecommunications, there is still no unified and valid definition of the term in the academic literature [10-12]. According to our

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

research, there is currently a different understanding of what is meant by IoT, which in turn makes it difficult to discuss. In order to counteract this situation, we have set ourselves the goal of developing a universally valid definition of IoT in science and practice. In particular, we want to counteract marketing terms such as Industry 4.0 and analyze the technical bases of the terms. From our point of view, IoT is nothing new, but merely the linking of existing technical components with corresponding business models. Some researchers have also noted a clear need for research in this area [1], [11], [12]. In order to define an object, it is necessary to become aware of all facets of it. For this reason, we have conducted an extensive investigation of existing applications of IoT. Since the variety of IoT applications ranges from music events to intelligent devices in the medical field, we have limited ourselves to the business process of value creation in a company in order to be able to make an abstraction on this basis [13], [14]. By identifying all facets of the IoT along the value chain, we try to investigate all similarities and then summarize them into a common definition. The paper on hand aims to present our research idea and the first results of the far-reaching literature analysis.

2 Theoretical Background

2.1 Research Methods

As part of this work and the associated search strategy, the literature analysis process was extended or modified in some places according to vom Brocke et al. [15] (cf. Figure 1). In addition to the aforementioned five-step search process, reference was also made to the information flow diagram of Frost and Lyons [16].

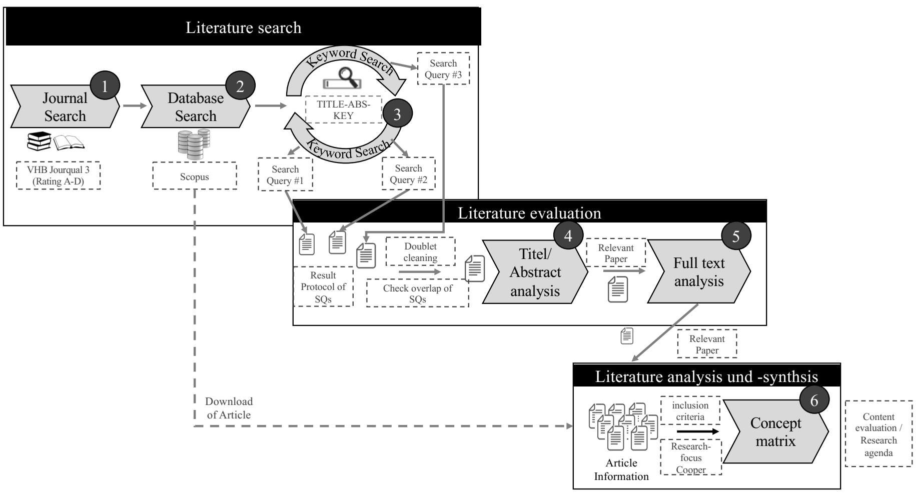

Figure 1. Approach to literature research

The figure illustrates the extended, six-stage search process which was carried out within the framework of this literature search. It should be emphasized that the keyword search consists of several iterations (phase 3). After defining the framework conditions within the first and second phase according to the research question, the actual search process can be started. The basis for this search is the so-called extraction log, in which all the necessary article information for each iteration is stored and which is used at the end for a final concept matrix. The matrix consists of articles, which are filtered out and the final search string can be worked out step by step. After the third phase has been successfully completed, the actual analysis steps (phase 4 & phase 5) can be started, which in this case do not differ from the procedure of vom Brocke et al. [15]. At the end, the result is the final extraction log, which in turn can be used as the basis for the concept matrix. It should also be mentioned that although forward and backward searches are relevant for the classic vom Brocke et al. [15] method, they were not part of the literature search strategy in the context of this work. The results of the individual phase and the number of identified contributions after the various search iterations are explained in more detail in the following chapter and evaluated accordingly.

2.2 Literature Review

As literature addressing definitions of IoT is very limited, we expand the focus of our research goal by looking at every facet of IoT. Due to the huge amount of literature concerning IoT and in line with scholars who recommend focusing on high quality outlets, we only considered articles published in outlets ranked (A+ to D) in the VHB-JOURQUAL3 [17]. For this purpose, the respective sub-ratings of the VHB were used as the basis for the search. We conducted a structured literature review following the methodology explained above. We used a search query consisting of three building blocks. On the one hand, these consisted of the IoT focus and the Value Chain focus with the respective key words following Porter [18], which can be seen in Figure 3, and on the other hand of the scientific outlets mentioned above. The keywords had to appear either in the title, abstract or keywords.

Our search resulted in an initial set of 596 papers. We analyzed the applicability of the cases presented in the papers by their title and abstract. The main reason for the exclusion of papers was that they either did not reveal any facets of IoT or they did not present any abstractable use cases for our research objective. The number of results was already reduced by more than half after this step. This analysis step can already be described as very accurate, because the subsequent full text analysis only classified 32 of the remaining articles as not relevant, leading to 225 articles for the content evaluation.

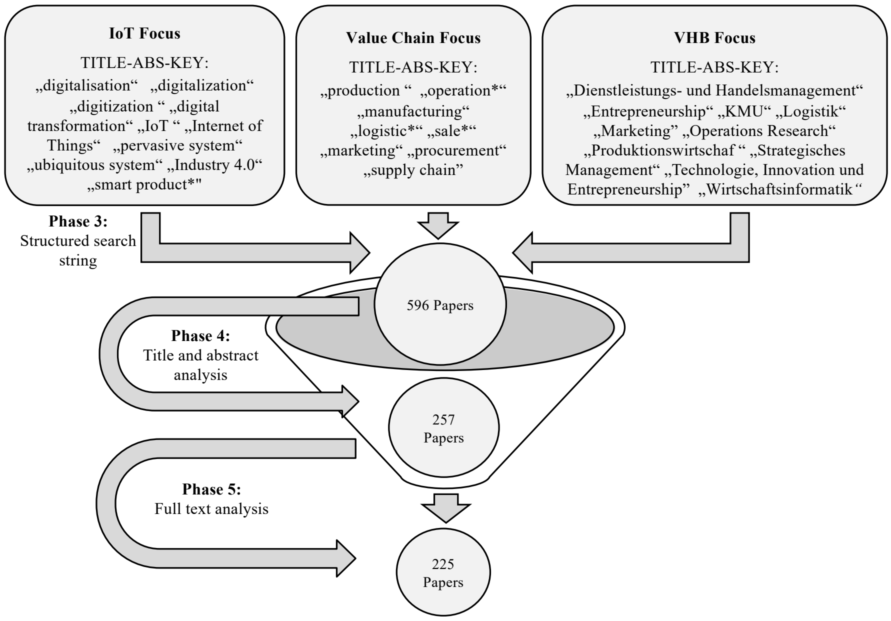

Figure 2. Literature analysis process

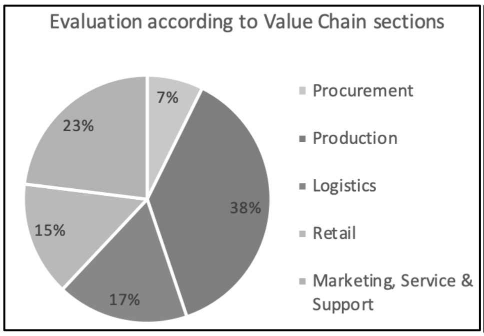
3 Evaluation

In this chapter, the content of the literature within the different concepts or business areas of the value chain is examined for concrete application scenarios of IoT. Therefore, the results are first clustered according to their respective value chain areas in order to then graphically analyze the individual technology approaches and their connections to each other. With regard to obtain a compact overview of the literature, we have not looked at each article individually, but have worked out the most frequently occurring application potentials of IoT. The following analysis is therefore based on exemplary IoT scenarios, which should not be regarded as exhaustive, but merely reflect a representative section of the literature. The focus lies on the technology drivers behind the recent transformation wave and their integration approaches among each other, since most technologies do not occur in isolation, but in interaction and therefore, compatibility is of crucial importance. However, before we go into the detailed evaluation, the following illustrations should give a first graphical overview of the article distribution per company division as well as the technology distribution. It might occur that an article deals with several or even all divisions.



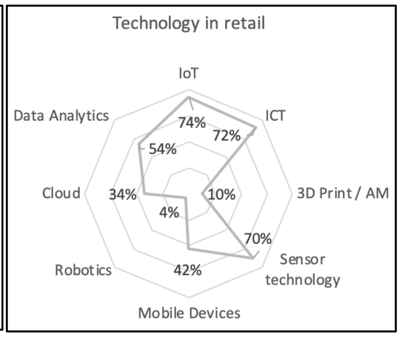


Figure 3. Evaluation by value chain area **Figure 4.** Technology distribution in retail

59 of the 225 identified articles deal with the IoT topic in the sales environment. In this context the concept of "smart retailing" was introduced, which refers to the use of retail IoT technologies to improve the quality of the shopping experience. In this scenario, smart and intelligent technologies are seen as enabling innovation and improving the quality of life of consumers [19]. How these technologies are reflected in the literature identified as relevant can be seen in figure 4.

It should be noted that in the case of sales-related processes, the smartphone is most frequently mentioned as IoT technology – compared to the processes in other value chain areas. Customers usually carry these devices with them and companies have the ability to access the display or payment function of such devices easily and integrate them into their business activities. The authors also see many application potentials for data analytics on the sales floor. For example, the product and customer data can be analyzed to dynamically adjust prices at any time. More details will be explained in the context of the appropriate subchapter. The evaluation of the literature has also shown that sensors and corresponding chips can be used in the retail context on different levels (product, shelves, cash machines, e.g.) or are already actively used. It is not surprising that robotics and additive manufacturing (AM) have a low number of hits because the overall evaluation across all value chain areas has already revealed this trend. In the case of retail processes, information and communications technology (ICT) can be seen as a basic module for all the other technologies because it provides the appropriate network or platform, integrates other IoT technologies and interfaces with other technologies or systems (n = 36).

On the one hand, smart products can provide support during the actual purchasing process (i.e. still on the sales floor), but on the other hand they can also be useful in the after-sales area and thus in the private domestic environment. In an article, the authors Miranda et al. [20] dealt, among other things, with sustainability considerations in the various phases of the life cycle of an intelligent product, and in this context can name some advantages in the area of product use and the end of product life. For example, after-sales maintenance and repair costs can be reduced through the use of e-services and remote diagnostics, thus increasing customer satisfaction [21]. If customers no longer need their products after a certain time, manufacturers can, for example, simply take back the old products, reconfigure them and then reuse or resell them [22]. Such functionalities can of course only be implemented to a limited extent with purely mechanical products, which is why the added value for smart products from the customer and company point of view can be seen in economic, environmental and social aspects [20].

Cloud Computing

Current trends in the Industry 4.0 research environment show cloud computing as one of the key technologies for IoT applications [23]. Especially in the context of sales processes, the provision of digital services requires the combination of cloud content, a physical product with embedded hardware and software, and a link channel to provide the services to the customer [24]. Such a service provision for the customer can be implemented, for example, by a cloud-based smartphone-app like the start-up BEXT360 within the coffee industry [25] or by integrating smart refrigerators into a cloud-based ecosystem [22].

ICT

Companies such as Google, Apple and Microsoft have been competing in the area of Enterprise System Software (ESS) for many years. The shift from ESS to web services, cloud computing and PSS, rather than installed components, provides future researchers new possibilities [26]. In addition to platform strategies, cyber-physical systems (CPS) also play an important role. A mechatronic system that uses CPS is an intelligent product due to its composition that integrates embedded systems and enables communication with other smart products. In general, a product can be smart if it uses ICT to improve its functionality and productivity. This is how the concept of PSS emerged, which integrates products and e-services into individual solutions for customers [20]. In the context of radio-frequency identification (RFID) different information systems or platforms may be used, depending on the industry or technology focus. One article speaks of a so-called EPICS-System (short for electronic product code information service). In this case, a GS1 standard automatically detects the movement of RFID tags and processes events according to predefined policies [27]. The result can be regarded as an RFID-based self-contained information system, which brings enormous advantages on the customer and company side.

Data Analytics

The authors Simchi-Evi and Wu [28] have analyzed the potentials of Big Data analysis in the context of price optimization models and price strategy adjustments, because not until now the retail sector has been in such a complex and competitive environment as in the current digitalization age. For example, based on product images and supplier information, customers in the Netherlands have the opportunity to bid online using a virtual auction watch [29]. Other authors have also focused on pricing strategies and models in the context of Big Data analysis tools. For example, in his article Weber [30] dealt with artificial intelligence systems in connection with sharing markets. By embedding intelligence in products, businesses and individuals, a so-called collaborative consumption arises. These recent developments have also encouraged some players in the automotive industry to develop new sharing solutions for urban mobility. The business initiative ENJOY, which was developed through a joint venture between Fiat Chrysler and ENI, can be shown as an example. With their smartphones, customers can quickly find, book and activate the desired vehicle and pay for the service based on their actual usage [31]. Amazon has tremendous potential to customize the value proposition for its customers. Through intelligent algorithms, Amazon knows where its customers live, what they have bought and what they might be interested in [32]. Nevertheless, companies such as Google or Ebay have also discovered these analytical capabilities and offer intelligent marketplace platforms as a service [33].

Sensor technology

The first study, which was considered relevant in the field of sensor technology, examines the needs of older consumers in the food sector and their implications for the food supply chain in a more holistic demand chain approach [34]. As a central result of this study, the following could be stated: Although the aging society also poses new challenges for the sales process, it can be positively counteracted by the use of IoT technologies. Among other things, the authors mention RFID technology, because RFID can significantly simplify the purchasing process on the customer side. Another author differentiates between two distinct RFID-based product applications on the sales area: (1) RFID as a central feature of the object itself and (2) RFID as a marking for the respective objects. The first group represents a central benefit for the customer, whereas the second option brings significant benefits to producers or companies [35]. Practical examples in the context of the first deployment scenario include a smart mirror, such as one from Panasonic, which is currently on the market, and OAK's smart changing room. Smart shelves, on the other hand, can be assigned to both RFID product applications. For example, Shelf Vending refrigerators are equipped with a system that recognizes and monitors the quantity and type of food being stored, so it automatically detects when consumers or employees remove products from the shelves [22]. No matter whether RFID chips are used on products, shelves or mirrors, the advantages for the authors are always the automation, the clear identification as well as the additional sources of information and the future will enable an easy customer and product profiling.

Mobile computing

Front-end digitization enables completely new types of customer interaction, such as creating self-service touch points with personal digital assistants, tablets or smartphones [36]. The first relevant articles deal with smartphones in the context of mobile coupons [19], [37]. The remaining articles all deal with the same application: smartphones as product information display. Quick response (QR) codes on the products give customers access to product information or product reviews directly on their smartphone display [22], [34]. Most common are applications that are not limited to providing product-related information, but also allow the sharing of product images and experience within a public network [19], [23]. Companies like Tesco and Amazon have taken advantage of the possibility to scan products via QR-codes and install appropriate applications within their business models [22]. Mobile payment systems have also become a hotspot for digital innovations. Smartphone manufacturers, telecommunications operators, payment service provider, software companies and start-ups are increasingly entering the payment market. We are not only talking about well-known companies like Google, Facebook or Apple, but also early-payment entrepreneurs such as Square, Paypal and Izettle [38]. These developments should significantly improve and automate the entire purchasing process – from information provision to payment process – on the customer and company side. Consequently, smartphones can be part of the IoT in various ways and making life easier for customers, companies and manufacturer.

AM

One of the articles considered the methodology of rapid prototyping (RP) as relevant in the context of AM. RP is currently mainly presented in the areas of production or research and development. According to the authors, however, the technology is being used more and more within the sales area. For example, RP can be used for product presentation to demonstrate the products in real. The big advantage is that the technology provides a prototype without long production time and allows to be modified several times, depending on the customers' needs. This deployment scenario is only possible due to the latest developments in machine learning and artificial intelligence techniques [39]. This shift of the product design phase to the customers can be seen as a decentralization approach, which creates a so-called temporarily supply chain. As a result, organizations are able to adopt ever-changing businesses and customer needs, without significant costs and time penalties [23].

Robotics

Robotics, on the other hand, currently has little acceptance in the context of sales processes, as only one article deals with this kind of IoT technology. The authors focus on a special kind of robotics, namely the so-called wearable robotics. Wearable robotics is a new field of research, focused primarily on the development of intelligent assistive devices and exoskeletons, which support human movement or enhance human performance. In this case, the robots consist of a series of actuators and sensors and require the development of advanced software and algorithms to process the data and control the system. Currently smart auxiliary devices (e.g. for arms) are commercially available and used by logistics providers. They can support different kinds of physical tasks, e.g. lifting and picking heavy food packs. Nevertheless, research on exoskeletons is still at an early stage and primarily focuses on military or medical applications [22].

In the context of sales-related business processes, all technology directions could be identified as relevant and explained using a wide variety of practical examples. One the one hand many authors have dealt with same or similar technology approaches and, on the other hand, some niche potentials have been addressed in some articles. As a result, there are smart products that can be found in multiple industries or business sectors – such as the location function of smartphones and corresponding apps – and those that are more specially designed for their use.

4 Conclusion and Future Work

The paper provides practical insights from manufacturers in various industries who have already had advanced experience with the implementation of IoT technologies. These insights can be seen as a source of learning effects for other companies or researchers, which plan to implement IoT solutions in their value chain.

From the scientific literature a clear mandate for further research of IoT can be derived [11], [12]. This also serves as motivation for the research approach presented below.

The results of the literature analysis presented here serve as an impetus for the research project. Use cases were extracted from the multitude of literature. Furthermore, on the basis of these, properties and facets of IoT can be subsumed. The far-reaching literature base then also serves further to create a taxonomy, if one follows Nickerson et al. [40].

The methodological approach by Nickerson et al. [40] can be used to structure IoT services based on conceptual and empirical observations. A taxonomy is defined as a set of dimensions, each consisting of different, mutually exclusive, and collectively exhaustive characteristics such that each object under consideration has one characteristic for each dimension [40]. Taxonomies play an important role in structuring novel terms and technologies to provide a deeper understanding of emerging fields of research and application [41]. Haas et al. [42] for example developed an empirical taxonomy in the field of crowdfunding intermediaries. Through the development of this taxonomy and the subsequent analysis of the collected data, they identified three archetypes of crowdfunding intermediaries.

Through collecting empirical and conceptual data in the area of IoT, common characteristics and dimensions can be identified. Subsequently, a common definition can be derived from the general characteristics.

Despite the fact that the literature analysis was conducted with a methodical rigor to improve the representativeness, the results should not be generalized to other empirical areas. There are still the natural limitations: (1) restriction on German and English language, (2) selected keywords search, (3) the selected database and the number of articles that it contains, and (4) the geographic and content characteristics of the articles identified as relevant, making it difficult to generalize to all sectors and countries.

As future work we will employ a seven-step method as proposed by Nickerson et al. [40]. For this purpose, we will collect a unique empirical data set of IoT applications and define meta-characteristics. These characteristics serve as a reference point for the dimensions and characteristics which are to be identified. Furthermore, we use the suggested subjective and objective ending conditions to determine when the taxonomy is robust. At this stage, we are able to derive a common definition of the term IoT.

Through the above-mentioned process, we are seeking for successful results within our future research.

Is the Technostress Creators Inventory Still an Up-To-Date Measurement Instrument? Results of a Large-Scale Interview Study

Thomas Fischer[1], Alexander Pehböck[1], and René Riedl[1,2]

Abstract. Self-report measures are of great importance for technostress research and particularly the Technostress Creators Inventory has been amongst the most frequently applied measurement instruments since its inception in 2008. As the technological environment has progressed since then, we investigated whether this inventory still completely represents the phenomenon of technostress today. We conducted interviews with 75 individuals in four companies on their technostress experiences. We asked them about their personal experiences with eight stressor categories in the workplace, the original five dimensions of the Technostress Creators Inventory (techno-overload, techno-invasion, techno-complexity, techno-insecurity, and techno-uncertainty) and additional three categories (techno-unreliability, IT-based monitoring, and cyberbullying). We found that techno-insecurity was the least prevalent stressor category throughout all companies, while techno-unreliability, one of our new categories, was the most prevalent stressor. Based on this evidence, we argue that a revised inventory is urgently needed to guarantee content validity of technostress measurement in future studies.

Keywords: Technostress, Stressors, Measurement, Self-Report, Interviews

1 Introduction

Technostress is a phenomenon that arises from the individual use of information and communication technologies (ICT) [1]. The body of knowledge concerning this dark aspect of IS use has grown rapidly in recent years (e.g., [2–4]) and its investigation relies strongly on the use of self-report instruments [5]. The main self-report instrument used for technostress measurement is the Technostress Creators Inventory (TCI) introduced by Ragu-Nathan et al. [1]. This instrument conceptualizes technostress as a superordinate construct with five first order constructs each having three to five reflective indicators. Specifically, the instrument conceptualizes technostress as being manifested in the five dimensions techno-overload (*too much*),

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

techno-invasion (*always connected*), techno-complexity (*difficult*), techno-insecurity (*uncomfortable*), and techno-uncertainty (*too often and unfamiliar*) [6].

As this instrument celebrated its tenth anniversary recently, we wanted to know whether it still offers the necessary content validity to capture technostress in a rapidly evolving technological environment. More specifically, we focus on the instrument's first-order constructs, and in line with MacKenzie et al. [7] (p. 304) pose the question: *Are the [first-order constructs] as a set collectively representative of the entire content domain of the construct*? Answering this question is important as it may reveal the need for a revision of the instrument. Such a revision could further improve the diagnostic abilities of the Technostress Inventory, which are crucial to investigate the phenomenon and its detrimental effects efficiently (e.g., to avoid missing important facets that may have emerged during the last ten years).

An initial indication for the need to revise the instrument can be found in previous technostress research. In a number of studies, only a subset of the original five technostress creators were used. For example, Tarafdar et al. [8] used only four of five creators (i.e., overload, invasion, complexity, insecurity) or D'Arcy et al. [9] used only three of five (i.e., overload, complexity, uncertainty). Importantly, it is also critical to assess whether further dimensions are necessary to completely represent the technostress phenomenon. Hence, in addition to the five existing technostress creators we added three additional dimensions (i.e., unreliability, monitoring, cyberbullying). Based on a series of interview studies in four companies in Austria, we investigated whether the original five Technostress Creators are sufficiently representative of the entire content domain. Regularly checking this property is critical as the technological environment that causes technostress evolves constantly. While technostress was originally caused by automation in the workplace, it evolved into a computer-related problem later [10], and may again manifest differently nowadays.

In Section 2, we introduce the TCI in more detail and why we expect that a measurement instrument so tightly connected to the technological domain would benefit from an update. In Section 3, we present an overview of our research methods including the interview guide that was used for all 75 interviews, a characterization of the companies that were used as the sample for our investigation, and a description of the data analysis process (including the coding process and interrater agreement computation). In Section 4, we present the results of our investigation. Finally, in Section 5, we close with conclusions, including the implications of our findings.

2 Theoretical Background

The Technostress Creators are not the first inventory that was developed to measure stressors related to ICT. Another noteworthy, but far earlier inventory was developed by Richard Hudiburg, called the Computer Hassles Scale [11], [12]. This self-report inventory serves as a good example for the necessity to regularly update measurement scales related to technology as Hudiburg himself emphasized the need to make an update of his original instrument within only a few years. This was necessary as the original instrument included items that were related to specific technologies that were somewhat new and stress-inducing at the time (e.g., automatic bank tellers or library computer scanners) [12], but became common technologies fast and were therefore removed as potential sources of stress in a later version of the inventory [11].

Developments of this kind have also been acknowledged by Ragu-Nathan et al. [1] who stated that "…modern ICTs have changed the work environment and culture." (p. 418). We endorse this statement and see no reason why this development would have stopped in the last decade. Additional evidence for the need for such an update was provided by Fischer and Riedl [5], who argued that the current conceptualization of technostress in the inventory may not fully encompass common types of technologies found in the workplace (e.g., as evidenced by the need to adapt techno-overload for the context of social media).

For our investigation, in addition to the original five technostress domains, we selected three potential technology-related stressors that have received significant interest by both researchers and practitioners, namely unreliability of technology (e.g., unexpectedly long system response times), monitoring via technology (e.g., electronic performance monitoring), and cyberbullying (e.g., impolite remarks made through electronic communication media). It has to be noted, that although important, these categories reflect a convenience sample of technology-related stressors which could be added to the Technostress Creators Inventory. In addition to this explorative investigation, therefore, a more systematic quantitative investigation is needed to further assess whether these categories, or other eventually also other categories, can strengthen the factorial structure of the inventory.

Unreliability. Reliability is an important feature of information systems that may never be completely achievable as stated by Butler and Gray [13] who expected that "…many important systems are not (and perhaps cannot be) inherently reliable." (p. 212). It has also been shown that system reliability is an important stress-related feature of ICT. For example, Ayyagari et al. [2] showed that system reliability is negatively related to perceived work overload, and Riedl et al. [14] demonstrated the detrimental effect of the malfunction of a webshop on individual stress physiology (i.e., a significant increase in the levels of the stress hormone cortisol).

Monitoring. Employee dissatisfaction related to electronic performance monitoring has been an early topic in technostress research. For example, in a nation-wide survey study amongst 762 employees in the USA, Smith et al. [15] found that monitored individuals report higher levels of job-related stress and physical strains independent of profession (e.g., sales representatives, but also clerks). In more recent years, workplace monitoring has also received considerable public interest, particularly as the threat for individual data privacy has become a more important focus [16], [17].

Cyberbullying. A more recent phenomenon in the workplace is related to the use of electronic communication media for negative behaviors (e.g., offensive comments and insults). Thus far, cyberbullying has mostly been focused on in the context of school children and young adults[1]. Using a sample of white-collar workers, Snyman

[1] https://www.nytimes.com/topic/subject/cyberbullying [07/17/2018].

and Loh [18] more recently confirmed the positive relationship between cyberbullying experiences at work and perceived daily stress in a survey study.

3 Methods

We investigated the prevalence of technological stressors through 75 interviews in four companies. Specifically, we constructed an interview guide, collected data, extracted relevant data in the transcripts (i.e., experiences related to technology-induced stress), coded the interview material, and summarized the data [19], [20]. We chose qualitative interviews because they allow us to grasp a wide area of individual experiences and give us the opportunity to make clarifications wherever needed (e.g., related to the definition of "stress", which can have different meaning across individuals).

Interview Guide. We first constructed an overall interview guide (originally in German) that was then slightly adapted for each company context (i.e., using a pre-test with 2 to 3 employees and adaptations in wording to increase comprehension by our interview partners). Keywords and descriptions for the original Technostress Creators were taken from Tarafdar et al. [6] and the remaining category descriptions were constructed in a comparable fashion:

- Unreliability (*Too unstable*): IS users are confronted with system malfunctions and unexpected system behaviors.
- Monitoring (*Controlled*): IS users feel constant levels of pressure as their behaviors can be tracked by technology and hence evaluated by other individuals.
- Cyberbullying (*Vulnerable*): IS users feel threatened by social misconduct facilitated by communication technologies and social media.

Sample and Data Collection. The sample included two small family-owned businesses and two medium to large sized organizations in Austria with up to several thousands of employees. In each organization, we aimed for a sample of individuals that was representative of the departments of the local branch of the organization or the organization as a whole (e.g., focusing on the largest departments). Participation in the 75 face-to-face interviews was voluntary. All interviews were recorded based on written consent given by the interview partners. An overview of the sample characteristics and the collection periods can be found in Table 1.

Each interview started with the interviewer first explaining the general topic of technostress, then asking the participant to sign a written consent form, and afterwards the technostress categories were briefly explained before the interviewee was asked to tell the interviewer about personal experiences with each technostress category they had at work. For the technostress categories, we used the same order every time (i.e., overload, invasion, complexity, insecurity, uncertainty, unreliability, cyberbullying, monitoring, other stressors); it has to be noted though that at each point interviewees were able to talk about their experiences related to each category. Interview lengths ranged from 9 to 78 minutes with a slight variance between organizations (company A: 18 to 70 minutes; company B: 14 to 78 minutes; company C: 9 to 26 minutes; company D: 13 to 53 minutes). The particularly short length of interviews in company C could be attributed to efficient coping with technostress, facilitated by a high level of decision latitude in the organization (e.g., individuals can switch easily between activities and are not mandated to be available for further tasks as soon as they leave the workplace).

Table 1. Sample characteristics and overview of collection periods

ID	*Type of business*	*N*	*Age Median*	*Collection Period*
A	Software development	15 (2 f)	42	03/16/2017-05/04/2017
B	Passenger transportation	21 (8 f)	50	12/06/2017-03/12/2018
C	Publishing	24 (20 f)	38.5	12/14/2017-03/21/2018
D	Petrochemical production	15 (2 f)	43	11/20/2017-03/28/2018

Content Analysis and Interrater Agreement. The interviews were transcribed by the interviewers and potential experiences of technostress (e.g., instances were individuals showed annoyance or anger related to technology) were highlighted in each transcript using MAXQDA (version 11).

A total of 380 text passages related to technostress were then coded by the first and second author independently, using the stressor categories. Cohen's Kappa was used as a measure of interrater agreement [21]. Overall, a Cohen's Kappa of .84 was achieved, which indicates a strong agreement between the coders [22], with a range of .83 (company C) to .87 (company B). The remaining text passages, for which no initial agreement was achieved, were then discussed by the first and second author until a consensus was reached.

4 Results

In the following sections, we present insights for the original TCI and our additional stress categories, including concrete quotations from the interviews (literally translated from German). In addition, for each stressor we report on the share of individuals (rather than the absolute number, because of differences in samples sizes) who have had experiences with it before as well as an average (AVG) across all organizations (please note that this average is not weighted based on the sample size per company).

4.1 Technostress Creators Inventory (TCI)

From our investigation, we can conclude that there is a large variance in the share of individuals who had stressful experiences with techno-overload and techno-invasion across companies, while that share is widely consistent for techno-complexity, techno-insecurity, and techno-uncertainty.

Techno-Overload (A: 93%; B: 52%; C: 42%; D: 80%; AVG: 67%). In this category, we found a large discrepancy between companies, with the software developer (A) having the highest share of individuals who had experienced techno-overload before, while individuals in the transportation company (B) and the publishing company (C) had far less experience with this kind of stressor. In company A, most of the interviewed employees have short-term problem solving as part of their job responsibilities, which could explain the high prevalence of overload in this context. Particularly the dependence on communication technologies in some cases leads to a strong need to keep a focus on inboxes, with one software developer (A01, male, 44 years old) stating that: "*My main medium is e-mail. Within that medium, it is absolutely massive. Practically speaking, I spend about 80% of my time with e-mails*."

In the cases of companies B and C, this problem is far less prevalent and decision latitude seems to have an impact on this matter and in particular timing control [23], which is evident in the statement of one member of the management in company B (B01, male, 52 years old): *"On one hand, I think that [ICT] is stress-reducing, because it lets me know what is still to do. Back in the day, I had to wait until the evening until I received a long list of tasks for the next day. Now I know exactly what to do and can schedule ..."*

Techno-Invasion (A: 73%; B: 38%; C: 4%; D: 40%; AVG: 39%). In this category, we find more support for the assumption that timing control may have a strong influence on technostress perceptions. One of the manifestations of this relationship can be found in company A, were individuals have to cope with rigorous customer demands and a large variety of customized systems. A member of the support team (A02, male, 42 years old) addresses this point directly, stating that: "*As soon as I am awake, I basically look into it all the time and react to them [i.e., e-mails]. Because there is an implicit demand and our customers get really angry when they write an e-mail on Sunday and do not get a response."*

This pressure, which takes timing control away from the individual, as quick responses and solutions are needed, is far less of a problem in company C, as indicated by an employee who is responsible for managing online media outlets of the company (C01, female, 30 years old): "*Generally, if somebody is calling me in the office, I am taking the call. If this person then starts to chat away, for which I might not have time at work, I try to reschedule the call towards the evening*."

Techno-Complexity (A: 40%; B: 38%; C: 46%; D: 53%; AVG: 44%). Being overwhelmed by the possibilities and functionalities of ICT was a recurring problem in all companies, mostly caused by large numbers of different systems or a wide variety of different use cases that were not all needed regularly. One member of the research and development department in company D (D01, female, 39 years old) pointed out that there is often a lack of time to get used to operate complex systems, stating that: "*For example SAP, something like that is extremely complex. ... if you find the time to use it and get used to it… then you get able to handle such a system. Yet, that time is often missing.*"

Techno-Insecurity (A: 13%; B: 33%; C: 8%; D: 0%; AVG: 14%). The level of perceived threat to one's job security and potential changes to the job profile was generally low across all organizations. The highest prevalence of this stressor was in company B, with bus drivers fearing that they might get replaced someday. As one bus driver (B02, male, 55 years old) puts it: "*When the bus is controlled by computers someday, then I will not sit in it anymore. This will definitely become a reality, but I* *will not experience that during my time. We do not have to discuss that, this will definitely come to pass!*"

Techno-Uncertainty (A: 53%; B: 52%; C: 42%; D: 53%; AVG: 50%). As a stressor, the prospect of unexpected and rapid changes in the used technologies was comparable in its frequency to techno-complexity. There were also no main differences between companies in this domain, with most individuals reporting stress due to the uncertainty whether they would be able to use systems again after some sort of update. What is interesting though, is that the prospect of changes themselves is not that stressful, but what may come after, as expressed by a customer support employee in company A (A03, male, 27 years old): "*In our case, there are constant changes and new additions to programs. In many instances I do not really know if some added part works already or not*."

4.2 Techno-Unreliability

Unreliability of systems turned out as the most frequently cited stressor (A: 80%; B: 76%; C: 75%; D: 67%; AVG: 74%). In some cases, smaller hassles were reported as stress-inducing as they occurred frequently and therefore led to a chronic experience of stress. For example, a software developer in company A (A04, male, 37 years old) reported on his constant problems with a slow Internet connection: "*This is amongst our biggest topics – the stability of the Internet connection. ... There is nothing worse than hitting a button and there is a delay until it loads. Or when you try to scroll down on your monitor and you can watch it go down very slowly*."

In other cases, singular, non-frequent instances of unreliability, sometimes with serious consequences, were reported, such as lost work as reported by a member of the sales department in company C (C02, female, 54 years old): "*When an order gets lost or, in the case of e-mail, when I have written a comprehensive offer, was almost done and then it suddenly gets lost. That does not make you happy…*"

In each case, ICT behaved differently from what individuals expected and therefore caused anger or insecurity. In addition, comparable to techno-uncertainty, there is a spiral of problems that is related to unreliability. While slow response times themselves may not be problematic, these delays may lead to work overload as the current task cannot be handled sufficiently fast. Hence, time pressure is an important contextual factor for unreliability-related stress, just as the job-related dependence on technology [24]. This was indicated by a bus driver in company B (B03, male, 50 years old) who stated: "*Simply, because you are dependent on that stuff and in a crucial moment it often does not work. That is pure stress! When your navigation device does not work and you are not sure where to go*."

4.3 Monitoring

Comparable to techno-overload, there was also a large variance of the prevalence of experiences with monitoring between companies (A: 53%; B: 43%; C: 0%; D: 27%; AVG: 31%). While none of the individuals in company C had any stressful experiences with monitoring, more than half of the individuals in company A had made such experiences before. A potential connection here can be drawn between these observations and the level of control that is exerted in each company, for varying reasons. For example, regulatory demands (e.g., documentation of working hours) were often quoted as potential reasons for monitoring, which although often acknowledged as reasonable, nonetheless led to substantial stress. In company B, one of the bus drivers (B04, male, 58 years old) argued: "*I do not find it distracting, but not right, as we are completely supervised. It does not matter who it is ... they know at all times exactly where I am.*"

In the same vein, a customer support employee in company A (A05, female, 23 years old) stated: "*What I fear is that everything can be checked. What I do, what I say ... internal support can check everything. ... That leads to ... pressure*."

Monitoring and data collection are also often accompanied by a lack of transparency on what types of data are collected and why they are collected. Even if being monitored was not directly stress-inducing, the lack of transparency itself led to concern in individuals, which was particularly expressed by individuals in company A and D, who are knowledge workers handling extensive amounts of data. For example, a software developer in company A (A01, male, 50 years old) expressed particular concern stating: "*You do not feel threatened ... it is more of a concern due to the uncertainty of what will happen with the data and for how long it is kept*." An employee in the innovation and process management department in company D (D02, male, 52 years old) extended this thought and told us of a case that justified that type of concern: "*We had the case, where e-mails from the last 15 years were opened. I was also often involved. [It creates] fear that you are completely transparent.*"

4.4 Cyberbullying

Experiences with mobbing or bullying via ICT were the least prevalent type of stressor, comparable to techno-insecurity (A: 13%; B: 38%; C: 0%; D: 0%; AVG: 13%). In two companies, none of the interviewed individuals reported about any own experiences with stressors of this category, though they were mostly aware of the possibility of this type of behavior.

In those few cases were individuals reported on related experiences, they mostly traced rude or unsocial behavior back to the type of impersonal communication that ICT allow for. For example, a member of the management of company B (B05, female, 49 years old) felt that communication amongst employees was more confrontational if it was done via ICT: "*In our WhatsApp group we are often confronted with subservient messages by our drivers. What really annoys me is when pictures of a dirty vehicle get posted, just because there are some crumbs in it ... They make a mountain out of a molehill ... and everybody can see it*."

A potential explanation for the low prevalence of this type of stressor are coping mechanisms that individuals employ to avoid such issues related to ICT-mediated communication. One internal support employee in company A (A06, male, 23 years old) even stated that he now detests online communication and he explained that he tries to avoid it: "*I personally prefer to not write via ICT ... because something always comes back. In that moment I feel like [telling that person] that I am also not* *the perfect human being and also cannot deliver a 100% perfect answer. I am not interested in getting rebuked ten times in ten e-mails ….*"

4.5 Additional Technostressors

In addition to our eight stress categories that were defined and presented to the interviewed individuals, we also gave them the chance to talk about additional instances were ICT may lead to stressful experiences. With the exception of company B, individuals in every company told us about such instances (i.e., 13% of individuals in company A, 21% in company C, 20% in company D). We clustered these instances in two broader categories, with the first one being related to ambiguity in communication via ICT and the second one being related to information system security.

In company A and company C, some individuals expressed that they were sometimes confronted with confusion and misunderstandings when they communicated via ICT, about issues that could otherwise be resolved quickly when they interacted personally. For example, a customer support employee in company A (A07, male, 26 years old) reported about a case were a program misbehaved: *"[The function of the system] does not work and [another employee] shows it to me today and tells me that it does not work. I try all the necessary steps and it works. ... None of the software developers were able to [solve it]. They had exchanged 20 e-mails amongst each other, sometimes with 10 people in carbon copy ... and we solved the problem quickly in a casual interaction.*"

Relatedly, previous research has found that communicating the way we would usually do (e.g., using gestures and voice tonality) is mostly not possible using communication channels such as e-mail, which can lead to messages being interpreted in a different way [25].

The second area that was prevalent in companies C and D was stress from security threats, either directly (e.g., hacking attacks) or indirectly (e.g., stress from security measures to avoid security threats). A member of the sales department in company C (C04, female, 48 years old) reported on her concerns regarding the possibility of threats from outside the company: "*My brother-in-law told me that it is enough to open an e-mail. That can be enough for hackers to cause some damage ... and that is why you have to be really careful. For example, when an e-mail only with an attachment and nothing else comes in, then I am instantly nervous, because I do not know what it is. I immediately delete it then!*"

The steps that are then taken to avoid such threats should be planned carefully. If security measures are too rigorous, they might create stress on their own as indicated by a member of the marketing department in company D (D03, male, 48 years old): "*It becomes a problem when I want to load a website of one of our customers or potential customers and they include some words that are usually under embargo for us and ... the pop-up-blocker stops me ... that can be annoying right then*."

5 Conclusion and Future Research

Recently, Tarafdar et al. [26] presented updated definitions of their original constructs (see [1]), which now envelop some of our proposed stress categories. For example, aspects of unreliability are now included in techno-complexity as "interruptions, complications, hassles", monitoring is included as part of techno-invasion and security-related stress is spread out across techno-overload (adhere to security requirements), techno-invasion (surveillance and monitoring), techno-uncertainty (no control over IS use policies), and techno-complexity (hard to understand IS use policies). Yet, although the authors have acknowledged through this update that their original conceptualization of technostress was out-of-date to some degree ten years after its inception, or eventually lacking in completeness at all, we are not aware of an updated technostress measurement instrument that reflects this extended conceptualization on the item level.

In addition, it is questionable whether new aspects of technostress can simply be assigned to dimensions in the existing framework of Ragu-Nathan et al. [1] or whether additional dimensions are needed. For example, Ayyagari et al. [2] made a clear distinction between complexity and reliability as technology features. In our investigation, unreliability was the most prevalent technostress creator, but only occurred together with complexity to a limited extent (i.e., 48% of individuals who reported experiences with unreliability also had stressful experiences with complexity, which is less than uncertainty with 50% or overload with 63%).

Based on this evidence, we therefore make a call for additional quantitative investigations into the dimensionality of technostress, which acknowledges the current status of affairs. Based on the usage of a new set of items, it would be possible to demonstrate whether the same dimensions of technostress creators emerge again and therefore uphold the test of time or whether extending their definitions has led to a bloating of these first-order constructs beyond their conceptual usefulness.

Our research study also has limitations. First, though we used a sampling procedure that was comparable to Ragu-Nathan et al. [1] (i.e., firm-specific samples, selection of organizations based on contacts, self-selection of respondents), this naturally leads to a sample that is not generalizable to a wider population and results should therefore only be interpreted in the context of the specific companies and individuals involved. We also used a conservative approach in our coding procedure, only focusing on own accounts of previous stressful experiences. This may have led to an underestimation of certain stressor categories, for example indicated by the account of an employee in the research and development department of company D (D04, male, 30 years old): *"...when somebody is sitting next to you and receives a WhatsApp message or an SMS every 10 seconds and it rings all the time with some weird noise. That is not only stressful for them ... but it also stresses me if it rings all the time*." In addition, personal interviews may have led to some individuals not wanting to talk about their previous experiences in detail, as was sometimes the case for cyberbullying, where individuals hinted on some type of experience, but did not go into detail on their own (a form of social desirability bias). To minimize the influence of this bias, interviews were always conducted by a person that the individual was familiar with (to ensure a level of trust) using a standardized interview guide. We avoided conducting interviews ourselves as outsiders might be perceived as "agents" of the company management.

In summary, we argue that a systematic investigation of the factorial structure of technostress is needed. Further, we recommend the use of data triangulation in order to elicit stressor categories that were not considered before (e.g., bullying), but may be more important than self-report data alone could reveal initially.

Abstract. Today in many industries it is common to work in virtual teams. At the same time companies must innovate to retain their market share and stay in the market. One possible method to come up with innovations is Design Thinking. However, this method is originally not intended to be used in a virtual team. The objective of this research is to provide a guideline on how to practice Design Thinking in a remote setup, thus travel expenses and planning efforts could be saved. This guideline is based on the media synchronicity theory which is applied to the process of Design Thinking. As a result, it is deduced that the diverging phases in Design Thinking are best supported with asynchronous media. In contrast to the converging phases which are supported best by synchronous media. These results could be used by practitioners to choose the best fitting media for each phase.

Keywords: Virtual Teams, Design Thinking, Media Synchronicity Theory, Creativity, Innovation

1 Introduction

To survive in a globalized market, companies have to come up with innovative services, new products and efficient processes [1]. Through constant innovation they can serve their customers better than the competition and even grow their market share. In order to innovate at scale, many companies started to work with creativity methods like Design Thinking to enhance their ability to come up with strong ideas [2].

At the same time, not only the markets became global markets, also the companies themselves opened locations all over the globe. For example, in the software industry, it is very common that teams are distributed over multiple locations and only communicate through information and communication technology. Such teams are called virtual teams. To communicate, they use, for example, e-mail, social networks, instant messaging, telephone conferencing and many more technologies. Nevertheless, also

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

virtual teams must solve creative tasks, to come up with innovations in their area of work.

This paper examines the intersection between these two fields. Therefore, we consider the usage of communication technology in virtual teams to solve creative tasks. As a method to solve creative tasks this paper employees Design Thinking, which enables a team to come up with innovative ideas. However, Design Thinking is originally a method, which is practiced in one location and not in a distributed set up. In this paper we develop a guideline on how a remote setup for virtual teams might look like. We apply the media synchronicity theory (MST), to analyze whether a certain medium fits to a task. With the perspective of the media synchronicity theory on Design Thinking, we focus on the research question "Which media capabilities should a tool for virtual Design Thinking have to enable high team performance?" The remainder of the paper is structured as follows. In the next section, we describe our methodological approach. In chapter three we explain how Design Thinking may be used to leverage creativity in teams and in chapter four we introduce the media synchronicity theory. After that we apply MST to the method of Design Thinking and we deduce recommendations for virtual teams. We conclude the paper with a discussion of our results and limitations.

2 Research Method

In this paper we apply a methodology from the domain of design science research [3–6]. We focus on the development of knowledge in information systems through the design of artifacts [7]. In our effort, we follow the guidelines for design science research as put forward by Hevner et al. [4]:

Design as an Artifact. The artifact that we develop in this paper is a concept that consists of guidelines for the application of specific types of media in virtual Design Thinking. The guidelines describe a category of media for every phase of Design Thinking which should enable a high task performance.

Problem Relevance. It is vital that research satisfies a strong business need. The business need for virtual Design Thinking originates from the conflict area between virtual teams, innovation needs and cost restrictions. As indicated above, Design Thinking can be used to come up with innovative solutions, however it is usually practiced in one place. In the case of a team with distributed team members, one solution is to travel to one place and to conduct the Design Thinking workshop there. This poses a large planning effort and it is rather expensive. This conflict between creativity and expenditure might be improved through the concept which we propose.

Design Evaluation. The artifact will be developed through the analysis and application of an existing theory (namely MST). We apply a deductive-argumentative approach using abstraction and reflection [8] when we relate MST to the different phases of Design Thinking.

Research Contribution. Our concept for virtual Design Thinking represents a first approach to make it possible to use Design Thinking in virtual teams. To the best of our knowledge, there is currently no guidance available for practitioners to use Design Thinking remotely.

Research Rigor. The contribution builds on the knowledge base in virtual team research, and Design Thinking. Therefore, a take a closer look on MST, and Design Thinking. Our approach is aligned with the research category of "design and action" which was proposed by Gregor [5].

Design as a Search Process. The starting point is the relevant practical problem, to which we apply a well-documented theory. The proposed concept is deduced from the application of MST to the Design Thinking process. In doing so, we analyze which capabilities are required to support each phase of the Design Thinking process. Hence, we are able to identify appropriate media for each phase.

Communication of Research. To communicate our research, we have designed this paper in a way that it addresses technology-oriented as well as management-oriented researchers. Furthermore, it is suited as a guideline for practitioners.

3 Leveraging Creativity in Teams Through Design Thinking

In the last decade, Design Thinking has evolved into a method, not only to support innovation, but also to offer a process to improve and to accelerate the creativity of teams [9]. Thus, Design Thinking isn't limited to the design space anymore. It can be used in different fields and for different applications. As it has evolved over time, multiple definitions of Design Thinking were developed [10]. Here we use the commonly accepted definition of Tim Brown (CEO of the innovation consulting firm IDEO): "Design Thinking is a human-centered approach to innovation that draws from the designer's toolkit to integrate the needs of people, the possibilities of technology, and the requirements for business success." [11] This definition highlights that Design Thinking should aim at the intersection between the human desirability, the technical feasibility and business viability. If all these factors are given, an idea has the potential to be a break through innovation [12].

After a first glance on the purpose of Design Thinking, we describe the process. This process is iterative, so it is possible to cycle back, or to revisit the results of earlier phases and improve them again [10]. We use the Stanford Design Thinking Model (see Fig. 1), because that model allows to classify the phases according to the communication processes of the MST. In other models the phases are starting and ending at different times. That would make a matching to MST more difficult.

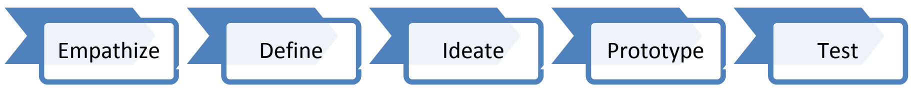

Figure 1: Stanford Design Thinking Model [13]

Empathize. The goal of this phase is to explore the problem and to get a common understanding [14]. An essential part of this phase is the knowledge transfer between the team members. Design Thinking teams should consist of experts from different areas to provide diverse inputs and to ensure a good result [15]. After the team members developed a common understanding of the problem and its context, the user research may be started. The goal of the user research is to develop empathy for the user. Therefore, the behaviors and feelings in the problem context have to be observed [13].

Define. The *definition* phase starts with the end of the phase *empathize*. The goal of this phase is to specify the problem and the context more precisely [14]. Furthermore, the user for whom the problem should be solved, will be defined. In a discussion about the results of the phase *empathize*, the team can find patterns in the data and also detect anomalies. Thus, the data can be framed into a narrow problem description [13].

Ideate. The *ideation* phase is the core of Design Thinking, in this phase most of the creativity and innovation takes place. In the first two phases, the empathy for the user is developed to guide the idea generation process in a good direction. Primarily, group brainstorming is used to generate new ideas in this phase [16]. However, also other smaller creativity methods are used in this phase.

Prototype. The *prototype* phase has two main goals. One is to concretize the generated ideas and the second is to make it possible to validate the concept with the user in the testing phase [13]. The prototype is helping the team and the customer to better understand the generated ideas [14]. Hence, possible constraints or limitations might be found in the testing phase and they might be used to improve the concept in a next iteration.

Test. The *test* phase is all about feedback from users and stakeholders. The ideas are presented to them with the help of the prototype. This allows a precise feedback [13]. The team will observe the customers' behavior while interacting with the prototype and ask them for feedback. Based on the feedback they are able to decide if the concept is ready for implementation yet.

4 Media Synchronicity Theory

In reviewing the literature about the media selection of virtual teams, we could find seminal relevant theories. According to the media richness theory (MRT), richer media should be used for tasks with high equivocality and simpler media should be used for standard tasks [17]. However, research has found that MRT does not explain the media choice well enough, because there are more factors that influence the media choice and different subtasks might have different media requirements [18]. The second theory considered was the task/technology fit theory. This theory explores the fit between a task and a medium on an individual [19] and group level [20]. The theory defines five different task types, which are supported by three different dimensions of media. This was an improvement on the issue of subtasks, however the research doesn't address if experience within the group might have an influence on the performance. MST tries to overcome these limitations and proposes the necessity of a fit between the communication processes, the appropriation factors and the capability of the medium to support synchronicity [21].

In MST there are two kinds of communication processes. Conveyance processes transport new and diverse information, so the receiver needs time to process and understand them [22]. In contrast, convergence processes transmit already known, or familiar information and the goal is to negotiate a shared understanding. MST proposes that conveying communication needs low media synchronicity and converging communication needs high media synchronicity [23]. Nevertheless, as shown in the model (see Fig. 2) also the appropriation factors, like familiarity with the medium and past collaborations between the team members have influence on the media fit. In the next sections, all factors will be discussed in more detail, so a good understanding of the theory can be developed.

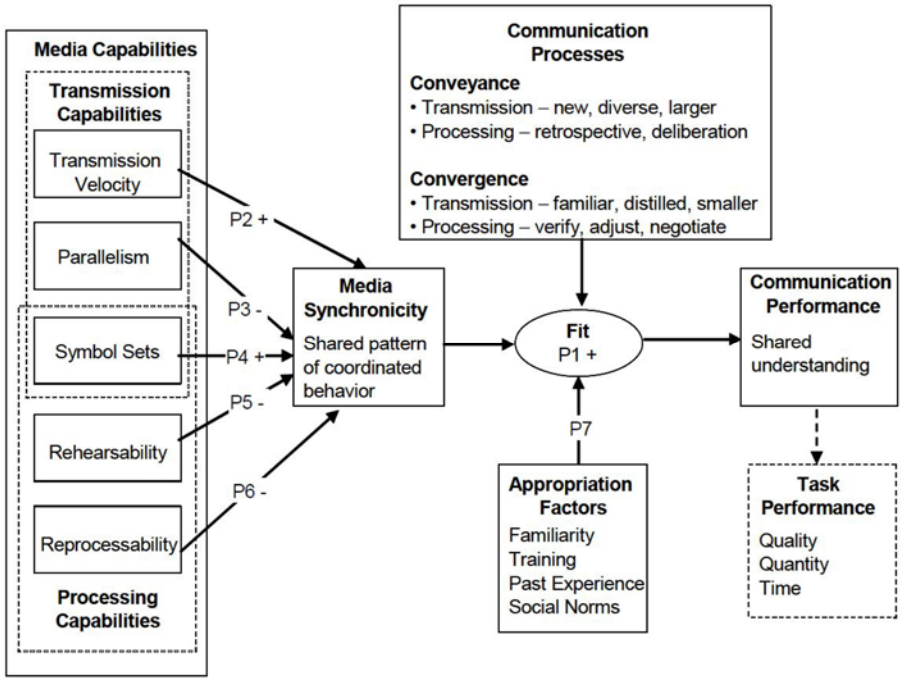

Figure 2: Media Synchronicity Theory [22]

4.1 Communication Processes

There are two types of communication processes. First, conveyance processes are used to deliver a large amount of new and diverse information to the receiver. This might be information like a report, but also a collection of raw information. So the receiver has to process the information and to interpret the meaning [24]. To fulfill this task the receiver needs time to go through the heap of information. For the receiver this task gets easier, if he has the possibility to revisit the content of the message multiple times and to make sense out of it [25]. On the other hand, the sender could support the receiver by carefully crafting the messages [26].

Second, in contrast, converging communication deals with already familiar information or preprocessed information [22]. In this case the participants of the conversation already have given an own meaning to the information. Hence, the goal is to discuss towards a common understanding of the information [27]. Therefore, only small quantities of information are transmitted. The receiver doesn't need much time to process the information. A high transmission velocity could ensure that sender and receiver have a smooth and fast communication [28].

Almost every task involves a mix between the two communication types. Thus, the theory can be applied to the dominant part of the communication processes. Or multiple media types can be combined to support the communication best [22]. Larger tasks like the development of a concept by using Design Thinking can be divided into subtasks. So, the subtasks might be analyzed, and appropriate media can be used.

4.2 Media Capabilities

In this section we describe the media capabilities which define the media synchronicity. A medium with high media synchronicity, like video conferencing, allows its participants to communicate almost synchronously [29]. In contrast, there are media with low synchronicity, for example, e-mail. According to MST there are five media capabilities, which build the medium's capability to support synchronicity. These capabilities are transmission velocity, parallelism, symbol set, rehearsability and reprocessability [23]. The first three media capabilities are adopted from the Shannon and Weaver communication theory [30]. Rehearsablity and reprocessability were added to describe the influence of encoding and decoding in the communication theory [22].

Transmission velocity describes, if the medium supports a fast feedback on the understanding and the meaning of the last message [25]. As indicated by the plus symbol next to P2 in figure 2 a high transmission velocity causes a higher media synchronicity. The opposite is the case for parallelism here the minus symbol indicates that high parallelism causes lower media synchronicity.

Parallelism describes the capability of a medium to support multiple conversations at a time [26]. The media synchronicity is lower, because the participants aren't focusing on one conversation.

Symbol set describes the mediums capabilities to encode a message [28]. For example, in phone calls there is only sound to transport the information, but video conferencing additionally has the video and as a consequence a larger symbol set.

Rehearsability describes the mediums capability to rephrase the message before sending it [31]. A high rehearsability indicates a low media synchronicity.

Reprocessability describes the mediums capabilities to replay or show the received message multiple times [22]. So, the receiver can reread the message while making sense out of it in conveyance processes.

Table 1 sums up, which media supports high synchronicity and which media supports low synchronicity.

4.3 Appropriation Factors

The appropriation factors are the third part which has to fit to ensure a high communication performance. The appropriation factors describe whether the group already has experience working together, working on a similar task, or working with a certain communication medium [22]. The idea behind the appropriation factors is: If the team has no experience with one, or more aspects out of *people*, *task* and *media* there is more coordination required [21]. Consequently, a higher media synchronicity is required, since coordination mainly involves convergence processes. Nevertheless, over time the team develops a shared understanding of the task, the media and the people on the team [22]. As a result, the need for synchronous media out of the appropriation factors decreases over time.

Table 1: Classification of various media regarding MST's media capabilities [31]

Media	Immediacy of feedback	Symbol variety	Parallelism	Rehearsability	Reprocessability
Face-to-face	High	High	Low	Low	Low
Video conference	Med.-High	Medium	Low	Low	Low
Telephone conference	High	Medium	Low	Low	Low
Instant messaging	Med.-High	Low-Med.	Low-Med.	Medium	Med.-High
Synchronous electronic conferencing	Med.-High	Low-Med.	Low-Med.	Low-Med.	Medium
Asynchronous bulletin board	Low-Med.	Low-Med.	High	High	High
Asynchronous e-mail	Low-Med.	Low-Med.	High	High	High

5 Application of Media Synchronicity Theory on Design Thinking

In this chapter MST is applied to the Design Thinking process. However, Design Thinking involves both conveyance and convergence communication processes. In order to get a more specific result, the Design Thinking process phases will be classified into categories. As discussed by Lindenberg et al., there are diverging and converging thinking phases. Figure 4 shows, that the *empathize* and the *ideation* phase are divergent phases and the phases *define*, *prototype* and *test* are convergent phases [32, 33]. The small circles represent the ideas which are created in the diverging phases and afterward are chosen by the group to work on further, or not. For example, in the phase *empathize* the team explores multiple problems and user groups, which are involved in the design challenge. In this stage, they create choices, by exploring many options. In the following definition phase, the team must take the choices and for example decide for a user group. As the example shows at first the team have to think diverse, to explore all the possibilities and afterwards they have to converge to a group point of view [34]. For the ideation, followed by prototyping and test, the argumentation is analogous. At first, a large amount of ideas is created and then the team selects the best one for a prototype.

In a kickoff meeting before the *empathize* phase the team has the chance to get a first impression of the *task*, the *people* and the *media*. In most situations one of the factors is new, even when the team is used to work in a remote setup. However, in many cases either an entirely new team is formed, or the group is complimented with experts from different areas and Design Thinking coaches. The kickoff meeting should be used to discuss the process, the media which should support every phase and to introduce the team members. The meeting should give the team the chance to discuss questions, get to know each other and negotiate the working mode. All these tasks involve convergent communication processes and are therefore best supported by synchronous media.

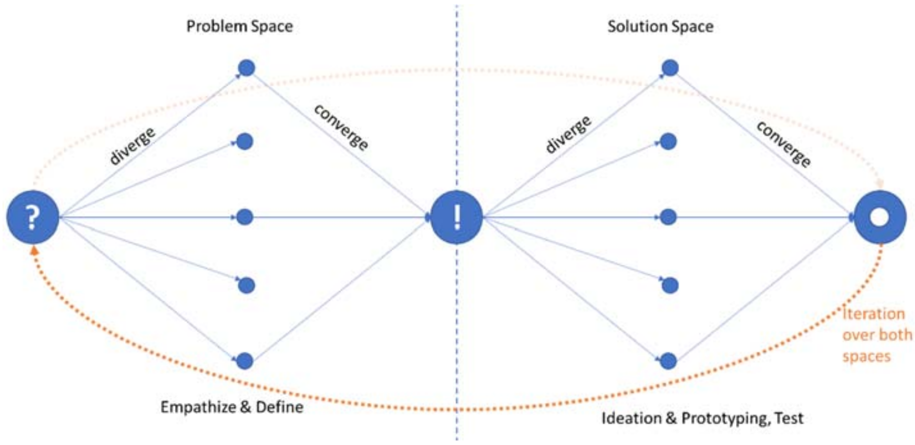

Figure 3: Problem and solution space in Design Thinking adopted to the Stanford Design Thinking model [32, 33]

5.1 Diverging Phases

As described in the section on Design Thinking, in the phase *empathize* the different experts sharing their views on the problem space. Additionally, the user research takes place. These two exercises mainly involve conveyance communication, because a large part of it is sharing the different points of views. For this the team could use a digital whiteboard, which allows to work in a similar mode as in an onsite workshop. In the virtual setup the team shouldn’t only capture the thought in a few words, but also add some explanation to make it easier for others make sense out of it. Nevertheless, there are also some convergence processes involved. Thus, it could be beneficial to do a video conference before the user research takes place. This enables the team to discuss a common questionnaire and work on the appropriation factors. Afterwards each team members can interview people at their location and convey the information back to the team. Consequently, there are synchronous and asynchronous media capabilities required in the phase *empathize*, with a tendency to asynchronous media.

In the *ideation* phase, the main goal is to create as many ideas as possible. In this phase, all participants share their ideas and build new ideas on top of ideas from other participants. The shared information is mainly new and diverse information, which should be considered by the other participants. According to the MST these are the characteristics of conveyance communication, resulting in a bigger need for asynchronous media. By using this type of media, the team could make use of the high rehearsability and reprocessability. The team would carefully craft the messages so that the ideas are easy to understand. In addition, there would be always the possibility to revisit an earlier message.

When there are multiple time zones involved, the divergence phases *ideation* and *empathize*, also allow to work at different times. Thereby, the duration of the work will increase due to less parallel work. The working time on the tasks itself should be comparable to onsite workshops. However, in the first phases the team might need some more time to find a proper working mode.

5.2 Converging Phases

After multiple problem areas and user groups were explored in the phase *empathize*, the team has to specify a smaller subset in the *definition* phase to go on with. Such decisions require a lot of coordination and interactions between the team members [22]. They involve a quick back and forth between the team members, as they discuss which problem should be prioritized. This dominant part of the conversation is optimally supported by synchronous media, since it involves mainly convergence communication. Synchronous media provides the team with a high immediacy of feedback and a rich symbol variety. For example, by using a video conferencing each team member becomes fast feedback on the arguments used and will observe additional facial or gestural reactions. However, it can be argued, that a combination with a form of asynchronous media could be also helpful in this stage. An asynchronous medium, like a digital whiteboard, could support the team in this stage by providing an overview on the results of the last session and give the group guidance in this session.

Similar to the *definition* phase also in *prototyping* and *test* the team has to make some decisions. Furthermore, the group has to build the prototype and discuss the results in the testing step. Prior to building the prototype the group has to select the best solution to prototype. Analogously to the *definition* phase this requires a lot of discussion and coordination, which makes it a converging communication. On the other hand, the team also has to build a prototype, which could involve more inputs from one of the experts. So again, a mix between synchronous and asynchronous media is needed.

5.3 Media Capabilities for a Tool to Support Virtual Design Thinking

This section summarizes the results of the analysis and give some guidance, which media types might be used to reach a good team performance in virtual Design Thinking. Summarized in one sentence: Asynchronous media are appropriate for the diverging thinking phases and synchronous media are better suited for the converging thinking phases.

More precisely, the start of a virtual Design Thinking workshop is best supported by a synchronous medium. It supports the participants best in getting to know each other and to get a common understanding of the way of collaborating. Therefore, a medium like video conferencing, which supports a high immediacy of feedback and offers a high symbol variety, would be appropriate. As the team begins to work on the first task (*empathize*), a more asynchronous medium will be appropriate, like a digital whiteboard (cp. the asynchronous bulletin board in table 1). This allows the team to profit from high parallelism, rehearsability and reprocessability. As described in Redlich et al. [35] a digital whiteboard and a chat could be used permanently. With that combination the distributed Design Thinking teams almost reached the performance of the onside Design Thinking teams [35].

In the *definition* phase, the team could be using video conferencing again to profit from the synchronicity of the medium. At the same time the whiteboard could be used for documenting the results and facilitate the session. Afterwards, in the *ideation* phase the team goes back to using an asynchronous medium. Finally, the team will reach the *prototyping* and *testing* phase, which again requires a synchronous media, like telephone conferencing.

6 Conclusion and Outlook

In Design Thinking there are two main styles of thinking, the converging thinking and the diverging thinking. Hence, the research question "Which media capabilities should a tool for virtual Design Thinking have to enable high team performance?" had to be answered for both thinking styles. For phases, which involve diverging thinking a medium with low synchronicity will lead to a higher team performance. And on the other hand, for phases which involve converging thinking synchronous media should be preferred. A medium which supports high synchronicity has the following media capabilities: It has high transmission velocity, low parallelism, a large symbol set, low rehearsability and low reprocessability. Media which support low synchronicity have the opposite media capabilities. By transferring the media synchronicity theory to the domain of Design Thinking we propose recommendations of which media type is suited in different phases of virtual Design Thinking. Therefore, we were able to answer the initial research question in an argumentative and deductive approach. However, as any research, this study comes with some limitations: So far, there is no empirical evidence for the results yet. To the best of our knowledge Redlich et al. [35] is currently the only study, which indicates that virtual Design Thinking might be successful. Yet, this study used a digital whiteboard in combination with a messenger. In contrast, the guideline proposed in this paper also employs synchronous media in convergence communication phases, which should increase the task performance further. To validate the approach of our work, future research could validate the general approach of our work in case studies. In addition, a bigger empirical evaluation with different team setups involving multiple time zones could be done to provide further evidence.

katrin.hartwig@stud.tu-darmstadt.de
reuter@peasec.tu-darmstadt.de

Abstract. The importance of dealing with fake news on social media has increased both in political and social contexts. While existing studies focus mainly on how to detect and label fake news, approaches to assist users in making their own assessments are largely missing. This article presents a study on how Twitter-users' assessments can be supported by an indicator-based white-box approach. First, we gathered potential indicators for fake news that have proven to be promising in previous studies and that fit our idea of a white-box approach. Based on those indicators we then designed and implemented the browser-plugin *TrusyTweet*, which assists users on Twitter in assessing tweets by showing politically neutral and intuitive warnings without creating reactance. Finally, we suggest the findings of our evaluations with a total of 27 participants which lead to further design implications for approaches to assist users in dealing with fake news.

Keywords: Fake News, Social Media, Twitter, Plugin

1 Introduction

Fake news can be defined as "*news articles that are intentionally and verifiably false and could mislead readers*" [1]. Recently, the term has gained popularity, especially in discussions concerning the political context. The U.S. presidential election in 2016, as well as the German parliamentary election in 2017 among others, showed a great perceived significance of fake news for the society. Although studies have shown that there were no impacts on the election outcomes [1], the society fears the effect of fake news in social media. Our previous representative study on the perception of fake news in Germany revealed that 84 % of the citizens agree with fake news posing a threat [2]. Those concerns are not groundless as fake news can indeed have serious consequences. For example, in 2013 the official Twitter account of Associated Press (AP) was hacked. In consequence, the stocks experienced a temporary loss of $130 billion [3]. Furthermore, fake news can be relevant in the context of peace and political propaganda [4]. Thus, finding adequate strategies to counteract the negative effects of fake news, especially in social networks, is of high interest. Examining fake news in online information is highly relevant in the IS research field [5]. Several studies have already

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

shown that labeling and deleting fake contents is not effective and sometimes counterproductive. Instead, scientists argue that the training of media literacy is a promising strategy [6], [7]. (Media) literacy is defined as the ability to access, analyze, evaluate and create messages in a variety of forms [8]. However, most approaches concentrate on black-box algorithms to automatically detect and label fake news. In black-box approaches one can observe the input (in our case e.g. a tweet) and the output (here e.g. the label as "fake") but there is no information about what happens in between (e.g. why the tweet was labeled as "fake"). The counterpart is called white-box approach, where internals can be reviewed. In our context, white-box approaches facilitate the comprehension of reasons that indicate fake content, so that the user has all necessary information to understand why an algorithm has a specific output.

The objective of this article is to examine how users on Twitter could be supported in dealing with fake news by a white-box-based browser-plugin. Our research questions are: How can we provide a transparent, politically neutral and objective assisting tool for users of social media? Moreover, does a white-box approach counteract reactance and encourage a learning effect? The article is organized as follows: Section 2 presents related work on assisting tools to counteract fake news. Section 3 presents our research approach of *design science* [9], which focuses on the design of an artifact for a relevant problem and rigorous evaluation methods. In section 4 we propose the concept of *TrustyTweet*, a white-box plugin for users on Twitter whose evaluation will be presented in section 5. Finally, we discuss the potential scientific contributions and limitations of our approach in section 6.

2 Related Work & Research Gap

While the effect of fake news has proven to be significant in specific cases and the debates in politics and society continue, several approaches try to find answers on how to counteract fake news. Recently, many studies have been conducted to detect and label fake news. Viviani and Pasi present a survey on how approaches automatically assess credibility in online review sites, microblogs and sources of online health information [10]. Rubin presents the state-of-the-art technologies on fake news detection, divided into linguistic and network approaches [11]. Both studies show that most of the approaches use machine learning techniques to identify fake contents. Despite machine learning algorithms, blacklists and whitelists of websites are commonly used. In the following list, an excerpt of existing browser-plugins and smartphone apps is presented which we found searching the Google Play Store, browser add-on sections and scientific contributions. Relevant associated characteristics were extracted from the official descriptions and are given in **Table 1**.

- **TweetCred**: Browser-plugin with a semi-supervised ranking model using SVM-rank to assess credibility in tweets. Displays a credibility score from 1 to 7. [12]
- **B.S. Detector**: Searches all links on a given webpage for references to unreliable sources, checking against a manually compiled list of domains. (http://bsdetector.tech)

- **Fake News Detector**: Allows users to tag news stories on Facebook and Twitter. Tags will be stored in a database and used by an AI to learn. In the future contents will be highlighted based on user input and the AI. (https://fakenewsdetector.org)
- **Fake News AI**: Uses a neural network to analyze writing, sophistication, site popularity, content and many more. (http://www.fakenewsai.com)
- **Fake News Check**: A smartphone app that does not detect fake news automatically but causes to reflect by asking 19 relevant questions which the user needs to answer to receive feedback. The app was developed for students to train media literacy. (https://www.neue-wege-des-lernens.de/projekte/fake-news-check)

Table 1. Limitations of existing approaches

Name of application	*Binary labels*	*Gives transparent reasons*	*Provides learning effect*	*Uses a database (black- or whitelist)*	*Based on training data*	*Big effort for users*
TweetCred					X	
B.S. Detector	X			X		
Fake News Detector				X	X	X
Fake News AI	X				X	
Fake News Check		X	X			X

Rehm states that fully automatic technologies are partly suitable to support the user in dealing with fake news but cannot take over all necessary tasks. Additionally, approaches have to be based on human intelligence [13]. The stand-alone usage of blacklists and whitelists works only for websites or other texts that contain links to URLs included in one of those lists. Since the online environment is much more complex, manually compiling lists with reliable or unreliable sources does not lead to sufficient results [10]. Despite the absence of gold standard datasets to train the classifiers [10], machine learning algorithms have another major flaw if used to assist the user. As machine learning techniques are black-box procedures, they cannot reason why they label a content as fake. Showing the user a label, it might even create reactance if it does not fit his or her own perception. That effect is caused by the *Confirmation Bias* due to which messages are particularly considered true if they fit the own ideology [14–16]. None of the existing approaches gives transparent reasons or encourages a learning effect while leading to little effort for the user.

Studies have shown that a promising way to counteract fake news is increasing media literacy [17, 18]. Improving the capacity to evaluate online contents as autonomously as possible using white-box instead of black-box approaches can minimize reactance and prevent the *Backfire Effect*. While several approaches use machine learning techniques to label contents as fake or not fake, there are no approaches that work with a white-box technique despite “Fake News Check”. This application, though, involves a big effort for the user as he must manually go through 19 questions for every text he wants to check before receiving a feedback. The approach itself does not include an automatic check to detect fake news. To date, no approach to detect fake news is based on the ideas of media literacy or white-box methods.

3 Research Design

Keeping in mind the detected limitations of machine learning-based approaches, for instance regarding created reactance, our intention is to offer a first survey on how white-box approaches can help to counteract fake news in social media. Our aim is to find answers to the following research questions: *How can we provide a transparent, politically neutral and objective assisting tool for users of social media? Furthermore, does a white-box approach counteract reactance and encourage a learning effect?* To encounter the lack of empirical findings regarding white-box approaches in the given context, we present a browser-plugin for Twitter which has been developed and evaluated in an iterative process. The plugin focuses on Twitter as it is a popular platform for breaking news with a high relevance of fake news, for instance in emergency situations but also in political campaigns [19]. As a popular communication channel, it is commonly used in scientific studies to examine social media from various perspectives (e.g. [20 21]). We used the *design science* approach [9] which focuses on the design of an artifact for a relevant problem and rigorous evaluation methods. In our case, the artifacts will be versions of our plugin and evaluations will take place in form of thinking-aloud studies. The method applies five steps, namely (a) achieving a problem awareness, (b) suggesting solutions, (c) development of solutions, (d) evaluation and finally (e) conclusion. The *design science* approach has proven to be an appropriate method to create new and innovative artifacts [9].

4 Concept of *TrustyTweet*

Instead of labeling and deleting, acquiring a high standard of media literacy is considered to be a promising approach in combating the impact of fake news. Given a number of transparent and identifiable indicators for fake news, the user of social media can be supported in forming an opinion about online content. In that context, it is crucial to differentiate between assistance systems that give neutral hints based on transparent indicators to train media literacy and systems that create reactance. Müller and Denner indicate that warning messages might lead to a *Backfire Effect* [6]. Especially in political contexts, users might rate the warning message as an illegal attempt to persuade the user which can result in believing in the content even more. Using a white-box instead of a black-box procedure is an important step to prevent or minimize reactance.

Our aim is to support the user in dealing with fake news in tweets and to increase his media literacy. We present *TrustyTweet*, a browser-plugin that intends to support users on Twitter in dealing with fake news by giving politically neutral, transparent and intuitive hints. This approach particularly aims to be a helpful assistant without creating reactance. The user continues to be in the power of his own assessments. We intend to create a learning effect regarding media literacy to make the plugin redundant after a longer regular usage. Therefore, different from other approaches, *TrustyTweet* is based on white-box technology. The plugin was developed in a user-centered design process using the design science approach. We identified potential indicators for fake news by considering what has already been proven in studies to be successful. The focus is on heuristics that are used intuitively and successfully by humans and are easily comprehensible for everyone. In several qualitative thinking-aloud studies we evaluated the perceived helpfulness, the users' perceived autonomy and usability of the plugin on Twitter.

4.1 Identification of Indicators

Since the plugin aims to be a white-box approach it intends to show transparent warnings which the user can comprehend at any time, regardless of his level of media literacy. Morris et al. [22] found that users assess contents especially using features that are visible at a glance. In our approach, we intend to follow that idea. Potential indicators that fit our intentions and that largely have already been proven in studies to be promising in indicating fake news are the following:

- Consecutive capitalization [23-25]
- Excessive usage of punctuation (e.g. "*!!!*") [22], [23]
- Wrong punctuation a the end of sentences [22], [24]
- Excessive usage of emoticons [23], [25] and attention-grabbing emoticons
- Default account image [22]
- The absence of an official account verification seal (especially for celebrities) [22]

The potential indicators were assessed in a first thinking-aloud pre-study with six participants aged 23 to 28 (4 female, 2 male, all university students) in an average duration of 33 minutes. All six indicators have proven to be easily comprehensible for our test subjects. Furthermore, the detection algorithm for each indicator has an acceptable runtime to support users on Twitter dynamically and in real time. It is vital to clarify that our approach does not claim to comprehend all relevant indicators for fake news. The mentioned group of indicators includes those that are fitting our white-box idea since they are easily comprehensible.

4.2 Underlying Technology and Components of the Plugin

TrustyTweet was developed for the Firefox browser and uses jQuery and Semantic UI. Its main components are a textbox containing all indicators detected in a specific tweet which serves as a warning, two distinct icons to report if indicators have been detected in the specific tweet or not and an icon to open the settings in a pop-up window. The indicators were detected by searching the DOM tree of Twitter. Next to each indicator, there is a link to open more generic information about the indicator in a pop-up window (see **Figure 3**). When hovering the mouse over an indicator, the underlying component of the tweet is being highlighted dynamically (see **Figure 1**). Hence, the user can see immediately why the warning is being displayed. The main icon of the plugin serves as a toggle button for the textbox. The user can decide if he wants to see all detected indicators next to each tweet or if he prefers to see only the icon and toggle the textbox whenever he is interested in why the warning is being displayed. Additionally, it guarantees that other contents like “*Who to follow*” do not remain hidden. A central feature of *TrustyTweet* is the configuration pop-up (see **Figure 2**). Using checkboxes, the user can switch the examination regarding specific indicators on and off. Hence, the plugin intends to build a stronger sense of autonomy and to counteract paternalism.

Figure 3. Pop-up with additional information

5 Evaluation

5.1 Methodology

Using the design science approach, we iteratively applied five steps to achieve a problem awareness, to suggest solutions in form of potential plugin-designs, to implement those solutions, to thoroughly evaluate them and to finally draw a conclusion. The iteratively conducted evaluations were based on the thinking-aloud method in which the user explains why he carries out which activity, which information is incomprehensible or does not meet his expectations and what he likes or dislikes. The audio and video material was recorded using the Xbox DVR-tool. While using *TrustyTweet* on Twitter, the subjects were asked to execute usability tasks and answer open questions. The average durations were 33 minutes in the first pre-study and 11 minutes in the second and main study. The participants were informed beforehand that there is no "*right*" or "*wrong*" for answering the questions. To guarantee the same conditions for all subjects in the first subtest, tweets were generated by a test account by which the subtest was performed. Additionally, a second subtest was performed on real-time tweets of a politician and a German news page on Twitter to receive an impression of the usage of the plugin in a realistic environment. After each study, the detected flaws were patched and suggested improvements were implemented to receive better results in the next iteration. While the tasks in the first formative study focus mainly on the comprehensibility of the suggested indicators and gather ideas on how to increase the perceived autonomy, the second study includes an examination of the central configuration feature and the realization of dialogue design principles. Since interactions are a central component of our plugin, we want to gather information about the fulfillment of dialogue principles as conformity with user expectations and self-descriptiveness. The third study intends to examine to what extent a well-usable version of the plugin supports the user in dealing with fake news, including a summative evaluation of usability. Continuing the iterative process our aim is to understand to what extent users feel autonomous or patronized during the usage of our white-box-based plugin. Furthermore, we intend to examine the perceived helpfulness of the plugin. Therefore, the test subjects were asked to perform several tasks (e.g. Open the configurations of the plugin. Check the tweets on "*capitalization*" and "*emoticons*" only.) and answer specific questions (e.g. To what extent do you feel patronized or autonomous when assessing the tweets? / How do you like the plugin contentwise? Is it helpful or is it obstructive?).

Characteristics of Study Participants. In the first pre-study, a number of six participants (4 female, 2 male) took part, in the second pre-study a number of five (2 female, 3 male) and in the main study a number of 16 participants (7 female, 9 male). The participants' age ranged from 23 to 28 years in the first and second study and from 21 to 34 years in the main study. The majority of the test subjects were university students (19 out of 27 in total) due to their good accessibility for scientific studies and their relevance as potential Twitter-users. The remaining eight participants stated to be employees. In the first pre-study, three out of six participants and in the second pre-study three out of five participants stated that they have a Twitter account or that they had an account in the past. In the main study, it applied to half of the test subjects. Participants in all studies that stated to have never had a Twitter account were introduced to the central aspects and components of Twitter and its tweets before they started completing the tasks.

Analysis. Following the standard proceeding for thinking-aloud tests according to van Someren, Barnard & Sandberg [26] we examined the obtained qualitative data of all thinking-aloud studies by reviewing the video and audio material, transcribing all important statements and assigning the statements to their associated tasks and actions. The statements were then clustered thematically and gathered for all test subjects. Eight categories were developed inductively from the data (helpfulness, autonomy, additional information, configuration, toggle-feature, mouseover-feature, salience, other). Each statement was assigned to a category by looking for keywords (e.g. "patronized": autonomy), considering the context of tasks. Hence, conclusions were drawn from the various categories. The most noteworthy contributions of the main study will be presented in the following chapter.

5.2 Empirical Results

Perceived Helpfulness. When asked about helpfulness or obstructiveness of the plugin, 13 out of 16 participants regarded it to be a helpful tool. Most participants appreciated particularly its transparent nature and the simple visual feedback as well as the possibility to toggle the textbox while still getting a feedback from the icon: *"I like it a lot. You must keep thinking for yourself, but the plugin makes it easier and things attract your attention faster. It says: Attention! Here it would be wiser to think about the tweet again" (E12 #00:09:28).*

On the other hand, three participants argued that they personally do not need the plugin and therefore could not yet see the added value. They pointed out, that the warnings were based on very simple indicators, which they were able to detect by themselves: *"I think I do not need it. It is very interesting, that the displayed warnings are exactly the things I use as a search filter in my head when I read texts." (E15 #00:08:53).* One participant was concerned about the plugin showing too many false alarms, for example when warning of non-celebrity users that are not verified: *"If after every storm you warn against there are only three drops of rain, I will eventually not pay attention to it anymore. Therefore, it might be better to raise the threshold or to show graduated warnings." (E27 #00:07:24).*

More positively, one participant highlighted the desired learning effect of the plugin: *"I can imagine that it is very good to learn what you have to pay attention to. At some point when you have enough practice, you have taken on the same policies." (E14 #00:06:14).* Additionally, the participants had some interesting ideas to improve the plugin. For instance, it would be a helpful feature to display a link to the scientific sources of the chosen indicators. This is in the spirit of our white-box approach and would enhance transparency and objectivity. Furthermore, as the plugin does not include checks on videos and images, that should be pointed out to the user.

Perceived Autonomy. When we asked the participants to what extent they felt autonomous or patronized when assessing the tweets, all 16 participants regarded not to feel patronized at all. They highlighted the neutrally phrased additional information and the fact, that the plugin does not decide if a tweet contains fake news: *"I did not find it patronizing at all, especially because the explanations are written very neutrally. (…) You still must keep thinking for yourself. The plugin says there might be an indicator, but it does not have to be fake." (E14 #00:06:58).* The perceived autonomy was also enhanced by the configuration feature: *"When punctuation is not a criterion for me, I can just switch it off" (E27 #00:09:07).*

Plugin Features: Usability and Layout. All but one participant managed to interact with the additional information pop-up intuitively and very fast. Five participants noted explicitly that the additional information was helpful and necessary to understand the indicators completely. The configuration-feature has proven to be a substantially important aspect to enhance the perceived autonomy already in the two first studies using low-fidelity prototypes. The fully implemented version was used effectively and

intuitively by all 16 participants of the third study: *"Wow, that is easy! I do not have to think at all" (E21 #00:02:25).*
12 out of 16 participants managed to toggle the textbox containing the detected indicators straightaway. On the other hand, four participants struggled initially to find the correct button and tried a Twitter-internal button before toggling the textbox successfully. Most participants valued the feature since it can make the feedback more compact. The highlighting-feature was appreciated a lot by all participants. Some participants even said it was the most helpful component of the plugin as it helps the user to comprehend all warnings. Hence, the feature is central to our white-box approach. Using the highlighting-feature, all participants were able to match a specific warning to the correct referring part of the tweet successfully. All but two participants stated to like the layout of the plugin. While eleven out of 16 participants said it was noticeable enough, four were undecided and one found it was too noticeable. To avoid misunderstandings, participants suggested to add a mouseover-effect to the icon which appears when no implemented indicator was detected in a specific tweet.

5.3 Concluding Design Implications

Considering the presented results regarding perceived helpfulness, autonomy and usability of the plugin, we present five design implications to enhance the value of an indicator-based white-box approach to support users on Twitter in dealing with fake news. Those implications were extracted from statements that were mentioned particularly often or highlighted as very crucial by the participants. They support the view of existing studies, for instance by highlighting the relevance of transparent information (e.g. [6]) and the minimization of false alarms [27]. Moreover, they expand existing knowledge by a first scientific contribution on how to successfully develop an indicator-based white-box approach in that specific context.
Personalization to enhance autonomy. The configuration-feature is substantially important to enhance the perceived autonomy of the users and to prevent reactance. Our test subjects endorsed the possibility of deciding for themselves, on which indicators the tweets should be checked.
Assisting with transparent and objective information. The indicators need a detailed description that explains why they are relevant with regards to fake news. According to our test subjects, it is crucial, that the descriptions are formulated in a politically neutral and objective way. Adding a link to the associated scientific study can increase credibility in the spirit of our white-box approach. Warnings should always clarify that are assisting but do not replace the users' own assessment. Furthermore, the users must be aware of what functionalities the plugin does not include (e.g. our plugin does not examine images and videos).
Unambiguousness of warnings. Highlighting parts of the tweet in a mouseover-effect concerning a displayed warning was rated as one of the most helpful features of the plugin. Matching specific warnings to the correct referred part of the tweet is central to enhance the desired learning effect.
Personalized noticeability. The toggle-feature of the warnings was rated positively by the test subjects. Since the icon still gives a simple visible feedback, it is a pleasant way

of making the plugin more compact and adjusting it to the users' preferences concerning noticeability.

Minimizing false alarms. Minimizing false positives is crucial to prevent users from not paying attention anymore or uninstalling the plugin before having achieved a learning effect. Therefore, the threshold of warnings should not be too low. Some participants see advantages in showing graduated warnings in different colors.

6 Discussion & Conclusion

Dealing with fake news has proven to be one of the big current challenges in society and politics. Studies have shown that there is a need for assisting tools to support users on social media. There has been previous research on using machine learning algorithms to detect and label fake news. For example, Gupta et al. [12] present a browser-plugin to automatically assess the credibility of contents on Twitter. Further approaches (e.g. Fake News AI) use machine learning techniques as well. Other approaches are based on whitelists or blacklists (e.g. B.S. Detector) to detect fake news. The usage of black-box approaches though is not able to give reasons for its decisions and therefore, it runs the risk of creating reactance. In our eyes and according to other studies ([6], [7]), improving media literacy is a crucial strategy to help users dealing with fake news. Therefore, white-box approaches are necessary. However, all presented plugins, applications and approaches are based on black-box methods. Although the smartphone application Fake News Check can give transparent reasons on why contents might be fake, it does not automatically check for indicators and it comes with a big effort for the user.

Our scientific contribution is to theoretically explore the potential of an indicator-based white-box approach to assist users on Twitter and more practically to design, implement and evaluate a consistent browser-plugin as an artifact regarding to the design science approach. The plugin includes a warning with regards to six easily comprehensible and politically neutral indicators for fake news, further information about every indicator and a configuration-feature to support personalization. To answer our first research question (*How can we provide a transparent, politically neutral and objective assisting tool for users of social media?*), the empirical findings in Section 5.3 reveal that our indicator-based white-box approach to support users on Twitter in dealing with fake news can be considered suitable, applying the following five design implications: personalization to enhance autonomy, transparent and objective information, unambiguousness of warnings, personalized noticeability and minimization of false alarms. Moreover, we intended to answer the second research question: *Does a white-box approach counteract reactance and encourage a learning effect?* Our study shows that our white-box approach is a promising way to support users on social media without creating reactance but encouraging a learning effect and can therefore be considered a suitable alternative to black-box approaches.

Following our concept of design science, we intend to evaluate the newly suggested features (e.g. graduated warnings) in the future. Moreover, we intend to integrate further relevant user groups in our evaluation. In addition to our qualitative studies, a quantitative study is desirable to guarantee an evaluation on a larger scale. On the other hand, it would be interesting to examine if there is a beneficial way to combine our white-box tool with the features of a machine learning approach to receive the advantages of both methods, namely the transparent and easily comprehensible indicators of our approach and the accurate classifications of black-box approaches.

Application of Process Mining Techniques to Support Maintenance-Related Objectives

Richard Horn[1], Patrick Zschech[1]

[1] Technische Universität Dresden, Business Intelligence Research, Dresden, Germany
{richard.horn,patrick.zschech}@tu-dresden.de

Abstract. The variety of data types generated in manufacturing environments leads to a situation where data-driven approaches for analytical maintenance support no longer have to be limited to the equipment level, but rather can be extended to further perspectives. To this end, this paper examines how process mining (PM) as an approach to extract knowledge about process-related relationships can be applied to support maintenance-related objectives. Our research is carried out by using exemplary data from a manufacturing company, where we successively take different data attributes from various source systems into account and apply selected PM techniques to demonstrate their applicability. As a result, we showcase how different insights can be provided, such as the analysis of a machine's internal behavior, examination of error dependencies across multiple production steps, determination of a machine's relevance within the equipment network or the discovery of bottlenecks regarding frequencies, cycle times and costs.

Keywords: Data-Driven Maintenance, Maintenance Objectives, Process Mining, Data Mining, Business Analytics

1 Introduction

In no other sector, more data are generated than in the field of manufacturing, ranging from process control and production status records to condition monitoring data of the overall equipment [1]. The variety of machine-generated data provides a vital asset for industrial maintenance, where approaches like condition-based maintenance (CBM) are applied for diagnostic and prognostic purposes to guarantee high reliability, low environmental risks and human safety [2-4]. Such approaches primarily focus on the equipment level and make use of data mining (DM) algorithms like clustering and classification techniques [5]. However, due to the diversity of manufacturing data, there are also other methodical approaches which allow a consideration from more distinct perspectives. Such further perspectives could be provided, for example, by applying techniques from the field of process mining (PM), where sequentially generated event data are utilized to extract hidden knowledge about process-related relationships and patterns [6]. In this way, it possible to obtain insights that are no longer based only on an instance level, but rather extend to an inter-unit consideration, making this approach also interesting for maintenance questions beyond a scope on the equipment level.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

While PM has already been applied successfully in various domains like transportation, healthcare, banking, retail or education [7], an application to the field of industrial maintenance is rather scarce within the current literature. For this reason, our paper aims to demonstrate its applicability within this particular context and addresses the following research question (RQ):

RQ: *How can process mining techniques be applied for knowledge extraction in manufacturing environments to support maintenance-related objectives?*

To carry out our research, we used exemplary data records from a manufacturing company, where we successively took data attributes from various source systems into account and applied PM techniques derived from the literature. Following this approach, the remainder of this paper is structured as follows: In Section 2, we provide the conceptual background for both disciplines of interest. We then showcase the applicability of PM techniques to support maintenance-related objectives in Section 3. Finally, we draw a conclusion and give an outlook for further research in Section 4.

2 Conceptual Background

2.1 Industrial Maintenance

Industrial maintenance can be understood as a broad field with many accentuations and facets. Therefore, a consideration of various maintenance definitions is required to derive central objectives for which analytical approaches based on different data assets can provide a methodical contribution.

In general, maintenance can be defined as a combination of all administrative and technical activities that are required for preserving the desired operating condition of the production equipment [8]. This statement can be extended by the British Standard Institution including the activities to restore the operating condition of production equipment [9]. Likewise, the guarantee on plant availability as well as part of the plant safety through resilient systems are connected to those objectives [10, 11]. Additionally, the DIN EN 13306 includes the aspects cost efficiency, environmentalism and product quality [12]. [13] augments this list with the efficient use of resources, which have divergent manifestations. Thus, [14] distinguishes “main resources” and “other resources”. Conclusively, the Maintenance Engineering Society of Australia announces “(…) that maintenance is about achieving the required asset capabilities within an economic or business context” [15] and specifies the optimization of production equipment as another aspect of maintenance. As a result, nine different core objectives of maintenance can be extracted as listed in Table 1, which will be referenced in the following by referring to their respective objective identifier (OID).

The actual maintenance execution is then carried out via different programs like time-based or data-driven concepts [2, 4], whereas our focus is on a data-driven support. Given the strong emphasis on the equipment level, the majority of data-driven concepts like CBM or predictive maintenance primarily concentrates on a particular unit of interest and thus employs classical DM techniques from statistics and machine learning [5]. This includes, for example, cluster analyses to detect unusual machine behavior, classifiers to determine heterogenous fault modes or artificial neural networks to predict a machine's remaining useful life [4, 5, 16]. However, due to the diversity of generated data in manufacturing environments, it is also possible to establish further analytical perspectives. As specified by our research goal, this will be demonstrated by applying techniques from the field of PM.

Table 1. Core Objectives of Industrial Maintenance

OID	*Objectives*	*References*
O1	Increase of machine lifetime	[8-11]
O2	Optimization of production equipment	[15]
O3	Retention or increase of product quality	[12]
O4	Minimization of machine downtimes	[8-11]
O5	Guarantee of safety	[10]
O6	Reduction of risk of failure and damage	[8-11]
O7	Efficient use of resources	[10, 13, 14]
O8	Retention of environment protection	[10, 12]
O9	Increase of cost efficiency	[12-15]

2.2 Process Mining

PM is characterized as a young research area that has been researched in the information systems domain in the last decade and established as a connection between business process management on the one hand and data science/business analytics on the other hand [6]. In general, PM tries to gain, aggregate and visualize both company- and process-relevant information by evaluating and analyzing great amounts of data in the sense of so-called event logs. Up to now, PM has been used in diverse fields like retail, education or healthcare, thus showing wide application areas. For example, while [17] and [18] use PM for the maintenance of web pages and their optimization and improvement, [19] tries to achieve personalized learning based on students' performance data. Furthermore, [20] show how PM can be used to identify deviations in healthcare processes from existing policies and best-practices, whereas [21] show a possibility to use PM to discover the customer fulfillment process in a telecommunication company.

Overall, there are three components of PM, each specialized on one remit. First, *process discovery* handles the creation of process models that are representative in behavior towards the underlying event logs. Hence, process discovery can be seen as the most relevant but also most difficult task of PM and offers many possibilities because of divergent process perspectives, such as the organizational or time-based perspective. By contrast, *process conformance checking* focuses the conformity of process models with the operative behavior observed within the event logs [6]. The aim of this comparison is to detect similarities, differences and deviations to evaluate "if actual processes follow prescribed behaviors or rules" [22]. As a last type of PM, the extension of existing event logs by additional attributes is characterized as *process enhancement*. These attributes define new perspectives and analytical possibilities in and on the process, whereby PM is opened for potential adjustments to reach subjective goals [6].

3 Maintenance Support with Process Mining

The following section demonstrates the applicability of PM towards the support of maintenance-related objectives. For this purpose, exemplary anonymized data from a manufacturing company producing car tires were used. The production process extends over various steps that are carried out on distributed machines. For the application of PM techniques, data from different source systems had to be brought into a standardized event log structure [6]. Here, we started with the minimum of required attributes at the lowest level and then successively considered additional attributes and levels to apply further perspectives. Relevant data were extracted from systems at different application layers, such as energy meters, programmable logic controllers, a manufacturing execution system (MES) or an enterprise resource planning system (ERP). For demonstration purposes, data samples from all systems were filtered and strongly simplified. Thus, the focus was primarily set on the overall feasibility instead of quantitively evaluating specific scenarios with regard to the current status and possible improvements.

3.1 Starting with the Minimum of Required Data

The minimum required data for PM is defined by the existence of two attributes: i) an *activity* that refers to an event class of interest and ii) a *case ID* that relates each event to a particular process instance. Since most PM tools also require a *timestamp* to ensure the event order, this attribute was integrated as well. With this basic data, it was possible to perform *process discovery* to investigate procedural structures at different levels [6].

At the lowest level, process activities can be defined by events derived from different machine components like logical elements, transistors or switching circuits. This allows to track consecutive states of a single machine and derive insights into a system's internal behavior without considering the entire production process. Thus, irritants like a high number of skipped events in machines or increased operation time can be detected at an early stage to trigger proactive maintenance actions and prevent further damage.

At a next level and this will remain the primary focus in the following considerations, process activities can be defined at the scope of the actual manufacturing process with all its steps and sub-steps mainly derived from MES data. This leads to multiple advantages as it becomes feasible to analyze the entire manufacturing setting regarding frequencies and durations of steps/sub-steps as well as variants, whereby one variant describes a specific path through the production process [23]. As a result, bottlenecks, time per step or variant and many other process statistics can be evaluated.

In an analogous manner, it is also possible to examine event data generated by the execution of maintenance tasks. This allows to reconstruct and critically analyze the procedures of operational maintenance activities. However, since most maintenance tasks are still executed manually without leaving extensive digital traces - as in the particular case where only scarce information could be extracted from the ERP - the focus will remain on the investigation of existing machine and production data.

Subsequent to the discovery of process structures, the results can be used to realize the *process conformance checking,* following [6]. As already stated, this allows to explore deviations and commonalities between the intended/documented processes on the one hand and the real as-is processes on the other hand. Moreover, it is possible to determine if specific process steps exceed predefined control limits like excursion rates, cycle times or a predefined amount of process instances to run on one single machine.

Overall, in terms of the maintenance objectives regarding machine lifetime (O1) and equipment optimization (O2), all those insights can be used to reveal unintended behavior of the production process at different abstraction levels and thus help to schedule maintenance activities proactively to prevent machine failures. Furthermore, this methodical approach offers the possibility to validate performed maintenance actions and their impact by comparing the process performance before and after an intervention.

3.2 Including Machine Attributes to Enrich Process Activities

While in the preceding scenario the activities of the production process were primarily considered in isolation, the database can further be enriched with resource information in the sense of *process enhancement*. Therefore, the process steps to be explored are subsequently not only specified by the production activities, but also by the machines performing those activities. Thus, after the *process discovery*, it can now be observed that all process steps consist of activity/machine-compositions, as shown in Figure 1, where the first step *"PSc3e047c7"* is performed by the machine *"S_636gt"*.

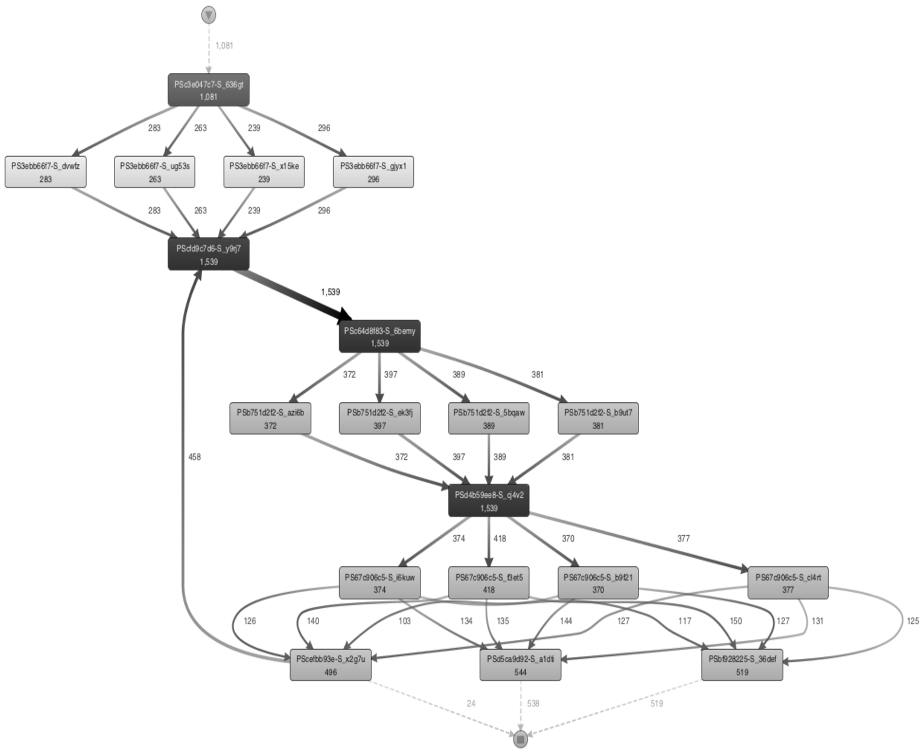

Figure 1: Simplified Production Process with Machine Data (Recorded in Disco)

With this representation, the workload of the machines can be expressed by frequency numbers and different color schemes indicating the different intensities. Thus, it is possible to detect machines with high workloads that are possibly more exposed to continuous stress. Those machines often occupy central positions within the production flow (like in the first, third, fourth and sixth step in Figure 1) and therefore require more attention to proactive maintenance, since a failure may disrupt the entire process (O4).

Similarly, the distribution of the workload between different machines performing the same production step can be examined. For example, the second step is executed by four different machines in parallel. However, while machine *"S_gjyx1"* was running 296 instances, unit *"S_x15ke"* was only executing 239 instances. In combination with scheduling information, these insights can be used for an optimal allocation of process instances to machines, with the goal to equalize the number of processed products (O2) and thus to lengthen the machines' lifetime (O1).

Moreover, by not only focusing on a single activity level but also considering their transitions, different process variants can be evaluated in terms of distinct production paths. Here, the activity/machine-composition offers the advantage to gather insights about sequential machine interdependencies. As such, it can be assessed, for example, whether some incidents primarily occur within process paths where certain machines were previously involved. This can also be relevant for quality assurance (O3), where specific machine combinations throughout the production flow may lead to different quality levels of the final product (c.f. Section 3.5).

Another perspective can be provided by analyzing durations of activities and transitions using timestamps instead of solely concentrating on frequencies. Analogously, time attributes can directly be incorporated in the process model to detect activity/machine-combinations with high cycle times in terms of bottlenecks and inefficiencies (O2). Simultaneously, exceptionally long cycle times are an indicator for faulty machine behavior to trigger further inspections and respective interventions.

3.3 Implementing and Expanding the XES-Lifecycle Extension

The exploration of failure events within the process is another relevant facet of maintenance support. For such a consideration, the given event log requires an additional attribute to document the production status of each step.

This can be implemented by employing the XES-Lifecycle Extension as introduced by [24], which provides predefined values like *"start"*, *"complete"*, *"suspend"*, *"resume"* or *"pi_abort"*, with the last value defining an interruption of the current process instance. It is conspicuous though, that with these values only the possibility is given to analyze interrupting machine errors and suspending errors. However, with regard to errors that do not interrupt the production process, this framework requires an extension. Thus, we created an additional state, called "*fail_complete*", to describe the completion of a process step while errors take place in execution. This allows to focus on failure events in the process analysis and generates high profit for subsequent analysis, such as tracking overall failure times. For example, the PM tool Celonis allows to define domain-specific key performance indicators (KPI) that can be monitored live during process execution. By using this feature in combination with the newly created state, KPIs for the number and the ratio of failure events in a single production equipment can be defined. This live-monitoring of the production process combined with the historical process data gives some indication of past and future machine behavior. For instance, this enables to determine the average number of internal errors until the process instance is finally interrupted by a serious error (O4).

Moreover, also the duration of failure events is of high relevance for maintenance. At this point, there are multiple ways to achieve the documentation of these downtimes. Enhancing the event log by inclusion of an additional attribute containing these data represents one way to accomplish this goal. However, this approach contradicts with one of the fundamental principles of PM, as the downtimes exhibit a direct reference to the processing machine and not to the activity. Another option arises when saving the desired information in an additional event log defining the production equipment as events. But this leads to a loss of the process perspective. Therefore, it's necessary to calculate the downtimes by using existing data and to add another dimension to the predefined time perspective. Based on the assumption that the downtime is calculated by the timestamps of the failure and the reactivation of the machine, the dead times can be computed by using the pseudocode depicted in Figure 2. In contrast to the previous approaches, this allows to view dead times directly in the process and to analyze them in case specific or cumulative way by using all advantages of *process discovery*.

```
# get_breaktime:
n = max(#CaseID)
FOR i=0 TO n-1 DO
  current_machine = #Machine(e)[i]
  current_LC_transition = #LC(e)[i]
  IF current_LC_transition == "stop" THEN
      FOR j = i+1 TO n  - 1 DO
          next_machine = #Machine(e)[j]
          IF current_machine == next_machine THEN
              #Starttimestamp(e)j - #Endtimestamp(e)i
          END IF
      END FOR
  ELSE
      continue
END FOR
```

Figure 2: Pseudocode for Calculating Downtimes

Apart from this, dependencies between different errors in the process are focused. For the discovery of such dependencies, different techniques from statistics and machine learning can be used, such as support vector machines or logistic regression [25]. Exemplarily, we use the logistic regression that allows to receive direct failure probabilities. Transferred to the present context, this enables to determine if the probability for a specific machine documenting an error increases, when another machine earlier in the process also documented an error. It could be found, for example, if station *"S_636gt"* documents an error, then station *"S_dvwfz"* is 2.56 times more likely ($B = 0.94, p < 0.001$) to also write an error in reference to the state in which station *"S_636gt"* would not have documented one ($\mathrm{X}^2(1) = 23.84, p < 0.001$). In this way, failure dependencies in the process can be revealed and provided for decision support by directly visualizing this information within the process model.

This particular scenario illustrates the successful combination of PM and DM techniques. PM first aims at uncovering sequential patterns to identify process complexities and distinct paths. This allows the detection of discrepancies between the desired and actual process behavior, for example, in the form of anomalous paths, bottlenecks or deviating process performance. Once such discrepancies are detected, DM techniques can then be used to identify non-local and multi-causal effects that possibly span over multiple process steps [26]. Referring to machine failures during the execution of production processes, it is possible to determine patterns which classify a specific sequence of error events. Thus, the option arises to predict the breakdown of a machine based on the error events that occurred in previous stages, which allows to interfere in the process at the right time and to perform tasks to prevent upcoming machine failures (O1, O4).

3.4 Adding the Organizational Extension

Another perspective provided by PM is the organizational view, with the goal to extract and visualize social network structures between different entities involved in a process environment [7]. In this context, a social network consist of i) nodes representing organizational units and ii) relationships representing the connections between those units [6]. Transferring this approach to the current setting, the first part can be defined by the production equipment, whereas the second part is characterized by ingoing- and outgoing connections according to the manufacturing process. To achieve this kind of networks, the XES Standard defines the "organizational extension", encompassing the name or the ID of the respective operator in the event log [24].

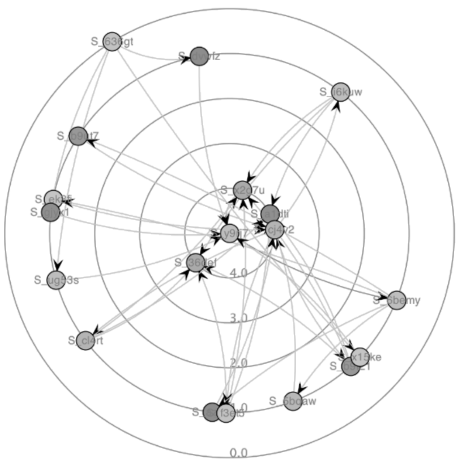

Figure 3: Network of Production Equipment (Recorded in ProM)

Besides the creation of a visual network (c.f. Figure 3), the machines can additionally be assessed according to their importance within the network using centrality measures. Following this, the most valuable machine in the network is characterized by the highest number of connectors [27]. Focusing on the reduction of risk and failure damage (O6), it can be concluded that theoretically station *"S_y9tj7"*, positioned in the center, is of high relevance for the production process, as its failure may influence different other machines which could lead to a high capacity loss. Nevertheless, this approach only indicates a high equipment relevance based on relations to other production equipment, whereas ramifications of failures, like emission of harmful substances, are not included in this risk estimation.

3.5 Integration of Domain-Specific Attributes

When executing production steps, machines usually consume different input resources like energy and materials while simultaneously producing waste and other by-products. As such, the event log can further be enriched with attributes in terms of measured values and specific KPIs to illustrate the resource flow at a machine and process level.

Data attributes can be gathered from various systems, as in the current case where power consumption was measured via energy meters and material flows were collected from the MES. However, event characteristics are generally not limited to those aspects, but rather can extend to any other subject of interest, such as further environmental indicators [28] or quality-related attributes [29].

The integration of attributes can be done in two ways: On the one hand, it is possible to simply add them to the event log by appending it as a property to the corresponding events. On the other hand, an explication of an additional extension to the XES-Standard is possible to achieve a certain level of standardization by specifying concrete definitions of the attributes in the extension definition. This also permits to create domain-specific extensions for a complete set of properties, which then can be in the center of further analysis with a predefined prefix for their identification [24].

Once the event log is enriched with further attributes, they can be examined at the different levels addressed previously, i.e. for i) the overall production process, ii) individual production steps, iii) individual machines, iv) activity/machine-combinations, or v) distinct paths. In this way, it is possible, for example, to monitor resource efficiencies (O7), but also to track material flows in terms of waste and harmful materials (O5, O8).

In addition, it is also advisable to not only consider each attribute in a univariate manner, but rather to analyze them in combination with each other along the entire manufacturing process. Here, the combination with DM techniques proves to be helpful again, where each attribute either serves as a target variable of interest or as an input feature to predict the respective output [26]. This makes it possible, for example, to determine the relationship between the final product quality, measured at the end of a process, and the machine and process attributes at each individual production step (O3).

3.6 Evaluating the Cost Efficiency

In a production process, there are many different types of costs that need to be regarded when evaluating the overall cost efficiency. Therefore, an individual cost model needs to be applied to determine which parameters to include to the event log. In the given context, the costs for one process activity e in the set of all process activities E will be calculated with $\#_{TC}(e) = \#_{EC}(e) * \#_{t}(e) * EP + \#_{MC}(e)$ with TC as total costs of event $e \in E$, EC and EP as energy consumption and its current price, t as duration and MC as material consumption. When enriching the event log with the not yet included (external) data, it is noticeable that, due to the event centric focus of PM, there is a loss of information or costs regarding the event transitions of the process model. These transitions also need to be regarded as they are in the time or frequency perspective of a process. It is conspicuous that there are costs like the energy consumption in standby mode of a machine, required energy to get in production ready state or the consumption for cooling down in the time between two process steps in a production process. In conclusion, there are costs right before and after executing a specific task that are not yet regarded by an event centric focus. By further adding the cost calculation at the start and end timestamp of a process activity, possibilities arise to determine these unregistered costs and to provide a cost perspective of the process. Therefore, the costs before activity execution can be determined by subtracting the costs at the start of an event $\#_{StartCosts}(e_i)$ from the costs at the end of the previous executed event $\#_{EndCosts}(e_{i-1})$, whereas the costs after execution are determined by the subtraction of all cost attributes of an event: $cae(e_i) = \#_{EndCosts}(e_i) - \#_{ActivityCosts}(e_i) - \#_{StartCosts}(e_i)$. Given these attributes, it can be stated that the overall costs of a transition ct between events can be calculated by adding the pre-execution costs of an activity to the post-execution costs of the activity before that:

$$ct(e_i, e_{i+1}) = cae(e_i) + \left(\#_{StartCosts}(e_{i+1}) - \#_{EndCosts}(e_i)\right) \mid e_i \succ e_{i+1} \qquad (1)$$

In conclusion, a cost perspective on the process can be realized that allows to gather all information available through *process discovery* and to achieve a long-term validation and possible predictions of future production costs. Therefore, cost referred bottlenecks and cost intensive areas of the process can be identified (O9). Moreover, by focusing on process variants, optimization potentials can be realized, e.g. by distributing process instances to less cost-intensive machines (O2).

4 Conclusion and Outlook

The goal of this paper was to demonstrate the application of PM techniques in manufacturing environments to support maintenance-related objectives. Using successively more data attributes from various source systems at different application levels, it could be shown how insights from multiple perspectives were achievable. This includes, for example, i) the discovery of a machine's internal behavior by tracking its consecutive states, ii) the identification of error dependencies across multiple production steps by combining PM with DM techniques, iii) the determination of a machine's relevance within a network by using organizational mining, iv) the examination of bottlenecks by analyzing different process levels (e.g., process paths vs. single activities) with regards to time, frequency and cost indicators, or v) the evaluation of a machine's input and output efficiencies based on domain-specific attributes. Consequently, all maintenance objectives (ranging from aspects like lifetime extension and equipment optimization to resource efficiency and quality assurance) could be addressed to some extent.

While the focus at this stage was mainly on the demonstration of the overall applicability and feasibility, future work will be devoted to a more detailed examination in the sense of a quantitative evaluation. As such, it is planned - in accordance with given confidentiality restrictions - to provide more details about the data samples in each analysis scenario and then quantitatively discuss the results of applied approaches. For example, such an in-depth consideration could be based on a large number of summary statistics and indicators on the recorded behavior of machines and processes, which are then compared with the expected results from technical experts to evaluate how the generated insights can be used for better decision support.

Likewise, further work will place greater emphasis on the necessary data preparation steps, as this was largely ignored in the current study. For demonstration purposes, different data samples were filtered and strongly simplified. However, the integration of different data attributes from heterogenous systems into a standardized PM event log structure has to be considered as a challenging task [6]. For example, most of the involved manufacturing systems provide required event data only as by-products, which then have to be selected and merged at an adequate abstraction level on which a process flow is to be analyzed. Similarly, specific event attributes like energy or material consumption are often not recorded by default for each individual machine at each single production step. The challenge is therefore to assign such attributes in the event log according to their cause, thus enabling more fine-grained analyses. Consequently, those and many other aspects still remain as data preparation challenges [30], that may considerably hinder a successful PM application. However, once these steps are taken, our study showed a possible direction for how PM can provide multi-perspective insights to support decision making in maintenance as well as manufacturing settings in general.

How Voice Can Change Customer Satisfaction: A Comparative Analysis between E-Commerce and Voice Commerce

Daniel Kraus[1], Victoria Reibenspiess[1], Andreas Eckhardt[1]

[1] German Graduate School of Management and Law, Heilbronn, Germany
{daniel}@lorenzenkraus.de

Abstract. Voice commerce is a newly evolving e-commerce channel where consumers communicate with dedicated systems on smart speakers or other devices using their voice, in order to find products. This paper comparatively investigates factors for customers' satisfaction in voice commerce and e-commerce. Being the first study to scientifically analyze customer satisfaction factors in voice commerce and compare them with e-commerce, we conducted a survey with 178 consumers and used structural equation modeling for statistical hypotheses testing. The results show, that consumers have higher expectations in convenience for voice commerce than they have for e-commerce. Transaction process efficiency significantly influences satisfaction in voice commerce, but not in e-commerce. This research provides implications for future research on voice commerce strategy and system design.

Keywords: Voice Commerce, E-Commerce, Conversational Agent, Recommender Systems, Customer Satisfaction

1 Introduction

Since their introduction in 2014, the use of intelligent virtual assistants based on smart speakers like Amazon Alexa, Apple HomePod, Microsoft Cortana and Google Home is increasing [1]. Moar [2] estimates that there are currently 450 million voice assistant devices in the US, expected to reach 870 million by 2020. These systems make it possible to conduct a "zero-click" purchase in business to consumer (B2C) commerce scenarios. Communicating with the assistant using only their voice, consumers can formulate search queries and confirm purchase actions without the need to use common visual or typing interfaces. Electronic Commerce (e-commerce) experts label this scenario "voice commerce" and expect it to be one of the most important innovations to shape the next years of e-commerce development (e.g., [3-4]). E-commerce describes commerce conducted over electronic media, such as the use of the internet to facilitate and process business transactions [5]. Voice commerce as a subset of e-commerce provides consumers with computerized voice technologies

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

(e.g., speech recognition, voice identification, and text-to-speech) to execute these business transactions [6]. These systems involve natural language processing (NLP), intent recognition, speech synthesis, recommender systems and artificial intelligence (AI) technologies (e.g., [3],[5]).

Despite a long-standing research interest in customer satisfaction and loyalty factors for e-commerce applications (e.g., [6-7]) as well as on e-commerce using conversational text-based interfaces (e.g., [10]), specific research on e-commerce in a human-to-AI voice-based scenario is, however, sparse. Research related to customer satisfaction factors in voice commerce is entirely missing from current literature, as well as research aiming at possible differences in customer satisfaction factors (CSF) between e-commerce and voice commerce. Similar to mobile commerce (m-commerce) in comparison to e-commerce, voice commerce is subject to special restrictions and presents different opportunities and value proposition to customers. Therefore, it is likely that satisfactory factors for voice commerce might differ from those of e-commerce both in existence and importance.

To support voice commerce software design and implementation, managers need to know which factors influence customer satisfaction. While many CSF for e-commerce applications are known, it is difficult to ascertain factors for voice commerce from current literature. Therefore, our research question is:

RQ: *How do the influencing factors for customer satisfaction differ in voice and e-commerce?*

To identify customer satisfaction factors for voice commerce, we first review research related literature. Based on this review, we develop our research models regarding customer satisfaction and its predictors, consisting of four comparative hypotheses (cf., [11]). Following this, we describe our research design and methodology to empirically validate our models for both e-commerce and voice commerce. Afterwards, we analyze the data gathered by a survey using structural equation modeling and present our findings. Finally, the paper discusses theoretical and practical implications for management as well as presents limitations and gives directions for future research opportunities.

2 Theoretical Background and Hypotheses Development

E-commerce describes commerce conducted over electronic media. For example, Kwon and Sadeh [5] define e-commerce as the use of the internet to facilitate, execute, and process business transactions. However, in science the term is mainly used for electronic commerce conducted via computers and laptops, as opposed to mobile devices (e.g., [5]), although these devices also use the internet. Researchers label the latter scenario mobile commerce or m-commerce [12], defined as a subset of all e-commerce transactions [5].

One subset of e-commerce is conversational commerce utilizing neuro-linguistic programming (NLP) (e.g., [13]). Such interfaces can be either text-messaging or voice recognition systems [14]. One form of conversational commerce are commercial chatbots (e.g., [15]). The actual interaction is text-based, in which both human and machine generate written text to convey information [16]. Some commercial chatbots can also display product images and other visual information [17]. Animated or embodied agents (sometimes also called avatars) are conversational systems that provide a visual representation of the virtual agent in addition to a text or speech interface [13, 18]. Luger and Sellen [3] use the term conversational agent for an emergent form of dialogue system that is becoming increasingly embedded in personal technologies and devices. Galanxhi and Nah [6] define voice commerce as e-commerce involving computerized voice technologies: speech recognition, voice identification, and text-to-speech. In our context, we define voice commerce as a subset of e-commerce providing consumers with computerized voice technologies to facilitate, execute, and process business transactions (e.g. [6]).

2.1 Recommendation Complexity

Conversational recommender systems, like voice commerce and chatbots, converse with users to learn their preferences and incorporate feedback from users (e.g., [19]). Liang et al. [20] found that recommendation accuracy of these systems is positively linked to customer satisfaction. Xiao and Benbasat [21] point out that recommender systems can decrease the information overload facing consumers, as well as the complexity of online searches. For e-commerce applications, Xiao and Benbasat [21] investigate the usage of recommendation agents and created a complex interactive model of recommendation effectiveness, were product type and complexity play significant roles.

Recent research provides limitations for voice commerce using only auditory interfaces. The cognitive cost-benefit framework [22] predicts that consumers search less as media richness decreases because of higher cognitive effort for searches in low media richness environments [23]. E-commerce, due to its higher media richness and visual/text efficiency, usually presents a larger evaluation set [24]. Research by Maity and Dass [23] shows a negative impact of an "overwhelming amount of information" in low media richness channels, like voice commerce, compared to high media richness channels such as e-commerce and physical stores. This can also be applied to the presentation of recommendations, which are usually presented in the form of result lists, similar to normal search results [25]. However, to avoid exceeding user's information capacity and to reduce the time spent by a consumer to listen to recommendations, the complexity of recommendations in voice commerce can be reduced intentionally. Recommendation complexity can be subdivided into quantity of product recommendations and complexity of a single product presentation (i.e., the length and level of detail of the product description). Possibly, consumers appreciate more options than just a single one. In essence, these considerations lead to the assumption that voice commerce only supports a lower customer decision complexity. Therefore, we hypothesize:

Hypothesis 1 (H1): *Recommendation complexity has a larger effect on customer satisfaction in e-commerce than in voice commerce.*

2.2 Recommendation Personalization

In most current e-commerce platforms, search engines use recommendation features and personalize results for the consumer and also enrich them with data from social media [26]. Personalized recommendations are known to increase customer satisfaction and conversion rates, and to lower the size of the evaluation set [26-27]. The use of personalized recommendation agents generally reduces the number of products for which users want to retrieve detailed information [29]. Users of digital assistants expect a highly personalized system, as Chopra and Chivukula [4] report for Indian consumers.

If voice commerce benefits from a lower recommendation complexity, it implies a greater need for highly accurate recommendations, of which personalization is a main factor. A buying decision becomes easier if the user herself has made that same decision before, or if the system can draw upon preferences it knows about the user. Product-wise, customers are less likely to purchase high-involvement goods like a television or a dishwasher via voice commerce because of informational complexity involved. In contrast, it is more likely that customers have a tendency to purchase low involvement goods, as indicated by Maity and Dass [23] that customers are likely to undertake simple decision-making tasks on channels that incorporate low levels of media richness. Additionally, customers have a tendency to buy goods they have bought before. Personalization in recommendations can also be based on inferred or mentioned preferences from previous user-machine dialogue [30] or even based on learned body measurements (e.g., for clothing). Therefore, we hypothesize:

Hypothesis 2 (H2): *Personalized recommendations have a larger effect on customer satisfaction in voice commerce than in e-commerce.*

2.3 Convenience

Convenience is one of the most prominent CSF in e-commerce (e.g., [30-31]). Choi et al. [33] define convenience as the degree to which a person believes that navigating or engaging in transactions through e- or m-commerce is free of effort. Further they subdivide convenience into ease of use, ease of access, ease of understanding, usefulness and functionality [33].

A study by Chai et al. [34] found that most users preferred a commercial chatbot interface over a classic search interface as they liked the idea that they can express their needs in their language without being restricted to menu choices and that the computer does all the work for them [34]. For voice-based interfaces, Luger and Sellen [3] report that the principle use-case for the CA (conversational agent) was “hands free”, which was tied strongly to the theme of time-saving and convenience. This fits well to the previously mentioned idea that audio interfaces facilitate multi-tasking [35]. The efficiency and easiness of speech input is a value proposition that also plays a role. According to Luger and Sellen (2016), customers feel it is often easier and more convenient to use speech input than to type, one reason being that speech was felt to be faster. In their comparative studies, Choi et al. [33] and Cao et al. [12] found customers scored convenience higher for m-commerce than for compared to e-commerce. Since voice commerce should rank lower than e-commerce in media richness, convenience should be of greater importance. We hypothesize that customers have higher convenience expectations of voice commerce than of e-commerce:

Hypothesis 3 (H3): *Convenience has a larger effect on customer satisfaction in voice commerce than in e-commerce.*

2.4 Transaction Process Efficiency

Transaction time is a known CSF in e-commerce research (e.g., [36-37]). For example, Devaraj et al. [36] found that subjectively, excess time spent in the transaction process decreases satisfaction in e-commerce, whether it is spend on communication, searching and choosing or payment. Choi et al. [33] define the e-commerce CSF of "transaction process" as a combination of efficiency, total transaction time, clearness of the process and response time for each step. Their results show that these performance indicators very significantly in influencing satisfaction of different types of e-commerce.

Chatbot users frequently mention a high performance expectation, with subcategories of fast, efficient, and reliable [38]. Users expressed that the use of chatbot systems should reduce interaction time and increase efficiency [34]. In this context, they define efficiency as the number of clicks and the amount of time required obtaining the relevant information. By investigating task-oriented spoken dialog systems, Walker et al. [39] also found that a significant satisfaction factor is user's perception of elapsed time. According to research on users of current generation conversational agents, timesaving was a key related motivation to use these systems [3]. Therefore, we hypothesize:

Hypothesis 4 (H4): *An efficient transaction process has a larger effect on customer satisfaction in voice commerce than in e-commerce.*

3 Research Methodology

We conducted focus groups with e-commerce experts of an e-commerce consulting company in order to verify the importance of the listed constructs above (i.e., Recommendation Complexity, Recommendation Personalization, Convenience, and Transaction Process Efficiency).

To empirically test the proposed hypotheses, a survey was executed with the help of the crowd-sourcing platform Amazon Mechanical Turk (MTurk). Our questionnaire[1] consists of 39 questions, of which 13 serve demographical, 26 are related to the identified CSF and reflected both research models on e-commerce and voice commerce. Respondents have to answer the items for both types of commerce. We derived the questions for convenience from a study by Choi et al. [33] (e.g., "Ordering products **on websites**/*with my voice* is easy.", whereas the bold phrase represents the e-commerce and the italic characterizes the voice commerce construct).

[1] A comprehensive table of the measurement items can be accessed here: https://www.dropbox.com/s/ahovk0cfgcgihg5/Appendix_Studentstrack.pdf?dl=0

The measures for the construct transaction process efficiency are also adapted from Choi et al. [33] (e.g., "When ordering products on **a website**/*with my voice*, the process should take as little steps as possible."). Recommendation personalization as a construct was used by Komiak and Benbasat [28]. For example, we took items as "When ordering products on **a website**/*with my voice*, I benefit from product recommendations based on what I ordered before". Further, we adapted items for recommendation complexity (e.g., "When ordering products on **a website**/*with my voice*, I benefit from very detailed product recommendations.") based on product complexity in recommender systems [21]. Customer satisfaction was measured with items, such as "I am generally satisfied when ordering products **on websites**/*with my voice*." adapted from Chang and Chen [40]. To eliminate wording inconsistencies or comprehension problems we ran an independent pre-test with some participants, who were then excluded from the main survey [41].

The survey was restricted to only those US residents who have been consumers of both voice commerce and e-commerce systems in the previous three months. Therefore, we filtered out inappropriate participants before we conducted the main study. In a total 178 people answered the survey completely. Out of these 178, 53.9% were women and 44.9% men (1.1% did not give any information). The age distribution was: 25-44 years (70.2%), 18-24 years (17.4%), 45-64 years (9.6%), and 65 years and older (2.8%).

4 Data Analysis

In order to analyze the proposed research model and to validate the proposed hypotheses, the model has been transferred into a structural equation model [42]. For this examination the software IBM AMOS 21.0 was used to determine path influences. The suggested ratio of sample size to number of free parameters of 10:1, in order to reach trustworthiness, is fulfilled [43, 44].

4.1 Measurement Models

To begin with further data analysis, we calculated Cronbach's alpha to assess the internal consistency and reliability of the sub-scales. In the first iteration, some items showed low item-total correlation. All values calculated exceeded the recommended minimum value of 0.6, which indicated that the constructs show a high level of reliability [45, 46] (see Table 1).

We carried out a principal component analysis to identify component fit. Furthermore, we applied main component analysis as extraction method and Varimax (as our employed factors are not correlated) as rotation method (Kaiser-Normalization, convergence after 6 iterations). The model with four components fits well with an average loading of 0.82 and no cross loadings above 0.43, also indicating convergent validity. By calculation, the four factors account for 73.6 % of the total variance. The Kaiser–Meyer–Olkin (KMO) measure of sampling adequacy was 0.68 and 0.69, representing a relatively good factor fit by exceeding the threshold value of 0.5 [47]. Bartlett's test of sphericity was significant ($p < .001$), indicating that correlations between items were sufficiently large for performing a factor analysis (compare table 2).

Table 1. Evidence of reliability

Model	*Construct*	*Items*	*Cronbach's alpha*
eCom	Convenience (EC)	3	0.62
	Recommendation personalization (ERP)	2	0.84
	Recommendation complexity (ERC)	2	0.72
	Transaction process efficiency (ETP)	2	0.62
vCom	Convenience (VC)	3	0.80
	Recommendation personalization (VRP)	2	0.83
	Recommendation complexity (VRC)	2	0.80
	Transaction process efficiency (VTP)	2	0.68

Table 2. KMO and Bartlett tests

Model	*Test*	*Indicator*	*Value*
eCom	KMO	Measure of sample suitability	0.68
	Bartlett	Approximate chi-square	425.461
		df	36
		Significance	< 0.001
vCom	KMO	Measure of sample suitability	0.69
	Bartlett	Approximate chi-square	634.8
		df	36
		Significance	< 0.001

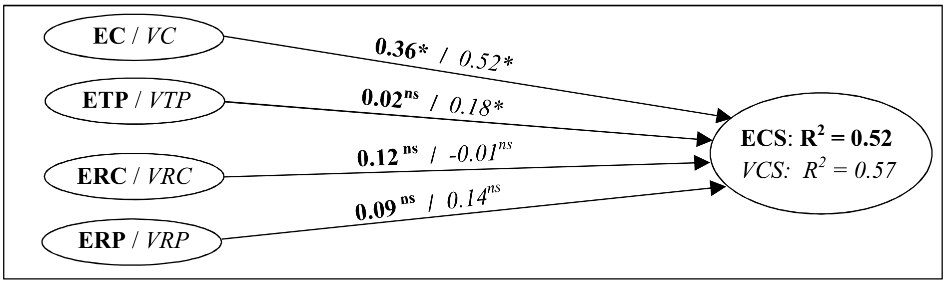
Tables 3 shows the factor correlation matrices for both models including composite reliability (CR) [48]. CR is above or near 0.7, except for transaction process efficiency. The latter achieved a CR value of 0.652 in the e-commerce model. The square root of the AVE is represented by the diagonal elements in table 3. The values show that the square root is bigger than each off-diagonal element [49]. We infer that there is an acceptable and logical extent of discriminant validity in the measurement model for all constructs.

Table 3. Factor correlation matrix

Model	*Construct*	*CR*	*ERP*	*EC*	*ERC*	*ETP*
eCom	ERP	0.835	**0.847**			
	EC	0.693	0.025	**0.659**		
	ERC	0.790	0.620	0.061	**0.816**	
	ETP	0.652	0.202	0.497	0.074	**0.699**
Model	*Construct*	*CR*	*VRP*	*VC*	*VRC*	*VTP*
vCom	VRP	0.838	**0.850**			
	VC	0.809	0.260	**0.766**		
	VRC	0.813	0.653	0.321	**0.829**	
	VTP	0.697	0.347	0.272	0.067	**0.735**

4.2 Structural Models

We created two structural models and performed an initial factor estimation using the maximum-likelihood method (see Figure 2). Straight arrows connecting each latent construct to customer satisfaction represent unidirectional effects, annotated by the standardized path coefficient. The total variance in customer satisfaction explained by the independent variables (R^2), which reflect the predictive power of the models, is above 50% in both models (0.52 in e-commerce and 0.57 in voice commerce).



^{ns}: not significant above $p < 0.05$ level, * : significant above $p < 0.05$ level; Bold = e-commerce model, Italic = voice commerce model

Figure 2. Structural model (e-commerce and voice commerce)

Table 4 shows the results for all predictors for ECS and VCS in the model. The effect of convenience is statistically significant in both e-commerce and voice commerce. Based on the convention on interpretation of correlations by Cohen [50] and Durlak [51], we classify the effect size of convenience on satisfaction as middle (0.36) for e-commerce and large (0.52) for voice commerce. Although transaction process efficiency significantly influences satisfaction in voice commerce, it does not show significance in e-commerce. The results for the rest of the constructs were not statistically significant. Recommendation complexity influences e-commerce satisfaction positively. The effect of recommendation personalization on voice commerce satisfaction has an effect size of 0.14 and a p-value of 0.13.

Table 4. Predictors for satisfaction in e-commerce and voice commerce

Path	*Estimate*	*Beta*	*p-value*
EC ↑ECS	0.52	0.36	<0.001***
ETP ↑ ECS	0.04	0.02	0.793
ERP ↑ ECS	0.10	0.09	0.355
ERC ↑ ECS	0.13	0.12	0.228
VC ↑ VCS	0.68	0.52	<0.001***
VTP ↑ VCS	0.34	0.18	0.01*
VRP ↑ VCS	0.16	0.14	0.13
VRC ↓ VCS	-0.01	-0.01	0.896

Significance levels: * p<0.05, ** p<0.01, *** p<0.001; positive effect ↑, negative effect ↓

Table 5 shows the results for the comparative hypotheses in this approach. To assess hypotheses H1-H4, we first performed a t-test to analyze statistically significant differences between datasets. The test resulted in significant difference for all constructs. We then compared the respective path coefficients (Beta) and noted the absolute numerical difference (Delta). Whenever the difference exceeded 0.10, the hypothesis is considered as supported. Convenience significantly influences both e-commerce and voice commerce satisfaction, but clearly does so more in voice commerce. Transaction process efficiency also presents a more sizable effect for voice commerce, as predicted. However, the results present the issue that this construct significantly influences satisfaction only in voice commerce. This indicates that the concept is only relevant (or only valid) in voice commerce. We also compared coefficients that were not found to be significant. The results do not support a difference between recommendation personalization for voice and e-commerce, as the numerical delta is only 0.05. The assessment of recommendation personalization shows a delta of 0.13. Thus, both effects are not significant.

Table 5. Comparative hypotheses results

Hypothesis	*Description*	*Beta*	*Delta*	*t-test*	*Conclusion*
H1	VRC < ERC	-0.01 vs. 0.12	0.13	-5.99***	Not supported
H2	VRP > ERP	0.14 vs 0.09	0.05	-5.15***	Not supported
H3	VC > EC	0.52*** vs. 0.36***	0.16	22.55***	Supported
H4	VTP > ETP	0.18* vs. 0.02	0.16	20.55***	Not supported

Significance levels: * $p<0.05$, ** $p<0.01$, *** $p<0.001$; Delta = numerical difference between standardized beta coefficients

5 Discussion

The first objective of this study was to identify and understand factors of customer satisfaction for e-commerce and voice commerce systems. The second objective was to compare these effects between these two channels of e-commerce. We conducted a survey to test the research models. The results confirm one out of four hypotheses and provide some support for the conceptual models. They particularly show that convenience significantly influences customer satisfaction in both e-commerce and voice commerce, and that the effect is in fact larger in voice commerce. Results also show that transaction process efficiency, in terms of overall process speed and number of process steps, significantly influences voice commerce customer satisfaction. This was explained by higher efficiency expectations through increased efficiency of the speech interface. Further the results inferred that users prefer to browse and take their time using the e-commerce channel when compared to voice commerce. According to the results, complexity, extent and degree of detail of recommendation presentation as well as personalization of recommendations do not have a significant effect on satisfaction.

When designing voice commerce applications, developers and designers should keep in mind that convenience and efficiency expectations are higher than those towards e-commerce systems. This may lead to the following design choices: 1) The voice commerce system features increased ease of use and effortlessness over comparable e-commerce systems. 2) The process of searching and buying is designed to be as quick as possible; there are neither detours nor long dialog stages. 3) The number of steps in the process is limited to a necessary minimum. Time intensive input of address or payment data should be omitted. 4) Since a significant number of my sample uses voice commerce on mobile phones, designers should think about creating voice commerce systems for these platforms. There, visual output could be added to increase media richness and usability.

This is the first study to investigate voice commerce customer satisfaction predictors and comparing these with those of e-commerce, which adds knowledge to academic literature and will improve the understanding of the relationships between these system types. It is also one of few studies to compare two structural equation models to assess comparative hypotheses. This approach should increase reliability, because the same participants provide their input on both models.

6 Limitations and Future Research

This study is subject to several limitations, such as sample selection. We collected data from Amazon MTurk, and so reached mainly young users with high IT affinity. However, it is not representative of the general population of any country [52]. Additionally, only US users participated in the survey. While this was motivated by the higher diffusion rate of voice commerce in the US and the large absolute population size, it presents a limitation when it comes to transferability and generalization of the results.

Because voice commerce is an area currently evolving, many opportunities for future research arise. A future study could try to ascertain data from voice-exclusive scenarios for clearer insights into its intricacies and avoid intermixture systems that combine voice and visual interfaces. If however the trend of these systems gains more significance, research should focus on this area.

A dedicated, detailed study to investigate how product complexity interacts with customer buying behavior and decisions, akin to Maity and Dass [23] investigations on this topic in e-commerce, m-commerce and in-store purchasing, could generate insights on how consumers handle search and experience respectively low and high involvement goods in voice commerce. A study covering detailed customer preferences for each channel could shed light to this and similar questions, for example whether repeat purchases are more likely to take place via voice commerce and whether products bought are predominantly of low-complexity as well as which factors generally influence customers in their decision to use voice commerce over other channels.

A number of assumptions concerning recommendations could be assessed more effectively with local, hands-on laboratory settings, especially those motivated by media richness and cognitive overload. For example, in an experiment where participants actually experience the difference between very long and detailed and very short product descriptions and possible cognitive overload, results may be much more distinct than in a self-administered survey. Alternatively, real-life e-commerce environments present opportunities for experiments using A-B testing.

Business Process Compliance and Blockchain: How Does the Ethereum Blockchain Address Challenges of Business Process Compliance?

Anja Meironke[1], Tobias Seyffarth[1], and Johannes Damarowsky[1]

[1]Martin Luther University Halle-Wittenberg, Chair of Information Management, Halle (Saale), Germany
{anjameironke}@gmail.com
{tobias.seyffarth, johannes.damarowsky}@wiwi.uni-halle.de

Abstract. Second generation blockchain technologies such as Ethereum can be used not only for financial transactions but also for cross-organizational processes, for applications in the pharmaceutical industry and even in the field of Business Process Compliance (BPC). However, there are many challenges in the field of BPC. Thus, we raised the following research question: How does the Ethereum blockchain address challenges of BPC? To answer this question, we conducted a structured literature review to identify challenges in BPC as well as features of the Ethereum blockchain that may solve the selected BPC challenges. As a result, we identified 21 BPC challenges and categorized these into legal, organizational, human-centered, technical and economic challenges. We found that the technical and organizational BPC challenges were those that Ethereum could best solve, while human-centered challenges could be less well addressed. Furthermore, the implementation of the Ethereum blockchain leads to additional challenges, such as the immutability of illegal content within the Ethereum blockchain or the error-proneness and zero-defect tolerance of smart contracts.

Keywords: Blockchain, Ethereum, Business Process Compliance, Challenges

1 Introduction

In the time of digital innovation, advanced technologies are emerging and changing the way business is done, especially business between organizations. One of the recent technologies which is said to be disruptive in nature is blockchain [1–3]. Currently, the most prominent blockchain technology is Bitcoin, due to its correlated and identically named cryptocurrency [2, 4]. However, modern blockchain deployments such as Ethereum provide even more elaborate functionalities and, therefore, have also gained attention. Ethereum reaches beyond digital currencies, enabling applications in cross-organizational business processes, logistics and pharma [5–7]. Another potential area of application is in Business Process Compliance (BPC), which denotes the execution of business processes in adherence to compliance requirements such as laws or contracts [8]. However, there are various challenges within BPC such as the complexity

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

of business and compliance processes, the high administrative efforts required to ensure compliance in business processes and the lack of automation and standardization to adequately support BPC [9, 10]. Whereas research and earlier blockchain applications mainly concentrated on financial applications and use cases in the field of cross-organizational business process execution [6, 7, 11], further applications are of interest as well. Therefore, our goal is to answer the following research question: *How does the Ethereum blockchain address challenges of BPC?*

The remainder of this paper is organized as follows. In Section 2, we describe the applied methodology to answer our research question. In Section 3, we briefly highlight the technological underpinnings of the blockchain deployment Ethereum and its main features. Section 4 provides an overview of the major challenges within the field of BPC. In Section 5, we map the features of Ethereum to the different BPC challenges and discuss the potential of the findings derived. Finally, Section 6 concludes the paper.

2 Methodology

We performed a three-step approach to answer our research question. First, we worked out the features of the Ethereum blockchain. Second, we identified challenges in the field of BPC, which were then mapped to the Ethereum features in the third step.
We conducted a literature review according to vom Brocke et al. [12] to identify relevant literature for each step. Table 1 shows the applied search terms within each database, the initial hits and the numbers of selected and relevant papers.

Table 1. Literature search

Step	Search term	Database	Hits	Selected	Relevant
1	ethereum AND (functionality OR "mode of operation" OR "way of functioning")	Google Scholar	211	6	5
2	("business process compliance" OR BPC) AND (challenge OR lifecycle)	Google Scholar	Aborted after 610	80	17
	"Business Process Compliance" challenge	KVK	104	12	12
3	("business process compliance" OR BPC") AND (blockchain OR ethereum)	Google Scholar	38	9	1
	“business process compliance” ethereum	KVK	36	28	17
Backward search					19
Sum					71

The literature search was performed using Google Scholar and Karlsruher Virtueller Katalog (KVK), which includes the following databases: GBV, SWB, BVB, HBZ, HEBIS, KOBV, DNB, StaBi Berlin and Worldcat. In Google Scholar we searched within the general search field, while we used the keyword search within KVK, which only allowed restricted search strings and no connectors. The initial hits were selected based on their titles and abstracts. In the next step, the papers' abstracts and several papers in full were read to identify relevant publications. We also conducted a backward search, which led to 71 relevant papers that were considered to help answer the research question.

3 Fundamentals of Blockchain and Ethereum

Blockchain is the technology that supports Ethereum [4]. The Ethereum blockchain is a public and distributed ledger, which stores all of the transactions occurring within the Ethereum network. Transactions are processed between different accounts. Every party of the blockchain network can create any number of accounts without restrictions and third party authentications. The creation of accounts and the authorization of transactions are based on asymmetric cryptographic mechanisms. When creating an account, a public and a private key are generated whereby the account address is derived from the public key, which guarantees a certain degree of anonymity. The sender authorizes the transaction using the account's private key. Processed transactions are visible to every party of the network. Due to the implemented consensus mechanism, the blockchain technology is tamper-proof, without any need for a trusted third party (e.g. a bank or a notary) to avoid double spending.

One consensus mechanism is proof-of-work (PoW), whereby so-called miners have to solve a puzzle using cryptographic methods. Next, new transactions are published in the blockchain network and are approved by the miners. Miners summarize a number of transactions to blocks, validate their signature and the transaction nonce and check that the sender's account balance covers the amount, including the fees to execute the transaction. Then a hash is computed over the current and previous block of transactions and their metadata. A valid hash must correspond to a certain pattern (for example, in the case of Ethereum, the hash must be below a certain threshold). In order to achieve this, a nonce is added as a further input of the hash function. It is not possible to simply compute this nonce. Nonces have to be tested randomly. After finding a matching nonce, the blocks are chained together to form a blockchain. Finally, the miner who first finds a valid nonce is awarded with an amount of new crypto-coins and all transactions fees of the respective block. Based on chaining blocks by means of their computed hash values, a manipulation can be easily detected by recalculating the hashes of two linked blocks and their nonce.

Additionally, there are further design parameters for blockchain solutions. Blockchains can be differentiated between public and private and between permission-less and permissioned blockchains. In a public blockchain, everyone can be part of the blockchain network, whereas private blockchain access is only granted to dedicated participants. Within a permission-less network, everyone can approve new blocks, while in a permissioned network only certain parties are allowed to [13]. By default, Ethereum represents a public, permission-less blockchain [5].

Finally, two generations of blockchains are discussed in the literature. The first generation of blockchain is able to transfer tokens (e.g. Bitcoins) between nodes. The second generation, to which Ethereum belongs, allows more elaborate bytecode to run on top of the blockchain, which is denoted as so-called smart contracts. A smart contract is a user-defined program executed within the blockchain network [14]. In Ethereum, smart contracts are written in Solidity and executed within its execution environment, the Ethereum Virtual Machine. They can be executed automatically and allow a flexible adaption of the blockchain technology to other fields of application [5]. Based on the five technical underpinnings explained above, we derived fourteen main features of Ethereum in Figure 1.

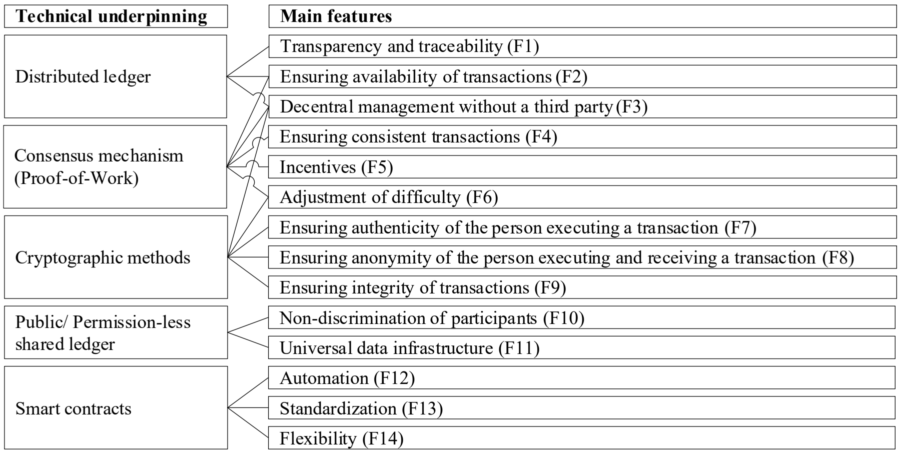

Figure 1. Technical underpinnings and main features of the Ethereum blockchain

4 Challenges in Business Process Compliance

The successful management of BPC is associated with various challenges. We classified these challenges into groups, including legal, organizational, human-centered, technical and economic challenges. Table 2 shows an excerpt of the concept matrix. The entire concept matrix can be found at: `https://bit.ly/2A3O35O`.

Table 2. Concept matrix of BPC challenges (H: Human-centered | T: Technical)

		[15]	[16]	[17]	…
H	Lack of awareness and acceptance (C_H 1)	x	x		
	Conscious or unconscious misconduct (C_H 2)		x		
	…				
T	Technical support and automation of BPC (C_T 1)		x		
	Complex IT architecture and low system integration (C_T 2)		x		
	Proprietary service providers and centralized services (C_T 3)		x		
	Data security and data privacy (C_T 4)			x	
…	…				

Legal challenges include the complexity of the compliance requirements that must be taken into account [8, 10]. A compliance requirement is an assertion resulting from the interpretation of compliance sources, such as laws, norms, standards or internal policies [18]. Compliance requirements change rapidly, which requires a continuous adaptation of related business processes [9, 19]. Moreover, the vagueness of compliance requirements and differing interpretations by the stakeholders make it difficult to interpret compliance requirements unambiguously [15, 20].

Further, organizations are often confronted with **organizational challenges**. In addition to different organizational structures, the complexity and multitude of business and compliance processes can turn BPC management into a difficult task [9, 10]. Organizations cooperate and interact on an increasingly global level [21]. Therefore, not only must internal business processes be checked for compliance, but entire cross-organizational business processes of the involved partner organizations must also be checked [21, 22]. In these cases, BPC management is difficult and time-consuming, especially because different legislation may be applicable for each country and the stakeholders involved may pursue different objectives. Often there is a problem of trust concerning the exchange of information between different organizations [13, 22–24]. Further organizational BPC challenges comprise the modelling and verification of compliance rules and their integration into the corresponding business processes [25]. Additional organizational challenges include the monitoring of compliance requirements and their operationalization in business processes, for example through compliance processes [19], the associated documentation of compliance process execution and verification, as well as adequate transparency and traceability. Business processes and their instances must be checked for compliance during and after runtime by either external auditors or internal evaluations by means of reports or log files [17, 25, 26]. For this purpose, documented evidence must be tamper-proof, available and easily accessible to the parties involved [13, 16]. In addition, the traceability of compliance requirements back to their relevant business process models and vice versa is often inadequately designed, meaning changes of compliance requirements and business processes cannot be implemented adequately, due to a lack of referential clarity [16].

Closely linked to organizational challenges are **human-centered challenges**. The lack of stakeholder acceptance and awareness, combined with insufficient communication and awareness measures on the part of management, impede the successful implementation of necessary BPC measures. Moreover, a successful BPC is limited by either conscious or unconscious misconduct due to deficiencies in knowledge or by the deliberate violation of compliance requirements resulting from malicious intent, a lack of motivation or fear [16].

Technical challenges generally reside in the low level of automation. There are often manually performed BPC tasks, such as the modeling of compliant business processes and the verification and monitoring of business processes according to their compliance requirements, which are not only time-consuming but also error-prone [9, 10, 13, 16, 27]. Moreover, not all tasks within the BPC management lifecycle [28] can be automated; for example the generation of compliance requirements deduced from different compliance sources requires a broad understanding and complex, strategic thinking [16]. Additionally, the management of information technology (IT) architectures is also challenging because these are usually heterogeneous, distributed, isolated and mutually incompatible [15]. Therefore, the integration of common tools to support BPC across several organizations and the reduction of parallel IT systems, as well as redundant and inconsistent data fragments, is a challenging task [29]. Above all, the implementation of tools to support BPC often leads to dependence on the corresponding service provider in terms of financial aspects, data security and data privacy [16]. Moreover, sensitive data of an organization is to be treated confidentially and therefore must be protected against unauthorized access and manipulation [13, 17, 24]. Additionally, a service provider may become a single-point-of-failure, if used as the sole provider for data processing [27]. At the same time, successful BPC management must be able to provide information at all times and therefore requires consistent information that is available and documented in a comprehensible manner [30]. Consequently, the simultaneous protection of privacy and availability of BPC-relevant information are often conflicting objectives [16, 17].

Economic challenges include, among other things, a lack of cost and resource efficiency. Companies and organizations have to face increased compliance, IT and staff-related expenses for the management, evaluation and adjustment of complex compliance requirements and business processes or as a result of legal claims for damages due to uncovered compliance violations [8, 21, 31]. Additionally, due to redundant processes, inconsistent data and a low degree of automation, BPC tasks are often inefficient and time consuming [10, 13]. The lack of adequate methods and indicators to analyze the efficiency and effectiveness of BPC so as to assess their cost-benefit ratio constitutes another difficulty [16, 31]. Finally, poor standardization as well as the ad hoc-oriented tasks of the BPC lifecycle make it difficult to optimize business and compliance processes or to react appropriately to compliance deviations [16].

5 How Does Ethereum Address BPC Challenges?

In the previous sections, we focused on the technical underpinnings and main features of Ethereum and on the identified BPC challenges. In the upcoming section, we answer the research question by explaining how Ethereum can potentially address these BPC challenges. For this purpose, the main features of Ethereum were mapped to the identified BPC challenges. The classification of the results is based on our own assessment and the findings of the literature analysis. Table 3 shows an excerpt of our classification. The complete classification including a short explanation and literature references can be found at: `https://bit.ly/2ygavHk.`

Table 3. Classification of Ethereum features referred to BPC challenges (excerpt)

In terms of **legal BPC challenges**, there is low potential for improvement by the features of Ethereum. According to [32], it is conceivable to store compliance requirements, such as laws and standards, as independent objects of a smart contract within the Ethereum blockchain to make them tamper-proof and publicly accessible. Thus, compliance and business process managers can be informed automatically if changes in the status of a referred requirement occur.

Ethereum offers promising opportunities to address **organizational BPC challenges**, such as the modeling of business processes according to their compliance requirements and the monitoring of compliance requirements and verifying their documentation, transparency and traceability. The decentralized and distributed structure of the Ethereum blockchain supports the streamlining of business and compliance processes, especially with regard to cross-organizational business processes. Accordingly, certain organizational units or trusted third parties that are in charge of monitoring BPC can be omitted (e.g. the central banks for foreign transfers), since transactions may be carried out directly between the transaction partners [7, 33]. Using the Ethereum blockchain as a universal data infrastructure for accessing and coordinating shared data and processes between different stakeholders also reduces data traffic and complex procedures necessary for reconciling, managing and controlling data and processes [34, 35]. In addition, Ethereum contributes to the modelling and verification of compliance rules and their integration into business processes. Logics and rules associated with business and compliance processes can be expressed and automatically checked with the help of smart contracts. However, business and compliance processes as well as their associated rules cannot always be translated seamlessly from natural language into program code [36]. Additionally, due to the overly domain-specific expertise of programmers or legal experts, smart contracts may be programmed inaccurately and might not reflect the underlying rules and process models as intended [36, 37].

Besides supporting BPC-modelling, Ethereum also offers various options for monitoring, verification and transparent documentation within the context of BPC. With the help of smart contracts, a large part of BPC tasks like monitoring and verification can be automated and outsourced to Ethereum, thus reducing manual effort and various process activities [1, 11, 13]. Applying an if-then pattern, smart contracts also automatically enforce compliance with defined rules, with the result that violations cannot occur in the first place, making a permanent monitoring unnecessary. An illustrative example would be a locked leased car that can only be opened by means of a digital key after payment was made [33].

Additionally, the connection to or general accessibility of the blockchain as a public and shared ledger enables extended transparency towards internal and external compliance units and supervisory authorities [7]. Transactions that are documented in the Ethereum blockchain in a verifiable and tamper-proof manner can be verified by internal and external auditors and legislators [2, 13, 17, 38]. In addition, specific verifiable documents and records (e.g. certificates, contracts) or material assets (for example motor vehicles, land) can be stored as digital assets. If their status changes, for example in the case of value transfers and changes of ownership, changes can be documented in a tamper-proof way [7, 11, 13, 39].

However, relevant process participants, such as supervisory authorities or employees, have to be an integral part of the Ethereum network to provide access to information on transactions [33, 37]. Moreover, illegal contents (e.g. child pornography or unauthorized personal data) are also problematic, since they cannot be simply removed from the blockchain and therefore risk making the entire blockchain illegal [3].

In contrast to the organizational aspects mentioned above, Ethereum has a moderate potential for solving **human-centered BPC challenges**. Ethereum shows potential in terms of reducing conscious (e.g. fraud and deliberate disregard of rules) or unconscious (e.g. lack of knowledge) misconduct. On the one hand, knowledge deficits, errors or deviations can be diminished by mapping compliance requirements, compliance processes or entire business processes as smart contracts for (partial) automation so that they are prevented from circumvention [33, 37, 38]. On the other hand, the manipulation of transaction data causes high costs due to the enormous computing effort necessary to find a valid nonce. Furthermore, fraud and erroneous practices are immediately recognizable due to real-time transaction processing and transparent documentation in the public ledger, so that problems like payment defaults or insurance fraud can be avoided [1, 7, 37].

Ethereum also contributes significantly to addressing **technical BPC challenges**. This particularly concerns aspects of automation, IT architecture, data security and data privacy. As already mentioned, entire business and compliance processes can be (partially) automated with the help of smart contracts [3, 33, 37, 39]. When defined events act as triggers or when pre-defined conditions are met, the smart contract code is validated and executed by the miner according to if-then patterns and, finally, documented in the Ethereum blockchain [32, 36, 38, 40]. However, with regard to deviations from defined rules or algorithms during execution, [33] considers the zero-defect tolerance of smart contracts to be problematic. What happens, for example, in terms of a package delivery, if the order is delivered later than stipulated in the smart contract, but has nevertheless been delivered?

In addition, the Ethereum blockchain can be used as a universal infrastructure to connect and coordinate different stakeholders and organizations, which is often a serious challenge, especially with regard to the modeling, verification and monitoring of compliant business processes within BPC [11, 13, 33]. Redundant and non-compliant business processes and data management may be reduced, as the same business processes and data basis can be used equally by the parties involved [10, 13, 33]. The question that arises at this point is to what extent a public blockchain is suitable for making (partly) sensitive data from cross-organizational business processes generally accessible and public [33].

Nevertheless, with regard to aspects of data security, Ethereum has a particularly high potential due to its inherent properties. In contrast to client-server architectures, the decentralized structure of the Ethereum blockchain and its redundant data distribution ensure a high degree of reliability [7, 33]. If a party of the blockchain network fails due to technical faults or manipulation, all other parties have a local copy, ensuring that the data remains available [2]. Moreover, Ethereum offers an additional security mechanism by charging transaction fees for code execution, which ensures that transactions are reversed when their limit is exceeded. Thus, failures due to maliciously built-in loops causing a program code to run infinitely are prevented [40].

The most important feature of the Ethereum blockchain is the guarantee of integrity by means of cryptographic hashing and linking of the data blocks, as described in

Section 3. Due to high energy costs incurred for recalculation, attacks would be unprofitable for attackers [1, 2]. In addition, manipulated data and attempted fraud would be detectable not only in the context of consensus checks, but also after publishing the data in the Ethereum blockchain [24, 33, 39]. Furthermore, the authenticity and anonymity of the transaction participants can be guaranteed by the use of digital signatures and anonymous account addresses (see Section 3). [1, 10, 13, 39].

According to [41], however, there are vulnerabilities regarding long-term data security. Due to improved computing power and mathematical advances, it is doubtful whether current cryptographic hash methods will maintain their current security level in the foreseeable future. Then the data within Ethereum could be compromised retroactively [23]. Besides, users do not know where their data is stored or to what extent it is processed [42].

Finally, Ethereum offers potential approaches for the solution of **economic BPC challenges,** such as suboptimal cost and resource efficiency, measurability and standardization. Thus, the automation of compliance processes and business processes and their streamlining, by eliminating unnecessary process activities and intermediaries, enables a better cost and resource efficiency, especially on a cross-organizational level [6, 7, 11]. Cost and resource efficiency benefits can also be realized using the Ethereum blockchain as a universal data infrastructure for managing shared data, since multiple data checking by the individual transaction units might become obsolete. This can reduce inconsistent, redundant information as well as the associated work effort, since the Ethereum blockchain is turned into a single-point-of-truth [2, 32, 33].

Interesting approaches also arise in terms of the measurability of BPC efficiency and effectiveness. Due to the public and shared nature, it is possible to implement comprehensive methods for a better monitoring of transaction data. Thus, BPC-relevant process and transaction data can be collected and evaluated in real time [10, 13, 24]. Since transaction fees have to be paid and compliance processes can be partially automated by smart contracts, BPC costs can be determined on process activity level [43].

However, the high energy consumption for performing the PoW and the local memory requirements for redundant blockchain replications are considered to be critical [44]. All in all, Ethereum offers comprehensive possibilities to address different BPC challenges. Nevertheless, resulting risks must be considered as well.

6 Conclusion

The second generation of Blockchain technologies, such as Ethereum, allows not only for the processing of financial transactions [11], but also for elaborated applications in various fields, such as BPC. Since there are a lot of BPC challenges (e.g. [9, 10]), we raised the following research question: How does the Ethereum blockchain address challenges of BPC? By conducting a literature review, we identified 14 main features of Ethereum. Furthermore, we identified 21 BPC challenges and categorized them according to legal, organizational, human-centered, technical and economic challenges.

A large portion of the challenges is of organizational and technical nature. It has been shown that the main contribution of the Ethereum blockchain is to solve technical and organizational challenges, whereas human-centered challenges are less solvable. The following main features are of utmost importance to meeting BPC challenges: automation with the help of smart contracts; the transparent design and traceability of the public ledger; and the possibility of using Ethereum as a universal data infrastructure. However, the use of the blockchain also results in new risks, such as the immutability of illegal content or the error-proneness of smart contracts due to a lack of knowledge or their zero-defect tolerance during execution [3, 33, 36, 37].

A well-known shortcoming of any literature review is the fact that it is not possible to consider all relevant work. However, by documenting the literature research according to vom Brocke et al. [12], comprehensibility in the development of arguments is provided in a scientific manner. The assignment of BPC challenges and Ethereum properties is not always documented in the literature and therefore results from an argumentative assignment. Additionally, each property of the Ethereum Blockchain in our reference table has an equally weighted potential to meet the respective BPC challenges. Our future research aims to investigate these potentials explicitly, according to their specific impact on solving BPC challenges.

Abstract. In the competitive context of agile innovation cycles, it is necessary for companies to construct their business model leading them to a creative strategy innovation. There already are a number of methods to create business models, many of which are also implemented in software. However, these are often unstructured, unguided and static, resulting in diverse and heterogeneous business models. This complicates automated evaluation allowing recommendations. The aim is to develop a question-based tool yielding for comparable and, thus, analyzable business models based on a developed standardized taxonomy. The questions guiding through the configurator were derived from this taxonomy. A tool was developed implementing the question-based concept. User tests were conducted as part of an evaluation showing promising results concerning usability in addition to the already achieved standardization.

Keywords: business model, business model configuration, business model innovation, tool development, question-based design

1 Introduction

1.1 Motivation

Today's development in digitalization and fast innovation shows the necessity for companies to remain profitable and competitive [1]. The constraint to keep up with change pressures companies to rush transformation without really knowing where to begin [2–4]. One significant trend to achieve durable success in the market is to utilize business models as a navigation instrument towards increased profits or finding their niche in the market [5]. They indirectly define the strategy being realized in an organization [6].This explains the necessity of a consulting-based support besides conventional consulting services.

Hence, a faster and simpler way to promote innovation in a complex, uncertain and dynamic environment needs to be available [7, 8]. By describing an organization in a

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

clearly arranged way, business models display weaknesses and potentials [9]. However, even with newly emerging business modelling tools, the construction process can still be considered a self-service, where companies utilize implicit knowledge to depict their organization [10]. The common online business model configurator comprises business model canvases and removable and exchangeable sticky notes [11, 12]. Therein lies the difficulty of business model configuration. Lacking any degree of moderation, users are left to device elements of their own. A question-based instruction of modelling a business can give users momentum to ponder their strategic direction without any refactored domain knowledge and take advantage of already available explicit knowledge [10, 13].

1.2 Objective

The research objective is to improve already existing modelling methods by using a question-based approach to guide the user more efficiently and effectively through the configuration process.

Our central artifact is an online-based business model configurator which should enable companies to describe their business model as completely as possible and on a high enough level to create a certain degree of standardization. For this, the construction can be based on a general process framework reducing the effort for the user. Focus of this paper is not to describe how the developed tool works in detail, but much rather the improvement of business model configuration. Based on a developed questionnaire, the user can fill out their business model by providing input through answering questions [14]. The aspects stem from a generic, high-level business model framework. If companies want to further expand their model, they can add items, which can durably be included in the configurator. The configurator's implementation allows technologies to be matched to certain business model aspects. Ultimately, interdependencies can be detected when a significant number of users is reached.

The question-based configurator should be easy to use and aim at enabling an intuitive, flexible and guided business modelling with a low error ratio. This offers an effective and standardized solution considering more aspects than would be possible if the practitioners fill out an unguided business model canvas. It also has to support the efficient and effective construction of an informative business model with minimal effort. It also enables companies to understand, map and share the business logic [8].

1.3 Methodology & Structure

The derivation of the question-based business model configuration is based on the design science approach [15]. Iterative steps help reevaluate and validate findings at any point during the construction phase [15]. After a research review of business models and existing business modelling tools, the business model framework will be explained, which is based on an extensive literature analysis, which ultimately poses the foundation for the questionnaire [16]. It will utilize the building block system according to the business model canvas from Osterwalder et.al. [5, 8]. As a result, a software product is conceived in form of a business modeling tool [17]. The evaluation is conducted with unrelated test subjects to validate the effectiveness and efficiency of the configurator over an unguided paper-based canvas and post-it approach.

The paper itself is structured as followed: in chapter 2, a general research review of business models and existing modelling tools is given. In section 3, the business model framework and the questionnaire are constructed followed by the proof-of-concept in section 4. Chapter 5 depicts the evaluation and section 6 concludes the paper and gives implications on further research and developments.

2 Related Work

2.1 Business Model

Business models essentially describe how organizations function [18]. They reproduce a generic strategy as a mapped-out list of aspects the organization focuses on in order to remain successful. A digital business organization should be reviewed continuously to ensure its consistency concerning effectivity and efficiency [4]. Thus, a business model is a simplified structured image of reality and consists of connections and elements with characteristics and relations [19, 20]. However, different component compilations exist due to the lack of a uniform understanding of which elements constitute a business model and business models themselves. Depending on the objectives an organization has, the number of potential business models is endless [21]. Therefore, a standardized taxonomy needs to be developed.

As part of a continuous business model improvement, influencing factors such as political, economic, social, technological, legal or ecological changes have to be considered [22]. This enables business model innovation by consciously altering the already existing business model [23]. Hence, a flexible and adaptable way of assembling a business model has to be used to continuously work and improve it. One example of such a tool is the business model canvas by Osterwalder [5].

2.2 Business Modelling Tools

Besides the most frequently used business model canvas [5, 24], a number of other canvas-based business modelling tools can be found online [25]. These tools focus on the visualization of business models, closely resembling the business model canvas, but non-offer any support during the configuration.

As an example of a not question-lead canvas-based configurator, the Canvanizer [11] does not provide any support. It is a static tool to textually describe the user's business model, basically digitalizing the otherwise paper-based canvas approach. The only reference to the required input comes from the title of the building block as determined by Osterwalder [5], but it does not lead through the configuration process.

The only identified semi question-lead canvas-based configurator is the Start-Green [12] sustainable business model configurator. For each building block, different key questions are specified. However, the questions have a strong reference to sustainability aspects, instructing the user to describe their company textually on a very high and abstract level. The user is given the option to declare a question irrelevant and further explanations are provided through keyword examples. Nonetheless, no answers are available towards which the user can be oriented. This prevents standardization and leads to fewer considered aspects then otherwise possible.

3 Concept Development

In the previously mentioned tool survey [25], the business model canvas is the basis of most of the identified construction tools. Since this is also the tool most users are familiar with, it seems appropriate to also base the tool to be introduced in this paper on the business model canvas by Osterwalder. In order to facilitate a certain degree of standardization of the resulting business models, a taxonomy of possible aspects constituting the business model has to be created. Building on an extensive literature analysis, aspects subdividing Osterwalder's building blocks were created, forming an incomplete and not disjoint taxonomy as can be seen in table 1.

Table 1. Extract from the business model taxonomy

Building Blocks	Aspect	Items
Source of Income	Distribution Type	Sales
		Royalties
		License Model
		Leasing, Rental
		…
	Revenue Stream	Core Business
		Diversification
		Large Product Portfolio
	Payment Terms	…
	…	

This is necessary, since the criterion of completeness is unachievable and a termination has to be made after a certain hierarchy level. The aim is to allow users to extent the taxonomy depending on their own requirements, ultimately also lowering the frustration because researchers have not considered all potential responses [26]. Eventually, these aspects will be durably considered in the taxonomy after a certain threshold is crossed. A questionnaire is a formalized set of unambiguous questions translating the researcher's information need to questions, in order to obtain information from applicants [27]. By offering specific response options through a drop-down box, the collection of standardized data is possible. Subsequently, this data can be compared and analyzed. It also enables a faster and more accurate recording of the data. The target is to enable the user to configure their company's business model in its entirety. Hence, the questions themselves and the questionnaire's structure are predefined by the underlying business model taxonomy. The questions are worded around the aspects using natural language to convey further information to the user.

Most questions follow the multiple-choice structure, covering a full range of possible mutually exclusive and collectively exhaustive alternatives. This also eliminates the wording problem, since it is aligned with the taxonomy and the provided answers.

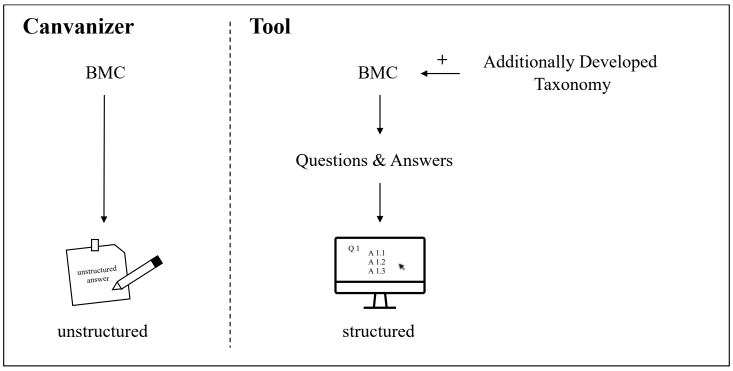

Figure 1. Schematic diagram of the approach

Each selected item is linked to a free text box where they can further explain their selection. For these boxes, information is provided describing the kind of information which can be added in each respective box. This data will only be collected to display in the user's final business model. Since the users are either part of a company's strategy team or, in case of a SME, know the company as a whole, it is ensured that the person using the configurator can actually provide the requested information [28, 29].

Through the question-based approach, refactored domain knowledge is not necessary. By providing answers and giving the option to further expand or explain their selection, the user is also encouraged to be creative and explore different possibilities in the sense of giving more answers than otherwise possible and inspire business model innovation. Whereas, in non-question-based approaches, the level of detail of the resulting business model solely relies on the creativity and experience of the user as can be seen in figure 1. Also, standardization is created allowing the resulting models to be compared and analyzed.

4 Tool Implementation

Based on the conceptualization, an exemplary software prototype was developed that implements the requirements defined in the previous sections. It is built as a modular system as shown in figure 2. The chosen web-based architecture was determined by the framework conditions of the project, the tool is part of. The system consists of two separate user interfaces and a backend. One of the user interfaces offers administrative functionalities. This includes the definition of the business model taxonomy and the creation of the question sequences, the definition of answers to the respective questions and the matching of questions and answers to aspects of the developed business model taxonomy. To do that, the administrator can choose from aspects of the taxonomy or chose his own naming, that can also be linked to a free text field. The question type, i.e. whether only one, multiple or a specific number of answers to a question can be selected.

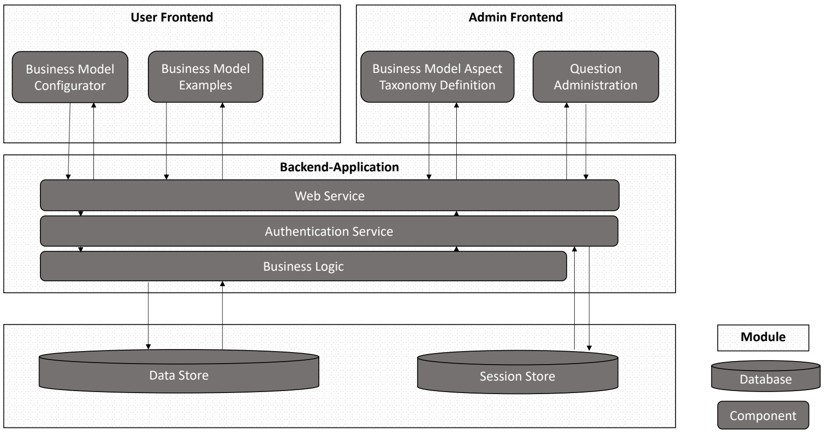

Figure 2. Architecture of the implemented tool

The other UI targets the end user. A user can create, edit and delete business models that are based on the business model canvas. When creating a new business model, the user is first guided through the canvas with the task of answering a number of questions per canvas element. Figure 3 shows an example of such a question as well as the interaction mode via selectable checkboxes and the navigation. Researchers rarely spend sufficient time on the physical layout of their questionnaire, believing that the science lies in the content of the questions and not in such details as the font size or color. Yet empirical studies have repeatedly shown that low response rates are often due to participants being unable to read or follow the questionnaire [28,29].

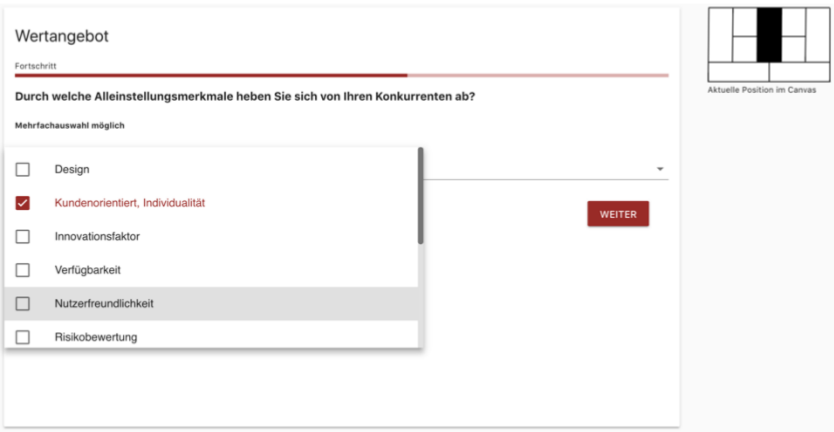

Figure 3. Screenshot of the developed tool's question approach

These aspects are considered in the developed tool, which uses only a small number of UI elements and only a primary and a secondary color. The current position within the canvas as well as the current progress is continuously shown to the user. Navigating between the building blocks of the canvas is also possible. Apart from the actual questions and answers, the aspects are explained using examples. Once the user has answered the questions, the resulting business model is shown in a canvas view.

Figure 4 shows an excerpt of the questions used in the configurator together with their corresponding headline, which are based on the aspects. Answers to the questions are the taxonomy aspects on the lowest hierarchy level.

Building Block	Headline	Question	Type
Customer segment	Market	In which market do you offer your products and services?	Single
	Business relation	With whom does your company maintain business relations?	Multiple choice
	Customer region	Where are your customers settled?	Single
	Industry sector	Which industry sectors do your customers belong to?	Multiple choice
Value Proposition	Products	What kind of products do you offer your customers?	Multiple choice
	Service	What kind of services do you offer your customers?	Multiple choice
	Corporate Responsibility	Through which aspects do you display your sense of responsibility?	Multiple choice
	USP	Through which unique selling proposition do you differentiate yourself from your competitors?	Multiple choice

Figure 4. Excerpt of the developed question catalogue.

This view allows to navigate through the building blocks of the canvas to specify and edit aspects of the created business model with free text elements being offered as shown in figure 5. In this view the user can also decide to revisit some of the questions individually or answer all questions of a building block again. The overview also offers this opportunity and allows the user to download and print the resulting canvas. Since the configurator collects sensitive data, trust in the security of their data needs to be established. This is achieved by implementing a secure login, a session-based authentication and the data being stored in an on-site hosted database. Security aspects are implemented in the backend application. All requests are directed to a web-service that calls an authentication middleware. Valid requests are forwarded to the business logic, which queries a database storing the user specific business model data or if an administrator request arrives taxonomy and question definition data.

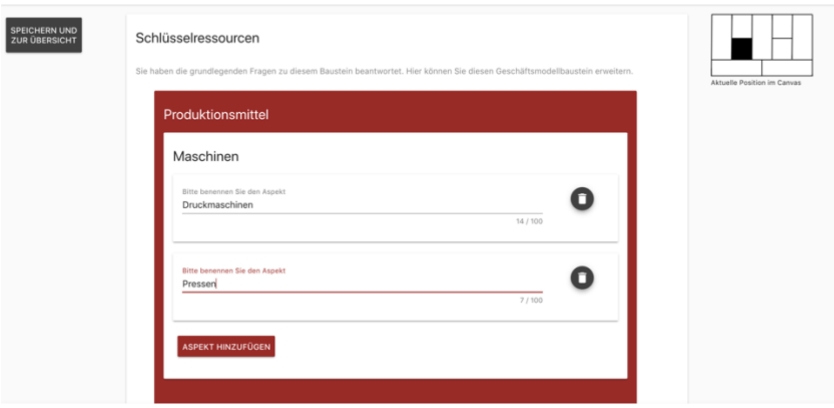

Figure 5. Screenshot of the developed tool’s aspect view

5 Evaluation

5.1 Evaluation Approach

The developed concept and its implementation can be evaluated in various ways. However, a content-based evaluation of the resulting business models is difficult to carry out within the limited time. An evaluation aimed at the comparability of the results could be done with an ontology mapping. However, since the approach developed in this paper is based on a taxonomy, it can be expected in advance that an object of comparison will perform worse in matters of comparability and standardization.

Therefore, the effectiveness of the developed concept will be demonstrated in a case study aiming at the usability evaluation of the implemented prototype. The study design was as follows: a user test was conducted with the following hypothesis: the developed question-based tool is more usable in terms of the NASA TLX score, than non-question-based tools. In the experiment, the system serves as the independent variable with two levels: the implemented prototype, using the concept proposed in this paper and the Canvanizer introduced before, which is representative for non-question-based business model configuration. A semi-question-based tool was not considered, since only one could be found and the target was to evaluate the difference in usability compared to a question-based approach. The dependent variable is the previously mentioned NASA TLX score [32], resulting from an established questionnaire for evaluating mental demand, physical demand, temporal demand, performance, effort and frustration when interacting with a system to accomplish a task. The experiment task consists of the creation of a business model for a well-known company whose name and details are handed to the participants at the beginning of the experiment. Based on the knowledge of said company, the participant is asked to create a business model with the respective tool. As the task of creating a business model is complex, a between-subject approach was used, where each participant is assigned a group. Each group operates on one of the tools. This avoids learning effects or fatigue effects.

Each group had a size of ten participants, each participant was asked to construct a business model on their own. The participants had a general business background. This supports the assumption that the configurator can also be used by people who have no strategic or entrepreneurial prior knowledge. First, the participant was given a short introduction into the concept of business models and was told the company the business model should be created for. After they had finished their task, they were asked to fill out the NASA TLX questionnaire, which asks for the assignment of subjective weights to several evaluation criteria. Finally, they were asked several questions about the system they used.

5.2 Results

The participants were asked to fill out the NASA TXL questionnaire including pairwise comparisons of the evaluation criteria, yielding weighted scores as well as raw scores.

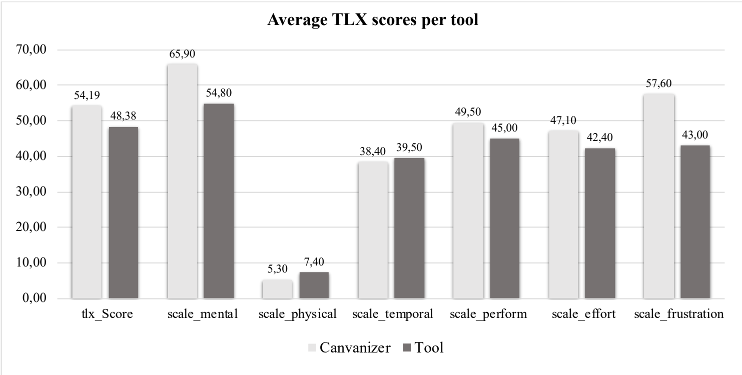

Figure 6. Average TLX scores per tool

Figure 6 shows the average global TLX score and the average scores of the individual criteria per tool. On a scale from 0 to 100, where 100 is the worst possible score. The raw scores are well-suited to evaluate the individual criteria per and across participants to identify general defects. The weighted scores emphasize, which aspects are of central importance for the participant and reveal which criteria contributed most to their workload, when executing the task. Each participant compares the six criteria in pairs. The number of times a criterion is selected represents the weight, which is multiplied by the corresponding raw score and then divided by 15, to get the weighted score. The weighted scores show how much significance the participants assigned to the influence of the criteria to the workload when performing their task.

5.3 Discussion

The results indicate that the participants consider the question-based tool to be significantly less frustrating to use. The improvement compared to the non-question-based tool is clear in the raw scores, but even clearer when the criteria are weighted. The deviations found in the average score were validated and emphasized by the weighted values, because users creating the business model with the non-question-based tool have to ponder about the aspects they want to include. In contrast, the developed tool already gives hints to the expectation of what should be included in a particular building block. This allows for a more creative interaction with additional aspects of innovation. Moreover, the participants found the mental demand to be considerably lower when using the question-based tool, suggesting that the guidance of the user was successful.

Apart from that, the question-based tool performed better when looking at the global TLX score. Except for the mental demand all scores of the question-based tool are below 50 indicating that those criteria are met. Even though on average, the participants, that used our tool, took 33% longer to complete their task, the estimation of temporal effort is only slightly higher. This suggests, that the use of the tool is perceived as engaging by the users.

6 Conclusion & Outlook

The developed tool is a flexible, intuitive and question-based alternative for a standardized business model development, ultimately supporting innovation through an overview-based display of highly comparable business models. It offers an effortless and user-friendly tool for an effective, efficient and guided business model configuration with low error ratio. The resulting business models are homogeneous in terms of detail. This is the case down to a certain hierarchy level, when the taxonomy is terminated for standardization reasons and because completeness cannot be achieved. Evaluation results have shown, that the mental demand is significantly lower in the developed tool than the Canvanizer, implying a success in the developers' effort to make to tool more user friendly. Test subjects stated, that aspects were offered which the user would not have considered otherwise and expressed their content with the instructions and the resulting business models. Furthermore, the evaluation showed, that the perceived time needed to complete the business model was only marginally higher while the perceived frustration level was significantly lower. In long-term empirical studies it should be tested, whether the derived questions serve their purpose. Furthermore, the taxonomy needs to be validated and reevaluated, since the matching of individual aspects to categories could not be deduced from the literature analysis.

Available business modelling tools omit background domain knowledge, neglecting the users' need for a guided model configuration. Hence, important interdependencies between business model elements indicating weaknesses and threats are not revealed. This jeopardizes the exploitation of an organization's total strategic potential.

As can be derived from the average TLX scores, the developed tool performs significantly better than a non-question-based tool. However, the evaluated criteria can be improved even further. The user interface can be adapted in order to guide the user through the configurator more time-efficiently – ultimately lowering the users' frustration even further.

The underlying **taxonomy** was derived under the premise of being flexible. Thus, the aspects added by the user under "other" will be considered in the taxonomy when crossing a certain threshold in relation to the total number of configured business models. Eventually, these aspects will be available for other users as well. Another possible future step could be to reconstruct the questions based on the gained knowledge through the **users' input**. When using the answers to expand the taxonomy's hierarchy levels, a more detailed representation emerges. Also taking the user profiles into account, the provided answer options for selected questions could be prefiltered depending on the answer of previous questions. When a sufficient number of business models is available in the tool, it will be possible to enable a graph-based analysis. By calculating a distance measure between business models and the companies' user profiles, their similarity can be determined. Hence, considering the companies' financials provided through the user profile, an anonymous **recommendation for suitable aspects** can be given – provided the compared organization is more successful than the active user's one.

Abstract. Immersive virtual reality (iVR) is becoming increasingly popular for learning. But how such learning applications are designed is crucial and determines their success. Designing suitable feedback mechanisms in a learning environment manifests through gamification elements. Nevertheless, previous research has shown that the effect of gamification is ambiguous and depends on several aspects. The setting in which the gamification is used can affect the learner's perception of the feedback and, in turn, their motivation. Since learning systems are usually aimed at increasing the user's learning performance but also their inherent enjoyment of learning, investigating effects on the user's intrinsic motivation is essential. This study proposes a research model, and an experimental approach is outlined in order to examine how situational factors influence the effect of gamification on intrinsic motivation and learning performance in iVR learning environments.

Keywords: Learning, Immersive Virtual Reality, Intrinsic Motivation, Gamification, Situational Factors.

1 Introduction

Virtual Reality applications are becoming increasingly popular since the rise of Oculus Rift (Development Kit 2) in 2016. Especially, immersive Virtual Reality (iVR), realized by presenting a virtual environment through a head-mounted display (HMD) which encloses the user into the virtual world and lets the them interact within it by using hand-held controller, is used in different domains and fields. One area of application for iVR is learning [1]. Due to the nature of this technology, different contexts and scenarios can be displayed allowing the user to be completely involved and immersed into the given setting and task within it. Such applications are already deployed at schools and universities as well as in healthcare and process learning [2]. Not only does immersion and interactivity allow for engagement and fun [3], it also furthers concentration by eliminating external distractions [4]. Such deep involvement with the task presented in the virtual environment shows a positive influence on learning and performance [5].

Another important aspect of learning, especially in iVR, is feedback. Evaluating the user's actions and showing them if and what was performed correctly or could be

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

improved is a key aspect of improving their learning performance and avoiding the habituation of erroneous behavior. A popular approach for realizing such technological feedback within such systems is gamification [6]. Gamification can be found in different settings. By applying game elements to work- or learning-related contexts and tasks it provides feedback in a game-like fashion. It is designed to motivate users by awarding them points, badges and level-ups, etc. for desired, correct behavior within the given context or for the specific task.

The aim of such feedback and reward systems is to achieve the fulfillment of the need for competence. This, in turn, is aimed to increase the intrinsic motivation of the users such that they perform the activity for its own sake [7]. This way, the enjoyment and performance of the user is increased inherently through the performance of the task instead of externally motivated by the expectation of rewards [7]. But how gamification is influencing the user's motivation and performance has rarely been empirically investigated [6]. Whether the intended growth in intrinsic motivation actually takes place by introducing gamification to learning tasks and scenarios is not yet clear [6].

While feedback systems and rewards, as they are used in gamified applications, are usually considered to be extrinsic motivators, it is important that these do not reduce but rather even heighten the intrinsic motivation of users - not only because long-term performance and engagement are dependent on intrinsic motivation but also the user's satisfaction and their overall well-being [8]. Hence, it is essential to investigate how gamification can be utilized such that it does not stifle but foster intrinsic motivation and with that the long-term performance, satisfaction and well-being of the user.

This question is difficult to answer as the effect of gamification varies depending on the context it is used in, how it is designed and realized and what situation it is used in. Mekler et al. demonstrate how situational factors have an impact on the performance of users as well as on their intrinsic motivation [9]: If the feedback in the gamified application is understood and perceived by the user as neutral and merely informational, it positively impacts the user's intrinsic motivation. However, if through the situational factors the feedback is perceived as controlling, it has a negative influence on the user's intrinsic motivation. As a consequence, this shows the importance of not only the feedback itself but also points to the significance of its perception by the user. Investigating how the effect of gamification, especially within an iVR setting, is influenced by situational factors promises to deliver clues as to how the intrinsic motivation of a user as well as their learning performance is affected and how these aspects need to be integrated into an iVR learning setup and application. Therefore, this work-in-progress paper proposes an experimental setup with which the following research question can be addressed:

RQ: How do situational factors influence the effect of gamification on intrinsic motivation and with that learning performance in an iVR learning environment?

To answer this research question, the paper is structured as follows. In Section 2 the research background on iVR, gamification and intrinsic motivation is presented. The hypothesis development and the research model are outlined in section 3, followed by the description of the research method and intended data analysis in section 4. Lastly, in section 5 an initial discussion and an outlook is presented.

2 Background and Literature Research

2.1 Immersive Virtual Reality

Immersive Virtual Reality (iVR) is achieved by using complex interfaces and hardware, such as head-mounted displays (HMD), which allows the user to be completely shut off from their surrounding and exclusively perceive the virtual environment. By using controllers or through hand-gestures the user is able to interact with the virtual world and the objects within it. This kind of immersion can lead to the feeling of (tele)presence in the virtual environment and a sense of actually being in this virtual world [10, 11]. This immersion and sense of presence increases engagement with the virtual environment and in turn with the task within it [5]. Besides this, iVR offers several advantages. Due to that, it is used as the environment of choice for many learning applications. For instance, because of the provided interactivity iVR environments are used as medical training tools for medical students [12]. Another example of such applications are games helping students in certain areas of math like, for example, geometry [13]. The main reasons why iVR is utilized in such cases is that it allows to visualize and display complex and abstract information and explanations in a more tangible and interactive way. Enabling this type of interactivity and good visualization positively influences learning outcomes [5] which is why iVR is a popular tool for realizing learning application and serious games.

2.2 Intrinsic Motivation

Intrinsic Motivation is defined as the drive to do a certain activity for its own sake rather than because of any expected consequences or rewards which follow it [14]. As opposed to extrinsically motivated activity, which is elicited by anticipated external rewards and, therefore, dependent on external factors, intrinsically motivated behavior driven by the inherent joy of the activity. In order to reach and foster this intrinsic type of motivation, it is important to fulfill certain needs. According to the Self-Determination Theory by Ryan and Deci [8], increased intrinsic motivation, and with that, well-being can be achieved by meeting the psychological needs of competence, social relatedness and autonomy. This means that by creating and enabling (social) structures and situations which allow the fulfillment of these needs or at least a part of them, the development of self-motivation and overall healthy mental development and state can be supported [8].

In order to foster intrinsic motivation towards learning, it is important to take these psychological needs into account. Since a crucial part of learning is based on receiving feedback [15], the way in which this feedback is presented can influence the satisfaction and fulfillment of these needs. It is important that external feedback does not diminish but rather support intrinsic motivation. To be able to provide feedback in a helpful fashion such that it can promote feelings of competence and/or autonomy could positively affect the overall motivation to learn. As a consequence, integrating this insight and designing learning applications and feedback mechanisms with this type of need satisfaction in mind can be beneficial.

2.3 Gamification and Situational Factors

Gamification can be understood as the application of game elements to non-game contexts [16]. Which elements are utilized can vary: for example, it is possible to include ranks, badges, levels, etc. [16]. Hamari et al. [3] demonstrated, through their meta-analysis of 24 gamification studies, that such game elements have a positive effect on users. Two effects which were found across all studies are fun and engagement. This is supported by the results from Buckley et al. [17], who also found that gamification positively affects users. However, the impact of each element depends on the context in which it is used as well as how it is implemented [3, 18]. An important game element which is frequently used in gamified applications and which is also highly context-sensitive is feedback [16]. Feedback can be realized and displayed to the user in several forms with the most common and basic type being points [19]. They are the basic building block on which other elements such as level-ups and badges, for instance, are based on. Points are the simplest form of reward and feedback for certain actions within a game or task [6, 20, 21].

How the user perceives this feedback is crucial. If it is understood as purely informational it can support the fulfillment of the psychological needs mentioned above. But if the user experiences it as controlling, it can stifle intrinsic motivation and only be extrinsically motivating [8]. Therefore, if the points and the setting and context in which they are presented to the user are informational, this can lead to an increase in their perceived competence [19, 21]. However, if the situational factors are such that the feedback from the points is considered controlling, they could increase a feeling of pressure and therefore diminish intrinsic motivation.

Mekler et al. [6] showed that the game element of points can not only provide feedback to the user but can increase their intrinsic motivation in an image annotation task. For this, they let the user name and tag images on a computer and provided points for quantity and quality of their tags. Their findings show an increase of intrinsic motivation in subjects who received feedback in the form of points for their actions as opposed to the control group who did not receive any feedback in form of points. However, there are also findings, for instance by Mekler et al. [18] and Sailer et al. [21], which demonstrate that the gamification elements, as points, are not necessarily effective in increasing intrinsic motivation per se.

3 Research Model and Hypothesis Development

In this section the research model is proposed, and the hypotheses will be derived (Figure 1). While previous research does not conclusively show that higher intrinsic motivation leads to increased learning, there are clear tendencies in this direction. Intrinsically motivated subjects often demonstrate at least equal or better learning performances to their extrinsically motivated counterparts. Several studies showed the positive influence of higher intrinsic motivation on learning [22], goal achievement [23] and persistence in education, i.e. lower drop-out rate in education [24]. This points to a positive influence of intrinsic motivation on, especially long-term, learning. Based on this, users of a learning system who exhibit increased intrinsic motivation should be able to show higher learning performance than those who are less intrinsically motivated. This leads to the first hypothesis:

H1: Intrinsic motivation positively influences the learning.

Furthermore, studies like Hamari et al. [3], have clearly demonstrated that the effect of gamification is positive on engagement, fun, and partly on learning outcome [5] and intrinsic motivation [6]. Since the user has to be attentive and is engaged as if they play a game, such positive effects can occur. However, since such results are not conclusive, this needs to be further investigated. In addition, to the best of our knowledge, none of the previously conducted studies on gamification and situational factors are set within and focused on an iVR technologies. Using gamification elements to provide neutral feedback and increase the feeling of competence can lead to fostering intrinsic motivation. Since points are the most basic game element on which previous research builds upon ([19], [21]) it is picked as the element of choice in this study. By combining these aspects, the second hypothesis is:

H2: Providing feedback in an iVR learning environment in form of points, as a gamification element, positively influences intrinsic motivation.

However, the effectiveness of such gamification elements dependent on which game element is used specifically, how it is integrated, and in which context it is embedded in [3, 18, 21]. Therefore, it is important to account for situational factors which could influence the perception and with that the effect of the feedback. Examining situational settings is, therefore, crucial as well. By creating situational settings which can either be considered controlling or informational and neutral allows for an investigation into these situational factors and their impact on the user's intrinsic motivation [8]. Hence, if users perceive the gamification feedback as informational and neutral, they will be more intrinsically motivated than in a controlling setting since no external pressure will affect their performance. This leads to the third hypothesis:

H3a: Adjusting situational factors such that the gamification element is perceived as informational rather than controlling will positively influence intrinsic motivation.

But even if the gamification element and, therefore, a learning or performance feedback is omitted, previous research shows that situational factors still are of important. Situational factors, for example, as the allocation of authority and power, can influence intrinsic interest [25]. In addition, a setting strongly emphasizing the importance of good performance tends to induce pressure and is found to be negatively correlated with intrinsic interest [26]. In contrast, a neutral setting which is focused on learning instead of performance is less pressure-inducing and positively correlated with intrinsic interest [26]. This means, adjusting the situational factors such that they are neutral should lead to higher intrinsic motivation compared to a controlling setting. Therefore, the last hypothesis follows:

H3b: Adjusting situational factors such that they create an informational and neutral setting positively influences intrinsic motivation as opposed to a controlling setting.

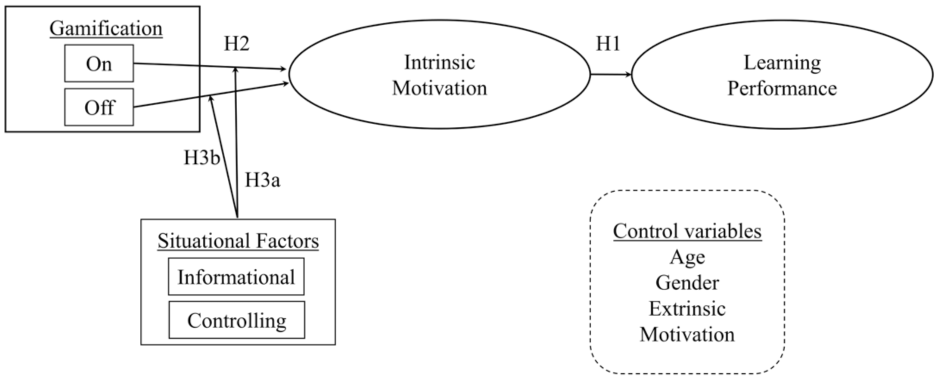

Figure 1. Research Model

4 Method

4.1 Design and Participants

In order to investigate the research question at hand, a randomized 2 (gamification: on vs. off) x 2 (situational factors: informational/neutral vs. controlling) between-subject experimental set up will be used. The experiment will take place in a laboratory in which the participants will be set in a virtual environment, implemented in Unreal Engine 4. For this, an HTC Vive VR-HMD and its controllers will be used. This allows full visual immersion into the virtual environment and interactivity by moving around and move virtual objects. The aim is to recruit 120 participants, with 30 participants per group, with most of them being university students who will receive monetary compensation for their participation in the experiment.

4.2 Learning Task

The learning task used in the experiment is set in a virtual post office. The task is based on the processes in real post offices. This post office is set up in the following way. The participants will stand in front of a desk behind a counter. The customers enter and interact with them straight ahead from this standpoint. In front of them, on the desk, are a scale which allows them to weigh an item and simultaneously show them its measurements like height and length. In addition to that, the stamps and tags for special orders and requests are on the desk. To their left, on the wall, is the price list as well as specific boxes for certain sizes of items. The participants are required to take the role of a post worker interacting with a virtual customer. The customer gives the participant a postcard, letter or package to mail. Which item is brought in by the customer is randomized such that the process varies in each trail. The participant's task is then to execute all necessary steps in order to successfully set up the shipment of the customer's item. That way, the participant is supposed to learn the execution of the customer interaction and shipping process. The steps taught in the experiment at hand will be described in the following:

1. Receive customer item and listen/read their instructions (for example, how should the letter be mailed)
2. If special order: add tag
3. Weigh and measure the customer's item
4. Look up the price of such an item on a price list
5. Bill the customer accordingly by typing in the right price into a number pad
6. Attach stamp to the item
7. Sort the item according to its size and weight into the right shipment box

Occasionally, a customer will have a special order or requirement which adds an extra step (see step 2). At this point, they have to an attach a tag that indicates that this is, for example, express shipment.

The system is designed in a way such that it does not allow for the participant to make a mistake and finish the process regardless of that. Instead, the participant cannot continue with the next steps until the mistake it corrected, and the steps can be followed in the right order again.

4.3 Procedure

The experiment takes place in a virtual reality laboratory and participants are tested individually. Firstly, the participants receive a short introduction by the experimenter regarding the consent form and the general set up of the experiment. If participant decide to take part, they receive oral as well as written instructions by the experimenter regarding the task. After the task is clear and the participant knows what to do, the experimenter explains how the VR Headset and its controllers work and how participants can navigate and interact in the virtual world.

Given that the participant is in the group in which the gamification is tested, they will see a board in the virtual post office on the upper right corner of the virtual desk they are working on. On this board their current point score will be displayed. If the participant is in the non-gamification group of subjects, the board will not be shown. Instead of serving as extrinsic motivators, these points are aimed to increase the subject's perceived competence and in turn intrinsically motivate them.

Depending on which condition the participant is in, they either receive task instructions which are phrased in an informational and neutral or in a controlling way. The instructions are based on the ones used in an experiment by Shalley and Smith [27]. The phrasing is specifically adjusted in each condition with either neutral or pressure-inducing and autonomy-depriving words [28]. In the controlling condition, the participants are also told by the experimenter that they are an important part of the study, that they will be observed for the purpose of evaluating their performance during the task and that the time they take to finish the task will be measured as well. They are explicitly told to make no mistakes while working through the task as fast as they can. By introducing these instructions, we assume that the feeling of pressure will be increased in those subjects. The participants in the other group with neutral instructions are just told that they are a part of the study, that they should just simply try to do their best but that they are in no hurry and if something goes wrong it is not a problem. They also get told that the experimenter will be watching what they are doing, however, they are assured that this is just for their safety so that the experimenter can make sure that they do not bump into objects.

After an initial training period to get used to the environment and to the setting and interactions, the participants are required to start the task and their time and number of errors will be taken by the experimenter. After ten trails are completed, they can stop. Lastly, they get asked to complete a questionnaire for which they have to indicate their degree of agreement with certain statements. These statements are the items which are aimed at measuring the participants level of intrinsic motivation and perceived pressure. The measures are explained in more detail in the section below and the items used in the questionnaire can be found in Table 1 in the Appendix.

4.4 Measures

Learning Performance: To measure the learning outcome or the performance we use the point system in the virtual environment as well as an error count through observations by the experimenter. The system rewards points such that it counts three points for a process completed without mistakes, two points for a process in which one error was committed and one point for every other completed process. In addition, the experimenter will count the number of mistakes by observing the actions in the virtual environment.

Intrinsic Motivation: To measure intrinsic motivation we use the Intrinsic Motivation Inventory (IMI) [29]. Some items are adapted such that they fit this specific experiment (Appendix, Table 1).

Pressure: To measure pressure, the construct of "Pressure" within the Intrinsic Motivation Inventory was used. The items within this construct are also adapted to fit this specific experiment (Appendix, Table 1).

Perceived Learning: To measure the perceived learning of the participants, items by Goel et al. [30] were adjusted (Appendix, Table 1).

Learning Satisfaction: To measure the learning satisfaction of the participants, items by Goel et al. [30] were adjusted (Appendix, Table 1).

Manipulation Checks: Three manipulation checks are introduced. Since the display of the gamification element is manipulated in this experiment, the points are either shown or not presented to the participant. Due to this, the participants are asked whether they could collect and accumulate points from the system for their actions. Additionally, by using adjusted items by Suh et al. [31] it is checked whether the collection of points yielded any motivational incentive for the participants. Lastly, the situational factors are adjusted such that they are either controlling or neutral. Therefore, participants are asked whether the instructions were perceived as either pressure-inducing or neutral. The manipulation checks can be found in Table 1.

4.5 Data Analysis

In order to test the hypotheses and answer the research question different statistical methods will be utilized. For instance, a multiple regression analysis and ANCOVA to check manipulations and whether the participants in each condition (non-/gamification and neutral/controlling situational factors) performed differently and exhibited (significant) distinctions in their level of intrinsic motivation.

5 Discussion

This study is aimed at investigating the influence of situational factors on gamification in an iVR learning environment and their impact on intrinsic motivation and learning outcome. This work will contribute to the body of empirical research revolving around the subjects learning in iVR (for example, [1]), intrinsic motivation (for instance, [6], [8] and [9]), and the influence of situational factors (for example [26]). In addition to that, it will inform and provide insights for practitioners and designers of learning system as well as their users. Arranging and adjusting situational factors could help to motivate the learners and improve their performance. Therefore, questions of how to deploy, use, and get the most out of such systems needs to be answered, whereby the study at hand will contribute by its findings. In order to proceed, the next step is participant recruitment and conducting the experiment.

As every study, this research has certain limitations. Although gamification elements might affect the intrinsic motivation of a person, there might be further design-related and non-design aspect that affect the individuals' motivation. Hence, future research should extend this perspective by including other factors as well. For instance, future research might investigate alternative gamification elements (e.g., batches, leaderboard, etc.) as a promising aspect to influence learning performance and variation in motivation in more detail. Finally, since an experimental approach is proposed here, external validity might be an issue which could be considered in further studies.

Appendix

Table 1. Constructs and Examples of Items for Experiment.
For all items, participants have to indicate to which degree they agree with the given statement on a scale from 1 (not agree at all) to 7 (completely agree).

Construct		**Items - Examples**
Intrinsic Motivation Inventory (IMI) [29]	Enjoyment/Interest	I thought the task was quite enjoyable. I would describe the task as very interesting.
	Perceived Competence	I am satisfied with my performance at this task. I think I am pretty good at the task.
	Perceived Choice	I believe I had some choice about doing the task. I did the task because I wanted to.
	Effort/Importance	I put a lot of effort into doing the task. It was important to me to do well at this task.
	Pressure/Tension	I felt very tense while doing this task. I felt pressured while doing the task.
Perceived Learning [30]		Doing the task increased my knowledge about the process.
Learning Satisfaction [30]		I am satisfied with the way I learned about the process.
Awareness of Point System (MC) [self-developed]		The system offers me the possibility to accumulate points I have gained.
Points and Motivation (Manipulation Check) [self-developed]		The system motivated me by offering the possibility to obtain more points if I try hard.
Situational Factors (Manipulation Check) [self-developed]		I felt pressured by how I was instructed to do the task.

Evaluation von ITSM-Tools für Integration und Management von Cloud-Diensten am Beispiel von ServiceNow

Abstract. Im Kontext der digitalen Transformation nimmt die Nutzung von IT-Services aus der Cloud in Unternehmen rasant zu. Diese Entwicklung führt zu neuen Herausforderungen im IT Service Management (ITSM). Das auf das Management interner IT-Services ausgerichtete ITSM muss erweitert werden, um externe IT-Services aus der Cloud zu integrieren und zu managen. In Literatur und Praxis wird Service Integration and Management (SIAM) als vielversprechender Ansatz zur Erweiterung des ITSM um diese Fähigkeit diskutiert. Dabei stellt sich auch die Frage, wie sich geeignete ITSM-Tools ermitteln lassen, die Prozesse und Komponenten von SIAM mit ihrem Funktionsumfang abdecken. Diese Fragestellung wird mittels kriterienbasierter Evaluation am Beispiel eines ITSM-Tools des Herstellers ServiceNow untersucht. Basierend auf den Ergebnissen der Evaluation werden Aussagen über die allgemeine Abdeckung von ITSM-Tools hinsichtlich der Umsetzung von SIAM abgeleitet und diskutiert.

Keywords: IT Service Management, Service Integration and Management, SIAM, Evaluation, ITSM-Tools

1 Einleitung

Im Kontext der digitalen Transformation, womit fundamentale Veränderungen unter anderem der Geschäftswelt durch disruptive IT-Innovationen gemeint sind [1], nimmt die Nutzung von IT-Services aus der Cloud in Unternehmen rasant zu. Laut Bitkom nutzten im Jahr 2016 bereits 65 Prozent der deutschen Unternehmen Software, Speicher oder Rechenleistung aus der Cloud [2]. Trotz der stark gestiegenen Verbreitung ruft das Cloud-Computing bei IT-Entscheidern auch kritische Reaktionen hervor [3]. Ein Grund dafür ist, dass die Nutzung von IT-Services aus der Cloud in Unternehmen zu weitreichenden Veränderungen im IT Service Management (ITSM) führt. Vor diesem Hintergrund hat sich unter der Bezeichnung Service Integration and Management (SIAM) ein neuerer ITSM-Ansatz herausgebildet, der dazu dient, IT-Services aus der Cloud zu integrieren und ganzheitlich zu steuern [4]. SIAM verfolgt damit das

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Ziel, eine einheitliche geschäftsorientierte IT-Organisation abzubilden. Das Konzept kann als Erweiterung des herkömmlichen ITSM nach IT Infrastructure Library (ITIL) um spezifische Aspekte des Multiprovider-Managements verstanden werden [4].

Damit SIAM in der ITSM-Praxis einen zusätzlichen Nutzen entfalten kann, müssen ITSM-Tools erweiterte Anforderungen erfüllen, die sich aus den bei SIAM beschriebenen Fähigkeiten ergeben. Unternehmen können am Markt aus einer Vielzahl unterschiedlicher ITSM-Tools auswählen [5]. Obwohl die Erweiterung des ITSM um die Fähigkeiten von SIAM bereits seit etwa 2005 [6] diskutiert wird, scheint sich die Umsetzung von SIAM in die Praxis noch in einem Frühstadium mit zögerlichem Fortschritt zu befinden. Unter der Annahme, dass der Abdeckungsgrad von SIAM-Funktionalitäten in am Markt erhältlichen ITSM-Tools dabei eine wichtige Rolle spielt, wird in der vorliegenden Arbeit eine kriterienbasierte Evaluation am Beispiel des ITSM-Tools Kingston [7] des Herstellers ServiceNow entwickelt und durchgeführt.

Die Arbeit ist wie folgt strukturiert: Nach der Einleitung werden in Abschnitt 2 verwandte Forschungsarbeiten zu SIAM und ITSM diskutiert. Aus einer semiformalen SIAM-Beschreibung [8] wird in Abschnitt 3 der Gesamtansatz in einzelne Komponenten untergliedert, die für die Durchführung der Evaluation relevant sind und als Basis für einen Kriterienkatalog dienen. Anschließend wird die Evaluation am Beispiel des ITSM-Tools Kingston von ServiceNow exemplarisch durchgeführt (Abschnitt 4) und diskutiert (Abschnitt 5). Die Arbeit schließt mit einem Fazit und Ausblick in Abschnitt 6.

2 Stand der Forschung

Es existieren verschiedene Untersuchungen, die sich mit ITSM im Umfeld des Cloud-Computings befassen. Pröhl et al. [3] setzen sich mit den Prozessveränderungen im ITSM auseinander, die sich aus der zunehmenden Nutzung von IT-Services aus der Cloud in Unternehmen ergeben. Dabei wird die Bedeutung dieser durch das Cloud-Computing veränderten bzw. zu verändernden Prozesse am Beispiel von ITIL aufgezeigt. Abschließend wird eine Neubewertung der ITSM-Prozesse in Cloud-Computing-Szenarien vorgenommen. Heininger et al. [9] führen eine Literaturrecherche zu ITSM im Umfeld des Cloud-Computings durch. Sie zeigen, dass in der untersuchten Literatur die Notwendigkeit einer Erweiterung des ITSM zur Integration und zum Management von IT-Services aus der Cloud thematisiert wird. Zudem wird betont, dass im ITSM Handlungsbedarf besteht, um einheitliche geschäftsorientierte IT-Organisationen bestehend aus internen und externen IT-Services zu realisieren. Wie dieser Handlungsbedarf allerdings konkret aussieht, wird nicht erläutert. Robrecht et al. [10], Liebhart und Wischki [11] sowie Arabalidousti et al. [12] unterstreichen, dass in der Literatur zum Großteil nur theoretisch auf ITSM im Zusammenhang mit Cloud-Computing eingegangen wird. In diesem Kontext werden häufig identische oder ähnliche Handlungsbedarfe aufgezeigt und begründet, die praktische Auseinandersetzung mit diesen Handlungsbedarfen jedoch als weitere Forschungsthemen in Ausblick gestellt.

Neuere Quellen beschäftigen sich mit SIAM, um verstärkt die Handlungsbedarfe der ITSM-Praxis im Multiprovider-Umfeld anzugehen. Von Holland [8, 13] werden Prozesse beschrieben, die aus spezifischen Komponenten bestehen und die Integration sowie das Management von IT-Services ermöglichen. Nägele et al. [14] identifizieren kritische Erfolgsfaktoren des IT-Multisourcings mit SIAM. Hallikainen [15] befasst sich mit der Überlegung, einen Service-Katalog und die Configuration Management Data Base (CMDB)-Struktur als Basis für die Verknüpfung von ITSM und SIAM zu nutzen. Ein konkretes Vorgehen für die Einführung und Anwendung von SIAM in Unternehmen beschreiben Armes et al. [16] und Virri [17]. Armes et al. gehen auf Grundsätze und Vorgehensweisen für die Einführung von SIAM ein. Darauf aufbauend fokussiert sich Virri [17] auf den Einsatz der Vorgehensweisen in konkreten Anwendungsfällen. Lehtonen [18] thematisiert praktische Leitlinien zur Auswahl eines geeigneten SIAM-Modells.

Einige dieser Beiträge betrachten SIAM weitgehend isoliert von herkömmlichen ITSM-Ansätzen. Es ist jedoch sinnvoll, SIAM und ITSM gemeinsam zu untersuchen, da die SIAM-Prozesse und -Komponenten erst dann einen Mehrwert bieten, wenn sie zur Beherrschung des Multiprovider-Managements in das bestehende ITSM integriert werden. Im Umgang mit IT-Services aus der Cloud gewinnt das Multiprovider-Management zunehmend an Bedeutung. Vor diesem Hintergrund erwächst aus der komplementären Anwendung von SIAM und ITSM ein großes Nutzenpotenzial.

In der Literatur werden verschiedene Möglichkeiten betrachtet, um SIAM auf Toolebene in das ITSM zu integrieren. Eine Möglichkeit ist die Entwicklung eigenständiger Tools basierend auf SIAM. Hintergrund dieser Überlegung ist es, Inkompatibilitäten zwischen den von IT-Service-Anbietern und IT-Service-Empfängern genutzten ITSM-Tools zu überwinden, um heterogene IT-Services zu integrieren und zu managen [19]. Zur Verknüpfung unterschiedlicher ITSM-Tools bei IT-Service-Anbietern und IT-Service-Empfängern lassen sich dedizierte SIAM-Tools einsetzen, wie bspw. ServiceFlow [19]. Eine andere Möglichkeit ist es, ausgewählte SIAM-Komponenten in klassischen ITSM-Tools zu implementieren. Es gibt bereits ITSM-Tool-Anbieter, die ihre ITSM-Tools um SIAM-Komponenten erweitert haben [19].

3 Konzeption der kriterienbasierten Evaluation

Die Beurteilung informationstechnischer Artefakte wie bspw. Software gilt als ein spezifisches Evaluationsproblem der Wirtschaftsinformatik [20]. Heinrich [21] begründet die Notwendigkeit eines einheitlichen Evaluationsverfahrens und gibt Hinweise für die Ableitung von Kriterien aus dem Evaluationsobjekt. Das im folgenden beschriebene Verfahren basiert zudem auf dem bei Krcmar [22] beschriebenen allgemeinen Verfahren zur Softwareauswahl. Evaluationsziel ist die Bewertung von kommerziellen ITSM-Tools hinsichtlich ihrer Eignung für die Unterstützung einer IT-Organisation gemäß SIAM. Dazu werden aus einer semiformalen SIAM-Beschreibung [8] einzelne SIAM-Komponenten abgeleitet und in einen Kriterienkatalog überführt.

Die Konstruktion des Kriterienkatalogs erfolgt in zwei Schritten. Im ersten Schritt werden aus der SIAM-Beschreibung [8] drei Domänen abgeleitet, die die horizontale Struktur des Katalogs festlegen. Domänen definieren einen thematischen Zusammenhang für die darin zusammengefassten Komponenten. Im zweiten Schritt werden die Domänen durch SIAM-Prozesse und dazugehörige SIAM-Komponenten weiter strukturiert. Prozesse unterteilen Domänen in verschiedene Themenbereiche und gruppieren Komponenten. Durch die weitere Strukturierung der Domänen entsteht eine vertikale Struktur bestehend aus drei Detailstufen. Domänen beschreiben die geringste Detaillierung, Prozesse stellen die zweite Detailstufe dar. Die SIAM-Komponenten bilden die feinste Detailstufe des Katalogs und werden als Vergleichskriterien für die Durchführung der Evaluation verwendet.

Abbildung 1 zeigt die aus der SIAM-Beschreibung abgeleiteten Domänen und Prozesse. Domäne 1 beschreibt übergreifende Prozesse, die sich schwerpunktmäßig mit der Geschäfts- und Kundenorganisation, sowie dem Beziehungsmanagement befassen. Sie sind ebenfalls für die anderen beiden Domänen relevant. Domäne 2 fokussiert sich auf Prozesse, welche zur Integration und zum Management extern bereitgestellter IT-Services notwendig sind. Domäne 3 legt den Schwerpunkt auf das Management interner IT-Services.

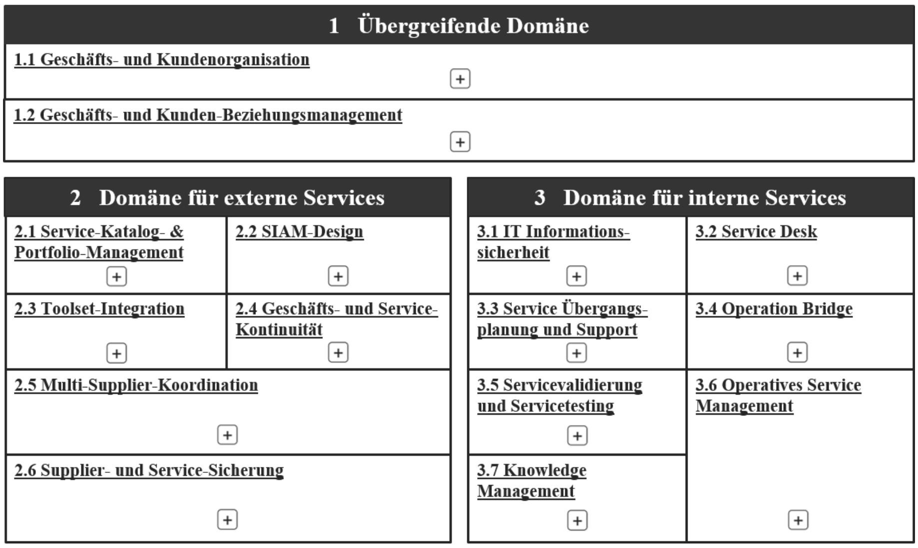

Abbildung 1. Domänen und Prozesse des Kriterienkatalogs (in Anlehnung an [8])

Da in der vorliegenden Arbeit untersucht wird, inwieweit die Funktionalitäten von ITSM-Tools SIAM zur Integration und zum Management von IT-Services aus der Cloud abdecken, liegt der Fokus auf extern bereitgestellten IT-Services. Aus diesem Grund wird im Folgenden die zweite Domäne fokussiert, weiter detailliert und die entsprechenden SIAM-Komponenten werden zur Durchführung der Evaluation verwendet. Die Eingrenzung des Fokus der Evaluation auf Domäne 2 erfolgt außerdem, um das Evaluationsvorgehen anhand eines konkreten ITSM-Tools zu evaluieren und die Qualität der Analyseergebnisse zu beurteilen. Die Erweiterung des Scopes auf die Domänen 1 und 3 ist denkbar, jedoch nicht Gegenstand dieser Arbeit.

Die Detailstufe des in Abbildung 1 abgebildeten Kriterienkatalogs ist für die Durchführung einer Evaluation nicht ausreichend. Es werden detailliertere Zielvorgaben der Domäne für extern bereitgestellte IT-Services benötigt. Der Detaillierungsgrad der Zielvorgaben muss ähnlich sein wie der der Funktionalitäten des in der Evaluation zu analysierenden ITSM-Tools. Deshalb werden die Prozesse 2.1 bis 2.6 weiter zerlegt und relevante dazugehörige SIAM-Komponenten aus [8] zugeordnet. Die ausgewählten Komponenten bilden die dritte Detailstufe des Katalogs ab. Die Prozesse 2.1 bis 2.6 und deren Komponenten sind in Abbildung 2 aufgeführt.

2 Domäne für externe Services	
2.1 Service-Katalog- & Portfolio-Management 2.1.1 Service-Katalog-Management 2.1.2 Service-Portfolio-Management	**2.2 SIAM Design** 2.2.1 Design-Abstimmung 2.2.2 Design des Verfügbarkeitsmanagements 2.2.3 Design des Kapazitätsmanagements
2.3 Toolset-Integration 2.3.1 Unterstützung der Prozessausführung 2.3.2 Service-Warnungen und -Monitoring 2.3.3 Diagnosen 2.3.4 Sicherheit 2.3.5 Reporting 2.3.6 Analysen 2.3.7 Entscheidungsunterstützung	**2.4 Geschäfts- und Service-Kontinuität** 2.4.1 IT-Service Kontinuitätsmanagement 2.4.2 Geschäftskontinuitätsmanagement
2.5 Multi-Supplier-Koordination 2.5.1 Change Management 2.5.2 Release-Planung und -Konfliktmanagement 2.5.3 Kapazitätsmanagement 2.5.4 Major-Incident-Management 2.5.5 Problemmanagement 2.5.6 Innovation 2.5.7 Kontinuierliche Serviceverbesserung	
2.6 Supplier- und Service-Sicherung 2.6.1 Service Level Management 2.6.2 Audits 2.6.3 Bewertung von Prozessreife und Fähigkeiten 2.6.4 Bewertung von Supplierreife und Fähigkeiten 2.6.5 Test Sicherung des Supplier-Testings 2.6.6 Compliance-Audits anhand der Anforderungen 2.6.7 Compliance-Audits anhand von Standards 2.6.8 Monitoring von kontinuierlichen Serviceverbesserungs-Initiativen	

Abbildung 2. Prozesse und Komponenten der Domäne für extern bereitgestellte Services (in Anlehnung an [8])

Die insgesamt 29 Komponenten der Prozesse 2.1 bis 2.6 bilden zusammen die Prüfkriterien, anhand derer untersucht wird, inwieweit ein ITSM-Tool SIAM zur Integration und zum Management von IT-Services aus der Cloud bereits abdeckt. Die Komponenten definieren die Sollvorgabe der Evaluation. Jede einzelne Komponente muss vom ausgewählten ITSM-Tool implementiert werden, damit von einer vollständigen Abdeckung in Bezug auf die Ausgangsfrage gesprochen werden kann. Neben der Sollvorgabe für die Evaluation wird ein Ist-Zustand benötigt, der den Sollvorgaben zum Vergleich gegenübergestellt wird. Der Ist-Zustand ist charakterisiert durch Funktionalitäten eines ausgewählten Tools und wird nachfolgend definiert.

Für die Auswahl des ITSM-Tools wurde der sog. Magic Quadrant für ITSM-Tools von Gartner [5] herangezogen, der auch in der Praxis häufig als erste Orientierung für eine Auswahlentscheidung dient. Der Magic Quadrant kategorisiert ITSM-Tool-Anbieter entsprechend der Dimensionen Vision und Umsetzungsfähigkeit in Nischen-Anbieter, Visionäre, Herausforderer und Führer. Dem Magic Quadrant ist zu entnehmen, dass ServiceNow und BMC führende Anbieter von ITSM-Tools sind. Da ServiceNow zudem in den letzten Jahren den Marktanteil bei ITSM-Tools auf Kosten von BMC stark ausbauen konnte, wird das ITSM-Tool Kingston [7] von ServiceNow für die Durchführung des beschriebenen Evaluationsverfahrens ausgewählt.

Kingston gliedert sich in 17 Funktionalitätsbereiche, von denen IT Service Management und Cloud-Management zwei Beispiele sind. Aus den detaillierten Beschreibungen der Funktionalitätsbereiche wurden insgesamt 138 für die Evaluation relevante Funktionalitäten abgeleitet [7]. Darunter fallen beispielsweise das Service-Portfolio-Management und Change-Management aus dem Funktionalitätsbereich IT Service Management oder das Servicekatalog-Management und Cloud-Account-Management aus dem Funktionalitätsbereich Cloud-Management. Am Beispiel des Service-Katalog-Managements wird deutlich, dass es sich bei einigen Funktionalitäten um klassische ITSM-Funktionalitäten handelt, die im Rahmen von Kingston auch SIAM-Aufgaben abdecken. Anhand der Funktionalitätsbeschreibungen ist jedoch nicht für alle Funktionalitäten erkennbar, ob sie lediglich klassische ITSM-Aufgaben oder auch SIAM-Aufgaben abdecken, oder umgekehrt. Es wird daher die Annahme getroffen, dass klassische ITSM-Funktionalitäten und einige andere Funktionalitäten übergreifend sind und auch für andere Funktionalitätsbereiche verwendet werden können.

Die 138 abgeleiteten Funktionalitäten, die eine ähnliche Detailstufe wie die SIAM-Komponenten im Kriterienkatalog aufweisen, stellen den für die Evaluation benötigten Ist-Zustand dar und schließen die Vorbereitung der Evaluation ab.[1]

4 Exemplarische Durchführung der kriterienbasierten Evaluation

Die Durchführung der Evaluation besteht aus drei Schritten. Im ersten Schritt wird eine Tabelle erstellt, die als Arbeitshilfe für die Evaluation fungiert. Im zweiten Schritt wird die Abdeckung der SIAM-Komponenten durch die Kingston-

[1] Der vollständige Kriterienkatalog inkl. der Bewertungen für die untersuchte Kingston-Version steht interessierten Lesern online zur Verfügung: http://www1.hft-leipzig.de/auth/download/2018-11-30_SIAM_Evaluation_ServiceNow.xlsx

Funktionalitäten mithilfe der Tabelle analysiert (Komponentenabdeckung) und auf SIAM-Prozessebene zusammengefasst (Prozessabdeckung). Der dritte Schritt umfasst die Aggregation der einzelnen Prozessabdeckungen und die Berechnung eines kumulierten Abdeckungsgrads für Kingston. Der kumulierte Abdeckungsgrad gibt an, wie viel Prozent der zweiten Domäne des SIAM-Ansatzes Kingston abdeckt. Die untenstehende Abbildung 3 zeigt einen Ausschnitt aus der Tabelle, mit der die Evaluation durchgeführt wurde. Anhand dieses Ausschnitts werden die einzelnen Schritte und Ergebnisse der Evaluation nachfolgend detaillierter erläutert.

SIAM-Komponenten für externe Services (29)

Abbildung 3. Ausschnitt der Tabelle zur Durchführung der kriterienbasierten Evaluation

Wie Abbildung 3 andeutet, sind in der ersten Spalte der vollständigen Tabelle alle identifizierten 138 Kingston-Funktionalitäten aufgelistet. In der ersten Zeile sind alle Prozesse (2.1 bis 2.6) der Domäne für extern bereitgestellte Services aufgeführt, die gemeinsam alle 29 SIAM-Komponenten gruppieren (angedeutet in der zweiten Zeile). Der abgebildete Ausschnitt stellt nur die Komponenten der Prozesse 2.1 und 2.6, sowie 12 ausgewählte Kingston-Funktionalitäten dar, um den Rahmen für die Evaluation zu erklären. Die letzten beiden Zeilen der Tabelle umfassen die entsprechenden

Komponenten- und Prozessabdeckungen und werden für die Auswertung der Evaluation benötigt.

Bevor die Komponenten- und Prozessabdeckungen ermittelt werden können, muss im zweiten Schritt der Evaluation analysiert werden, inwieweit jede SIAM-Komponente durch die Kingston-Funktionalitäten abgedeckt wird. Um den Grad der Abdeckung einer SIAM-Komponente durch eine Kingston-Funktionalität darzustellen, werden zwei Ausprägungen von Harvey Balls verwendet. Ein voll ausgefüllter Harvey Ball bedeutet, dass eine Kingston-Funktionalität eine SIAM-Komponente abdeckt. Ein halb ausgefüllter Harvey Ball bedeutet, dass eine Kingston-Funktionalität eine SIAM-Komponente mit einer Unsicherheit abdeckt. Diese Variante eines Harvey Balls ist notwendig, da aus den Beschreibungen der Kingston-Funktionalitäten nicht immer eindeutig hervorgeht, ob eine bestimmte SIAM-Komponente abgedeckt wird. Die Verwendung der Harvey Balls sowie die Zuordnung von Kingston-Funktionalitäten zu SIAM-Komponenten werden im Folgenden beispielhaft erklärt.

Das Service-Katalog-Management (2.1.1) ist als SIAM-Komponente definiert, die alle den Nutzern bereitgestellten Services inklusive deren Preise, Verfügbarkeiten, Service Levels, Ressourcenprofile und Einschränkungen beschreibt [8]. ServiceNow [7] beschreibt das Service-Katalog-Management als Funktionalität, die es Nutzern ermöglicht, Servicekataloge zu erstellen, Angebote für Katalogeinträge wie Services und Produkte anzufordern sowie die Qualität und Verfügbarkeit von Services im Katalog sicherzustellen. Da beide Beschreibungen die gleichen übergeordneten Inhalte (Katalogerstellung inklusive Service-Beschreibung, Ressourcenbeschaffung, Qualitäts- und Verfügbarkeitsmanagement) enthalten, wird gefolgert, dass die SIAM-Komponente Service-Katalog-Management von der Kingston-Funktionalität abgedeckt wird. Dies wird in der entsprechenden Zelle durch einen vollen Harvey Ball abgebildet. Die SIAM-Komponente Bewertung von Prozessreife und Fähigkeiten (2.6.3) wird von keiner Kingston-Funktionalität abgedeckt. Es existieren allerdings die beiden Funktionalitäten Lieferanten-Performance-Management und Workflow-Management, die die genannte SIAM-Komponente mit einer Unsicherheit abdecken. Aus der Beschreibung der Funktionalitäten geht nicht eindeutig hervor, mit welchem Vollständigkeitsgrad sie die SIAM-Komponente abdecken. Aus diesem Grund sind in den entsprechenden Zellen halb ausgefüllte Harvey Balls platziert.

Nachdem die Analyse der Abdeckung aller SIAM-Komponenten erfolgt ist, gilt es im dritten Schritt, die Komponenten- und Prozessabdeckungen auszuwerten. Die Komponentenabdeckung fasst für jede Spalte und somit für jede SIAM-Komponente zusammen, ob sie durch die Kingston-Funktionalitäten abgedeckt wird oder nicht. Sofern in einer Spalte mindestens ein voll ausgefüllter Harvey Ball eingetragen ist und die SIAM-Komponente demnach von mindestens einer Kingston-Funktionalität abgedeckt wird, wird in der Zeile der Komponentenabdeckung für die betrachtete SIAM-Komponente ein voll ausgefüllter Harvey Ball eingetragen. Das ist zum Beispiel bei der SIAM-Komponente 2.1.1 der Fall. Wenn in einer Spalte kein voll ausgefüllter, aber mindestens ein halb ausgefüllter Harvey Ball platziert ist, wird für die entsprechende SIAM-Komponente in der Zeile der Komponentenabdeckung ein halb ausgefüllter Harvey Ball eingetragen, wie beispielsweise bei der SIAM-Komponente

2.6.3. Das bedeutet, dass die SIAM-Komponente von den Kingston-Funktionalitäten mit einer Unsicherheit abgedeckt wird. Ist in einer Spalte kein Harvey Ball eingetragen, bedeutet dies, dass die SIAM-Komponente von Kingston nicht abgedeckt wird. In diesem Fall wird in der entsprechenden Zelle kein Harvey Ball eingetragen. Es ist wichtig zu betonen, dass die Komponentenabdeckung nur durch eine der drei beschriebenen Repräsentationen (voller, halber oder kein Harvey Ball) ausgedrückt wird und die Bewertungen in einer Spalte nicht kumuliert werden. Sind in einer Spalte beispielsweise zwei voll ausgefüllte Harvey Balls eingetragen (siehe SIAM-Komponenten 2.6.6 oder 2.6.7), wird die Komponentenabdeckung durch einen und nicht durch zwei voll ausgefüllte Harvey Balls repräsentiert.

Die Prozessabdeckung in der letzten Zeile der Tabelle drückt aus, wieviel Prozent der SIAM-Komponenten eines SIAM-Prozesses durch die Kingston-Funktionalitäten abgedeckt werden. Um eine Aussage darüber zu treffen, werden alle Komponentenabdeckungen eines SIAM-Prozesses kumuliert und durch die Anzahl der SIAM-Komponenten im betrachteten Prozess dividiert. Die Berechnung der Prozessabdeckung ist in Abbildung 3 anhand der SIAM-Prozesse 2.1 und 2.6 verdeutlicht.

Der SIAM-Prozess 2.1 besteht aus zwei SIAM-Komponenten (2.1.1 und 2.1.2), deren Komponentenabdeckung jeweils durch einen voll ausgefüllten Harvey-Ball repräsentiert wird. In diesem Prozess werden folglich zwei von zwei SIAM-Komponenten durch die Kingston-Funktionalitäten abgedeckt, weshalb die Prozessabdeckung 100 Prozent ergibt. Der SIAM-Prozess 2.6 besteht aus acht SIAM-Komponenten (2.6.1 bis 2.6.8). Insgesamt weisen vier SIAM-Komponenten eine volle Komponentenabdeckung (2.6.1, 2.6.2, 2.6.6 und 2.6.7) und vier eine halbe Komponentenabdeckung (2.6.3, 2.6.4, 2.6.5 und 2.6.8) auf. Das bedeutet, dass vier der acht SIAM-Komponenten nur mit einer Unsicherheit durch die Kingston-Funktionalitäten abgedeckt werden. Kumuliert man die vier voll und vier halb ausgefüllten Harvey Balls, ergibt sich eine Summe von sechs Harvey Balls. Zusammengefasst lässt sich folglich die Aussage treffen, dass in dem SIAM-Prozess 2.6 insgesamt sechs von acht möglichen Harvey Balls ausgefüllt sind. Es werden demnach 75 Prozent der SIAM-Komponenten durch die Kingston-Funktionalitäten abgedeckt.

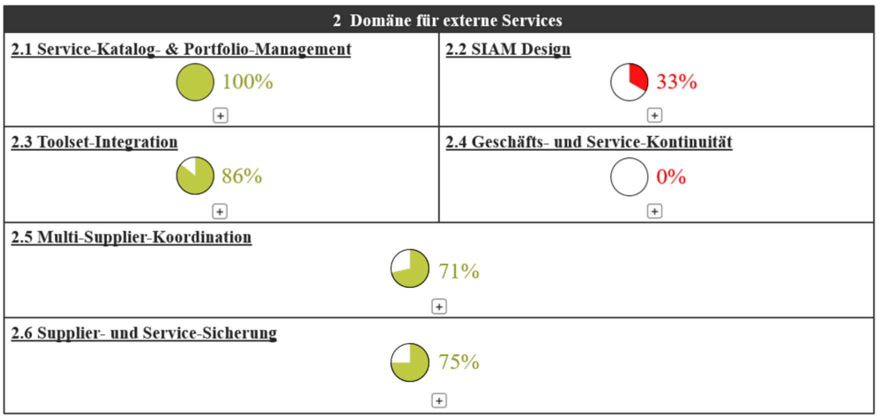

Abbildung 4. Prozessabdeckungen der SIAM-Prozesse der zweiten Domäne

In der vorliegenden Arbeit wird die Prozessabdeckung in Anlehnung an eine ITSM-Reifegrad-Studie [23] wie folgt klassifiziert: Ein SIAM-Prozess wird bei einer Prozessabdeckung unter 55 Prozent als rudimentär, zwischen 55 und 62 Prozent als mittelmäßig und über 62 Prozent als umfänglich angesehen. Die Berechnung der Prozessabdeckung dient dazu, eine übergreifende Aussage über die Abdeckung auf Prozessebene zu treffen. Die Prozessabdeckung ist allerdings mit Vorsicht zu betrachten, da sie die einzelnen Komponentenabdeckungen verschleiert und keinen Rückschluss auf die Abdeckung der einzelnen SIAM-Komponenten zulässt. Im Rahmen der Evaluation wurden die Prozessabdeckungen aller SIAM-Prozesse der zweiten Domäne ermittelt, die in Abbildung 4 dargestellt sind.

Die Übersicht über die Prozessabdeckungen lässt die Schlussfolgerung zu, dass insbesondere die SIAM-Prozesse Service-Katalog- und Portfolio-Management (2.1), Toolset-Integration (2.3), Multi-Supplier-Koordination (2.5) sowie Supplier- und Service-Sicherung (2.6) von Kingston umfänglich abgedeckt werden. Kingston ist jedoch gemäß Evaluation nur rudimentär für das SIAM-Design (2.2) und gar nicht für das Management der Geschäfts- und Service-Kontinuität (2.4) einsetzbar. Der durchschnittliche Abdeckungsgrad auf Prozessebene für die zweite Domäne liegt bei 61 Prozent. Damit ist die SIAM-Abdeckung von Kingston insgesamt als mittelmäßig einzuschätzen. Aufgrund einer Cloud-orientierten Vision von ServiceNow verfügt Kingston jedoch über ein ausbaufähiges Potenzial, um zukünftig ein umfänglich geeignetes ITSM-Tool für die Integration und das Management von IT-Services aus der Cloud zu werden.

5 Diskussion

Bei der Konzeption des Evaluationsverfahrens wurde besonderer Wert auf einfache Handhabbarkeit und geringen Anwendungsaufwand gelegt, um einen hohen Praxisnutzen zu erzielen. Um dieses Ziel zu erreichen, wurde eine gewisse Unschärfe der Bewertung in Kauf genommen. Diese resultiert zunächst aus der Verwendung von Harvey Balls in lediglich drei Ausprägungen (voller, halber, kein Harvey Ball). Die Verwendung der halb ausgefüllten Harvey Balls bedeutet nicht, dass die SIAM-Komponente durch die beiden Kingston-Funktionalitäten zu jeweils 50 Prozent und demnach zusammengefasst komplett abgedeckt wird. Ein Harvey Ball stellt keinen genauen Prozentwert dar, sondern dient der qualitativen Darstellung der Abdeckung einer SIAM-Komponente durch eine Kingston-Funktionalität. Hinzu kommt die Problematik des Skalenbruchs beim Übergang von ordinal skalierten Harvey Balls zur Repräsentation der Komponentenabdeckung hin zu kardinal skalierten Prozentwerten für die aggregierte Prozessabdeckung (vgl. [24]). Die Aussagekraft der Komponentenbewertungen ließe sich erhöhen, indem die betrachteten Tool-Funktionalitäten in einer Testumgebung unter Verwendung realitätsnaher Testdaten im Hinblick auf ihre SIAM-Konformität geprüft würden. Dadurch wäre die Verwendung von Prozentwerten auch für die Komponentenabdeckung möglich, ohne das Evaluationsverfahren substanziell zu verändern.

6 Fazit und Ausblick

Mit dem vorgestellten Evaluationsverfahren lassen sich ITSM-Tools hinsichtlich ihrer Eignung für ein integriertes Management von heterogenen Cloud-Diensten gemäß SIAM systematisch bewerten. Für das exemplarisch betrachtete Kingston wurde ein durchschnittlicher Abdeckungsgrad von 61 Prozent ermittelt, was einer mittelmäßigen Abdeckung von SIAM entspricht. Die weniger vollständigen Visionen anderer ITSM-Tool-Anbieter lassen vermuten, dass die SIAM-Abdeckung bei ITSM-Tools im Allgemeinen noch gering ist. Die starke Fähigkeit einiger Anbieter, ihre Vision umzusetzen, deutet jedoch ein großes Potenzial für eine schnelle Entwicklung der Abdeckung von ITSM-Tools an.

Um diese Folgerungen zu überprüfen, ist es erforderlich, weitere Evaluationen für ITSM-Tools durchzuführen. Auf dieser Basis wäre außerdem eine bessere Klassifizierung des Abdeckungsgrads möglich. Durch den Vergleich der Abdeckungsgrade verschiedener ITSM-Tools ließe sich besser einschätzen, ab bzw. unter welchem kumulierten Abdeckungsgrad ein ITSM-Tool reif bzw. unreif ist.

Für die durchgeführte Evaluation wurde der Fokus auf Domäne 2 des Kriterienkatalogs eingegrenzt. Um die Aussagekraft zu erhöhen, sollten bei weiteren Evaluationen ebenfalls die SIAM-Komponenten der Domänen 1 und 3 einbezogen werden. Des Weiteren erfolgte der Vergleich der SIAM-Komponenten mit den Kingston-Funktionalitäten basierend auf Beschreibungen und demnach subjektiv. Um die Analyseergebnisse zu verbessern, sollten für weitere Evaluationen objektive Bewertungskriterien und -regeln erarbeitet werden. Die praktische Erprobung vorausgewählter ITSM-Tools zur Bewertung der Abdeckung der SIAM-Komponenten ist eine Möglichkeit, eine objektivere und validere Bewertung zu realisieren.

How Software Promotes the Integration of Sustainability in Business Process Management

Maren Stadtländer[1], Thorsten Schoormann[1], and Ralf Knackstedt[1]

{maren.stadtlnder,thorsten.schoormann,ralf.knackstedt}@uni-hildesheim.de

Abstract. Business research and practice increasingly focus on integrating sustainability in organizations. To contribute to rising challenges related to the society and the environment, sustainability-driven concepts (e.g., environmental-friendly) have to be implemented in the daily business routines, and thus, need to be considered during the design of business processes in any organization. In this study, we conceptualize the field of Green Business Process Management (BPM) and use the derived concepts to classify supporting modelling tools and concrete software features. While our study indicates a lack of realization of the ecological and social sustainability in particular and a gap in supporting users during the redesign phase, there are software features that can potentially serve as a starting point to further incorporate sustainability in the design, implementation, and controlling of business processes.

Keywords: Green BPM, Classification, Tool Support, Software Feature.

1 Introduction

Due to complex challenges related to the environment (e.g., climate change) and our society (e.g., human equity) [1], sustainability has become of increasing interest in business research and practice [2, 3]. Facing these challenges, businesses need to transform themselves to allow changes in behaviour and practice as well as to fulfil new demands like being environmentally friendly [2, 4]. Therefore, novel and more sustainable business models need to be developed [5] that not only rethink separated aspects, but rather focus on radical innovations across entire businesses [6]. For implementing such new business models, it is important to align the daily, underlying business routines [7]. Therefore, on an operative level, approaches from business process management (BPM) come into play, contributing to the understanding, modelling, implementing, and optimizing business processes by, for instance, providing methods such as modelling techniques and (software) tools [8–10].

BPM is a widely used approach to develop or change organizational structures as well as increase awareness of business processes [11]. Since business processes are an essential aspect of organizations, it is necessary to properly consider sustainability-driven concepts during the design of such processes [12, 13]—it is assumed that this

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

will eventually lead to a more sustainable organization [14]. To design sustainable processes, an increasing amount of approaches for reducing energy or emissions in particular are proposed, which are typically discussed in the context of *Green BPM* [2, 15]. Green BPM takes a holistic view on the field and aims to respect sustainability across the entire lifecycle [16], for example, by integrating Green Business Process Patterns, Green Process Benchmarking, Key Ecological Indicators, or Energy-Aware Adaption (e.g., [17]). Corresponding modelling notations deal among other aspects with representing fuel or paper consuming activities [18], visualizing CO_2 footprints [19], or calculating energy flows [20] as well as support the representation of environmental impacts by integrating values and key factors for analysing the current state and optimization potential for reaching green goals [13, 15, 16]. To do so, these approaches often deal with adapting existing notations such as Business Process Model and Notation (BPMN) or Event Driven Process Chain (EPC) [16, 18, 21, 22]. Considering sustainability, according to existing literature in the field, also calls for changes to further parts of the six core elements of BPM, e.g., by using Sustainability Balanced Score Cards, adapting the process performance management to include sustainability factors, or drawing from Energy Informatics [17].

For contributing to sustainability in BPM and for applying such notations, following Recker's [23] statement that 'modelling with tools is easier', appropriate software tools need to be provided that fulfil new requirements [22]. However, although there is quite a large set of BPM software as well as different adaptions and extensions towards Green BPM, we currently lack matching these streams. To the best of our knowledge, only very few research studies (e.g., [24]) investigate some selected modelling software and compare it with criteria derived for BPM. Accordingly, this study is guided by the following key question: *How does current BPM software support the design, implementation, and monitoring of business processes in terms of economic, but primarily of ecological and social sustainability?*

For answering this question, as a first step, we conceptualized the field of Green BPM in order to derive types of adaptions, extensions, approaches, and criteria. Based on this conceptualization, we carried out an extensive software tool search and classified a selected subset of these tools. Afterwards, we analysed which software features are currently available and compared them to the derived concepts of Green BPM. Our contribution is a classification that helps academics and practitioners, for instance, to get an overview of available modelling software and to get insights on how to (re-)design current features (tool designer). Overall, we hope that our findings may also act as a starting point for more research on requirements for tools that support sustainability in businesses processes as they are important for any organization.

2 Software Tools for (Green) BPM

In this section, we outline the research background of our article in order to provide an overview of studies that already deal with conceptualizing or addressing both fields software tools for BPM and Green BPM in general.

Starting from a literature review summarizing the current state of Green BPM research [17], we identified an evaluation of supporting process modelling tools [24] and a comparative overview of process simulation tools for Green BPM [25].

Opitz et al. [24] chose BPMN as a suitable modelling language for monitoring energy efficiency KPIs as an instance of ecological process indicators and tested five of over 70 BPMN modelling tools against project-specific criteria. The highest-scoring software, ARIS Business Architect, was later used in three case studies and proved well-suited for Green BPM in the specific case of energy efficiency monitoring. The study, however, focused on the ecological dimension of sustainability, without considering social KPIs.

Lübbecke et al. [25] examined different tools for business process simulation and, upon identifying their limits, developed their own EPC-based approach for decision-making in Green BPM to support process simulation and optimization using an existing simulation tool (*Plant Simulation*) as well as energy consumption data from an external tool. To this purpose, they extended the functionality offered by the simulation tool using the built-in scripting language. However, they recognize the need for further research in order to make the data collection and modelling process easier and enable automated import of simulation data.

Riemer et al. [26] have conducted a review of BPM tools, analysing which functionality is used in order to support the (collaborative) modelling process. The tools for this review were discovered through an internet and literature search and underwent a filtering and classification process in which, starting from an initial set of criteria, each tool was evaluated. The criteria set evolved throughout this process by supplementing additional criteria and reclassifying already evaluated tools. The final set consisted of three subsets (process modelling, collaboration, and technical criteria), while the final list of evaluated software contained 11 process modelling tools. Drawing from their results, Riemer et al. [26] not only propose an extensive list of features in process modelling software focusing on collaborative modelling, but were also able to develop a high-level architecture of collaborative process modelling tool support.

3 Research Design

3.1 Conceptualizing Green BPM

As a first step, we applied a deductive approach to derive dimensions and characteristics from prior studies that are related to Green BPM. We initially focused on existing reviews and meta-analysis of Green BPM that already aim to summarize knowledge. To do so, we selected search items [27] and searched for the keywords *"green business process management"*, *"green BPM"*, and *"literature review"* in AISeL and Google Scholar (search was conducted in July 2018). By employing this search phrase, we identified 57 articles across both sources. These articles were evaluated by reading the title, abstract, and keywords. Articles that are not in the scope of this study were eliminated. Afterwards, we obtained seven articles that met our purpose of structuring different concepts of Green BPM [16, 17, 24, 28–31].

Next, we independently analysed the results to obtain fundamental concepts of Green BPM and consolidated the results to achieve a common understanding (Table 1). In the following stages, these concepts are used as a coding schema to identify features that should be implemented by software tools in the context of Green BPM.

Table 1. Consolidated concepts for Green BPM based on prior literature

Concept	*Description*	*Reference*
Notation adaptation	Adapting modelling notation elements (e.g., BPMN, UML, or EPC) for representing sustainability.	[17, 24, 28, 30, 31]
Notation extension	Extending modelling notations (e.g., adding new elements) for representing sustainability.	[17, 28, 30, 31]
Process calculation	Describing indicators and their (mathematical) relations in a formal way (e.g., to enable simulation).	[31, 32]
Process simulation	Simulating process parts and entire business process models for analysing sustainability.	[16, 17, 24]
Process optimization	Optimizing processes regarding their sustainable impact.	[30, 32]
Process benchmark	Benchmarking different processes in respect of sustainability.	[17, 29]
Process pattern	Adding patterns to apply existing knowledge to enhance processes towards sustainability.	[17, 31]
Process performance	Developed and/or adopted performance measurement methods to capture sustainable process performance.	[30]
Process indicator	Developing and analysing Green BPM indicators e.g.: *Ecological*: {energy, water, waste, resources, power usage, fuel, paper, oil, toxic} consumption; {CO_2, GHG, greenhouse, noise} emissions; recycling, air quality, renewable resources … *Social*: accidents, radiation, workforce size, health, safety, education, earnings, equity …	[17, 24, 28–32]
BPM Lifecycle Extension	Extending existing BPM lifecycles and frameworks to respect sustainability goals.	[28, 30]

3.2 Gathering BPM Software Tools

Due to the large number of available software tools for BPM, we decided to focus on tools using one specific process modelling language, namely, BPMN. Although further graphical languages such as EPC, UML, and Petri Nets exists, BPMN 2.0 is well-accepted in the context of BPM [33], and thus, selected in this study.

A Google search was conducted to reach a broad overview using combinations of the search items "*BPMN 2.0*", "*software*" (as well as the synonyms "*tool*" and "*program*"), and "*model*" (as well as derived terms such as "*modeling*/*modelling*").

Initially, after examining the first nine pages—that is, 90 individual web pages—an unevaluated list of 90 modelling tools was derived.[1]

After collecting the first results, each tool was examined. If a tool was no longer available but substituted with a new or updated version, the tool was replaced by the current software version. Tools that are part of a tool family, of which several tools allow for BPMN 2.0 modelling, were split accordingly. Software that no longer includes BPMN 2.0 modelling or was mistakenly marked as such was removed from the list. The list was cross-checked against a more extensive overview of modelling tools for various notations, leading to some additions.

The information on all tools was gathered from the software suppliers' websites and additional sources, such as product-related blogs (e.g., [34]) and studies [35, 36]. Due to financial and temporal constraints, the list for the analysis was narrowed down to 24 tools of which the majority is freely available. This choice was made because (1) academic modellers often use free software due to financial restrictions and higher perceived cost-effectiveness as well as (2) we would argue that especially (green) start-ups often lack the funds to acquire expensive software. For selection, the tools were grouped by the type of software (client, web-based, cloud-based, other, n. s.; though n. s. and cloud-based were excluded) and randomly selected in relation to the percentage of tools in each group. During the detailed analysis, *FujitsuRunMyProcesses* was removed as the current version does not support BPMN 2.0 anymore. Thus, only four shareware products remained.

3.3 Deriving Features for the Green BPM Concepts

For deriving software features, each tool was analysed regarding the concepts (cf. Section 3.1) in an inductive manner (i.e., empirically seeking for related software features). To do so, the modelling of a scenario—a simple artificial purchase and return process—guided this search, which was executed by the paper's main author. For modelling the scenario, the modeller had to carry out four main tasks, which attempt to cover all of the identified concepts: First, several sustainability performance indicators need to be included. Second, existing notation elements should be adapted and new elements need to be added. Third, the process should be monitored, simulated, automated, and analysed. Fourth, patterns and process optimization techniques need to be used. Thus, all defined concepts were covered by the case. Using the concept-based scenario, the supporting features were identified: if the software enabled fulfilling the concept—i.e., if it included a feature that could be used to model the new elements, performance indicators, or to monitor, simulate, or analyse the process etc.—the feature used was noted down. The features were accordingly clustered into groups (cf. Table 3, Section 4). On average, it took 20 minutes to examine each tool.

[1] Several institutions provide extensive lists of BPM software tools (e.g., Fraunhofer Institute or BPM&O GmbH). These lists were also included in our research.

4 Results

In Table 2, the results for each of the 23 software tools in our sample is summarized. For the classification, we particularly built on the conceptualization (cf. Section 3.1) and differentiated between the following five main dimensions:

- *Sustainability*—the first dimension differentiates between the common pillars of sustainability, namely, economic, ecological, and social (e.g., Triple Bottom Line), to indicate which type of sustainability is generally addressed by a software tool.
- *BPM lifecycle*—the second dimension makes use of the BPM phases from Dumas et al. [37] in order to visualize in which activity a software tool provides support.
- *Notation*—in the third dimension, we distinguish between adaptable (are notation elements modifiable?), extendable (can new notation elements be added?), and process patterns (included by the software manufacturer, community or modeller) to indicate how sustainability can be integrated in a modelling technique. The ability to modify or add notation elements may, among other things, indicate how much flexibility a user has to integrate their own ideas of how to depict sustainability.
- *Analysis*—the fourth dimension, for analysing business processes, differentiates between calculation (e.g., calculation of sustainability-specific variables), simulation (complete process simulation), animation (e.g., clicking through process paths), and comparison (of two or more process models, for example, through comparing simulation results). Especially simulation and comparison features may help a user to consider the ecological or social impact of their processes before implementation and enable them to compare different versions.
- *Performance indicators*—in the fifth dimension, we first aim to represent how indicators can be used by users and distinguish between usable as-is (e.g., if the tool offers an indicator), adoptable (an existing indicator may be repurposed), or extendable (new indicators may be added). This way, we may learn how difficult and/or time-consuming the use of sustainability indicators is in current tools. Further, we explored if software tools allow measuring specific ecological and social indicators found in the literature.

Moreover, to illustrate (1) how the sustainability-oriented concepts are realized by concrete software features and (2) how these are distributed in the tools (e.g., to indicate which features are often implemented as well as which features are rather neglected by software tools), we developed a morphological box (Table 3).

By using the morphological box, we aim to provide more detailed guidance on how features can be applied to contribute to sustainability in processes. Changing the colour of elements (here understood as process steps) and annotating processes (here understood as complete processes) represent easily implemented ways of highlighting (less) sustainable parts of the process. A user may, for example, decide to set the colour of process steps perceived as unsustainable to red, or add annotations (often in the form of virtual post-its or notes) describing social or ecological implications. More complex features such as calculating green KPIs during simulation or process execution, support sustainability monitoring and selecting a process with a better impact.

Table 3. Features for implementing the Green BPM-concepts

Concept	*Software featuress*				
Notation adaptation	changing colour of elements (10/23)	adapting BPMN tasks/events to trigger automated reports (1/23)	linking elements with other processes/other resources[1] (6/23)	annotating[1] (12/23)	
Notation extension	adding new elements (4/23)	adding new business objects/process variables (4/23)	adapting elements from elements of other notations (7/23)	adding views (1/23)	
Process calculation	calculating via simulation (5/23)	calculating during process execution (3/23)	generating reports (2/23)	calculating single variables (3/23)	calculating all variables (5/23)
Process simulation	using own simulation engine (7/23)	using external simulation plugin (1/23)	simulating to generate KPIs/ variables (6/23)	checking correctness via simulation[1] (1+/23)[2]	simulating reports (1/23)
Process optimization	using built-in comparison (1/23)	using built-in improvement feature (1/23)	importing customized process pattern catalogues (1/23)		
Process benchmark	using built-in comparison (1/23)	using external comparison (0/23)			
Process indicator	using implemented KPIs (5/23)	extending a set of business/process variables/KPIs: calculable (6/23)	extending a set of business/process variables/KPIs: non-calculable (2/23)	adopting risk models (3/23)	
Legend:	0	1-4	5-8	9-12	>12

5 Discussion and Implications

5.1 Describing the Current State of Software Tools for BPMN

Based on our analysis, the following main observations emerged: First, while most tools in our sample focus on *discovery* and *analysis*, the phase of *redesign* in the BPM lifecycle is rather neglected in current BPMN software, which complicates revising existing business processes towards sustainability. For instance, users may compare two versions of a process diagram—manually or by comparing simulation results—but only one software offers an option for redesign by allowing to include a library of process patterns. The process patterns included in other tools only consist of general workflow patterns, intended rather for saving time while modelling than for redesign.

Second, for visualization and increasing the awareness of sustainability-oriented aspects in current business processes, a number of tools allow applying elements of other notations or self-created elements. Extending the notation can be carried out by modelling the new elements in the BMPN 2.0 diagram itself, or by referencing between processes or process elements and elements within diagrams of other types. However, repurposing or creating elements defined by single users and not the software provider

1 Adapted from Riemer et al. [26].

2 As this feature was not part of our analysis criteria and the modelled example process, we cannot give the exact number of tools implementing it.

themselves, would most likely not be shared with a broader community of business process modellers, thus encouraging isolated (and heterogeneous) application.

Third, sustainability indicators are rarely implemented in our sample, with economic indicators (e.g., costs and time) outweighing ecological and social ones. This is surprising because in contrast to the tools research exists that already explores, for example, key ecological indicators in the context of BPM (e.g., [16]). The tools that contain indicators for costs use pre-set variables, often dubbed as 'resource KPI', 'KPI', or 'business variable'. Only *Prologics FireStart* includes one pre-set ecological indicator ('Umweltindex') in the form of a (unspecified) scale from 1 to 10, which leaves the interpretation open for users. Some other tools allow adding own indicators by using variables referencing risk model elements (including ecological, economic, and social risks, as defined by the modeller). In some cases, where no indicators for social or ecological sustainability exist by default, features are incorporated that may be repurposed to act as indicators: most notably risk models, user-created process variables, objects, or KPIs, or analysable extension fields. These would need to be explicitly created and adapted by the modeller. While this adaptation and repurposing enables, for example, the highlighting of fuel and paper consuming activities [18] or calculation of energy flows [20] as described in the literature, the lack of pre-installed extensions and examples for sustainability indicators may hinder reflection of ecological or social aspects within the modelling process.

5.2 Deriving a Preliminary Set of Requirements for BPM Software Tools

Based on our findings from exploring a sample of current software tools for BPM as well as comparing them with sustainability-oriented concepts that are grounded in previous literature, we aim to specify a first set of (new) requirements for such tools:

- *Integrated catalogue of Green BP Patterns*—Implementing a pre-installed catalogue of green patterns in order to support users to, for example, identify potential for improvement of current processes as well as get ideas on how to improve current deficits in terms of ecological and social sustainability (e.g., [25, 27, 38]).
- *Sustainability-oriented performance indicators*—Including pre-installed indicators for ecological and social sustainability in order to facilitate, for example, the measurement of business process outcomes (e.g., as researched in [17, 24, 28–32]).
- *Comparison of process variants*—Providing feature(s) for comparing the ecological, economic, and social impact of different processes or process variants in order to support the users in making informed decisions for the redesign.
- *Data import*—Implementing interfaces for (automatic) import of data related to sustainability-oriented indicators, for instance from sources like energy monitoring systems, to support both process simulation and real-time monitoring.
- *Sustainability-driven constructs*—Providing notations to visualize ecological (e.g., resource consumption) and social aspects (e.g., workplace conditions) in processes.

Of course, this set of requirements for software tools supporting Green GPM needs to be evaluated in future steps, for example, by building prototypes that instantiate derived requirements and demonstrate the utility of them (e.g., [39]).

6 Conclusion

In this study, we first conceptualized Green BPM and classified a sample of 23 existing BPMN 2.0 software tools in order to analyse the degree of satisfying the needs of Green BPM. Our results have yielded gaps in the support of Green BPM, especially in terms of social and ecological sustainability. Based on our results, we formulated a first set of requirements for such a class of software tools that need to be evaluated in future research. The analysis may help users who want to focus on the sustainability of their processes over the course of the BPM lifecycle to get an overview of suitable modelling software or how to reuse certain existing features for this purpose. Furthermore, it offers a guidance for software designers and researchers on where to begin enhancing existing software for Green BPM or designing altogether more sustainable modelling software.

Although we derived helpful insights for the field of Green BPM, this study is not free of limitations. First, the analysis mostly covers freeware tools, which may have a limited range of features compared to shareware software. Nevertheless, we aimed to select a representative set of tools as well as would argue that, for instance, start-ups with limited financial resources addressing sustainability might need freeware tools to support the operationalization of their ideas. Second, although we specified relevant concepts that should be implemented in software by reviewing previous literature, there might be more aspects that need to be considered in such tools. Third, the identification of corresponding features is based on own interpretations and decisions, which also have limitations (e.g., other researchers might identify more software features).

In future research, we plan to expand and evaluate the list of modelling software as well as the preliminary set of requirements. Using our analysis as a first step, it is now possible to generate guidelines for designing and developing BPM software that helps users examine ecological and social aspects and to examine the potential and necessity of implementing further sustainability indicators (e.g., as suggested by the Global Reporting Initiative). This is a necessary step in order to introduce a proactive consideration of multidimensional sustainability into the routine of organizations.

Abstract. Through providing digital services, machine tool manufacturing companies can address the customer demands for individual solutions and the increasing cost pressure. Applications are one way to provide these digital services, running on smart machine tools connected to software systems, known as industrial Internet of Things (iIoT) platforms. Despite the growing potential of iIoT platforms in the provision of industrial digital services and the increasing awareness of the platform approach among manufacturing companies, lack of requirements makes the platform challengeable for machine tool companies. Moreover, the domain specific industrial application of platforms has been limitedly researched, indicating a possible research gap. This paper presents a literature-based research on requirements for iIoT platforms, followed by the solution-oriented metrics, to fulfill each requirement. Together, the requirements and metrics form a structured criteria catalog for iIoT platforms, which can be used as a decision support tool for the machine tool industry.

Keywords: Platform Ecosystem, industrial IoT Platform, IoT Ecosystem, Criteria Catalog, Smart Machine Tool.

1 Introduction

1.1 Research Gap and industrial problem setting

Current machine tool manufacturing companies are challenged by the increasing product variety, offered by original equipment manufacturers (OEM) in different industries, and the related flexibility for their own products [1]. Customer demand for custom solutions, as well as the increasing role of the after-sales services in the competition, were also surveyed for the mechanical engineering industry by the German Mechanical Engineering Industry Association (VDMA) and McKinsey [2]. A machine tool manufacturer could address these challenges by offering digital or smart services within its service portfolio. Current empirical studies show a high interest within the machine tool industry to offer digital services to monitor machine data, in order to improve manufacturing processes [2-3]. Smart machine tools are estimated to increase machine productivity and life by about 5%, reduce maintenance costs by 10-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

40% and reduce the energy consumption by 20% [4]. Such smart and connected machine tools are equipped with embedded computers and networks, monitoring and affecting physical processes to achieve the improvements mentioned above, through digital applications [5]. The possibility to increase the flexibility turns smart machine tools into platforms, being simultaneously a product (machine tool) and a platform (modular extension through applications) [6]. Smart machine tools are also closely related to the concept of cyber-physical systems (CPS), as they can be controlled remotely and communicate with surrounding systems and the physical world [7].

However, as various case studies show, various companies have failed to establish successful platforms in the past [8]. Current state of the market on iIoT platforms pictures its highly fragmented state, thus including more than 450 iIoT platforms available on the market [9]. In contrast to the current state of the market for iIoT platforms, platform-based markets are rather affected by the "winner-takes-all" competition logic of a platform-providing keystone company [10]. Due to the high fragmentation of the market, the right choice and utilization of an iIoT platform is a challenging task for machine tool companies and represents an entry-barrier for a provision of platform-based digital services in the after-sales. The practical problem from the perspective of the collaborative customer in the iIoT lies in the complexity during the platform selection process. On the other hand, the variety of iIoT platforms makes it difficult for the iIoT platform providers to gain significant market share, becoming a "platform leader" [11]. From the research perspective, previous scientific work on platforms focuses primarily on business-to-consumer (B2C) industries and the information technology (IT) cases [12-13], while the consideration of specific industrial requirements in the area of platforms still need further research. Additionally, the empirical studies also highlight the fact, that providing smart services through digital applications is a challenge for machine tool manufacturing companies, since 59% of those surveyed do not offer market ready solutions [2]. Considering these factors, there is an apparent need for research on these platforms for smart connected machine tools.

1.2 Research Questions and Structure

The main goal of this paper is to provide a criteria catalog for iIoT platforms as a decision support tool in the domain of smart connected machine tools, based on the definition of two research questions:

- RQ1: What are the relevant platform criteria for smart machine tools?
- RQ2: Which metrics fulfill the criteria identified in RQ1?

The second section of this paper describes major concepts and research streams, related to iIoT platforms. The first research question is addressed in the third section. Firstly, the research design of the conducted literature analysis is described, followed by the extraction of the relevant criteria. The section after that focuses on the relevant metrics of each identified criterion. These metrics provide a more detailed description of each criterion and allow a systematical application of the criteria for instance during a selection process of an iIoT platform from the perspective of a mechanical engineering company. Together, the criteria and the assigned metrics are building a structured criteria catalog with relevant criteria for an application of the platform approach for smart machine tools. The criteria catalog builds the artefact of this paper. The scientific approach to achieve the first artefact is a structured literature analysis.

The overall scientific contribution of this paper is an extension of platform research for the industrial application. The focus on smart machine tools is justified due to the high importance of the industrial IoT in this industry and could be adjusted to other manufacturing industries.

2 Theoretical background and related concepts

This contribution relies on three major concepts related to the iIoT platforms, which are explained in this section: CPS, iIoT and technological platforms.

As mentioned in the introduction, the provision of customized solutions requires machine tool companies to extract data from machine tools and use this data to control them. This is achieved due to sensors, actuators, embedded computational power and connection of a machine tool to external data-processing platforms, thus creating loops between the physical assets (machine tools) and their digital counterparts [7, 14]. The analyzed machine data can be used for autonomous parameter change of the machine by the actuators. This goes beyond the traditional automation technology of machine tools. Hence, such machine tools are defined as smart and fit the definition of CPS.

The integration of CPS in machine tools is also related to the concept of iIoT. IoT is a paradigm of the integration of internet and communication technologies (ICT) and real-time data analytics in physical assets. The application of IoT on industrial assets in the manufacturing builds the concept of iIoT [15]. Even though, IoT can be applied in various industries [16], this paper is domain specific and is based on the application of IoT in the machine tool industry. Smart machine tools, in the context of iIoT (beyond the simple automation) are able to track various sensor data, monitoring the machine itself, the manufacturing process and the quality of the manufactured product [17] and this data can be used for digital services. However, the historical evaluation of sensor-based data and the provision of the analyzed data as a service to external companies requires additional software systems [18], known as iIoT platforms.

The data analysis and related visualization are hosted as platform-based applications, which can be developed by third-party companies. Therefore, iIoT platforms are related to the technology platforms concept, defined by Cusumano and Gawer [11] and platform-based innovation by the ecosystem [13]. This concept builds the third related theoretical concept of this contribution. According to this definition, technological platforms provide a dominant technology, including industry standards and transforming them into a complete customer solution. The provider of a technological platform is considered as a keystone company [19]. Due to the control over the platform, the platform-providing keystone company is enabled to form alliances and partnerships with third-party companies, which are considered as competing complementors, consequently building a platform-based ecosystem [13]. The participation of third-party companies is supported by the modular design of technological platforms, which in the case of iIoT is represented by platform-based applications. Those modular applications extend the value of the platform through network effects [20]: if for instance an application for cost reducing condition monitoring of a machine tool is presented in the application store of an iIoT platform, more machine tool companies would consider using the platform. Similarly, more developers would complement to the iIoT platform, if a platform-based ecosystems contains enough application customers. In order to enable such a complementary third-party development of complementary modules, the interfaces of the platform have to be open. The platform provider is in the position to determine how to share the interface specifications with the third-party companies. Empirical examples of iIoT platforms, as Mindpshere (Siemens) or Thingworx (PTC) correspond to the both classifications of open technological platforms, providing specification and tools for the integration of application by complementary third-party companies [21-22]. In addition, the application stores of both iIoT platforms show exemplary applications, provided by third-party companies [21-22]. Therefore, iIoT platforms fit into the theoretical concept of open technological platforms.

3 Creating the Platform Criteria Catalog for Machine Tools

3.1 Research Methodology

The aim of the literature review is the identification of the current state of research towards the derivation of relevant criteria for platforms for machine tools based on the found literature. The structured literature research approach is sophisticated, reproducible, systematic, transparent and scientific [23-24].

The methodological approach used in this work follows the scientific work of Webster and Watson [25]. In addition, the approach is based on the work of Rashman et al., Soni and Kodali [26-27] and Winter and Knemeyer [28]. The review period for the literature review is between January 2002 and December 2017, thus covering 15 years. The reason for choosing the year 2002 as the start point is that Gawer and Cusumano distinguish different platform types in their work and subdivide platforms into internal platforms, supply chain platforms and industry platforms in that year [11]. As stated above the platforms are examined in an industrial application context. For this reason, the focus of the platform analysis is the current state of practice in regard to the classification of the platforms according [11]. Therefore, the start date can be set to 2002, since it is ensured that the term industry platform does not exist before 2002. The reason for choosing December 2017 as the end date is that the latest scientific publications should be considered in order to develop the broadest possible set of criteria and this was the current date during the review period.

Three different databases are used to conduct the structured literature research: Business Source Premier (EBSCOhost), IEEE Xplore and Science Direct. Google Scholar is also included in the research to get a broader overview of existing relevant articles and include relevant papers, which are not covered by the three databases. Business Source Premier includes a large number of business, finance and management journals and is therefore selected. To cover the technical area in relation to CPS and the industrial context, Science Direct, which includes articles on technical and engineering subjects, is also included in the research. IEEE Xplore provides articles on the world's most cited publications in electrical engineering, computer science and electronics and completes the research. The databases are searched using the following terms: "Industry Platform", "IoT Platform", "Service Ecosystem", "Service Platform" and "Software Ecosystem"; linked by the Boolean operator AND with the following terms: "Cyber Physical System", "Industrial Internet of Things", "Industry 4.0", "Machine Tools" and "Smart Manufacturing". Only English-language articles are considered.

3.2 Results from the Literature

The review process returns 147 articles after the removal of duplicates. For this purpose, the title, the abstract and the conclusion are read first from each of the 147 articles. Looking at the titles, abstracts, and conclusions, many of the articles found do not address RQ1. Therefore, 125 articles are excluded, leaving a sample of 22 articles. The backward search on the related work lists of the identified 22 articles, followed by the forward search using Google Scholar, identifies six additional articles. The sample therefore contains 28 articles, which are completely analyzed. After reading through the articles completely, another seven articles can be excluded because their contribution cannot be used for RQ1. In the end, 21 articles provide possible relevant examination criteria for intelligent machine tool platforms. However, the search includes articles which do not explicitly refer to embedded systems in the machine tool industry, but provide general criteria, which can be relevant for open platforms for intelligent machine tools. The following matrix, as proposed by Webster and Watson, depicts the found criteria and the relevant articles.

The examined articles describe criteria for intelligent machine tools highlighting various perspectives on this field. These perspectives can be classified as CPS in manufacturing, Software-Product-Service-Systems, industrial IoT Platforms, service platforms for machine tools or they offer a generic view on platforms or software ecosystems. After the detailed analysis of the described concepts in the literature, 13 identified requirements are grouped in six criteria for the machine tool platform approach, which are depicted in the following table:

Table 1. Platform criteria list for intelligent machine tools

ID	*Criterion*	*Sources*
1	Security of the platform	[29-33], [36], [39-40], [43-49]
2	Modularity of the platform	[30], [32-37], [41-42], [45], [47-49]
3	Degree of openness (Platform and Interfaces)	[29-30], [32-35], [37-38], [42-44]
4	Functionalities on the platform	[29-30], [32-33], [36], [39-40], [45], [47]
5	Range of the platform	[30], [32], [36]
6	Autonomy of all stakeholders	[35], [37]

- **Security of the platform:** Data security, information security, system security and quality assurance measures could be summed up to a key criterion “Security of the platform". It seems to be currently the most commonly cited criterion in the literature (15 of the 21 articles). Some articles describe the aspects of safety and protection of sensitive production data as the most urgent challenge for platforms [40, 48] and some consider the data processing security of CPS as an important challenge [45]. Quality assurance as a criterion, which was also cited in six articles, additionally contributes to the safety of the platform. If the open platform brings various companies (for example a machine tool company and a third-party software company) quality assurance plays an important role. If a platform could internally assist the machine tool manufacturer in achieving quality measures on third party applications, it could increase the trust of the machine tool manufacturer in the externally developed software modules. System safety means the security of the machine to its environment and ensures no persons or work pieces are harmed by incorrectly programmed software. A failure could result in serious material or personal damage [29, 44]. However, as the literature mostly states the data security and the information security, the system security will be summed up under the generic term "Security of the platform".

- **Modularity of the Platform:** Modularity also increases the scalability of a platform, which is why both terms are summed up as in the criterion a "Modularity of the Platform". Modularity seems to be an important subject of research, as it is mentioned in 13 articles. The scalability of the platform does not currently seem to attract much attention, being stated in just one article. In order to develop a uniform knowledge base for an intelligent machine tool, various companies collaborate on the open platform across numerous corporate boundaries [30, 32, 36]. The modularity of an open platform for intelligent machine tool is necessary to use the different capabilities of the involved actors as third-party software developers or sensor manufacturers and to reduce the complexity for the machine tool manufacturer. It is also discussed that platforms enable synergies between all those involved companies and can lead to more innovations [34]. Though modularity leads to a reduction of the technological complexity of the intelligent machine tool, it simultaneously increases the management and governance complexity of the platform, which can also be a major challenge for a machine tool company, as it requires additional management efforts. Finally, the intelligent machine tool has to be manageable despite its modularity and the resulting platform complexity [34]. An intelligent machine tool produces great amounts of data that has to be stored, processed and analyzed, which could present a major challenge for a manufacturer. Consequently, the platform should handle this challenge and deliver scalable resources [36]. Moreover, it becomes important for the manufacturing company to decide which modules should be developed on his own and which should be outsourced to third party companies.
- **Degree of Openness (Platform and Interfaces):** This criterion sums up openness and the integration of the platform. During the life cycle of a platform, the degree of openness can change. It could make sense to keep the platform more closed in the beginning, until it gathers a certain amount of early adopting users and developers and open it afterwards. For a mature platform with a large group of developers and users it is preferable to increase the openness, as it generates more overall value for

all involved stakeholders, through increased innovation [44]. A high degree of openness with uniform standards helps to improve the efficiency of the integration of the intelligent machine tool as a platform in the systems operated by the customer [29, 32] (for instance manufacturing execution systems or other information systems). Moreover, it helps to access all the capabilities, know-how and data with a platform-based ecosystem with a smaller investment [36-38]. In order to attract a large number of complementing third-party companies, it is recommended to provide good documentation and interfaces for the complementors [30]. A lower degree of openness requires a higher beginning invest, though it can result in a competitive advantage through the full control of development modules of a platform [38] and preventing the unsuitable complementors to access the platform [30]. Additionally, empirical analyses show the dominant usage of closed platforms by manufacturing companies, preferring to restrict the degree of openness of the platform and to collaborate only with specific partners [35, 42].

- **Functionalities on the Platform:** Functionalities unite the user interface (UI), the functionality, support and services and the test environment and test access. According to the UI as a criterion the platform services and the machine tool interface should be understandable and easy to use for the user [30]. It is also recommended to provide the machine data analysis in the browser, making it accessible with mobile devices, in order to improve the UI [39, 45]. Functionality represents the variety of analysis options and applications for the customer. The support and services target two groups. On the one hand, the customer of smart connected machine tools could require support regarding the maintenance of the intelligence of smart connected machine tools [32]. On the other hand, the complementing third-party companies could require support of a platform provider during the development. A test environment is important for the customer of a smart machine to test, whether the platform sufficiently supports the required functionality, consequently reducing the risk of bad investment and sunken costs. The complementing third-party software company could also test their prototypes and reduce their risks and training costs [29-30].
- **Range of the Platform:** The range increases the awareness level of the platform among the customers and complementing third-party companies, which indicated to what extent the platform can prevail in the future as a standard. Uniform interfaces and industry standards are required to achieve high range of a platform, thus increasing the platform complexity for the platform provider [30, 36]. These uniform standards can only be enforced if the platform has a certain reach and market share. Support in terms of quality assurance by the keystone also increases the range [30].
- **Autonomy of all Stakeholders:** All participating stakeholders are autonomous to the platform and can independently decide, whether and how they participate in the platform ecosystem. This boosts the innovative strength within the platform, due to the resulting competition [37]. If not prevented, autonomous stakeholders will either complement or even compete with their complementary innovation with the platform provider. However, high degree of autonomy of the stakeholders, increases the competition and results in higher degree of platform-based innovation [37]. Furthermore, the positively perceived autonomy of the stakeholders, can be used by

the keystone and by the complementing stakeholders to attract new stakeholders in the platform-based ecosystem, because this indicates lower dependency risks for the stakeholders [35].

3.3 Matching Requirements and Metrics to Create a Criteria Catalog

The platform provider should fulfill all the identified criteria. Hence, this section provides metrics for each criterion. This paper uses the term metrics to describe solutions, currently offered by the platform providers, in order to fulfill the requirements for a platform in the area of smart machine tools. The criteria with their metrics form the criteria catalog, thus answering the RQ2 and representing the artefact of this contribution. The identification of the metrics is based on two relevant articles [8, 50], which were congruently identified through the literature research. Both articles build the foundation for the application of solution-oriented metrics on the identified criteria for two reasons. Firstly, both articles use a similar approach, separating requirements and solutions from each other. This approach matches with a core principle in the quality function deployment (QFD). QFD separates neutral requirements from the product-specific solutions. The application of the core principle of QFD is justified by the higher efficiency of this of this method during the product development in terms of customer satisfaction [51], which seems suitable considering the high fragmentation state of the market for iIoT platforms. Furthermore, the application of QFD on software design in the past [51]. Secondly, both articles list comparable platform criteria to those identified in this paper. The following table presents the criteria catalog with the metrics, which are suited to fulfill each criterion.

Table 2. Criteria catalog including metrics

ID	*Criterion*	*Metrics*
1	Security of the platform	Backup & Recovery Data encryption Threat prevention Traceability Management of access roles and rights Single-Sign-On Existing evaluation possibilities Existing certifications
2	Modularity of the platform	Scoping the ratio between own and external development Modular machine tool design (hardware) Specification of design principles
3	Degree of openness (platform and interfaces)	APIs for expanding the connected smart machine tool Functional description of the APIs Integration possibility of non-platform machine tools Technical description of the APIs Support of various formats for data exchange Presence of standards

		Accessibility of the platform
4	Functionalities on the platform	Uniform user interface
		Social media connection
		Systems for functional testing possibilities
		Test access to the platform or a demo version
		Trainings and Certifications
		Support and transaction processing by the platform
		Availability of a help desk for complementors
		Cooperation in development
5	Range of the platform	Number of end users
		Number of complementors and partners
6	Autonomy of all stakeholders	Autonomy of complementors

4 Conclusions and Further Research Outlook

The overall benefit of this paper is a structured criteria catalog, suitable for researchers and practitioners to benchmark the highly dynamic market for iIoT platforms, identify relevant concrete criteria of a platform a improve the platform selection process for a company, connecting its assets as the smart machine tools with the platform. Moreover, the criteria could also address the platform providing companies. The business model development of a platform providing company for instance could use the results to uncover similarities between the iIoT platforms and to change them, in order to differentiate the platform from the competition.

The results of this paper are surely limited, concerning the subjectivity in the choice of search terms. Additional search terms could reveal additional relevant criteria, which were not identified. In addition, the structured literature search is limited by the exclusion of German articles from engineering conferences, which also have strong research interest in the integration of a platform approach for smart connected machine tools. The literature analysis also does not consider some viewing levels on platforms, as platform governance or interactions of the platform ecosystem with its environment [50, 51], which could also influence the criteria or extend the catalog. However, the elaborated criteria catalog could influence the platform governance, as it has a strong intersection with the degree of the openness and the architecture of a platform [10]. The limited search period providers additional constraints, as it does not consider the high dynamics in the market of iIoT platforms, excluding newest possible metrics or features, implemented and introduced during 2018. Therefore, criteria and corresponding solution-oriented metrics introduced after the end of the search period are not included in the catalog. Moreover, the application of the catalog still needs an empirical validation, which is not addressed in this paper. Against these limitations, a follow-up multiple-case study on market-ready iIoT platforms would provide potential topics for future research. Consequently, the application of the criteria catalogue and the evaluation of the application will be the next steps. These steps would provide additional managerial implications for the iIoT platform-providing companies and offer potential for further development of the catalog.

The results also provide a foundation for an empirical evaluation of the researched criteria. Manufacturing companies could be suitable candidates for an empirical study in the future with the goal to extend and to prioritize the researched criteria.

Privacy-friendly User Location Tracking with Smart Devices: The BeaT Prototype

Jan H. Betzing[1], Marco Niemann[1], and C. Ingo Berendes[2]

`Ingo.berendes@upb.de`

Abstract. Customers use smart devices to share their location data with service providers to co-create personalized, location-based services. However, mobile apps that record movement profiles not only yield value-added service but also bear potential for abuse. Especially apps utilizing GPS-based tracking pose a privacy risk because they could–once enabled–unnoticeably record data in private situations. In response, we developed a privacy-friendly solution, called *BeaT*, that tracks user locations without GPS and gives users full control over the time and scope of data collection. We leverage Bluetooth Beacon technology to confine the perimeter in which tracking takes place. This paper presents the requirements, algorithmic design, prototypical implementation, real-world use case, and evaluation setting for BeaT.

Keywords: User Location Tracking, Location-based Service, Privacy, Smart Device, Bluetooth Low Energy Beacon

1 User Location Tracking–Friend or Foe?

Navigating by smart device or tracking a run in a fitness app are exemplary location-based services (LBS) where users share their location with service providers [1]. Even though service providers are limited in data exploration by data-protection regulations (e.g., required user consent and opt-in to data sharing), privacy risks and potentials for abuse remain [2,3]. Notably, once a mobile app has been granted permanent access to the GPS sensor, it can access the user's location even in private situations. As seen in the case of the fitness-tracking app Strava, unrestricted user tracking can–in the worst case–expose classified information such as the location of secret US military bases [4].

In response, this paper presents *BeaT, a privacy-friendly user location tracking mechanism for smart devices*, and its application in the smartmarket[2] research project, in which the authors developed a LBS for high street customers to track their shopping trips [see 3,5]. In addition to retail, BeaT can also be applied in other sectors such as healthcare or hospitality management to track time-logical user movement sequences.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Motivated by the disadvantages of existing solutions, we state the requirements for BeaT as follows: First, to prevent tracking in private situations, the solution must not use satellite or WiFi-based geolocation or access acoustic and visual sensors (R1). Additionally, the tracking perimeter should be defined ex-ante (R2). Second, while GPS only supports outdoor tracking, we want to track both indoor and outdoor locations (R3). Third, some LBS such as Foursquare use check-ins, i.e., users manually record the places they are visiting [1]. While this mechanism accounts for user control, it lacks convenience. Consequently, our solution should provide automatic tracking (R4) while retaining users' full control regarding the time and scope of data collection (R5). Fourth, users associate LBS such as navigation or AR games (e.g., Pokémon Go) with battery drain [6]. Our solution should limit mobile resource utilization regarding processing power, memory, (mobile) data, and battery to foster user acceptance (R6).

2 Prototypical Design and Implementation

2.1 Technology Selection and Setting

We selected Bluetooth Low Energy (BLE) beacons as the underlying tracking technology because (1) smart devices support the technology for a few years [7]; (2) beacons do not reach into private spaces (R1) as they have to be actively deployed in the perimeter within which tracking should commence (R2); (3) the BLE protocol has low mobile resource utilization (R6); and (4) beacons allow for both indoor and outdoor tracking (R3). Beacons are small low-range radio-frequency transmitters that frequently broadcast a predefined payload, consisting of a Universally Unique Identifier (UUID) and two alphanumeric values called major and minor [7]. Nearby devices can receive the signal, calculate their proximity to the beacon, and reason upon the payload [3].

In the smartmarket² case, customers can record their journey across multiple retailers that are geographically dispersed along the high street [5,8]. In return for their data, customers receive personalized offers from nearby stores. Beacon major values identify the store whereas beacon minor values indicate the purpose and location of a beacon (outside at an entrance, inside at a PoI, inside at a PoS) [3]. These purposes allow to distinguish customers passing by, entering a store, traversing a Point of Interest (PoI) such as a promotional display within a store, and visiting a Point of Sale (PoS). Additionally, a back-end database server holds the geocoordinates of each beacon.

Customers use a mobile app to record their shopping trips. On the first start, the app requests access to the Bluetooth sensor. Once granted, the device is able to listen continuously for beacon signals. However, smartmarket² is deployed individually for each high street to fulfill R2. Hence, the app only declares a single UUID to monitor. Given that 2^{122} UUID exist [7], it is unlikely to receive a matching beacon signal outside the predefined area. Concerning R4 and R5, smart devices can receive beacon signals automatically in the background, but customers have to actively start and stop tracking in the app before any signal is sensed. Additionally, the app lists active and past trips and allows to inspect and delete the collected information (R5). Lastly, current mobile OS indicate active Beacon tracking and inform users on continuous monitoring.

When the user starts tracking and relevant beacons are in range, the app receives a list of these beacons and their coarse distance (far, near, immediate) once every second. A naïve approach is to record this data entirely and transmit it to the back-end server. As this would pose substantial resource utilization and violate R6, we developed a solution to extract and send only relevant information from the raw data stream–BeaT.

2.2 The BEAcon Tracking (BeaT) Algorithm

Suppose we have an active trip `tr`, a set of recently seen majors `M` (representing stores), and a set of beacon sightings, henceforth called touches `T`. For each touch `t`, we call the procedure BEAT, given in Algorithm 1, to update customer journey information.

```
Input: (tr, M, t ∈ T)   ▷ tr is the current trip; M is a set of active majors; t is a newly received beacon touch
procedure BEAT
    te ← GETBYMAJOR(t.major)   ▷ Try to obtain a trip entry te based on the major of touch t
    if te != none and DIFF(te.end, t.time) < 10 min then
        tr.end ← t.time   ▷ Earmark current t as potential last t ∈ tr
        te.end ← t.time   ▷ Earmark current t as potential last t ∈ te
        switch t.type do
            case "entrance"
                if te.entrance_first == none then te.entrance_first ← t
                if t.dist == "immediate" then te.visited ← true   ▷ Mark te (store) as visited
                te.entrance_last ← t   ▷ Earmark t as potential last sighting
            case "PoI"
                if t.dist != "far" then
                    te.visited ← true   ▷ Mark te (store) as visited
                    if t ∉ te.poi then SENDTODB(t)   ▷ Send PoI touch t to the database server on first sight
                    te.poi ← te.poi ∪ t   ▷ Add t to the set te.poi of seen PoI
            case "PoS"
                if t.dist != "far" then te.visited ← true   ▷ Mark te (store) as visited
                if t.dist == "immediate" then
                    if te.pos_first == none then te.pos_first ← t
                    te.pos_last ← t   ▷ Earmark t as potential last sighting
                    if DIFF(te.pos_first, te.pos_last) > 30 sec then te.sale ← true
    else
        ENDEXPIREDTRIPENTRIES()   ▷ End expired te and remove respective te.major from M
        te ← CREATETRIPENTRY(t)   ▷ Create new trip entry te based on touch t
        M ← M ∪ t.major   ▷ Add t.major to active majors M
        tr.te ← tr.te ∪ te   ▷ Add te to current trip tr
        BEAT(t)   ▷ Execute BEAT again, having a te
```

Algorithm 1. BeaT

First we test, whether there was an interaction with this store (`t.major`) within the last ten minutes. If not, we create a new trip entry `te`, which represents one element in the customer journey, and add it to the trip `tr`. Also, inactive trip entries for stores that have not been seen in the last ten minutes are closed and their respective majors are removed from the set `M` of currently active majors. Depending on the type of touch (`t.type`) and the user's distance to the beacon (`t.dist`), the trip entry is updated. In effect, we store for each trip entry, when the store was first and last seen (`entrance_first|_last`), if the customer has entered the store (`visited`), a set of seen PoI, and if the customer has bought something (`sale`). The latter is approximated by testing, if the customer has been in immediate proximity to a PoS for at least 30 seconds. PoI sightings are directly transmitted to the back-end server so that it can potentially return relevant notifications for the user. Each trip is either terminated in-app by the user or by a timed function that closes a trip after three hours without beacon sightings. The trip `tr` and all associated `te` and `t` are transmitted to the back-end server en bloc and tracking is disabled.

3 Evaluation and Outlook

BeaT was added to the prototypical smartmarket² platform [5], which provides the socio-technical context to investigate user location tracking in the target high street environment. BeaT is the result of multiple cycles of building, testing and evaluation activities. We already asserted the general viability of beacon tracking in an artificial setting [3]. Advancing further along the continuum of Venable et al.'s *Human Risk & Effectiveness Strategy* [9] to evaluate IT artifacts, we will conduct a summative naturalistic evaluation in the fourth quarter of 2018. About 40 businesses in a German high street will install beacons and we invited about 400 high street customers to engage in customer journey tracking using BeaT over the course of two months. Besides judging how well BeaT achieves its envisioned environmental utility [9], we also designed our field test to shed light on the socio-technical issues of adoption and use of privacy-friendly LBS, which will subsequently yield additions to the knowledge base.

Large facilities such as hospitals, shopping malls, and airports already use BLE beacons to provide indoor navigation [7]. Besides its merits for high streets, BeaT could also constitute a viable extension to existing mobile service in these domains. For example, in hospitals, patients could use BeaT to record which doctors and wards (service providers) they have visited and–based on their current patient journey–receive further digital and personal service. Lastly, in future research, we will use the location data collected through BeaT to map, analyze, and predict customer journeys [8].

Abstract. The ARiA project communicates about new working worlds in nursing with participatory approaches in order to establish innovative solution models for the challenges of demographic change in the field of robotics in nursing among the public and at the same time generate practice-relevant approaches for future products and services in this field. In the past, technical solutions of this kind were often developed and communicated in a primarily engineering logic without appropriate involvement of end users. Robot-based products and services and the associated working environments in nursing care for the elderly are changing rapidly. Potentials and barriers for future innovations in this field have to be made accessible and tangible to the specialist and to the public. The project ARiA aims to fulfill this with an open science approach.

{sven.hoffmann,fabiano.pinatti}@uni-siegen.de

Abstract. This paper reports on the possibilities of an AR-based tool to support machine operators in a set-up scenario. The focus lies on the exchange and acquisition of knowledge-intensive human practices in the context of manual set-up processes on modern production machines. Thus we go further in comparison to well know AR use cases and implement AR-technology not only for visualisation purposes, but for knowledge exchange between workers.

{firstname.surname}@uni-siegen.de

Abstract. Nowadays meetings are no longer physically tied to one place. Especially in knowledge work, telephone calls or Skype conferences have long since complemented classic face-to-face meetings. Various research discourses, especially computer-supported group work, have been investigating for almost three decades how distributed group work can be supported in its various forms using IT. With the increasing performance of technologies focusing on Augmented Reality (AR) and Virtual Reality (VR), new possibilities have been added that offer a high potential for supporting distributed meetings. With this prototype, we present an approach that combines AR and VR to implement a communication system with various collaboration options for the appropriate support of distributed meetings. Our prototype focuses on scenarios in which two or more people are in the same room and one or more people are absent physically, but both parties can still cooperate remotely at the same time.

Keywords: Augmented Reality, Virtual Reality, Collaboration, Remote-Meetings

1 Introduction

Remote meetings have become a common feature of everyday work in many industrial and commercial contexts where cooperative tasks are required. Supporting such remote meetings through technology has long been one of the most important discourses within Computer-Supported Cooperative Work (CSCW) and Human-Computer Interaction (HCI) [1–6]. However, the problem of the appropriate degree of immersiveness has not gone away and representing work activities at a distance is still difficult. For instance, video conferences via Skype are based on face-to-face communications and lack support for dynamic and interactive activities such as work on whiteboards or with physical artifacts, which are important parts of practical collaboration during a meeting [7]. Other approaches focus on setting up complex structures equipped with multiple screens and cameras which offer an improved immersive experience, but are not necessarily applicable for mobile or ad hoc work tasks that are typical for modern cooperation [8–10].

With the increasing efficiency of technologies focusing on Augmented Reality (AR) and Virtual Reality (VR), new possibilities for supporting distributed meetings have opened up. Research to date already shows the possibilities of AR and VR for

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

improving remote cooperation [11–14]. However, the focus of current research remains for the most part either on VR as a digital meeting room or on AR as a supportive technology for face-to-face communication [15]. In our prototype we combine both technologies and contribute with insights into how to design an immersive approach that makes use of AR as well as VR to support remote cooperation within creative and object-oriented settings.

The system we present creates an immersive experience during remote meetings and offers additional collaboration options that are less fully realized in knwon video conferences. The goal is that the participants of the meeting, although they are at different locations physically, have the feeling of being together in a real room, using shared artifacts and being able to collaborate just like they would in face-to-face situations. Our prototype focuses on scenarios in which two or more people are in the same room and one or more people are absent but can cooperate remotely at the same time.

2 Description of the Prototype

In this section we present the implementation of the first iteration of our prototype. With regard to related research, we mainly focused on the topic of social presence and cooperation within remote meetings.

We built the entire system for the remote (VR) and local (AR) perspectives using the Unity game engine. For local participants, we used the Microsoft HoloLens, making use of its spatial mapping capability and hence its facilitation of free movement in the room, without being tied to a desk or immobile computer. For the remote person, we used the HTC Vive, because of its room scale tracking capability, which allows a more natural movement in the virtual environment. The remote person sees the virtual representation of an ideally well-known meeting room, which looks the same as the real room where the local participants meet. The virtual and real rooms are aligned by a visual marker, placed at a predefined position in the real room and scanned by each HoloLens user before joining the meeting session. Marker detection is done by Vuforia computer vision technology. The marker is used as a reference point to calculate the correct position for displaying the other participants and artifacts. All involved persons see a digital representation of the other participants as avatars exactly where they are in either the real or the virtual meeting room. Everyone is able to move freely and interact with each other naturally.

2.1 Creating a high sense of presence

One goal of our prototype is to involve (or at least create the illusion) the remote participants as actors in the exact same space as the local participants. We therefore try to satisfy the principal determinants of presence [16]. For further immersiveness, we created a fully virtual copy of the real room by using a combination of laser scanning and photogrammetry which, combined, delivers a highly detailed 3D model with almost photo-realistic textures. Besides visual information about the remote space, auditory cues are provided in the prototype. Therefore, the voice of all participants is transmitted as positional sound, in order to allow the users to locate people, even if they are currently not in their field of view.

We further implemented view independence for the remote person. The view independence is not limited to looking around, like in a 360-degree photo or video, because the VR-participant is also able to move independently in the virtual environment. The vividness of the environment is achieved through the presence of the other participants. Because the 3D model of the room is static, the environment itself is not interactive in its current state. With the goal to create a higher sense of presence, we therefore integrated specific elements in the room, so that all participants can interact with each other and the environment. Changes in these elements are transmitted to all other participants in real time. We assume that all these properties lead to a high degree of perceived presence, which should improve the involvement of the remote person.

2.2 Collaboration tools

As simple tools like a whiteboard help solving simple problems that are hard to articulate verbally, we implemented a virtual whiteboard. It is a simple white area in the size of classic whiteboards and it is placed at the same position where the real whiteboard is placed in the meeting room. The virtual whiteboard is visible to all participants, both remote and local, and everyone can draw on it. The drawing is transmitted in real time, so one can draw and explain his drawing at the same time. For our first iteration of the prototype we limited the functionality of the whiteboard to draw in four different predefined colors (black, red, blue and green), erase and to clear it completely. To select another color or to erase and clear, we placed six buttons on the left side of the board. The interface is looking the same locally as well as remotely, but the actual use differs through the interaction concepts of the hardware.

We also implemented a shared agenda for the current meeting. This agenda is placed on an empty wall of the room and is visible for all participants. The agenda is designed in a way that all participants are informed about the topics of the meeting. The agenda looks like a to-do-list where every user is able to check the tasks on the agenda.

An important factor of meetings is an appropriate time management. Schneider et al. [17] observed that the perception of time alters while being in a VR experience. To reduce this effect, we added an analog clock above the door of the meeting room, which is visible for all participants. Although our prototype has limited elements of this kind, we feel, that it carries some important implications with respect to the need to identify exactly what tools and implements need to be shared in what collaborative contexts. Our aim over time is to provide a library of virtual artifacts which can be used to construct a usable meeting room regardless of purpose.

2.3 Representation of the participants

In order to reach the goal of a more natural communication, all participants have to see each other or at least a representation of the participants. To keep the hardware setup simple, we chose three-dimensional avatars as a representation format. There is a wide range of different options for avatars. As Greenwald [18] pointed out, even very abstract avatars can enhance the perceived degree of social presence. We decided to use abstract avatars, which only consist of a head, a generic torso and hands. The head and hands are not connected to the torso. For the head we used two different abstract and low-poly 3D models of animal heads - a panda and a raccoon. Both models have clearly recognizable faces with eyes, but no mouth. Matching this, we implemented paws as hands. The pose of the HMDs is transmitted immediately to the head of the avatar. Even small motions like nodding are represented by the avatar. One is also able to recognize where someone is looking. This should lead to a more fluent and natural communication in the remote setting. This natural communication is supported by transmitting gestures. For the remote VR-participant, the poses of the controllers are transmitted to the paws of the avatar, but there is no animation for every single finger. On the local AR side, we use the hand tracking technology of the HoloLens. Unfortunately, the HoloLens only reports the position of the user's hand if it matches one of the predefined HoloLens gestures. The rotation of the paw is fixed and aligned to the yaw of the user's head because the HoloLens does not provide the rotation of the tracked hands. When the hands are not tracked by the HoloLens, the paws will disappear. The following figures give a short overview of the system:

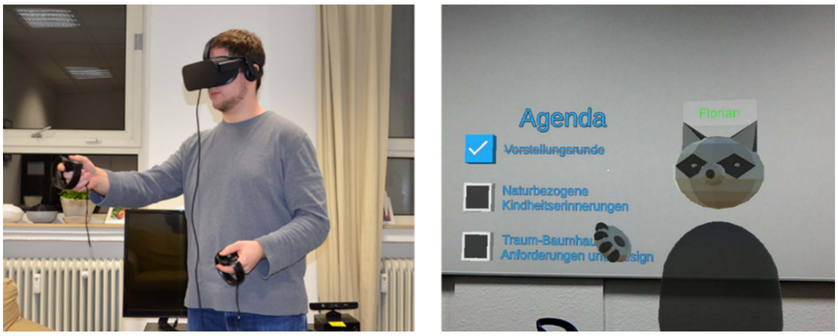

Figure 1: Left: Remote participant in his living room, right: his representation for the AR users.

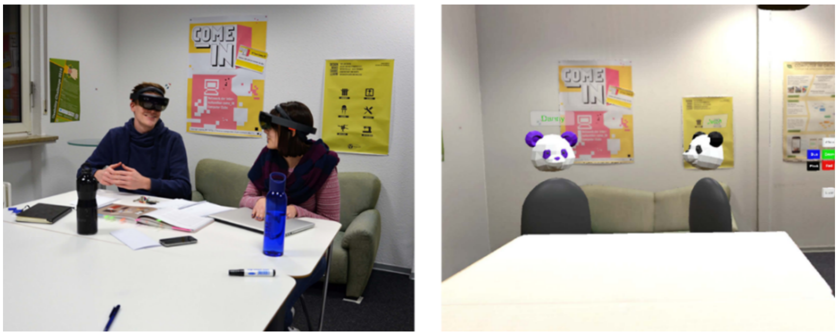

Figure 2: Left: Local participants in the meeting room, right: their representation for the VR users.

Gamification zur Motivationssteigerung von Werkern bei der Betriebsdatenerfassung

Christoph Kotthaus[1], Thomas Ludwig[1], Volkmar Pipek[1]

[1] Universität Siegen, Siegen, Deutschland
{christoph.kotthaus,thomas.ludwig,volkmar.pipek}@uni-siegen.de

Abstract. In Unternehmen bilden neben Stammdaten insbesondere Betriebsdaten die Basis für steuernde Maßnahmen bei der echtzeitnahen Produktionsplanung. Während Großunternehmen hierfür oft dedizierte Abteilungen und Technologien betreiben, ist dies für kleine und mittlere Unternehmen (KMU) oft unerschwinglich. Wenn überhaupt, werden Betriebsdaten nur handschriftlich erfasst. Die Weiterverarbeitung der Daten erfolgt allerdings meist zeitversetzt, sodass kurzfristige Handlungspotentiale ungenutzt bleiben. Außerdem stellt die Prozessdatenerfassung eine Nebentätigkeit für die Werker dar, wodurch die Dokumentation häufig entfällt, unvollständig oder fehlerhaft ist, zulasten der Datenqualität. Gegenstand dieser Arbeit ist, mittels Gamification die Motivation der Werker zu erhöhen, Betriebsdaten rechtzeitig und korrekt zu erfassen. Durch Interviews und Workshops mit Werkern und der Produktionsplanung eines KMU wurde ein praxisbasierter, digitaler Demonstrator entwickelt, worin Schichtmitarbeiter gemeinsam einen Avatar durch einen Parkour navigieren, indem alle ihre Betriebsdaten rechtzeitig und korrekt erfassen. Die Evaluation ergab ein ambivalentes Ergebnis, von zu spielerisch für ein als so ernst empfundenes Arbeitsfeld bis hin zu vielversprechend in Bezug auf die Betriebsdatenqualität.

Automatically Extracting and Analyzing Customer Needs from Twitter: A "Needmining" Prototype

Niklas Kühl[1], Dominik Martin[1], and Gerhard Satzger[1]

[1] Karlsruhe Institute of Technology (KIT), Karlsruhe Service Research Institute (KSRI), Karlsruhe, Germany
{kuehl,martin,gerhard.satzger}@kit.edu

Abstract. Automated and scalable elicitation of customer needs is still in its infancy. With the proposed "Needmining" prototype, we aim to enable automated customer need extraction from the micro blog platform Twitter.

Keywords: Customer Needs, Twitter, Machine Learning, Need Elicitation

1 Introduction

For modern businesses to thrive, they must design customer-centric, innovative products and services [1]. To achieve this goal, providers first need to identify the needs of existing and potential customers—so they can directly address them within their marketing activities [2], and, more importantly, create innovative offerings which are tailored to those needs [3].

For *customer need elicitation*, the application of different methods like interviews, focus groups or conjoint analyses is typical [4]. These methods, however, can be very expensive and time-consuming [5]. This is mainly due to the manual effort required, as these traditional methods do neither scale well nor can they be automated.

Fortunately for businesses, customers are in most cases well aware of what they actually need [6]. Today, it is very common for customers to voluntarily and intrinsically share personal information via social media. Some of these social media instances may contain valuable insights about their concerns, wants, demands and problems [7]. These insights are publicly available and free of cost—but any manual review would be laborious and would only allow a snapshot at the time of the analysis.

In the proposed prototype, we show the feasibility to automatically identify and quantify customer needs from a publicly available source like Twitter. The developed artifact utilizes natural language processing and machine learning techniques to provide innovation managers with an aggregated overview of customer needs—and does so on an ongoing, "always current" basis. This contribution has the potential to drive a step change towards automated, analytical support for customer need elicitation.

2 The Needmining artifact

Within an overall Design Science Research (DSR) effort of automatically identifying customer needs from Twitter data [8], a first cycle evaluated the feasibility of "need tweet" identification as a basis. We implemented an automated identification

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

of tweets containing customer needs with supervised machine learning models for the exemplary domain of e-mobility [9]. The results from the technical experiment of this first cycle show the feasibility by providing superior statistical classification results compared to all regarded baselines [10]. Additionally, the best-working classification model is deployed as a single service. The second DSR cycle requires this service to output “need tweets” only, as we analyze possibilities on how to identify the needs themselves from this output. As a result of the second cycle, we achieve an additional service which is able to automatically assign tweets to multiple need categories for the domain of e-mobility [11]. Therefore, the previous two cycles demonstrate the feasibility of (a) automatic “need tweet” identification and (b) automatic quantification of the needs themselves. Apart from showing the statistical evaluations for each cycle, two isolated services are designed: One capable of identifying tweets containing needs, one capable of assigning these tweets to pre-defined need categories—based on supervised machine learning. Both services, however, are not tailored to a non-IT focused user, since all other activities would need to be undertaken manually.

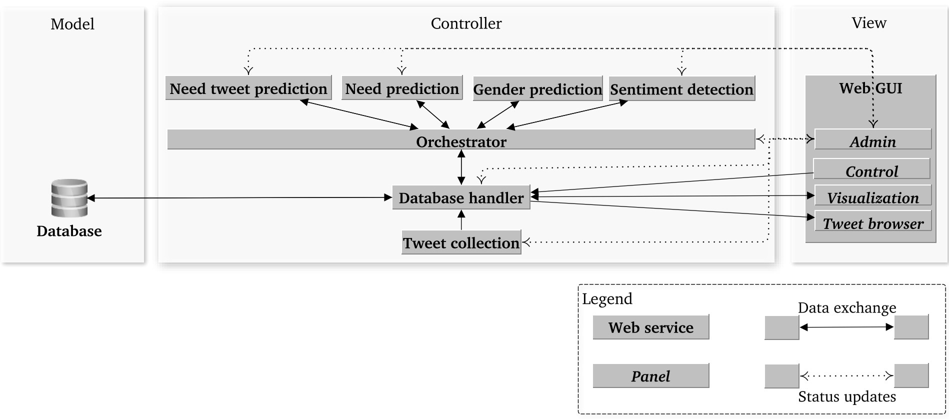

Figure 1. General architecture of the Needmining artifact

For the proposed prototype, we add a third DSR cycle to integrate both services into a comprehensive Needmining artifact. With this resulting artifact we later aim to evaluate not just statistical performance, but also (real) user acceptance. The Needmining artifact aims at automatically visualizing the most frequently expressed customer needs, which are autonomously posted on Twitter.

For a general architecture of the software design, we follow two principles: model-view-controller (MVC) [12] and service-oriented architecture (SOA) [13]. Figure 1 depicts the general overview of the architecture and its different web services. We structure our general architecture into three layers (model, view, controller) and a number of web services as independent instances, which can be accessed via a well-defined interface.

First, the tweets need to be received (*tweet collection*) and then stored for further processing. As multiple services need to access the storage, it is important to implement a *database handler*, which allows access to the database and monitors these accesses.

The *database* itself is part of the model layer. Apart from the tweet collection and the database handler, the controller layer consists of multiple other services. The *need tweet prediction* classifies whether a tweet from the database contains a need or not. In order to aggregate the needs themselves and achieve a distinct representation, they are automatically assigned to need categories as part of the *need prediction*. Moreover, the possibility of monitoring a change in needs over a specified period and differences due to demographic factors—like gender—can provide further insights into the development and the characteristics of certain needs. As an example, we additionally implement a self-built *gender prediction.* To automatically identify the sentiment of a tweet, we also utilize a *sentiment prediction* [14]. All these services (need tweet identification, need clustering, sentiment detection and gender detection) need to be orchestrated with regard to their access to databases as well as their sequence and error

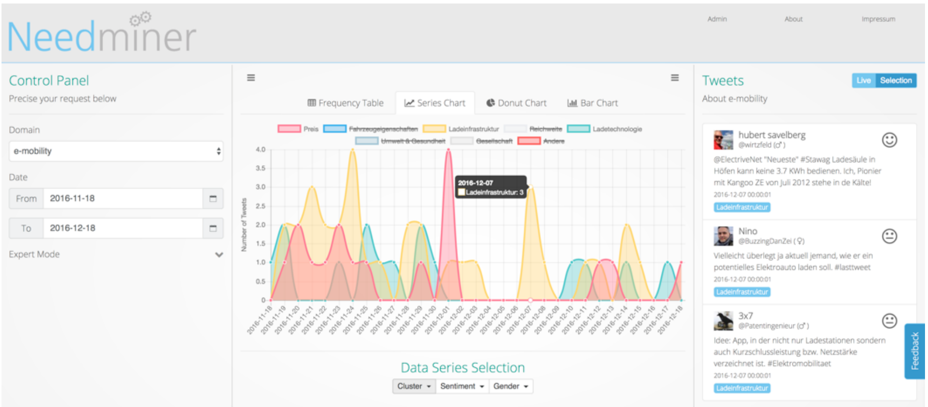

Figure 2. Screenshot from the Needminer GUI

handling. To address this, we implement a central *orchestrator* service, which orchestrates the main functions within the controller layer. As the orchestrator ensures a coherent processing of the data, the *Web GUI* from the view layer can directly access the data and visualize it for the end user (see figure 2). As the view layer is independent of the controller and the model, it can be enhanced or exchanged at any time, e.g. with a smartphone app interface.

3 Evaluation

As it is important to evaluate the artifact in a real-world scenario, we conduct an industry workshop with a large German utility and e-mobility services provider. The participants are from different divisions with different roles in the company. In total, seven employees take part in the three-hour workshop. The group consists of a product & innovation manager, a senior project manager, the head of a competence center, a group leader, a user researcher and an R&D project manager as well as an intern.

To evaluate the prototype, all participants can use the Needmining artifact for up to 30 minutes. Then, they fill out a further questionnaire regarding the experiences with using the software and we openly discuss positive and negative feedback. The questionnaire contains questions to assess (a) the helpfulness of the software, (b) its possible application within the company, (c) its ability to replace existing methods as well as (d) feedback regarding functionalities and design.

Out of seven participants, six regard the Needmining artifact as a helpful software. Furthermore, five participants can imagine using it for their daily business within their company. None of the participants states that the Needmining artifact in its current implementation can fully replace existing need elicitation methods. We further analyze the additional feedback, separated into functional and design feedback.

GaNEsHA: Opportunities for Sustainable Transportation in Smart Cities

Johanna Meurer[1], Volker Wulf[1]

[1] University Siegen, Institute of Information Systems and New Media, Siegen, Germany
{first.author,second.author}@uni-siegen.de

Abstract. In developed nations, cities experience a growing pressure to establish sustainable transportation solutions. However, currently cities have still only little knowledge about the transportation routines, needs and troubles of its citizens. A greater awareness of daily transportation activities could support cities to build up customized transportation infrastructures that meet sustainable requirements. To address this gap, we build the GaNEsHA mobile application. A mobile crowed-sensing tool to track mobility activities. We used the tool as a probe in an interview study with 14 citizens. Our findings indicated a need for ICT design to move beyond normative tools that simply aim to 'encourage' people to adopt sustainable practices. Instead, we identified different transitions how municipal mobility services can support sustainable mobility practices. These include: (1) creating awareness of environmental footprints, (2) supporting alternative transportation options, (3) optimizing towards individual needs, (4) facilitating local communities and participative approaches.

Keywords: Sustainable mobility, mobile crowd-sensing; smart city, behavior change.

1 Background

Private transportation currently accounts for about a quarter of global CO_2 emissions. Given current trends, this value is set to increase by roughly 50% between now and the year 2030. In particular, many German cities are suffering from too high nitrogen values [1]. Throughout the western world, a (neo-) liberal agenda has arguably placed a greater burden upon individuals as ‘citizen-consumers’ to both consume for the sake of the market whilst accepting responsibility for the sustainability of their actions [4]. Over the last decade the sustainable HCI community has seen papers presenting interactive technologies that variously aim to support, inspire or persuade people to adopt pro-environmental behaviors [5]. A core assumption here is that the right kind of information about one’s behavior and its environmental effects will encourage more environmentally-friendly and sustainable habits [2]. However, measures aimed at changing individual behavior often face very low levels of uptake, complex constraints and even resistance [6]. Critique of these approaches often points to the normative

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

stance of assuming sustainable mobility is the only ‘good’ mobility, which risks being unintentionally paternalistic and behavioristic [3].

Addressing this issue, we are not questioning hot to better persuade citizen-consumers to conduct a more sustainable mobility, but instead to focus on the question how cities and its local municipal mobility services can provide appropriate transportation infrastructure that support multimodal sustainable mobility choices. Nowadays cities have only very little knowledge how its citizen experience sustainable mobility in their daily activities and how it can be optimally supported. Therefore, we question in this paper the notion of simply 'encouraging' people to adopt more sustainable mobility practices not from the normative perspective of individual citizens, but from the perspective of local municipal mobility services in cities.

2 Method and Prototype

To explore on the research question, we conducted interviews with 14 ‘ordinary’ citizens. Within these interviews we aimed to explore daily mobility practices while addressing interviewees “as analysists of their own and others’ practices”. To tackle this issue, we used a prototype to track mobility activities, then used the collected data as a probe to trigger detailed descriptions. The prototype provided an outline of users’ various journeys and associated modes of transport. We recorded the movements of all interviewees over a period of four weeks prior to the actual interviews taking place. This allowed us to review the rationales for various journeys in relation to concrete situations during the interviews. Additionally, the prototype offered some simple visualizations to sensitize interviewees to the possible environmental impact of their private mobility (see Figure 1). Overall, we found that the records helped interviewees to remember specific events, which served as prompts for stimulating reflections or to trigger richer accounts of particular journeys undertaken. Focusing on concrete situations also helped people to articulate specific rationales for the use of a particular mode of transport and the circumstances that led to it.

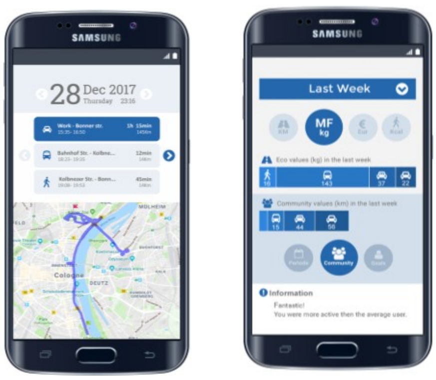

Figure 1. The picture on the left shows collected travel information. The picture on the right shows sustainability measurements. These designs were subsequently slightly modified to improve readability.

3 Results and Outlook

The analysis showed clearly that, although all participants spoke at some point during their interviews about the positive value of sustainability, sustainable mobility was not addressed as a driving factor in and for the organization of daily journeys. Moreover, we found that mobility practices were expressed to come with different practical exigencies that oriented to sustainable mobility in divergent ways. They incorporate: knowledge and information, self-reflection, thrift, comfort and collective responsibility. The prototype has helped to focus on these practical exigencies, how the interviewees actually handled sustainable mobility. We believe that the identification of practical exigencies is useful in order to use ICT to support sustainable mobility solutions beyond gross normative appeals (e.g. 'be sustainable!'). The points we have identified can be collected under more general themes that may inspire city services concerned with sustainable mobility. First of all, there is a need to design with a focus beyond a normative appeal of sustainable behavior, but to (1) creating awareness of environmental footprints. Secondly, we see opportunities by examining other values that are important for sustainable practices in (2) supporting alternative transportation options. Thirdly, this study offers a positive example to inspire the design regarding mobility practices and (3) optimizing towards infrastructural needs of the citizens. Lastly, we see a lot of potential in addressing different stakeholder groups who collaborate around processes of mutual learning and innovation (4) facilitating local communities & participative approaches. It would be interesting to study in future works more detailed how the prototype can be enhanced to take a deeper look at the daily mobility activities of the citizens. Cities could learn more about the concrete mobility needs and transport resources and how both can be better matched to support sustainable mobility.

TUCANA: A platform for using local processing power of edge devices for building data-driven services

Mirco Pyrtek[1], Sascha Xu[1], and Wolfgang Maass[1]

[1] German Research Center for Artificial Intelligence, 66123 Saarbrücken, Germany
{mirco.pyrtek,xiaguang_sascha.xu,wolfgang.maass}@dfki.de

Abstract. In the age of mobile cloud computing web-based systems are often designed to transfer data to large scaling online storage facilities in order to persistently save and analyze it with complex algorithms such as used in machine learning. These systems often require a reliable network connection, which does not hold for a variety of mobile business applications. As an alternative to traditional cloud-based systems the TUCANA approach makes use of the local processing power of mobile edge devices in order to come up with high complex AI pipelines processing data in real-time. By applying the idea of TUCANA to our service use-case called "nPotato" we developed an artificial, nociceptive potato that frequently measures and analyses acceleration data during the harvesting process of potatoes. In the given scenario sensory data is processed locally in real-time using the device's local computing power to gain higher productivity in the area of precision farming.

Keywords: Edge Computing, Internet of Things, Distributed AI, Web Technologies

1 Introduction

Mainstream mobile cloud computing architectures assume that local clients collect data and transfer this data to centralized data storage facilities. Major data processing is performed in these data storages and results are transferred to clients for presentation to users [1]. Examples are Google's Firebase or Microsoft's Azure.

These architectures normally assume high-speed Internet access so that data exchanges are performed without considerable latency. It also assumes that users are willing to transfer their data to centralized data centers, i.e. accept end-user license agreements (EULA) accordingly. These requirements do not always hold. In many areas, internet access is either unavailable or unreliable. This causes problems, for instance, for mobile business applications, such as used in farming.

With our new approach called "TUCANA" we aim at building a platform for the fast implementation of smart services that are working in closed local environments. This approach is based on modern approaches of mobile software development making use of distributed device capacities as given in the field of edge computing [2]. In this

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

scenario the execution of a service in a closed environment implies that a service does not rely on a stable internet connection and a high availability of computing capacities in cloud facilities since data measurement and data processing both can be done using the device's local sensors and processing power.

Moreover, since the communication of analysis results is important for most of the cases, the architecture comes with the opportunity to connect several local environments for sharing data through a secured peer-to-peer network . Each TUCANA environment (T-ENV) acts as a peer in this scenario. With the feature of connecting several T-ENVs there also comes the opportunity of building data processing pipelines making use of the capacities of multiple mobile edge devices and distributing the execution of AI models and other functionality within a connected network. With this approach computational complexity can be significantly reduced for single devices in their local environments but distributed to a variety of available peers in the network.

Applied to the context of real-time decision making in the area of farming such as described in [3] this means that problems based on low availability of computing resources during farming processes can be avoided in many cases. For instance, during the harvesting process of potatoes, connectivity errors of mobile monitoring devices harvested together with the crop such as the "nPotato" can occur because of a changing environment. If a measuring device used for monitoring the impact within the harvester needs to transfer large amounts of raw data for analysis to a central server, the connectivity most likely is not sufficient and the feedback to a farmer or a driver of the harvesting machine is either significantly delayed or not given at all. By processing the data directly on the measuring device, just the analysis results are necessarily transferred in order to give feedback to the farmer or the driver of the harvesting machine. This most likely results in a higher availability of the analysis results and provides the opportunity of reacting quickly to changing circumstances during the harvesting process.

2 Proposed demo

2.1 Demo description

Our demo showcases a cloud-independent AI platform for high complex problems, all solved in a protected, local software environment. Combining the sensory data and processing power of multiple mobile devices, TUCANA is a platform for distributed, privacy protecting smart services. Following this approach, we built a TUCANA application for the service use-case "nPotato". In this scenario the application assists a potato farmer during harvesting with real-time damage analysis and financial forecasting for market prices, all carried out on commonly available devices such as smartphones and laptops and without any necessary cloud infrastructure.

Figure 1. nPotato prototype

For realising this use-case we use a standard smartphone as a measuring device in and run our TUCANA application in it's Google Chrome Web Browser. After the smartphone is set up and running we put it into a case built by a 3D printer as shown in figure 1. In order to visualize what is going on inside the potato case we use the same web application on a tablet PC's Chrome Browser that is connected to the nPotato smartphone as a peer. Data sensed and analysed by the smartphone inside the case gets transferred through a peer-to-peer network to the remote tablet by using a technology called WebRTC[1]. The user of the tablet PC, in our case the driver of a potato harvesting machine or the farmer himself, now has access to realtime information about the current quality of the crop as well as the total expected yield. These predictions are based on the analyzed sensory data of the nPotato phone and directly sent to the tablet PC. Additionally, the data obtained from several connected potatoes is processed further on the tablet by analysing it in combination with future potato price estimates in order to give a prediction about upcoming incomes for the farmer.

Figure 2. Reliability testing during potato harvesting

Furthermore, we already tested the reliability of the application in a real world setting by harvesting the artificial potato with a real potato harvesting machine as shown in figure 2. This picture was shot during potato harvesting at a local farmer. To show the system also in controlled environments we developed a demo case. The demo proceeds as follows:

[1] see https://webrtc.org/ for further details

1. The smartphone is inserted into the case and connected to the remote tablet PC.
2. The application is started remotely through the tablet PC.
3. The nPotato is dropped from several heights and communicates the analysis results to the tablet PC.
4. The user gets information about the status of the potato in real-time.
5. The data is further analyzed on the tablet and the estimated monetary income for a farmer is shown.

2.2 Requirements

The demo has only minor technical requirements. It needs a space for executing the fall experiments with the nPotato. We usually used a tapeline for measuring the fall height and a pillow for reducing the noise of the fall experiments. Additionally the devices need access to a wifi access point as a basis for the secured peer-to-peer communication. Optionally, a larger screen for our tablet PC could improve the demonstration for the visitors.

2.3 Interaction Possibilities

Visitors can interact with our demo system in several ways. We provide nPotato cases with smartphones inside, so visitors can test the damage and fall detection on their own. Since our application is built as a web application, no installation is required to use it. If someone is interested in connecting to our system either as a potato measuring device or as the remote device that gets analysis results from several potatoes he or she can either use his or her own smartphone (Android required) or one of our phones we use to demonstrate the technology to interact with the system and process and transfer data on the device.

Abstract. Kleine und mittelständische Unternehmen haben oftmals große Probleme in der Einführung eines ISMS und einer Verbesserung der eigenen IT-Sicherheit. Besonders kritische Infrastrukturen wie Energienetzbetreiber sind gesetzlich dazu verpflichtet ein ISMS einzuführen und für eine bestmögliche Sicherheit zu sorgen. Diesen Unternehmen fehlt es jedoch oftmals an möglichen Mitteln und Erfahrungen. Mit dem Forschungsprojekt SIDATE soll dieses Wissensdefizit untersucht und analysiert werden. Es wurden mehrere leichtgewichtige Werkzeuge entwickelt, die auf einer zentralen Wissens- und Austauschplattform angesiedelt sind. So sollen mit der Entwicklung einer leichtgewichtigen Beschreibungssprache und dem zugehörigen Demonstrator kleine und mittelständische Energienetzbetreiber unterstützt werden. Mit dieser Arbeit möchten wir den Demonstrator zur Beschreibung, Visualisierung und Untersuchung auf IT-Sicherheit einer kritischen Infrastruktur vorstellen. Mit der Beschreibungssprache ist es zudem möglich Angriffszenarien und Angriffsbäume zu visualisieren, um mögliche Sicherheitslücken besser aufdecken zu können. Insbesondere soll dieses Werkzeug durch Exportfunktionen einen Erfahrungsaustausch zwischen den Nutzern bzw. Energienetzbetreibern fördern und eine Steigerung der IT-Sicherheit stärken.

Abstract. This paper intends to give a short overview on the development of a persuasive widget system to increase the level of physical activity in the context of participatory IT research for and with older adults. The complete work was embedded in the three-year research project Cognitive Village.

Keywords: Alternde Gesellschaft, Persuasive Systeme, Gesundheit, Sensorbasierte Systeme, Bewegungsmotivation, Participatory Design Approach

1 Einführung

Ältere Menschen prägen zunehmend das Gesellschaftsbild und damit auch den Alltag aller Bürger. Demnach ist jeder vierte Deutsche über 60 Jahre, jeder fünfte über 65, was im Jahre 2014 einen Anteil von 21% ausmachte [1]. Industrie wie auch Forschung versuchen dem entgegenzukommen und mit moderner Technik, z.B. Ambient Assisted Living (AAL) Systemen, ältere oder pflegebedürftige Menschen weitgehend zu unterstützen. Anwendungen im Bereich der Prävention, u.a. in den Feldern Ernährung und Bewegung, erhalten zunehmend Aufmerksamkeit als Beitrag für ein längeres und beschwerdefreies Leben [2]. Adaptive persuasive Systeme stehen dabei im Fokus, die Inhalte, die auf der Grundlage persuasiver Kommunikation beruhen, an das Verhalten, die Erfahrungen oder die Umgebung der Nutzer anpassen und damit Verhaltensänderungen stimulieren [3]. Die Arbeit beschreibt ein sensor-basiertes Widget in Form einer Blume, das zur Bewegungssteigerung für Senioren innerhalb des dreijährigen BMBF- geförderten Forschungsprojektes "Cognitive Village“ [4] auf Grundlage des Participatory Design Ansatzes entwickelt und implementiert wurde.

2 Stand der Forschung

Es fällt deutlich auf, dass viele AAL-Projekte im Feld der persuasiven Systeme nur wenig (qualitativ-) empirisch vorgehen, und die Konzipierung- und Gestaltungsarbeit somit eher auf bestehende Literatur oder vorliegende Statistiken stützen [5]. Die

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Herangehensweise ist nachvollziehbar, jedoch kann die oft fehlende Praxis bemängelt werden, da viele Konzepte erst im realen Alltagskontext ihre Wirksamkeit unter Beweis stellen. Daher fordern Autoren eine intensive Einbeziehung der Stakeholder in den Designprozess, beispielsweise mit Methoden des Participatory Design [6], [7]. Arbeiten wie von de Oliveira et al. (2010) [8] und Kumahara und Mori (2014) [9] zeigen, wie weit viele Projekte in der Entwicklung von persuasiven Systemen von den potentiellen Nutzern und realen Nutzungskontexten entfernt sind. Damit die Gestaltung persuasiver Systeme in Praxis funktioniert und nachhaltigen Erfolg hat, ist es besonders wichtig, konkrete Bedürfnisse gemeinsam mit den NutzerInnen zu verstehen, zu co-explorieren und Motivationsstrategien zur Verhaltensänderung entsprechen behutsam in Alltagspraktiken und –vorstellungen einzubetten [10].

3 Anforderungsanalyse

Zur Ermittlung der Nutzungsanforderungen wurde mit zehn TeilnehmerInnen im Alter von 67 bis 82 Jahren gearbeitet, die im Laufe des Forschungsprojekts unterschiedliche digitale Geräte erhalten haben. Dazu wurden verschiedene qualitative Methoden wie Fokusgruppensitzungen, als auch Interviews und Technology Probes [11] eingesetzt. Aus den Bedürfnissen konnten im weiteren Verlauf an das persuasive System Anforderungen abgeleitet und priorisiert werden. Dazu gehörten u.a. die Darstellung und Personalisierung des Systems, das Autonomiebewusstsein, die Kennzahlen z.B. aktuelle Schritte, die Abwesenheit von Ermahnungen und geringe Nutzungshürden.

4 Designidee und Funktionsbeschreibung

Auf Basis der Anforderungen wurden vom Autor potentielle Designideen konzipiert, eingegrenzt und mit Funktionen erweitert. Die ausgewählte Idee Blumenwidget bestand aus neun Elementen, die bis zum finalen Prototypen in abgeänderter Form übernommen wurden.

Fensterscheibe. Am Fenster wird immer das aktuelle lokale Wetter anhand der Postleitzahl angezeigt, wodurch sich auch die Fensterscheibe verändert. Für besondere Tage, wie dem Geburtstag des Nutzers oder an Weihnachten, werden besondere passende Elemente im Hintergrund oder auf der Fensterbank platziert, um die Gesamtszene personalisierter zu gestalten.

Topfpflanze. Die Topfpflanze ist das primäre Element des Widgets. Die Blume wächst in der Anfangsphase in 20% Schritten und symbolisiert immer die am letzten Tag gelaufenen Schritte. Dabei hängt die Wachstumsgröße von dem Füllzustand der Wasserkanne ab. Es gibt verschiedene Blumen und Farben. Bei 100% soll die Blume verhältnismäßig groß und kraftvoll wirken, damit der Nutzer ein positives Nutzererlebnis verspürt und erfreut ist, den Tag zuvor sein Tagesziel erreicht zu haben.

Wasserkanne. Die Wasserkanne zeigt die aktuelle Schrittzahl in 20% Etappen an, die zuvor individuell eingestellt wurde. Je mehr Wasser mit den gegangenen Schritten gesammelt wurde, umso stärker blüht die Blume am nächsten Tag auf. Morgens wird die Kanne geleert. Zusätzlich soll die Wasserkanne den Nutzer zum Trinken animieren und in einfacher Weise aufzeigen wie viel der Nutzer sich bewegt hat.

Post-Ist/Sticker (Achievements). Post-Ist oder Sticker, sind kleine aufmunternde Nachrichten für den Nutzer und zeigen bildlich erreichte Tagesziele der gesamten Woche auf. Diese kleben im Hintergrund an der Fensterscheibe. Da es mehrere Stickervarianten gibt und diese in zufälliger Reihenfolge erscheinen, sehen gesammelte Sticker im Gesamtbild bei jedem Nutzer anders aus. Zu Beginn einer neuen Woche verschwinden alte oder bisher gesammelte Sticker und das Sammeln fängt von neuem an. Hat der Nutzer dessen ungeachtet drei Sticker gesammelt, hat er die Möglichkeit Pokale zu erwerben.

Kalender. Der Kalender zeigt dem Nutzer das aktuelle Datum an. Dabei geht es vor allem um den letzten synchronisierten Stand.

Notizbuch. Das Notizbuch zeigt die aktuelle und auf Wunsch auch die persönlichen Maximalschritte an.

Einstellungen. In den Einstellungen kann der Nutzer seinen Namen, seine Zielschritte und seine Postleitzahl eintragen, damit das lokale Wetter abgerufen werden kann. Zudem kann der Nutzer auch eine Auswahl an Blumen vorfinden, für die er sich entscheiden kann.

Titel. In den Einstellungen kann der Nutzer dem Widget einen persönlichen Titel vergeben, wenn er damit einverstanden ist. Damit sollte das Widget noch persönlicher wirken, als ein generischer Widget-Name.

Verschiedene Modi. Neben den geplanten interaktiven Elementen werden auch verschiedene Modi eingesetzt, die den Inhalt des Widgets realitätsnaher aussehen lassen. Dadurch soll die Nutzungsakzeptanz des Widgets erhöht und die kritische Distanz reduziert werden, was bei älteren Menschen als Zielgruppe nicht außer Acht gelassen werden darf. Demgemäß wird zwischen fünf verschiedenen Modi unterschieden, zwischen denen das Widget je nach Ort, Uhrzeit und Datum wechselt.

4.1 Implementierung der Hardware und Softwarearchitektur

Für die Nutzung werden die Sensoren einer Smartwatch (Huawei Watch [12] und Nokia Go [13]) verwendet und damit Daten (Schritte) generiert, die am Ende eines iterativen Datenverarbeitungsprozesses in Form einer Veränderung des Blumen-Widgets, das innerhalb des Cognitive Village Dashboards open.Dash [14] eingebunden wurde, betrachtet wird. Open.Dash ist ein Open Source Visualisierungsrahmenwerk, das hauptsächlich in Javascript geschrieben wurde. Es bietet Nutzern ein Dashboard, das an bereits existierende Datenquellen angeschlossen ist, eine Nutzerverwaltung und andere http/websocket Quellen. Die Nutzung des Dashboards samt Widgets erfolgte über einen Webbrowser, im Falle von Cognitive Village über ein Samsung Tablet. Bewegt sich der Nutzer, so dass die Uhr eine Veränderung feststellt, werden über einen automatisierten Prozess die generierten Nutzerdaten an eine Middleware gesendet. Zur Synchronisation, Speicherung und Weiterleitung der Daten, wurde ein Smartphone eingesetzt. Die Middleware empfängt die Daten, verarbeitet sie und teilt sie den jeweiligen Funktionen zu. Dabei synchronisieren die Geräte alle 10 Sekunden miteinander und speichern die Daten, auch bei Internetausfall, auf dem Smartphone.

5 Zusammenfassung

Alle einzelnen Designideen und –iterationen wurden in enger Zusammenarbeit mit der Seniorengruppe exploriert, entwickelt und schließlich über mehrere Wochen genutzt. Der starke partizipative und alltagsnahe Ansatz, der sich auch in der Wahl der visuellen Elemente zeigt, hat in erfolgreicher Weise zu einer Annahme und längerfristigen Nutzungsmotivation geführt.

A browser-based modeling tool for studying the learning of conceptual modeling based on a multi-modal data collection approach

Benjamin Ternes[1], Stefan Strecker[1], Kristina Rosenthal[1], and Hagen Barth[1]

[1]University of Hagen, Enterprise Modelling Research Group, Hagen, Germany
{benjamin.ternes,stefan.strecker,kristina.rosenthal,
hagen.barth}@fernuni-hagen.de

Abstract. How do we learn conceptual modeling? What are common learning difficulties? Which tool support assists learners in what respect? The paper at hand reports on the design and development of a browser-based modeling tool integrated with a learning observatory in support of learning conceptual modeling and of studying the learning of conceptual modeling. Implementing a multi-modal data collection approach, the learning observatory tracks learner-tool interactions, records verbal data from learners and surveys learners about their learning processes to provide for analyses at the individual and aggregate learner levels in the quest for identifying patterns of learning processes, learning barriers and difficulties. We report on the current state of prototype development, discuss its software architecture and outline future development steps.

Keywords: Conceptual modeling, Modeling tool, Modeling tool development, Prototyping.

1 Introduction

Viewed as an activity, conceptual modeling involves an intricate array of cognitive processes and performed actions including abstracting, conceptualizing, associating, contextualizing, interpreting & sense-making, judging & evaluating, drawing & visualizing, and, in group settings, communicating, discussing and agreeing. Learning conceptual modeling is, hence, a complex task for learners associated with codified as well as tacit knowledge and a learning process involving knowledge acquisition through experience (e.g., [1]). Learning conceptual modeling involves mastering theoretical foundations, modeling methods and languages, and applying them to modeling tasks by critically reflecting on domain-specific technical language in the light of set modeling objectives [2, 3].

Research on learning conceptual modeling, hence, seems likely to benefit from taking multiple complementary angles on studying learning processes to account for their multifaceted nature. Related work on learning support tools include process-oriented feedback [4, 5], gamification [6] and serious games [7] as well as work on the collection, aggregation, analysis and evaluation of data on learners and their learning context

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

subsumed under the term learning analytics [8, 9]. Complementing prior work on tool development for supporting and studying learning conceptual modeling, we initiated a long-term research program to better understand how novice modelers learn a modeling language respectively modeling method and how tool support assists learners in what respect. The research program is based on the fundamental assumption that learning processes of novice modelers deserve study from several complementary perspectives. Therefore, it bases on mixed method research designs involving multi-modal data collection.

As part of that research program, we have been developing a learning observatory integrated with a modeling tool in support of learning conceptual modeling and of studying the learning of conceptual modeling. Overarching research objective guiding the implementation efforts is to identify patterns of learning processes, common learning barriers and learning difficulties. For that purpose, the learning observatory currently supports three modes of data collection on learners' learning processes: (1) tracking and recording (every) learner-tool interaction; (2) conducting written pre- and post-modeling online surveys of learners; (3) recording verbal data from learners while modeling (supporting 'think-aloud'-like data generation methods [10]).

The primary application context of the modeling tool and learning observatory are two introductory courses on conceptual modeling in a distance learning and teaching setting with large cohorts of students (1000+ and 200+ per semester). Based on a blended learning approach, these two courses presently pick out data modeling (in a variant of the Entity-Relationship Model), object-oriented modeling (a tailored subset of UML Class Diagrams) and business process modeling (a subset of the MEMO OrgML [11]). Development of the modeling tool is, consequently, tailored to the respective taught modeling languages and requirements for software development following from this specific application setting.

2 Prototype Presentation

The current working prototype has been under development since 2013 to explore design and implementation strategies for tracking interactions of learners with graphical editors. Two essential requirements drive the prototype development: (i) Platform independence as well as (ii) usability (especially an intuitive user interface). Technically, we opted for a web application with a JavaScript-driven browser frontend and a Java EE (Enterprise Edition)-based backend (see [12, 13]). The frontend design considerations, operating principles and essential requirements are outlined in [13]. A revised and extended version of the software architecture is depicted in Fig. 1. Note that the frontend user interface currently implements two graphical editors: First, an editor for constructing ER diagrams (in the variant used in the two introductory courses) and a second editor for creating MEMO control-flow and decomposition diagrams [11].

As a first step to realize tool support for learning conceptual modeling in the introductory courses, we have implemented an ad-hoc syntax validation to verify the syntactic correctness of conceptual models. Feedback on syntax errors is provided via natural language comments and the highlighting of graphical notation symbols. Additionally, a video-based step-by-step tutorial comprising short video excerpts has been implemented aimed at accelerating and fostering the general handling of the tool. Moreover, the tutorial provides an open discussion forum for learners to discuss emerging difficulties, e.g., with other learners while working on modeling tasks or to receive technical support on issues and news concerning the tool.

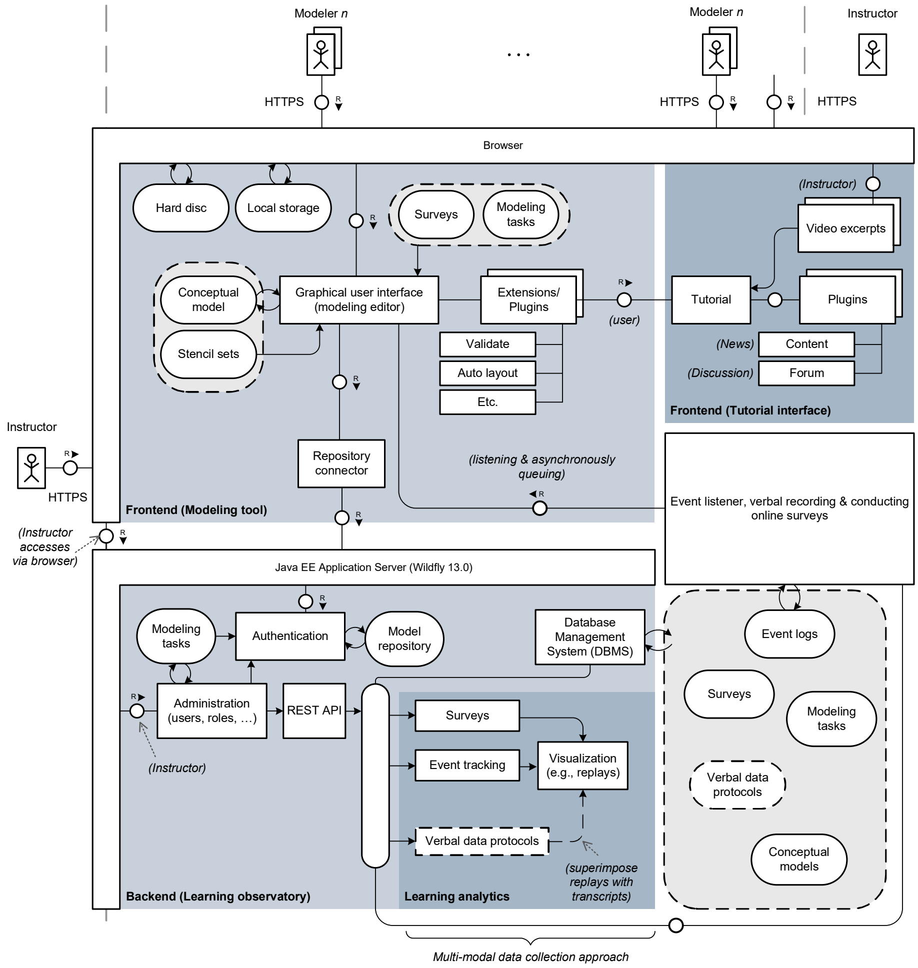

Figure 1. Revised software architecture at the conceptual design level depicted using FMC (Fundamental Modeling Concepts, see [14])

To include several complementary perspectives on learners' learning processes, we extended the learning observatory with further data collection approaches. Particularly, the learning analytics component has been extended for tracking, analyzing and evaluating learner-editor interactions, e.g., algorithms for tracking events. More specifically, the prototype implements an algorithm which tracks the learner-editor interactions, while working on, e.g., modeling tasks, by storing every learner-tool interaction with the graphical editor as a timed discrete event (*modelid, modelElementid, timestamp, userid, operation, type, content*). The tracking data is subsequently used for the learning analytics component. Currently, the learning analytics analysis and visualization component supports a step-by-step replay (i.e., visually showing every step of model construction), an automatic replay (i.e., visually showing model construction in real-time) and – based on prior related work on learning analytics (e.g., [5]) – a text-based console displaying further information about learner-editor interactions, e.g., manual use of the syntax validation.

Beyond these modes of data collection on learners' learning processes, we have implemented a software component to create and to conduct pre- and post-modeling online surveys of learners about their learning processes and demographic data within the modeling tool. Since learner-editor interactions are a rather restricted mode of observation of learning processes, we opted for additionally collecting verbal data by asking learners to think out load while modeling (e.g., [15]). Currently, a further component of the learning observatory is implemented to collect verbal data protocols by recording voice while learners are working on a modeling task. Generally, we view it as an open question whether and how to further enrich researchers' observations on learning processes beyond learner-tool interactions. As learning of conceptual modeling entails an intricate array of cognitive processes and performed actions, studying learners' learning processes suggests applying further complementary data collection approaches including, for instance, eye tracking (e.g., [16]) respectively video recording via webcam (e.g., [17]).

To evaluate the design and implementation, we are currently preparing for a small-scale study aimed at achieving first insights into barriers and difficulties faced in learning conceptual modeling and into learners' learning processes. Involving selected students working on a modeling task in the graphical user interface of the modeling tool, the design of the study utilizes the multi-modal data collection approach combining tracking learner-tool interactions, recording voice from learners and conducting pre- and post-modeling online surveys of learners. Informed by these preliminary insights, a large-scale study will be designed aimed at identifying patterns of learning processes, common learning barriers and learning difficulties.

Exergames & Dementia: An interactive System to for People with Dementia and their Care-Network

David Unbehaun[1] & Konstantin Aal[1]

[1] University of Siegen, Institute of Socio-Informatics, Siegen, Germany
{firstname.surname}@uni-siegen.de

Abstract. Dementia and its individual and social consequences can be positively affected by a range of activities that can postpone individual decline and the development of dementia. ICT can play a major role to have positive effects on people with dementia (PwD), but also on other stakeholders such as professional and informal caregivers. The aim of the presented system is to increase the physical and cognitive capabilities to cope with the activities of daily life (ADL) of PwD, as well as to relieve the caregivers and the social care-network. To this end, the MobiAssist System is being developed with and for people with dementia and their caregivers. The aim is to provide exercises (physically, cognitive and creative) to enhance mental and physical resources for ADL. Feedback from the participants were positive towards the general movement and cognitive capabilities, social and cross-generative interaction, and therefore a relief for informal and professional caregivers.

s.espana@uu.nl

Abstract. The aim of the first edition of the EMoWI workshop was to establish a new forum for Business Informatics researchers and practitioners to reflect on the various ways in which the concern with business information systems and digital technologies gives rise to questions and issues with an ethical dimension. The several contributions of the workshop have made it plain that ethical questions indeed crop up in many fields of Business Informatics, ranging from specific research objects such as digital platforms to methodological pre-suppositions of the discipline at large. This chapter provides an overview of the background and the contributions of the EMoWI workshop 2019.

Keywords: Ethics, Values, Morals, Moral Philosophy, Business Informatics, Information Systems.

1 Introduction

According to Immanuel Kant, ethics is concerned with the question, "What ought I to do?", as opposed to the other two basic questions "What can I know?" and "What may I hope?" [1, p. 635, AK 833]. "What ought I to do as a Business Informatics researcher?" was therefore the leading question of the workshop *Ethics and Morality in Business Informatics* (EMoWI'19), held in its first edition at the 14th International Conference on Wirtschaftsinformatik (WI 2019), in Siegen.

The idea for the workshop emerged from the recognition that while the examination of ethical questions has received a fair amount of attention in specific branches of information systems research, computer science, and the engineering sciences (see, e.g., [2, Part V] [3]), these examinations have tended to be underrepresented in major Business Informatics conferences in recent years. Yet the need for ethical reflections is more pressing than ever, given that information systems and digital technologies pervade both private and professional life to an unprecedented degree. The many developments in digital technologies bring forward classical problems of moral

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

philosophy in new guises, as well as genuinely new species of situations in which good and bad, right and wrong conduct needs to be distinguished.

These developments pose significant challenges for the discipline of Business Informatics. Given that Business Informatics is conventionally expected to develop new ways of dealing with the emergent opportunities and challenges in a socially and technologically evolving society, the discipline cannot focus on the design of socio-technical information systems in an instrumental sense alone. Instead, Business Informatics also has the responsibility to develop new ways of meeting the diverse and complex ethical ramifications of the use and design of information systems in society with prudence and responsibility. Our motivation in organizing this workshop was to advance the study of such moral responses to a rapidly changing world, and to promote reflections on the consequences for Business Informatics in research, teaching, and the public sphere.

2 Central Themes and Challenges of Ethics in Business Informatics

The discipline of Business Informatics is rife with ethical questions and issues. In common with its principal subject—the understanding and development of socio-technical information systems—ethics and morality in Business Informatics can be studied from a variety of perspectives. These perspectives may concern the actual research objects of the discipline, or they may concern meta-scientific, methodological issues. On the level of concrete research objects, many areas of Business Informatics are bound up with ethical issues. For example, the design of artifacts and methods of Business Informatics has an ethical dimension, as the developed artifacts will typically have normative consequences for the behavior of people developing and operating business information systems. Likewise, the study of observable behavior between humans and software systems can investigate a diverse range of moral aspects, as information systems in many ways affect the actions, perceptions, and language of people involved with them. It is also worthy of examination whether conventional self-conceptions of professionals in Business Informatics embody moral, or perhaps morally problematic, premises. On a methodological level, in turn, ethical questions can concern basic assumptions and paradigms inherent in the research methods of Business Informatics.

It would be hopeless to attempt to provide a more exhaustive review of ethical questions in Business Informatics here. To make our case more tangible, we instead wish to highlight two general areas in which both classical and novel ethical questions arise in particular.

Decision Support in Information Systems. It is conventionally assumed that decision support is one of the basic tasks of computerized information systems. The history of Business Informatics is inextricably entrenched with Management Studies and Economics, where the leading conception of rational decision making has long been the expected utility model in different variants [4]. When applied to decision problems with an ethical dimension, this model naturally lends itself to a *consequentialist* conception of moral philosophy, famously advanced, for example, by Bentham [5] where alternatives are evaluated by the aggregated amount of pleasure or happiness obtained. However, such moral philosophies tend to neglect absolute rights and wrongs, such as the unalterable obligation not to kill. Such absolute principles are emphasized by *deontologist* moral theories, such as Kant's moral philosophy [6]. It is a question worth considering whether ordinary forms of decision support implemented in contemporary information systems implicitly adopt specific species of moral philosophies—and whether this has an effect on the moral evaluation of the courses of action recommended by these systems.

The Ethics of Developing and Using Business Informatics Artefacts. Humans and organizations shape the technology they design and implement, infusing their values into the resulting artefacts. In turn, those technological artefacts shape human experience and society. Value sensitive design is a theoretically grounded approach to the design of technology that systematically accounts for human values throughout the design process [7]. Neglecting the role of ethical and human values in business informatics product developments does not make those projects and products value-free. Moreover, we are witnessing a recent increase of interest in researching the role and effects of ethics and values in software engineering [8] [9]. Researchers formulate questions related to the prominent values of software engineers themselves [10], the ethical concerns of software development organizations (e.g. diversity, workplace quality), and how software development processes should account for ethical values. Business Informatics, with its focus on supporting business management and operations, offers additional research questions, such as how software can contribute to increasing enterprise responsibility [11].

Overall, it is evident that ethical questions are deeply rooted in basic presuppositions and research objects of the field of Business Informatics.

3 Contributions of the Workshop

The contributions to this workshop address a rich spectrum of the ethical and value-related problem areas in Business Informatics outlined above. Out of seven submissions, after careful review by our program committee members, we have selected five papers for presentation at the workshop and publication in the workshop proceedings.

Paper 1. In studying how information systems can be used to improve human welfare, it is instructive to consider how classical and contemporary philosophical traditions have answered related questions. The paper *"Doing Good Better: What We Can Learn from Effective Altruism"* by Alexander Herwix demonstrates how the core ideas of a recent movement with philosophical and anthropological roots, effective altruism, can be applied in the field of Business Informatics. Effective altruism, making the case for a deliberate and measured use of resources so as to generate the greatest human benefits possible, provides a number of practices and principles to help promoting good in different areas. Applying two core ideas from effective altruism, 'Shared Goals, Principles and Measures' and 'Cause Neutrality and Focus Area Selection', to the field of Business Informatics, the paper by Alexander Herwix proposes a number of reorientations for the discipline so that it may achieve more altruistic impact than it has had to date.

Paper 2. A central aim of Business Informatics is the design of new artifacts to support the development and use of information systems, commonly referred to as Design Science Research (DSR). Whether recognized or not, the design of artifacts is necessarily laden with ethical decisions. To promote awareness and evaluation of value-related design decisions in DSR projects the approach Value Sensitive Design (VSD) has been advanced in the literature. The paper *"Value Sensitive Design in Design Science Research Projects: The Cases of Affective Technology and Healthcare Technology"* by Oliver Heger reports on how VSD has been applied in two recent DSR projects and reflects on the lessons learned. The paper finds that VSD can indeed help identify, systematize, and assess value-laden design decisions and related conflicts in DSR projects. At the same time, the author stresses that more work is needed to obtain a better understanding of how approaches like VSD can raise Business Informatics researchers' awareness of ethical aspects in the design of socio-technical artifacts.

Paper 3. A view of the societal repercussions of the collaborative use of information technology and resulting ethical questions is developed by the paper *"Analyse der ethischen Fragestellungen bei der Konstruktion von digitalen Plattformen"* ("Analysis of Ethical Issues in the Construction of Digital Platforms") by Olga Levina. Considering the four dimensions Privacy, Access, Property and Accuracy, the paper reflects on ethical aspects of the governance structures of digital platforms. The examination demonstrates that over time an information asymmetry to the benefit of platform operators grows, which provides platform operators with instruments of power that potentially promote abuse. As a result, the paper argues for a socio-political debate about ethical questions around the construction of digital platforms.

Paper 4. Nudging has become a widespread mechanism in interactive and persuasive technologies, given its potential to influence the decision-making process of users and, eventually, modify their behavior. In the context of assistive technologies, nudging can be used to promote healthy behaviors and increase the independence of users (e. g., elders or people with an impairment). In their paper *"Moral Challenges in Modeling and Simulation of Behavior Change in Care"*, Stephanie C. Rodermund, Fabian Lorig, and Ingo J. Timm discuss the ethical implications of modeling and simulating nudging mechanisms and their corresponding user reactions. As they point out, such research and engineering practices entail ethical risks related to safety and privacy, among other concerns. Nonetheless, from a utilitarian perspective, once the risks have been analyzed and managed, the potential benefits in the well-being and independence of users makes nudging a convenient feature in assistive technologies.

Paper 5. The short paper *"Das Wertequadrat als Werkzeug der Wirtschaftsinformatik"* ("The Square of Values as a Tool in Business Informatics") by Alexander Rachmann addresses ethical questions on the methodical level of Business Informatics. It suggests to incorporate a conceptual tool called Square of Values into the methodical range of the discipline. The tool provides a systematic approach to find a balance between a pair of conflicting ethical values which both appear desirable. Together with an example of an ethical conflict in the domain of health-care oriented Smart Home applications, which targets the conflicting values of controlling a person's health status versus respecting a person's privacy, the paper suggests to connect the Square of Values with established modeling techniques for goals systems in Business Informatics.

As a whole, the contributions demonstrate that there is indeed much potential and need for research on ethical aspects in the objects and the methods of Business Informatics. Considering the range of topics discussed in the papers, it is clear that ethical questions are not placed at the margins of Business Informatics, but are instead entrenched in the very core subjects of the discipline.

4 Conclusions

The workshop *Ethics and Morality in Business Informatics* (EMoWI'19) was held in its first edition at the 14th International Conference on Wirtschaftsinformatik (WI 2019) in Siegen. We hope to have reinforced that the study of ethics and morality has an important place in Business Informatics, and that many areas in the field are worthy, and actually in need, of a careful study as to their moral implications. If anything, it can be expected that the ongoing digital transformation will further advance the impact, and thus the ethical relevance, that information systems will have for all people's life.

Many colleagues have contributed to the success of this first edition of the Workshop on Ethics and Morality in Business Informatics, so we would like to express our appreciation. We are grateful to the international program committee members, who have carefully reviewed the submitted papers. We sincerely thank the authors who were inspired by the topic of the workshop and have submitted papers for consideration; also, we thank those authors whose paper was accepted, for presenting their work in the workshop and participating in the lively debates. Last but not least, we would like to thank the organizing committee members of the WI 2019 conference for their support.

The workshop proceedings have been published at http://ceur-ws.org/Vol-2297.

Model-Based Compliance in Information Systems – Foundations, Case Description and Data Set of the MobIS-Challenge for Students and Doctoral Candidates

Constantin Houy, Jana-Rebecca Rehse, Martin Scheid, Peter Fettke

Institute for Information Systems (IWi) at the German Research Center for Artificial Intelligence (DFKI) and Saarland University
Campus, Building D 3_2
66123 Saarbrücken, Germany
firstname.lastname@dfki.de

Abstract. Information systems (IS) can significantly support the organization of business processes. However, the proceeding digitalization of processes can also lead to an increasing organizational complexity and the need to more intensely investigate the adherence to external or internal compliance rules. Process-related data from IS and underlying process models can, however, also contribute to an effective compliance checking. This paper first presents conceptual foundations of model-based compliance checking that motivated the MobIS-Challenge workshop for students and doctoral candidates at WI 2019. Second, we introduce the challenge itself and its corresponding data set. The data describes an exemplary travel management process in a medium-sized consulting company and served for the development and validation of adequate solutions addressing the compliance checking requirements. Solutions accepted for presentation at the workshop are briefly outlined in this paper.

Keywords: GRC, Governance, Risk and Compliance, BPM, Business Process Management, Process Mining, Data Set

1 Introduction

Nowadays, business processes are increasingly carried out digitally with the help of information systems (IS), which can significantly support an effective, efficient and flexible management of business processes. However, the proceeding digitalization of business processes can also lead to an increasing complexity of organizations and the need to more intensely analyze and ensure the adherence to externally or internally specified compliance rules. In this context, process data from IS and underlying business processes as well as business process models can, however, also considerably contribute to an effective compliance checking. The usage of data from IS allows for an easier reconstruction of business processes, e.g. based on built-in logging mechanisms, and furthermore facilitates the identification of violations of internal or external compliance rules. In this context, there are some research streams,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

such as process discovery and conformance checking, that develop new methods and techniques to analyze the process data logged by information systems and to use the gained insights for the benefit of the company.

This contribution presents the WI 2019-Workshop "MobIS-Challenge for Students and Doctoral Candidates: *Model-Based Compliance in Information Systems*", the topic's conceptual foundations, the use case which was investigated by the challenge participants as well as the corresponding data set. Participants of the MobIS-Challenge were supposed to identify opportunities to use IT tools (e.g. existing process mining tools, BPM solutions, self-developed programs etc.) for analyzing and improving the business process compliance in the addressed business travel management scenario, specifically by examining the compliance of this process and pointing out its weaknesses.

The remainder of this paper is organized as follows: in section 2, we introduce some conceptual foundations of model-based compliance management with a particular focus on business process data from information systems. In section 3, we describe the travel management use case to be analyzed in more detail providing a verbal description as well as an according business process model which served as a basis for the simulation and development of the data set. Section 4 provides a detailed description of the data set focusing on the most severe compliance violations included in the approximately 6,500 business travel management cases contained in the data. Section 5 presents the tasks which had to be addressed in the challenge as well as a brief description of potential solutions by the authors of this paper, while section 6 introduces accepted solutions which participants submitted to the MobIS-Challenge.[1] Section 7 concludes the paper.

2 Business Process Compliance

Business process models can serve as an instrument to express and clarify the course of activities in the context of value creation in organizations [1]. While business processes can be understood as sequences of executions for the purpose of creating goods and services [2], business process models are representations of business processes which provide the basis for several different tasks of Business Process Management (BPM) [3], such as process implementation, execution, controlling or systematic process improvement [4].

In order to support their daily operations, business organizations use information systems (IS), like enterprise systems (ES) for enterprise resource planning (ERP), supply chain management (SCM) or customer relationship management (CRM) etc. Such IS – no matter whether they are process-oriented and explicitly produce so-called process log data or not – generate data, which can serve to obtain a view of the underlying business processes. The data generated by IS can, thus, also serve for the identification of compliance violations.

[1] We currently plan to separately publish a detailed report on the accepted solutions submitted to the MobIS-Challenge.

In literature, *compliance* is one major aspect of the comprehensive topic addressed by the umbrella term *Governance, Risk and Compliance* (GRC). GRC and its related policies and rules as well as technical support approaches and methods are supposed to ensure a good, responsible and sustainable management of organizations, which follow the applicable law and commonly accepted standards [5, 6]. Compliance management is supposed to ensure the conformity of "business processes, operations and practice […] with a prescribed and/or agreed set of norms" [7]. In this context, external and internal compliance requirements can be differentiated. Typical external compliance requirements are legal initiatives like the *Sarbanes-Oxley Act* (SarbOx) in the US or *Basel III* in the financial sector as well as the so-called *Bribery Act 2010* as an anti-corruption legislation example passed in the UK. Furthermore, many organizations have defined internal compliance requirements, which have not been formulated by external authorities, but which are supposed to ensure a voluntary conformity of the organization's behavior with common standards.

The term *business process compliance* is ambiguous and used to address different concepts in literature. Some contributions aim at checking the compliance of business process instances (*as-is processes*) in terms of a defined process model, focusing on their identity without looking at operational business issues. Other contributions refer to business process compliance as a means of checking the operational compliance of an organization based on the underlying business processes, e.g. using process logs to identify and investigate potential violations of external or internal compliance rules [8-12]. In this contribution, we use the term *business process compliance* according to the latter understanding.

FELLMANN and ZASADA give a comprehensive overview of the current state-of-the-art in their review contribution investigating a total of 84 business process compliance approaches [13]. They identified different dimensions for compliance checking (p. 5) which are described in Table 1.

Table 1: Dimensions of Compliance Checking (Fellmann and Zasada, 2014)

Nr.	*Dimension*	*Sub-Dimensions*
1	*Scope*	Order and occurrence, Information, Resource, Time, Location
2	*Lifecycle phase*	Design, Execution, After Execution
3	*Formality*	Verification / Validation, Business-oriented
4	*Contribution type*	Technical artefact, Method, Other

Known approaches for a business process-oriented compliance checking, e.g. use process mining techniques [14] or so-called control patterns [15]. Furthermore, there are several commercial tools, which already implement compliance checking techniques in different contexts [16]. The following section describes the underlying business travel management case treated in the MobIS-Challenge.

3 Case: Business Travel Management Process

3.1 Case Description and Process Model

The case that we provide for the workshop describes a business travel management process in a medium-sized software consulting company. While the data itself was generated by simulation, the process and its governing compliance rules are inspired by one we have encountered in a recent research project.

The goal of the business travel management process is to keep track of all business trips the employees take and their related expenses, such that they can be invoiced to the respective customer, for whose project the respective trip is taken. As is usual in consulting companies, the employees travel quite often to meet with customers, but as software consulting includes some work that can be done remotely, they are not constantly traveling. In order to better control the bookings, to take advantage of economies of scale in the booking process, and to avoid lengthy reimbursements, the company has decided to install a separate travel department, where multiple travel agents are responsible for booking business trips, always in accordance with the respective employee.

To improve the internal process organization, the company has developed its own internal workflow management system which can be accessed by each employee. Travel management is fully covered and logged by this system, with the travel management process implemented as a workflow and the tasks and rights assigned according to the employee's role in the company.

Within the process, there are four acting roles:

(1) the Employee, who wants to go on a business trip,
(2) the Manager, who has to approve the trip and the expense report,
(3) the Travel Department, which is responsible for bookings and price information, and
(4) the Accounting, which is responsible for calculating and reimbursing costs.

In our case company, there are 300 employees, 15 managers (including 3 directors), 5 travel agents, and 10 accounting clerks.

The process starts, when an employee files a travel request. Such a request offers two options: The employee can either directly file a request or she can initiate a preliminary price inquiry, which is helpful if the travel expenses and potential booking options are unclear. In this case, the request is forwarded to the travel department, where a travel agent provides a booking proposal and discusses it with the employee. If the employee accepts this proposal, she can adapt her price inquiry accordingly and then transform it into an official travel request. If the proposal is not accepted, she first has to check whether the trip is still necessary and all data is up-to-date, before requesting an update of the booking proposal from the travel agent.

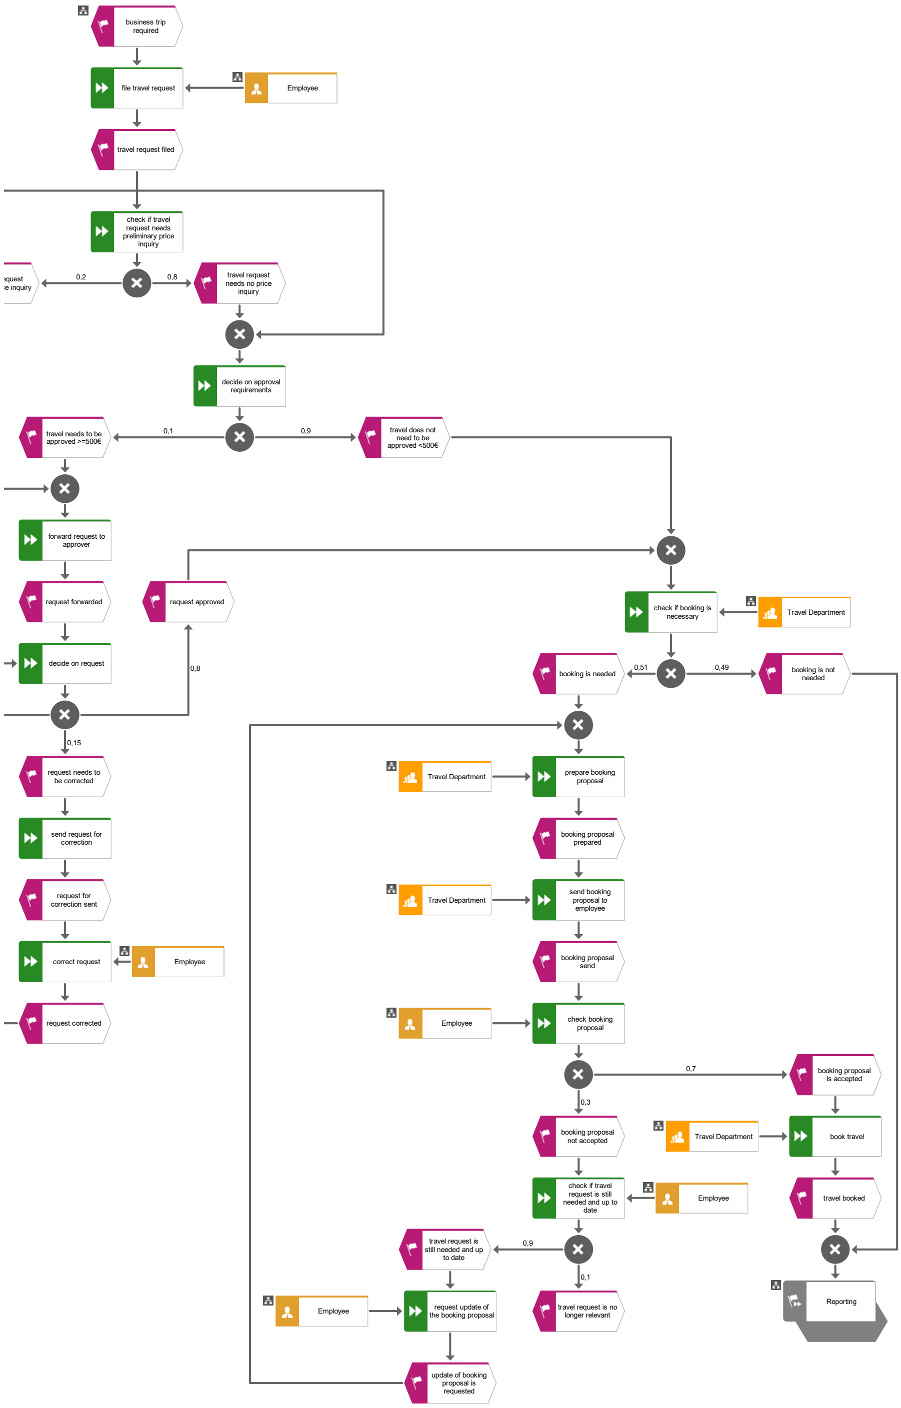

Figure 1: Excerpt of the *planning part* of the travel management process

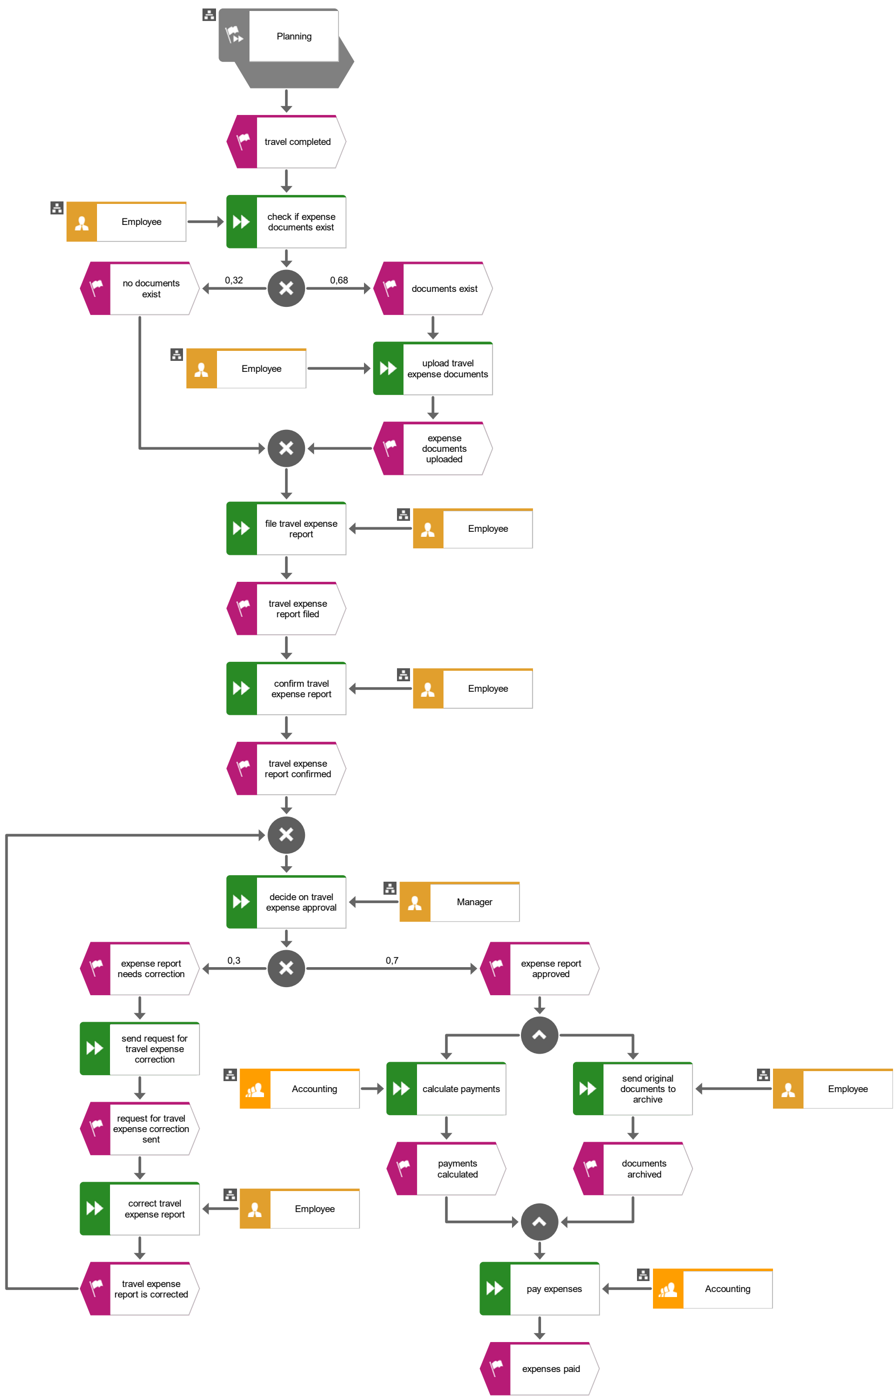

Figure 2: The *reporting part* of the travel management process

When the travel request is officially filed, it has to be checked for approval before it can be handled by the travel department. The workflow system automatically checks whether the request fulfills the approval requirements and forwards it to the responsible manager for approval. The manager checks the request and either approves it, rejects it, or asks for a correction. In the latter case, the system redirects the request to the employee, such that she can make adjustments according to the manager's requests. This correction process is repeated, until the manager finally approves or rejects the travel request.

Once a travel request is approved, or if approval is not required, it is forwarded to the travel department and assigned to a travel agent, who checks whether the request requires any bookings. If not, for example if the employee takes her own car or a company car for a business trip, there is nothing left to do for the travel department. If yes, the travel agent prepares a booking proposal according to the employee's specifications and sends it back for approval. If the employee approves the proposal, the travel agent confirms and pays for all bookings (e.g. hotel, flights, or rental cars). If the employee does not approve the proposal, she has to confirm the data and relevance of the travel request, before she can ask the travel department for an updated booking proposal.

After a business trip is concluded, the employee has to fill out a travel expense report in order to be reimbursed for any travel-related costs. To ensure correct accounting procedures, employees also have to fill out a report if no expenses have incurred. Therefore, the employee first needs to check whether she has any travel-related expense documents (e.g. invoices or receipts). If such documents exist, they have to be uploaded in a digital form, such as a scan. Afterwards, the employee fills out the travel expense report as provided by the workflow system. The confirmed report is automatically forwarded to the respective manager for approval. If the manager decides that the report cannot be approved, it is sent back to the employee for corrections. After the report is approved, the accounting department is in charge of calculating the total travel costs, archiving the travel-related documents, and paying the expenses of the employee.

3.2 Compliance Rules

Within the travel management process, there are a number of external and internal compliance rules, which must be followed. The internal rules are mainly important to keep the accounts correct and up-to-date, whereas the external rules are necessary for invoicing travel expenses to the customer. In detail, the travel management process conforms to the following compliance rules:

(1) For each business trip, an according travel request must be filed and, if necessary, approved before the beginning of the trip.
(2) Business trips must be necessary to ensure the success of a project. If this necessity cannot be documented, a manager might reject the request.
(3) A travel request must contain realistic cost estimations. The real costs in the travel expense report filed after the trip should not exceed this estimation.

(4) If the estimated travel cost does not exceed 500€, it does not need to be approved.
(5) If the estimated travel cost exceeds 500€, the trip must be approved by the employee's responsible manager.
(6) Managers' trips must be approved by a director. The three directors approve each other's trips.
(7) Managers should promptly approve, reject, or react to incoming requests.
(8) If possible, trips should be booked and paid for by the travel department.
(9) After a trip has ended, the travel expense report should be filed immediately.
(10) All travel-related expenses should be documented with a receipt.
(11) Travel expense reports must be approved by the employee's responsible manager. Again, managers' travel expense reports are approved by a director and the directors approve each other's reports.
(12) Managers should check requests and expense reports carefully and ask for corrections, if they find any rule violations.

4 Data Set[2]

4.1 Model Development

In order to generate a viable process log for the MobIS-Challenge case, we first developed a process model that we could use as the basis for data generation. We used the ARIS simulation component for data generation and modelled our process as an *Event-Driven Process Chain* (EPC). Then we enriched it with data that is required for simulation. According to the description above, we separated the process into two major parts. Large parts of the travel planning process are shown in Figure 1. While the price inquiry handling is described on the left side of the complete process (not displayed in the excerpt in figure 1), the right side of the process model deals with approving travel requests in the loop on the left and handling the bookings in the subprocess on the right. The second part of the process, expense reporting, is shown in Figure 2. First, the employee uploads all travel-related documents and produces an expense report, which is then approved by the manager in the loop on the bottom left. Expenses are reimbursed by the accounting department on the bottom right.

ARIS offers a multitude of attributes to be defined for each model element, some of which were necessary to ensure that our simulation would produce a viable data set. In our case, we needed to define an executing role for each function to assign resources in the process log, the number of employees that instantiate each role, probabilities for each XOR-connector to determine the path frequency, execution times for each function to allocate sufficient time for its execution, and schedules for employees to account for normal working hours. We also associated the start event

[2] Data set source: Scheid, M., Rehse, J.-R., Houy, C., & Fettke, P. (2018). *Data Set for MobIS Challenge 2019 [Data set]*. https://doi.org/10.13140/RG.2.2.11870.28487.

with an instantiation schedule and a fluctuating delay to introduce some randomness into the start times of each case.

As can be seen in the process model, each function is associated with a role that is responsible for its execution; roles without an explicitly associated role are automatically executed by the workflow system itself. Each role is associated with a schedule, which determines its typical working hours. Employees can work anytime between 6am and 11pm, which factors in that consultants sometimes do organizational tasks like travel management at odd hours. The administrative personnel, i.e. the travel agents and accounting clerks, work typical office hours from 9am until 5pm. We included one week of vacation time in July, where no travel agent was working. In the managers' schedule, we defined their working hours to be only between 1pm and 2pm to account for the fact that managers are typically very busy and only tend to administrative tasks like travel management at certain hours, e.g. after lunch.

We also defined a fluctuating execution time for each function. ARIS allows several options to set either strict or varying execution times and we decided to model them all as a capped normal distribution, specifying the expected value, standard deviation, minimum and maximum time for each function. Realistic values were set for each function, such that automated functions executed by the workflow system only take a few seconds, whereas time-intensive functions like preparing a booking proposal takes several hours.

The number of employees (300) and managers (15) in the company were predefined before simulation, but the necessary number of travel agents had to be determined empirically, such that some, but not too many cases were piling up at any given time. 5 travel agents turned out to be a sufficient number.

For most functions, we did not have to define static waiting times to account for employees being busy with other tasks that have nothing to do with travel management. All waiting times for the travel department are caused dynamically, because other cases are handled first. Only the accounting functions wait statically for a few days to account for other responsibilities of the accounting department.

4.2 Data Generation

After the model was developed, we used it as the basis for simulating the process data. This simulation consisted of multiple steps.

Process Simulation with ARIS. Based on the developed process model, we used the ARIS simulation component to generate execution data. To account for the travel time that occurred between the two process parts, we connected them with an artificial function ("travel"), with fluctuating static waiting times (to account for the time passing between a travel request and the trip itself) and execution times (to account for the duration of the trip). We wanted to simulate data for one year, so the simulation period was set from October 1st 2016 to December 31st 2017, with the first 91 days functioning as a warm-up phase to have plenty of cases in the system. ARIS used the specified process data to simulate its execution. Each simulation took about

15 to 20 minutes to complete. We exported the case data from ARIS and converted it into a CSV file to proceed further.

Generating Additional Data with Excel. The ARIS simulation was only able to generate the process steps itself, so we had to enrich the log with additional data on travel costs and the organizational structure. We defined the company's internal organizational structure, such that we could assign each case to an employee and the responsible manager. There were three cost values that had to be generated, the estimated travel costs, the real travel costs, and the reimbursed costs. The estimated costs were calculated randomly, depending on the length of the trip and whether or not the travel request has to be approved. The real travel cost was calculated to randomly fluctuate in both directions around the estimated cost. Finally, the reimbursed costs depend on whether the travel department booked the trip for the employee. If yes, they were lower than the travel costs, if no, the two numbers were equal.

Manual Data Cleaning. After all data was generated, we had to manually go over it to remove some mistakes and irregularities, such as business trips during Christmas time. After cleaning the data and introducing compliance violations (explained in the next section) our final data set contains 6,555 cases with 26 activities and a total of 83,256 events.

4.3 Violations of Compliance Rules

After the process log was simulated, enriched, and cleaned, we introduced compliance violations. From a data perspective, there are two types of compliance violations, those that were caused by simulation parameters and were already present in the log and those that had to be entered manually.

Violations caused by Simulation Parameters. We defined our simulation parameters (schedules, waiting times, cost calculations) such that we deliberately build some compliance violations directly into the log. They are listed in Table 2 and shortly explained in the following.

Table 2: Compliance violations caused by simulation parameters

ID	*Compliance violation*	*Simulation cause*
1	Long delays in manager's reaction	Managers are encouraged to answer promptly to incoming travel requests, to avoid not reacting in time for the trip. (*Rule 7*)
2	Long delays in expense reporting	Accounting should promptly reimburse the employees for their expenses, to avoid unnecessary payment legacy. (*Rule 9*)
3	Real travel expenses significantly exceed calculated expenses	Employees should give a realistic estimation of expected travel costs, to ensure necessary approvals and facilitate accounting. (*Rule 3*)

Violation (1) stems from a time restriction. According to their time plan, managers spend one hour each day for administrative tasks, causing requests to build up. This artificial restriction causes a bottleneck in the process, such that travel requests are delayed for several days before being approved or declined. Violation (2) can be accounted to fluctuating static waiting times, which we attributed to the functions to simulate other responsibilities of the accounting department. Finally, violation (3) is due to the fact that during cost simulation, we had real travel expenses fluctuate in relation to calculated expenses, such that they sometimes are much higher.

Manually entered Compliance Violations. However, most compliance violations (especially those that deviated from the normal process flow) could not be built directly into the log, but had to be manually entered. These violations, which include 9 of the 12 in total, are listed in Table 3. For each violation, we explain how it contradicts our compliance rules and give its frequency in the log, i.e. the number of existing cases which we altered to violate compliance in the described way.

Table 1: Manually entered compliance violations

ID	*Compliance violation*	*Compliance explanation*	*Freq.*
4	Travel request is submitted after the trip	Travel request must be filed and approved before the trip. (*Rule 1*)	8
5	Only price enquiry is submitted	Price enquiry must be converted into a travel request before the trip. (*Rule 1*)	12
6	Manager approves his own trip	Manager's trips must be approved by a director (four eyes principle). (*Rule 6*)	5
7	Manager approves his own expense calculation	Manager's expense calculations must be approved by a director (four eyes principle). (*Rule 6*)	10
8	Trip is approved by the wrong manager	Trips must be approved by the employee's own manager. (*Rule 5*)	11
9	Employee travels despite rejected travel request	Travel requests must be approved by a manager to ensure their necessity. (*Rule 1+2*)	2
10	Multiple travel requests (less than 500€) for one trip	Requests only have to be approved if the estimated costs exceed 500€. (*Rule 4+5*)	8
11	New travel request after rejection	The manager assessed the trip as unnecessary for the project success. (*Rule 2*)	3
12	Paid expenses exceed calculated expenses	The accounting department paid more to the employee than costs incurred for the trip. (*Rule 3*)	17

The following two sections give a brief description of the tasks and *potential* solutions to the problem to be treated in the MobIS-Challenge (section 5) and, furthermore, present the *submitted* solutions which were accepted for presentation at the MobIS-Challenge (section 6).

5 Tasks and Potential Approaches

The participants of the MobIS-Challenge were supposed to identify opportunities to use IT tools (e.g. existing process mining tools, BPM solutions, but also self-developed programs) for analyzing and improving process compliance and pointing out process weaknesses, even beyond conformance issues.

The tasks and leading questions for the MobIS-Challenge were as follows:

(1) *Describe the process depicted in the log with graphical means. From this description, derive meaningful compliance rules that go beyond the [.] description [given in the call for papers].*

(2) *Which compliance violations can be found in the data? How can these be prevented?*

(3) *Beyond compliance issues, which weaknesses in the process or the organization can be found in the data? How could these be improved?*

(4) *Which additional insights can be drawn from the data? You can use any tool to develop interesting additional insights in a creative way.*

To address and answer these questions, different approaches can be used. At first, the data should be carefully surveyed in order to get an overview of available data fields and their meanings in particular contexts. There is, e.g. a significant difference between the meanings of the different values in the field "cost" depending on the process step in which the costs play a role. In this context, we can differentiate between (a.) estimated costs, (b.) real costs and (c.) reimbursed costs.

Common *process discovery* approaches can be used to derive a graphical process model from the provided data set. In this context, different discovery algorithms (*heuristics miner*, *fuzzy miner*, *alpha miner* etc.) can be used and the different results can be compared. An adequate choice of the settings concerning activities and traces should be elaborated in order to develop a helpful process model which supports finding answers and solutions to the above problems.

Next, most process mining tools offer the opportunity to calculate distributions of cases, the identification of outliers and an overview of different process variants in the data set. Furthermore, time-related analyses can be conducted, e.g. to identify anomalous process durations.

Furthermore, there are several different possibilities to perform advanced analyses by identifying clusters in the data representing different classes of process variants as well as outliers which can then be analyzed in more detail to identify function deviations or anomalies. Moreover, the participants of the MobIS-Challenge could also "manually" develop a process model based on the data, e.g. a petri net, and then perform an automated conformance checking against the data set in order to identify outliers and anomalies. The same can be done in terms of rules. Obvious compliance rules which were followed in data set can be modelled and then be checked against the whole data set to identify outliers. The following section presents the solutions accepted for presentation at the workshop.

6 Solutions Accepted for Presentation at the Workshop

The following submitted solutions were accepted for presentation at the 2019 MobIS-Challenge workshop at WI 2019 in Siegen:

(1) In their extended abstract submission *Conformance Checking with Dynamic Condition Response (DCR) Graphs – An application to the MobIS Challenge 2019*, DUNZER, BAIER and STIERLE use a process conformance checking technique based on so-called *Dynamic Condition Response* (DCR) graphs [17]. Their approach follows the declarative process modeling paradigm and was instantiated as a software tool using Python. In order to answer the questions and fulfil the tasks of the MobIS-Challenge the CRISP-DM framework was used as a basis for structuring the project. The DCR graphs serve for the formulation of compliance rules which are then used for the identification of compliance violations in the data set.

(2) In their extended abstract submission named *Detection of Compliance Rule Violation in Business Processes using Sequence-to-Sequence Autoencoder*, WILLEMS and PFEIFFER describe the development of a framework for an automated detection of compliance violations based on neural networks. A sequence-to-sequence long short term memory (LSTM) autoencoder was trained using the entire event log from the MobIS-Challenge data set. By encoding and decoding traces from the event log, differences between input and output traces which are likely to indicate anomalous behavior can be calculated. The reconstruction error is used to find sequences of suspicious events. Furthermore, the extended abstract reports on the usage of state-of-the-art process mining tools like ProM, Disco, Celonis and bupaR for the further analysis of the event data set in order to provide detailed process mining-related analyses in the planned completed report.

7 Conclusions

This contribution presented the WI 2019-Workshop "MobIS-Challenge for Students and Doctoral Candidates: *Model-Based Compliance in Information Systems*". We provided a detailed description of the use case, which had to be investigated by the challenge participants as well as the corresponding data set. We have accepted two interesting initial descriptions of solution approaches. The challenge participants were invited to present detailed information concerning their solutions at the workshop.

Beyond the workshop in Siegen at WI 2019, we believe that the provided data set can also serve for and support further BPM research endeavors, e.g. in terms of the validation and evaluation of process mining or data analytics approaches for the investigation of data, which is relevant for business process compliance issues.

Report of the Workshop on Concepts and Methods of Identifying Digital Potentials in Information Management

Stefan Koch[1], René Riedl[1,2], and Manuel Mühlburger[1]

[1] Johannes Kepler University, Linz, Austria
{stefan.koch,rene.riedl,manuel.muehlburger}@jku.at
[2] University of Applied Sciences Upper Austria, Steyr, Austria
{rene.riedl}@fh-steyr.at

Abstract. Recently a discussion has been instigated in the scientific community on whether our understanding of information management (IM) is still up to date [1]. A workshop on the concepts and methods of an additional IM perspective which intends to identify possible technology applications (by putting the primary focus on the possibilities offered by information technology rather than on the support of existing organisational functions and task structures) was held at the WI Conference 2019. This paper summarizes the conceptual input of the workshop and provides an overview of the initial workshop contributions.

Keywords: Digitalization, Digital Transformation, Information Management,

1 Workshop Topic

The changing understanding of information management (IM) towards a more enabling and proactive instead of a supportive and reactive organisational function is creating pressure for practitioners to deliver value from IT use in organisational contexts [2]. The rise of the now omnipresent terms of digital transformation (DT) and digitalization have contributed to this increasing pressure and have also caused increased expectations regarding the IT function's contribution to organisational success. Practitioners are expected to instigate, plan, and execute DT projects which do not primarily focus on cost reduction and productivity increases, but also contribute to new innovative business model transformation. As a consequence of this development, the scientific community is expected to advance existing and to develop new models, frameworks and methods which describe and explain technology driven changes in organisational value creation. These concepts should enable practitioners to rethink and refine existing organisational value creation structures by more directly considering the opportunities provided by digital technologies.

Following the aspect of increasing market dynamics, a fast organisational reaction capability to technological innovations has been identified as a major success factor for organisations [3]. This organisational agility requires organisations to not only be aware

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

of technological possibilities and advancements, but also to identify their potentials for the organisation [4]. Understanding how these potentials can be identified and exploited by organisations is therefore a necessity for a modern and successful IM.

Existing IM perspectives, methods and frameworks have a traditional focus on the organisational integration of information technology by following defined business strategies [5]. Although early works identified the potential of a proactive and enabling IM [6], these works remained largely unconsidered in practice. In essence, despite opposing calls in the academic literature [7, 8], IM in practice often concentrated on fulfilment of a supportive role. Whilst such as approach enables organisations to implement and operate new IT systems once their potential is identified, they give little guidance on how different application scenarios of new technology can be identified.

Whilst the tasks of this classical support role of IM will not lose relevance in the future (because reliable systems are the foundation of successful business processes [9]), there is a growing need for organisations to identify new technology potentials [10]. The question by which mechanisms, structures, processes and capabilities organisations can efficiently identify potentials has not been a primary focus of the IM field, but is central if IM should fulfil a proactive and enabling role [10]. An additional perspective on IM which integrates organisations into a digital world, instead of integrating digital technologies into organisations, provides value to both academia and practice.

To contribute to this recent development, a workshop was held at the WI conference 2019. Specifically, this workshop focussed on the identification of digital potentials as a primary aspect of future IM, both from a conceptual and methodological perspective. The initial contributions to this workshop put the focus on three main methodological and structural aspects of the identification of digital potentials.

2 Overview of Workshop Contributions

The first contribution by Florian Rittmeier presents a research proposal and design for the development of an assistance system enabling organisations to identify digitalization potentials within existing business process structures. The author proposes a system supporting organisations specifically in the phases of process discovery, analysis and redesign. By specifying key process characteristics relevant for a later potential analysis, the proposed system provides support within the phase of process discovery. The proposed system would further support process analysis by identifying deficiencies within the process model based on formalized process weakness patterns. Based on the identified weakness patterns, a formalized set of recommendations is presented to further support the phase of business process reengineering. By combining weakness patterns and relevant recommendations into opportunity patterns the author intends to enable organisations to identify and restructure their processes in a more efficient and effective way that is less dependent on the experience and interpretation of individual process analysts. We understand the attempt of creating a formalized pattern set of digitalization opportunities within business processes as a promising approach which provides a valuable contribution to this workshop regarding methodological aspects.

The second contribution authored by Barbara Krumay, David Rueckel and Sabrina Schwarzgruber discusses aspects of assessing and evaluating technology potentials in agile environments. As the authors put forward, traditional assessment methods tend to limit the dimensions used to assess the value of IT-investments to certain short-term monetary aspects. The authors argue that in agile environments with fast changing organisational goals and structures more flexible assessment methods including additional levels of analysis are required. Real options are identified by the authors as a promising methodology to focus assessments on additionally created technology potentials. Furthermore, the authors discuss the possible value of impact assessments as a method for identifying and assessing additional potentials resulting from certain IT-investments. Impact assessments are used in a variety of disciplines as a methodology for identifying possible consequences of certain events. Whilst currently predominantly applied in environmental, social and legal contexts, the authors argue for an adaptation and adoption of such instruments in a technology context. We understand the approach of utilizing impact assessments and real options for the identification, evaluation and assessment of technology potentials as a valuable contribution to this workshop to complement existing methods.

The final contribution from Friedrich Holotiuk discusses the role of digital innovation labs (DILs) in enabling organisational ambidexterity. Ambidexterity describes managing the trade-off between exploration and exploitation activities and is traditionally conceptualized in the two different types of structural and contextual ambidexterity. Structural ambidexterity means managing the trade-offs by implementing "dual structures" with units focussing on either exploration or exploitation. Contextual ambidexterity refers to balancing exploration and exploitation tasks within existing units, teams or individuals. DILs are organisational units bundling necessary capabilities for the development of digital innovation. The author conducted an intensive single case study on an existing DIL and provides structured insights into this organisational design and its possible contribution towards enabling organisational ambidexterity. Based on the results of the case study the author concludes that existing ambidexterity concepts do not fully describe the type of ambidexterity enabled through digital innovation labs. This organisational concept allows the full focus of certain employees on either exploration or exploitation tasks based on a temporal aspect. We follow the conclusion of the author who identifies DILs as a promising organisational design for the identification of technology potentials within organisations.

peter.mertens@fau.de

Abstract. The emergence of global networks also results in the occurrence of systemic risks that might affect the stability of the overall system. To cope with these risks, this workshop on the "Control of Systemic Risks in Global Networks" provides a platform for the collection and discussion of innovative approaches, methods, and theories but also of practical problems from the areas of simulation, artificial intelligence, operations research, and statistics. This enables the exchange of experiences and methods between scientists and practitioners.

Keywords: Grand Challenge, Systemic Risk, Reference Framework.

1 Introduction

Modern communication networks lead to a stronger coupling of and interdependency between social and economic areas. Examples are electronic marketplaces, which enable ever faster transactions, worldwide production networks, which allow for higher specialization with increasing efficiency, and *smart grids*, which facilitate the provision of energy in the European Single Market by means of flexible control. The resulting worldwide and interconnected networks increasingly decide on the competitiveness of enterprises.

On the one hand, this development is promoted by a strong **demand pull** for innovative technologies that emanates from companies. This results from the companies' endeavor to take advantage of environmental differences in a "globalized world". Examples are increasing sales opportunities in emerging countries, low labor costs, special competences in the development and production of electronic components or software products, discoveries of raw materials, and tax conditions.

On the other hand, there is an increasing **technology pressure**. This is due to an increasing performance-cost ratio of data management as well as from the fact that modern multi and manycore systems accelerate or initially enable the solving of sophisticated planning, disposition, and control algorithms. Moreover, the advancement of traditional methods, e.g., artificial neural networks and deep learning,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

allows for the discovery of patterns and the investigation of systems that remained hidden or were inaccessible before.

Along with these worldwide networks, *systemic risks* emerge which affect the stability of the overall system [1]. Examples of potential failures are flash crashes in high-frequency trading, production downtime due to delivery delays, or blackouts in energy networks. For instance, on September 28th, 2003, power plant failures in Italy lead to disruptions of the Internet infrastructure, which relied on energy supply and at the same time was required to control other power plants. This resulted in a cascade of failures and has nearly caused the collapse of the entire Italian energy supply [2,3].

Obviously, not all risks are equivalent with respect to their probability of occurrence and of the consequences. Thus, those *systemic risks* must be identified, which – as illustrated by the example – affect the stability of the overall system and are not considered as part of the risk assessment of the independent subsystems. Here, the extent of the risk must be considered as well as the probability of finding an adequate countermeasure with reasonable effort.

In a joint initiative, which is steered by the *German Informatics Society* (Gesellschaft für Informatik; GI), Information Systems Research and Computer Science have selected the *control of systemic risks in global networks* as one of the five most important Grand Challenges for the future [4]. From an information system research perspective, two major interests can be identified: On the one hand, the availability as well as the situational aggregation and interpretation of decision-relevant information and on the other hand the autonomous identification, quantitative estimation, and flexible reaction to risks.

2 Current Technology Pressure

In information system as well as computer science research, there are ongoing discussions whether networks can be designed or dynamically emerge from the interaction of devices with network technologies: Worldwide networks are not designed as part of an "engineering process", they are created through the interaction of interconnected systems as emergent phenomenon and must be described and understood [5].

The need for a development of methods for the design of such networks can be identified when investigating the current technology pressures. Developments that can contribute to the control of systemic risks include but are not limited to:

1. **Communication Networks**: Advances in communication networks, e.g., an increasing performance-cost ratio of communication channels (hardware) and greater flexibility in routing (software), which allow for prioritized communication in case of emergency.
2. **Simulation**: Recent developments in simulation from a tool for planning support to a real-time assistance for decision support through the development of innovative formalisms, e.g., system dynamics or agent-based simulation, and due to the immediate availability of current data.

3. **Machine Learning**: Revolutionary progress in machine learning that is facilitated by the increasing availability and amount of (training) data as well as shift from multi to multi and manycore computing. This allows for the use of deep learning, convolutional neural networks as well as data, text, and opinion mining techniques.
4. **Decentralized Control**: The availability of approaches for decentralized and adaptive control with autonomous software agents, multiagent systems, and organic computing promotes the high-tech strategy "Industry 4.0".
5. **Transaction Processing Systems (Blockchain)**: New forms of transaction processing systems, e.g., blockchain, allow for the tamper-resistant and decentralized organization and logging of safety-critical operations in processes such as access or updates of sensitive data.
6. **Multilayer and Multiplex Networks**: A shift from the analysis of isolated and homogenous networks to the investigation of multilayer and multiplex networks (interdependent networks).
7. **Convergence**: The convergence of technical systems and processes leads to the unification of business models and technologies across sectors. Through this, technical and economic success of one domain might dominate another domain, e.g., successful business models of internet giants can compete with stationary trade in the physical world even though the horizon of experience is considerably lower.

Due to disciplinary barriers, the aforementioned technology areas are not yet sufficiently developed, applied, or transferred for controlling systemic risks. This limits the opportunities for action that can be undertaken to prevent the potentially dramatic consequences of systemic risks. Still, these technologies have a high potential to contribute as component of a solution for controlling systemic risks.

Considering disaster management strategies, for instance, it can be illustrated how disciplines can learn from each other and benefit from the experiences of other disciplines. Insurance companies make use of reinsurances to handle major claims which could result in their insolvency. Such approaches are also applicable to supply chain management as protection against supply shortages that might result in disruptions of the own production of goods. In this regard, supply chain management can also learn from insurances as systemic risks emerge from networks of reinsurances which can potentially result in uncontrollable chain effects that lead to global crises.

3 Reference Framework

Suitable technologies and methods for controlling systemic risks are diverse. Thus, to classify and distinguish different approaches, we suggest the use of a morphological box. It serves as a reference framework for discussion within the workshop as approaches can be classified and assessed according to different dimensions. In Figure 1, the morphological box is illustrated that is used for the assessment of the approaches that are presented as part of this workshop. For each approach, the aspects of *networks*, *risks*, and *decision situation* are focused.

To this end, the domain focus of the workshop lies on *logistics*, *finance & insurances*, and *public services*, yet, also contributions from other domains are welcome. With respect to the type of risk that is addressed by the approaches, it can be differentiated into five types, according to the domain the risk is related to: *production*, *market*, *finance*, *institution*, and *nature*. In addition, also the occurrence of the risk is classified as *regularly*, *periodically*, or *rarely*. Finally, the decision situation of the risk can be specified according to the risk's predictability as well as by the authority which is the decision maker.

Network	***Domain***	Logistics	Finance & Insurances	Public services		
	Network model	Available and fixed	Available and ongoing change	Situation-dependent change	Ad-hoc	
Risk	***Type of risk***	Production	Market	Finance	Institutional	Nature
	Occurrence	Regularly	Periodically	Rarely		
Decision situation	***Predictability***	Predictable and plannable	Predictable and not plannable	Not predictable but plannable	Not predictable and not plannable	
	Authority	Single person	Committee	Automated, with intervention of persons	Fully automated	
	Horizon	Enterprise	Network	Society		

Figure 1: Reference framework for the classification and discussion of approaches.

4 Discussion

To address the Grand Challenge of controlling systemic risks in global networks, this workshop aims at both the collection and discussion of innovative approaches, methods, and theories but also practical problems from the areas of simulation, artificial intelligence, operations research, and statistics. To this end, the goal of the workshop is to provide a platform for the exchange of experiences and methods between scientists and practitioners. Moreover, the development of a medium-term research agenda shall be promoted for targeting this Grand Challenge.

5 Acknowledgements

We would like to thank all those that contributed to the initiative on "Control of Systemic Risks in Global Networks" for their fruitful comments and innovative ideas.

Die Mitarbeiter von morgen - Kompetenzen künftiger Mitarbeiter im Bereich Business Analytics

Uwe Neuhaus[1], Hinrich Schröder[1], and Michael Schulz[1]

[1] NORDAKADEMIE Hochschule der Wirtschaft, Fachbereich Informatik, Elmshorn, Germany
{uwe.neuhaus,hinrich.schroeder,michael.schulz}@nordakademie.de

Abstract. Im hier beschriebenen Workshop soll diskutiert werden, welche Kompetenzen die „Mitarbeiter von morgen" in der digitalen Transformation, speziell im Bereich Business Analytics, aufweisen müssen und wie diese erlangt werden können. Workshopteilnehmer vertreten jeweils eine der folgenden drei Gruppen: (1) Unternehmen, die unter dem Druck des Fachkräftemangels und dem steigenden Grad der Digitalisierung auf der Suche nach geeignetem Personal sind, (2) aktuell oder zukünftig im Umfeld Business Analytics tätige Personen, die eine den Anforderungen entsprechende Ausbildung benötigen, sowie (3) Lehrstätten, also allgemein- und berufsbildende Schulen, Weiterbildungseinrichtungen und vor allem Hochschulen, die junge Menschen auf die Arbeitswelt von morgen vorbereiten sollen. Als Arbeitsziel ist das Diskutieren von gemeinsamen und unterschiedlichen Sichtweisen, sowie das Ableiten von Handlungsempfehlungen zu sehen.

Keywords: Digitale Transformation; Business Analytics; Mitarbeiter; Kompetenzen

1 Mitarbeiter als Erfolgsfaktor der digitalen Transformation

Digitalisierungsvorhaben in Unternehmen weisen unterschiedliche Zielrichtungen auf: Produkte und Leistungsangebote des Unternehmens können verändert, digitale Services kreiert sowie alle Phasen der Kundenbeziehung völlig neu gestaltet werden [1]. In einer eher nach innen gerichteten Betrachtung steht die Digitalisierung der Unternehmensprozesse im Fokus. Neben unterschiedlichen technologischen Treibern wie Cloud Computing, Robotik oder Künstliche Intelligenz bildet die Sammlung, Aufbereitung und Analyse von Daten in vielen dieser Vorhaben eine wichtige Grundlage.
Zur Umsetzung von Digitalisierungsvorhaben sind Voraussetzungen zu schaffen, die im Regelfall zu simultanen und tiefgreifenden Veränderungen in Unternehmen führen und den vielzitierten Begriff der „digitalen Transformation" prägen (zum Begriff vgl. [2]). Die notwendigen Veränderungen lassen sich den Bausteinen Technologie, Führung und Kultur, Struktur und Organisation, Kollaboration mit Partnern, Prozessarchitektur sowie Kompetenzen von Mitarbeitern zuordnen [1]. Müller et al. [3] fassen diese Zusammenhänge in einem Steuerungsmodell für die digitale Transformation zusammen (vgl. Figure 1).

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

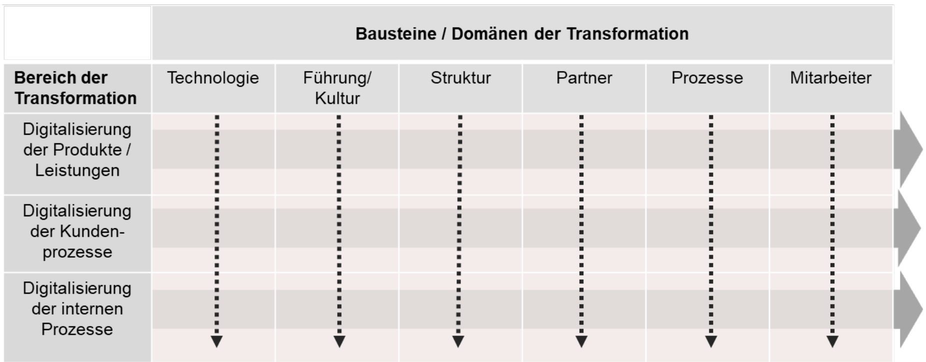

Figure 1. Transformations-Matrix (in Anlehnung an [3])

Besonders der letztgenannte Baustein – die Veränderungen auf Ebene der Mitarbeiter – kann als zentraler Erfolgsfaktor einer Transformation angesehen werden.
Die Akquisition und Entwicklung qualifizierter Mitarbeitern mit den für die digitale Transformation benötigten Kompetenzen stellt für viele Unternehmen angesichts demografischer Entwicklungen und massiver Veränderungen der Anforderungsprofile eine große Herausforderung dar [4].
In dem Workshop sollen diese Überlegungen aufgegriffen und die Frage diskutiert werden, welche Kompetenzen die „Mitarbeiter von morgen" in der digitalen Transformation aufweisen müssen und wie diese erlangt werden können.
Auch wenn Auswirkungen der Digitalisierung auf die Arbeit für nahezu alle berufstätigen Personen spürbar sind, vollzieht sich die Veränderung nicht überall im gleichen Maß. Die spezielle Betrachtung des Bereiches Business Analytics in diesem Workshop ist damit zu rechtfertigen, dass hier eine besonders starke Veränderung des Arbeitsumfeldes zu beobachten ist: Unternehmen haben in den letzten Jahren verstärkt in den Ausbau ihrer Business-Analytics-Systeme investiert. Dies liegt neben der grundlegenden Entwicklung durch die Digitalisierung daran, dass technische Restriktionen, die Analysen in der Vergangenheit langwierig und teuer gemacht haben, nur noch eine untergeordnete Rolle spielen [5]. Außerdem liegen immer mehr Daten heterogener Struktur, deren Analyse einen Mehrwert generiert, in digitaler Form vor [6] und nicht zuletzt ist verstärkt die Erkenntnis aufgekommen, dass neben strategischen auch operative Entscheidungen möglichst datenbasiert getroffen werden sollten [7].
Um die aus den genannten Entwicklungen resultierenden heterogener gewordenen Analyseanforderungen verschiedener Domänenexperten[1] in angemessener Zeit befriedigen zu können, wurden in den letzten Jahren einfache Softwareprodukte entwickelt, die es auch Gelegenheitsanwendern in Unternehmen ermöglichen sollen, (teilweise) eigenständig Standardberichte aufzubauen oder Ad-hoc-Analysen durchzuführen – ohne dabei Business-Analytics-Experten einbeziehen zu müssen [8]. Dies führt durch eine zeitgleich stattfindende Entwicklung jedoch nicht zu einer Substitution letzterer,

[1] Der Begriff Domänenexperte wird hier als Abgrenzung zu einem Business-Analytics-Experten verwendet.

sondern zu einer Verschiebung der Tätigkeitsfelder, die in vielen Berufen als eine Folge der digitalen Transformation zu beobachten ist [9]. Im hier fokussierten Umfeld schlägt sich diese Verschiebung durch einen vermehrten Einsatz fortgeschrittener Analysemethoden – häufig mit Begriffen wie Data Mining, Data Science oder maschinelles Lernen betitelt – nieder.

Die beschriebenen Veränderungen haben zur Folge, dass die Kompetenzen im Umfeld analytischer Informationssysteme, die bisher in Lehrstätten vermittelt wurden, nicht mehr geeignet sind, um sämtliche, an die Mitarbeiter herangetragenen Aufgaben lösen zu können. Generell können Mitarbeiter, deren Berufsfeld stark von den Auswirkungen der Digitalisierung betroffen ist, nicht davon ausgehen, dass die über Ausbildung und Erfahrung gewonnenen Kompetenzen ausreichen, die langfristig an sie gestellten Anforderungen zu bewältigen ([10 - 11]). Zur Sicherstellung einer dauerhaften Erwerbstätigkeit ist eine kontinuierliche Aus- und Weiterbildung vonnöten [12]. Weiterhin ist eine Individualisierung der Ausbildung erforderlich, die für die Mitarbeiter und das Arbeitsumfeld relevante Kompetenzen vermittelt [13].

Um geeignete Anforderungen an die Mitarbeiter von morgen und den damit verbundenen Veränderungsbedarf zu identifizieren sind drei Interessengruppen zu berücksichtigen:

(1) Unternehmen, die unter dem Druck des Fachkräftemangels und dem steigenden Grad der Digitalisierung auf der Suche nach geeignetem Personal sind,
(2) aktuell oder zukünftig im Umfeld Business Analytics tätige Personen, die eine den Anforderungen entsprechende Ausbildung benötigen, sowie
(3) Lehrstätten, also allgemein- und berufsbildende Schulen, Weiterbildungseinrichtungen und vor allem Hochschulen, die junge Menschen auf die Arbeitswelt von morgen vorbereiten sollen.

2 Mitarbeiter von heute

Ausgangspunkt für die Bestimmung der Anforderungen an die Mitarbeiter von morgen ist zunächst die Erfassung des Status quo. Dies bedingt die Beantwortung der Frage, welche Kenntnisse und Qualifikationen Personen, die im Bereich Business Analytics tätig sein wollen, bereits heute mitbringen sollten. Neuhaus & Schulz analysierten im November 2017 500 Stellenanzeigen im Kontext analytischer Informationssysteme [14]. Ziel dieser Untersuchung war es zu bestimmen, welche konkrete Bedeutung den häufig verwendeten Schlagwörtern *Analytics*, *Business Intelligence*, *Data Analytics*, *Data Science*, *Advanced Analytics* und *Business Analytics* in der betrieblichen Praxis gegeben wird. Durch die eingesetzte Untersuchungsmethode (Frequenzanalyse der in den Stellenanzeigen verwendeten Begriffe) entstand gleichzeitig aber auch ein präzises Anforderungsprofil der gesuchten Business-Analytics-Experten. Außerdem wurde deutlich, welche Tätigkeiten sie ausführen sollen, in welchen Branchen sie besonders gefragt sind und welche treibenden Kräfte ihr Arbeitsumfeld beeinflussen. Figure 2 gibt einen Überblick über die identifizierten Dimensionen und ihre Kategorien.

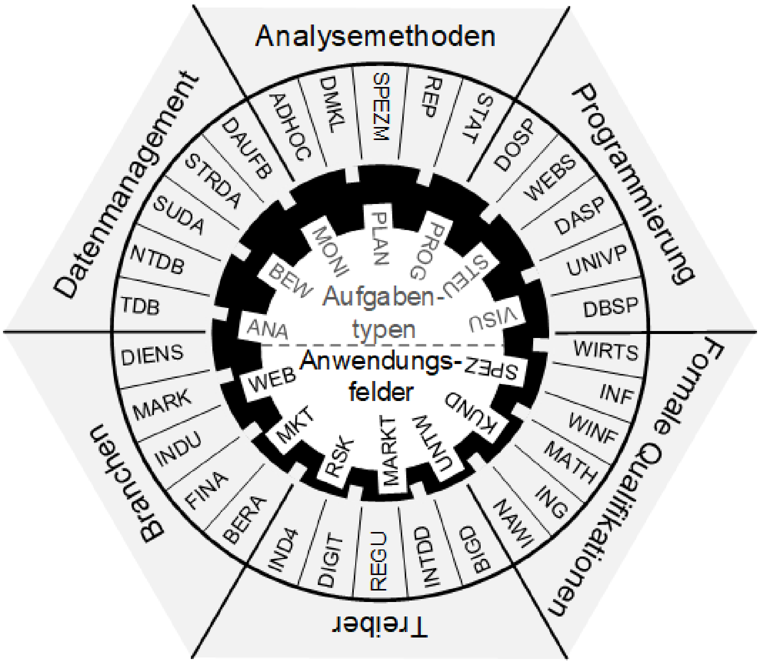

Figure 2. Relevante Dimensionen analytischer Informationssysteme und deren Kategorien (nach [14])

Aufgabentypen und Anwendungsfelder
Analytische Fähigkeiten stehen naturgemäß ganz oben auf der Liste der gesuchten Qualifikationen, meist jedoch in Zusammenhang mit ganz spezifischen Anwendungsfeldern. Hier sind insbesondere die *Analyse von Webdaten* und von *Marketingmaßnahmen* zu nennen, mit etwas Abstand folgen *Markt-*, *Kunden-* und *Risikoanalysen*. Häufig bildet die Analyse auch nur den ersten Arbeitsschritt, dem dann weitere Schritte wie *Steuerung*, *Prognose*, *Planung* und *Bewertung* folgen sollen. Von Bedeutung sind ebenfalls die *Visualisierung* von Analyseergebnissen sowie das *Monitoring* von Systemen.

Treiber
Die Begriffe *Digitalisierung* und *digitale Transformation* werden in den untersuchten Stellenanzeigen erwartungsgemäß häufig als Treiber für die Suche nach Mitarbeitern im Bereich analytischer Informationssysteme angegeben. Häufiger allerdings noch wird *Big Data* genannt. Da in den Stellenanzeigen jedoch selten konkretes Big-Data-Know-how nachgefragt wird, ist allerdings zu vermuten, dass dieser Begriff offenbar auch verwendet wird, wenn es generell um Datenanalyse geht und nicht speziell um die Analyse von großen, komplexen oder sich schnell ändernden Datenmengen. Ähnlich häufig wie Digitalisierung fanden sich Treiber aus dem Themenbereich *Regulatorik*. Typische Schlagwörter sind hier etwa Compliance, Audit und Governance. Stärker technisch orientierte Treiber, die noch nennenswert häufig erwähnt wurden, sind *Industrie 4.0* und *Internet der Dinge*.

Branchen
In zwei Branchen sind Experten für analytische Informationssysteme besonders stark nachgefragt: in der *Beratungs*- und in der *Finanzbranche*. Beides verwundert nicht. Beratungsunternehmen sind häufig Vorreiter bei der Einführung innovativer Technologien und häufig bedienen sich Unternehmen, die selbst noch nicht über ausreichendes Technologie-Knowhow verfügen, der Dienste von Beratern. In der Finanzindustrie spielen Datenanalysen traditionell eine große Rolle, sodass die Nutzung innovativer Analysemethoden naheliegt. Außerdem unterliegen Banken und Versicherungen vielfältigen Regularien, was – wie oben erwähnt – ein weiterer Treiber für den Einsatz analytischer Informationssystem ist. Weitere Branchen, die überdurchschnittlich viele Analyseexperten suchen, sind die *Industrie* (insbesondere der Maschinenbau, die Elektro- und Automobilindustrie) im Kontext der Treiber Industrie 4.0 und Internet der Dinge sowie die *Marketingbranche* mit ihren zunehmend wichtiger werdenden Datenquellen aus den Bereichen Online-Marketing, Mobile-Marketing und Social Media. Eine nennenswerte Anzahl an Stellenanzeigen finden sich außerdem noch in den Bereichen *Logistik*, *Gesundheit* und *Medien*.

Formale Qualifikationen
Betrachtet man die formalen Qualifikationen, die von den zukünftigen Mitarbeitern im Bereich analytischer Informationssysteme erwartet wird, so fällt zunächst auf, dass fast ausschließlich Akademiker gesucht werden, nur vereinzelt werden auch Bewerber mit einem Ausbildungsberuf angesprochen. Dies deutet auf die Komplexität der zu übernehmenden Aufgaben hin. Explizit genannt werden in den Stellenanzeigen außerdem fast ausschließlich traditionelle Studienabschlüsse. Spezialisierte Studienabschlüsse wie etwa als ‚Data Scientist' werden von den Bewerbern (noch) nicht gefordert. Am häufigsten gesucht werden Absolventen aus den Bereichen *Wirtschaftswissenschaften/BWL* und *Informatik*. Auch *Wirtschaftsinformatiker*, die ein Bindeglied zwischen diesen beiden Disziplinen darstellen, sind stark nachgefragt. In stärker technisch orientierten Branchen oder für spezielle Analyseformen werden aber auch *Mathematiker*, *Ingenieure* und *Naturwissenschaftler* angesprochen.

Datenmanagement
Die in den Stellenanzeigen explizit gesuchten fachlichen Fertigkeiten lassen sich grob in die drei Dimensionen Datenmanagement, Analysemethoden und Programmierung aufteilen. Das *Datenmanagement* umfasst nach Gandomi und Haider [15] Prozesse und Technologien, um Daten zu beziehen, zu speichern und für die Analyse vorzubereiten. Die zentrale Fertigkeit innerhalb des Datenmanagements ist die in 70 % aller Stellenanzeigen geforderte Kompetenz zur *Datenaufbereitung*. Erwartet werden hier von den Bewerbern Kenntnisse sowohl im Umgang mit *strukturierten* als auch mit *unstrukturierten Daten*. Dies deckt sich mit den Aussagen von Russom [16] und Chamoni [17], welche die zunehmende Bedeutung von semi- und unstrukturierten Daten für analytische Informationssysteme hervorheben. Als Datenquelle von großer Bedeutung sind beim Datenmanagement weiterhin Datenbanken. Sowohl Kenntnisse relationaler Datenbankmanagementsysteme (DBMS) als auch nicht-traditioneller DBMS (z. B. In-

Memory-Datenbanken, No-SQL-DBMS, multidimensionale DBMS) werden oft gesucht. Häufig wird in den Stellenanzeigen dabei Know-how in spezifischen Software-Produkten erwartet. Die Menge und Vielfalt der genannten Produkte ist dabei sehr groß, kein einzelner Hersteller nimmt eine dominierende Marktstellung ein.

Analysemethoden

Die Mehrzahl der untersuchten Stellenanzeigen erwartet von den gesuchten Experten auch die Beherrschung verschiedener *Analysemethoden*. Im Mittel werden in den Anzeigen drei bis vier solcher Methoden aufgezählt. Fast alle Methoden lassen sich fünf verschiedenen Kategorien zuordnen. Der am häufigsten genannte Begriff ist dabei das *Reporting*, die Aufbereitung der Analyseergebnisse in eine verständliche Darstellungsform. Hier scheint insbesondere die Datenaufbereitung in Form von Dashboards an Bedeutung zu gewinnen. Das Reporting ergänzt die *Ad-hoc-Analyse*, welche Entscheidungsträgern die unmittelbare, spontane Untersuchung von Analyseergebnissen ermöglicht. Wichtige Begriffe in diesem Zusammenhang Online Analytical Processing (OLAP), Self-Service-BI und Visual Analytics. Viele nachgefragte Analysemethoden entstammen auch der *Statistik*. Dazu zählen etwa die Regression, multivariate Statistik und AB-Tests. Die letzten beiden Analysemethodenkategorien lassen sich beide dem Bereich Data-Mining zuordnen. *Klassische Data-Mining-Methoden* stellen grundlegende Verfahren dar, die im Data-Mining weit verbreitet sind und bei vielen unterschiedlichen Analyseproblemen genutzt werden können. Beispiele sind etwa Clusteranalysen, Entscheidungsbäume oder Assoziationsanalysen. *Spezielle Data-Mining-Methoden* erfordern hingegen spezielles Experten-Know-how oder lassen sich nur auf spezifische Analysefragestellungen anwenden. Hierzu zählen z. B. Deep-Learning, Big-Data-Analytics oder Text-Mining. Wie schon beim Datenmanagement werden auch bei den Analysemethoden häufig Kenntnisse spezieller Software-Produkte gesucht. Die Vielfalt der Produkte ist hier sogar noch größer als im Datenmanagementbereich. Neben den Lösungen großer Software-Hersteller finden sich noch zahlreiche Produkte spezialisierter Anbieter sowie Open-Source-Werkzeuge.

Programmierung

Da auch bei Nutzung von Datenanalyse-Software häufig die Notwendigkeit entsteht, bestimmte Schritte des Analyseprozesses durch selbstgeschriebene Routinen umzusetzen, werden von Experten analytischer Informationssysteme häufig auch Kenntnisse in *Programmierung* erwartet. Auch hier lassen sich fünf Hauptkategorien identifizieren. Die ersten vier Kategorien umfassen dabei domänenspezifische Sprachen, also Sprachen die für einen speziellen Einsatzzweck entworfen wurden. In Ergänzung zum Datenmanagement sind häufig *Datenbanksprachen* von Bedeutung, insbesondere SQL und seine herstellerspezifischen Erweiterungen wie PL/SQL oder Transact-SQL. Die zweite Kategorie bilden *Web-Sprachen* wie JavaScript und PHP, die häufig zusammen mit der Auszeichnungssprache HTML genannt werden. Ihre Bedeutung erhalten diese Sprachen durch den hohen Bedarf im Bereich Web-Analytics sowie der zunehmenden Nutzung von web-basierten Analyse-Dashboards. *Datenanalysesprachen* wurden speziell für die Bearbeitung von analytischen Fragestellungen entworfen. Sehr dominant war in den untersuchten Stellenanzeigen die für statistische Datenanalyen entwickelte

Programmiersprache R. *Weitere domänenspezifische Sprachen* wie ABAP oder VBA verdanken ihre Nachfrage der weiten Verbreitung spezieller, herstellerspezifischer Systeme (SAP-Systeme bzw. Microsoft-Office-Produkte). *Universelle Programmiersprachen* wurden im Gegensatz zu domänenspezifischen Sprachen zur Software-Entwicklung in beliebigen Anwendungsbereichen entworfen. Daher können sie auch im Kontext analytischer Informationssysteme genutzt werden. Die am stärksten nachgefragten universellen Programmiersprachen waren in den Stellenanzeigen mit deutlichem Vorsprung Python (53 %), gefolgt von Java (20 %).

3 Kompetenzanforderungen an den Mitarbeiter von morgen

Auf Basis der in Kapitel 1 genannten Entwicklungen und der Erkenntnisse aus der in Kapitel 2 beschriebenen Ist-Analyse können Anforderungen an die Mitarbeiter von morgen im Bereich Business Analytics für mindestens drei Gruppen diskutiert werden:

(1) Mitarbeiter, die im Bereich Business Analytics tätig sind und vor der Herausforderung stehen, Kompetenzen aufbauen zu müssen, um den neuen Anforderungen an ihr Berufsfeld zu genügen. (Data Scientists und Business-Analytics-Experten)

(2) Mitarbeiter, deren Kerntätigkeit nicht im Bereich der Business Analytics liegt, die jedoch vor der neuen Anforderung stehen, eigenständig, einfache Analysen durchzuführen. Zudem wird von ihnen in einem gewissen Maße die Fähigkeit erwartet, auch Ergebnisse fortgeschrittener Analysen verstehen, bewerten und einordnen zu können. (Domänenexperten)

(3) Mitarbeiter, die durch geeignete Kompetenzen in der Lage sind, neue datenbasierte Produkte, Services oder Prozesse zu entwickeln und damit die zukünftige Wettbewerbsfähigkeit eines Unternehmens sicherstellen können. Sie müssen zusätzlich die Kompetenzen besitzen, die dafür notwendigen Veränderungsprozesse in Unternehmen umzusetzen und in der Organisationshierarchie entsprechend positioniert sein. (Entscheider)

Für alle Mitarbeitergruppen und auch für die Unternehmen, in denen die Mitarbeiter tätig sind, erwachsen Herausforderungen aus den zusätzlichen, sich schnell wandelnden Aufgabenbereichen [10], die im Folgenden einzeln diskutiert werden.

Data Scientists und Business-Analytics-Experten

Während für Business-Analytics-Experten traditionell das Standard- und Ad-hoc-Reporting, der Prozess der Datenaufbereitung und die geeignete Datenhaltung im Fokus ihrer Aufgaben standen, verlangt die Anwendung fortgeschrittener Analysemethode nach mathematischen Fähigkeiten, insbesondere im Bereich der Statistik, nach Kenntnissen in speziellen Programmiersprachen und nach einem Verständnis von Domänen, das weit über den traditionellen Anwendungsbereich analytischer Informationssysteme hinausgeht [14]. Um den Anforderungen gerecht zu werden, hält es die Mehrzahl von

in diesem Bereich tätigen Personen für notwendig, zusätzliche Methodenkompetenzen aufzubauen [18]. Auch eine stärkere Domänenfokussierung bei der Identifikation für den Aufgabenbereich benötigter Kompetenzen kann relevant sein: Während in der Vergangenheit primär strategisch-betriebswirtschaftliche Fragestellungen im Fokus analytischer Informationssysteme standen, sind es nun zusätzlich auch ganz andere, wie etwa aus dem Bereich der Operational Business Intelligence [19] oder der Predictive Maintenance [20]. Zusammenfassend kann weder aus Domänen- noch aus Methodensicht davon ausgegangen werden, dass ein Mitarbeiter in der erweiterten Ausrichtung des Aufgabenfeldes in der Lage ist, bei sämtlichen Unternehmensfragestellungen unterstützen zu können.
Der Wegfall traditioneller Tätigkeiten von Business-Analytics-Experten führt zu einer Reduzierung der Routineaufgaben, was ein Arbeitsumfeld auf der einen Seite zwar attraktiver, auf der anderen Seite aber auch anspruchsvoller macht [21]. Ein daraus resultierender Bedarf der Übernahme zusätzlicher Aufgaben führt wie beschrieben auch zu einem zusätzlichen Qualifizierungsbedarf. Dies stellt Mitarbeiter vor die Herausforderung der Auswahl geeigneter Angebote. Während das Ausbildungsangebot bereits sehr intransparent ist, zeigt sich der Markt der Weiterbildungsangebote noch unübersichtlicher [22]. Die Entscheidung für eine ungeeignete Entwicklung der eigenen Kompetenzen birgt eine Gefahr für die langfristige Sicherstellung der Beschäftigung.

Domänenexperten
In der Vergangenheit waren Domänenexperten vor allem Konsumenten von Standardberichten oder konnten gegebenenfalls Ad-hoc-Analysen auf Basis einfacher Datenmodelle durchführen. Heute benötigt jeder Mitarbeiter eine Basisausbildung im Bereich der Digitalisierung, die schon in der Regelschule beginnen [12] und in weitergehenden Ausbildungen ausgebaut werden muss. Im Kontext der Business Analytics kann diese vor allem in der Datenkompetenz, also der Fähigkeit Daten als Grundlage der eigenen Arbeit geeignet einsetzen zu können [23], gesehen werden. Anders als häufig angenommen, kann nicht davon ausgegangen werden, dass Digital Natives nur deshalb eine höhere Datenkompetenz besitzen, weil sie von Kind auf mit digitalen Produkten vertraut sind [24].

Entscheider
Die Entscheidung zur Digitalisierung von Geschäftsprozessen muss häufig unter großer Unsicherheit getroffen werden [10] und hat häufig umfassende Auswirkungen auf Unternehmen [25]. Trotzdem fehlt es vielen Organisationen an einer klaren Strategie, wie mit dem Thema der Transformation umgegangen werden soll [26]. Mitarbeiter, die die zukünftige Wettbewerbsfähigkeit eines Unternehmens sicherstellen müssen, benötigen nicht nur Methoden- und Domänen-, sondern zusätzlich auch Veränderungs- und Gestaltungskompetenz [10] und die Fähigkeit bzw. Stellung im Unternehmen notwendige Änderungen durchzusetzen, ohne das unternehmerische Handeln außer Acht zu lassen [27].

Neben den oben genannten, stark auf den Business-Analytics-Komplex fokussierten Aspekten sind bei der Diskussion der Anforderungen an den Mitarbeiter von morgen auch immer Themen der digitalen Transformation zu berücksichtigen, die das Arbeitsleben an sich verändern. Genannt werden können hier etwa die durch die Verwendung mobiler Endgeräte ermöglichte Flexibilisierung von Arbeitszeit und –ort, sowie die teilweise Aufhebung der Grenzen zwischen Arbeits- und Freizeit [28 – 29]. Auch ist nicht abzusehen, inwieweit die Digitale Transformation die Unterscheidung nach typischen Männer- und Frauenberufen aufzubrechen vermag, um eine geschlechterübergreifende Chancengleichheit auf dem Arbeitsmarkt auch im Bereich informationstechnisch fokussierter Berufe herzustellen [30].

4 Ziel des Workshops

Die Leitfragen die dem Workshop zu Grunde gelegt werden, orientieren sich an folgenden Kompetenzfeldern, die von Zschech et al. [31] übernommen und angepasst wurden:

(1) Basiskompetenzen, die unabhängig von dem individuellen Aufgabenbereich der Mitarbeitern digitaler Unternehmen erwartet werden,
(2) befähigende Kompetenzen, die systembezogene Kompetenzen genauso beinhaltet wie soziale Kompetenzen und eine Themenaffinität und
(3) vertiefende Kompetenzen mit einer Spezialisierung auf Aufgaben und Konzepte.

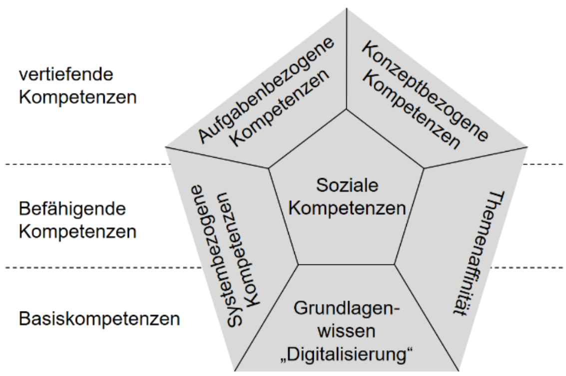

Figure 3. Kompetenzfelder der Mitarbeiter von morgen

Das Hauptaugenmerk des Workshops soll darauf gelegt werden,

- welche Kompetenzen Personen benötigen, die aktuell oder zukünftig im Umfeld der Business Analytics tätig sind,
- welche zukünftigen Herausforderungen und Verschiebungen von Aufgabenfeldern in dem Tätigkeitsumfeld gesehen werden,
- welche Erwartungen Unternehmen an die Qualifikation und Weiterentwicklung ihrer Mitarbeiter haben,

- ob der Fokus auf der Ausbildung in Softwareprodukten, Programmiersprachen oder Methoden liegen soll,
- welche Unterstützung und Informationen Mitarbeiter bezogen auf (Weiter-) Bildungsangebote seitens der Unternehmen und der Lehrstätten benötigen,
- welche Möglichkeiten existieren, um ein frühes Interesse für die Ausbildung von Business-Analytics-Kompetenzen zu entwickeln,
- wie Mitarbeiter an Lehrstätten in die Lage versetzt werden können, geeignete Lehre anzubieten,
- welche Form der Lehre geeignet ist, um benötigte Kompetenzen zu vermitteln
- und welche Konsequenzen aus den generellen Veränderungen der Arbeitswelt durch die Digitalisierung für Mitarbeiter im Business-Analytics-Umfeld zu berücksichtigen sind.

Der Zielsetzung des Workshops folgend ergibt sich aus der Beantwortung dieser Fragestellungen ein Set von Handlungsempfehlungen, das von Unternehmen und Lehrstätten genutzt werden kann, um den Herausforderungen der Ausbildung und Qualifikation der „Mitarbeiter von morgen" künftig besser begegnen zu können.

Abstract. Die Durchdringung der Gesellschaft mit IT-Artefakten führt nicht nur zu Veränderungen in der Arbeitswelt („Industrie 4.0“), sondern auch zu einem Wandel in Privathaushalten, etwa im Bereich der Digitalisierung von Verbraucherpraktiken. Dabei werden vor allem die klassischen Konsumfelder Ernährung, Wohnen und Mobilität zunehmend von „smarten“ Geräten und digitalen Diensten durchdrungen. Für VerbraucherInnen eröffnet dies neue Erlebniswelten und vereinfacht den Konsum. Gleichzeitig stellt die neue Qualität der Vernetzung jedoch auch eine Reihe von Fragen, etwa in Bezug auf Datenschutz und die digitale Souveränität der VerbraucherInnen, einen möglichen Digital Divide, sowie die Nachhaltigkeit digital ermöglichter Verbrauchspraktiken auf den Ebenen Gesellschaft, Ökonomie und Ökologie. Die Verbraucherinformatik nimmt dabei ein interdisziplinär verfasstes Forschungsfeld in den Blick, wobei die Bedeutung der Phänomene einer digitalisierten Welt aus Verbrauchersicht untersucht und gestaltet werden sollen.

Keywords: Verbraucherinformatik, Verbraucherforschung, Digitaler Konsum, Nachhaltigkeit, Hauswirtschaft.

1 Einleitung

Die bedarfsgerechte Gestaltung und kompetente Nutzung von Informationssystemen stellt schon lange ein zentrales Forschungsgebiet der Wirtschaftsinformatik dar. Traditionell liegt der Fokus dabei auf *betrieblichen* Informationssystemen. Die fortschreitende Digitalisierung der Gesellschaft reicht mittlerweile jedoch immer stärker auch in den privaten Bereich hinein und beeinflusst damit Verbraucherpraktiken. So werden

14th International Conference on Wirtschaftsinformatik, February 24–27, 2019, Siegen, Germany

z.B. Produktkennzeichnungen nicht mehr allein auf Verpackungen gedruckt, sondern sind vermehrt auch im Internet zugänglich. Bewertungsportale ergänzen traditionelle Ratgeberliteratur, auf denen sich VerbraucherInnen austauschen können. Bargeld wird durch neue Formen bargeldlosen Zahlungsverkehrs ersetzt und das Einkaufen selbst findet im Online-Handel verstärkt digital statt. Neue Haftungsfragen ergeben sich, wenn VerbraucherInnen, statt auf den Rat von BankmitarbeiterInnen zu vertrauen, auch online mit „Robo-Advisorn" interagieren. Entsprechend spielt Digitalisierung bei klassischen Themen der Verbraucherforschung wie Produktsicherheit, Verbraucherrechte, Verbraucherbildung, ethischer und nachhaltiger Konsum etc. eine zunehmend größere Rolle.

Dieser Wandel eröffnet neue Möglichkeiten, die Lebens- und Alltagsökonomien von VerbraucherInnen durch *Smart Services* – verstanden als Kombination von IT- und Dienstleistungs-Design – zu unterstützen. Dies führt jedoch auch dazu, dass VerbraucherInnen im Alltag mit einer zunehmenden Anzahl von Services, Apps, Systemen etc. konfrontiert werden. Durch die konsequente Anwendung von *Usability* und *User-eXperience (UUX)-Methoden* sind einzelne Dienste zwar meist einfach zu nutzen, jedoch entsteht durch die Masse und ihre Wechselwirkungen eine hohe Komplexität, diese zu kombinieren und in den eigenen Alltag zu integrieren. Der Beitrag der Verbraucherinformatik besteht u.a. darin, VerbraucherInnen und ihre Alltagspraktiken als Adressat solcher Systeme ganzheitlich in den Blick zu nehmen.

2 Verbraucherinformatik als interdisziplinäres Forschungsfeld

Der Begriff *Verbraucherinformatik* ist ein Neologismus, der Konnotationen zur Verbraucherforschung wie auch zur Wirtschaftsinformatik aufweist. In Anlehnung an die Definition der Wirtschaftsinformatik kann man die Verbraucherinformatik definieren als *die systematische, methodisch geleitete Untersuchung und Gestaltung von Informations- und Kommunikationstechnologien zur Unterstützung der Haushaltsökonomien und Alltagspraktiken von VerbraucherInnen sowie deren Aneignung und sozialer Einbettung*.

Die Verbraucherinformatik wirbt damit für einen Perspektivwechsel, bei dem nicht nur die Rolle als NutzerInnen eines Systems bzw. KundInnen eines Unternehmens, sondern die individuellen und kollektiven Lebenswelten von VerbraucherInnen möglichst umfassend fokussiert werden. Wie schon in der nicht-digitalen Welt können VerbraucherInnen und ihr Verhalten aus verschiedenen Perspektiven betrachtet werden. Damit ist die Verbraucherinformatik, wie die Verbraucherforschung allgemein [1–3], interdisziplinär konstituiert. Hierbei gehen wir davon aus, dass die digitale Welt nicht ein weiteres Anwendungsfeld der Verbraucherforschung wie Finanzen, Gesundheit, Ernährung, Mobilität etc. darstellt. Vielmehr hat Digitalisierung bereits heute in all diese Felder Einzug gehalten und restrukturiert diese sukzessive. Es stellt also nicht nur einen temporären Trend dar, sondern prägt als ein zentrales Strukturmerkmal des 21. Jahrhunderts weite Teile unseres Lebens – potenziell fortschreitend und zunehmend. Deshalb versteht sich die Verbraucherinformatik als Querschnittsforschung, die sich mit Phänomenen der Digitalisierung in unterschiedlichen Konsumfeldern befasst. Im

Folgenden sollen Anknüpfungspunkte zu bestehenden Forschungsfeldern diskutiert werden, die wichtige Impulse liefern sowie auch Anwendungsbereiche für die Verbraucherinformatik darstellen.

2.1 Die VerbraucherInnen im Blickfeld der angewandten Informatik

In der angewandten Informatik finden sich vielerlei Bezüge. So beschäftigen sich z.B. die Wirtschaftsinformatik, die *Human-Computer-Interaction* (HCI) und die IT-Sicherheitsforschung mit VerbraucherInnen und ihrem Verhalten:

In der **Wirtschaftsinformatik** treten VerbraucherInnen an verschiedenen Stellen in Erscheinung. So untersucht z.B. die wirtschaftsinformatische Nutzerakzeptanzforschung [4], welche Faktoren für die Adaption von IT-Systemen verantwortlich sind. Auf dieser Basis wurden diverse Systeme im Consumermarkt untersucht, wie z.B. Online Shopping [5], Games [6] oder Social Media [7]. In der konstruktiven Wirtschaftsinformatik tauchen VerbraucherInnen z.B. indirekt bei der Gestaltung von Handelsinformationssystemen [8] bzw. direkt bei der Gestaltung von Systemen des *Costumer-Relationship-Managements* (CRM) [9] auf. Beim CRM geht es darum, VerbraucherInnen in ihrer Rolle als KundInnen digital abzubilden sowie die Interkation mit ihnen in die unternehmerischen Prozesse und (IT-)Infrastrukturen einzubetten.

In der **HCI-Forschung** treten VerbraucherInnen primär in der Rolle der NutzerInnen in Erscheinung. Hierbei sind zwei Zweige besonders hervorzuheben: Auf methodischer Ebene ist es das *User Centered Design*, dessen Wurzeln im *Participatory Design* liegen. In den Anfängen ging es diesem primär darum, ArbeiterInnen in die Lage zu versetzen, bei der Gestaltung ihrer Arbeitsplätze mitzuwirken [10]. In der neueren Forschung nehmen demgegenüber die Alltagspraktiken der Menschen außerhalb des Arbeitskontexts eine zunehmend größere Rolle ein. Hierbei werden Ansätze aus der Kulturanthropologie [11], der Kritischen Theorie [12] und den Cultural Studies [13] aufgegriffen, um die Aneignung technischer Artefakte zu verstehen, Konsumpraktiken zu irritieren und vor dem Hintergrund der neuen technischen Möglichkeiten kritisch zu reflektiven [14–16]. Auf theoretischer Ebene sind auch die neueren *User-Experience-Design-Ansätze* hervorzuheben, die in der Bedürfnis- und Konsumpsychologie verankert sind [17, 18], sowie Ansätze des *Privacy By Design* als Reaktion auf die immer tiefergreifende Digitalisierung des Alltags in Kombination mit gängigen Technologien wie dem Erfassen des Nutzerverhaltens zu Werbe- und Optimierungszwecken [19].

In der **Umweltinformatik** [20] wird zunehmend die Bedeutung von VerbraucherInnen für nachhaltiges Wirtschaften (an-)erkannt. Insbesondere wurde die Rückspiegelung des Konsumverhaltens untersucht, um nachhaltiges Verhalten zu befördern [21–23]. Das passende Leitbild stellt dabei das handlungspsychologische Konzept des *Nudging* und des direkten Feedbacks dar, mittels dessen ein umweltbewusstes Handeln motiviert werden soll [24]. Studien zeigen jedoch, dass solche Methoden zwar einen kurzfristigen Effekt haben, jedoch in sich selbst meist nicht nachhaltig sind, weil sie den sozio-materiellen Kontext zu wenig berücksichtigen [25]. Neben Energie werden in der Umweltinformatik auch Konsumfelder wie Ernährung [26] und Mobilität [27] unter einer Nachhaltigkeitsperspektive untersucht. Hier machen z.B. Pakusch et al. [28–30] darauf aufmerksam, dass mit der Einführung autonomen Fahrens nicht nur positive

Nachhaltigkeitseffekte zu erwarten sind – z.B. effiziente Verkehrsflüsse oder der Umstieg vom Auto auf *Shared Autonomous Vehicles* –, sondern auch verschiedene Rebound-Effekte auftreten können. So würden ggf. längere Wegstrecken in Kauf genommen, da sich die Zeit im Auto besser nutzen lässt; ein Umstieg vom ÖPNV auf Shared Autonomous Vehicles ist zu befürchten, da sich Wartezeiten verringern und der Komfort steigt.

In der **IT-Sicherheit** werden VerbraucherInnen als wichtiger Bestandteil sozio-technischer Sicherheitsinfrastruktur betrachtet. Eine maßgebliche Rolle spielt hier auch das sogenannte *Volkszählungsurteil* des Bundesverfassungsgerichts [31], welches die „informationelle Selbstbestimmung" als Teil der Würde des Menschen ausweist. Insbesondere die Forschung zur informierten Einwilligung kann nicht allein technisch gelöst werden, sondern bedarf eines (empirischen) Verständnisses dafür, wie VerbraucherInnen Entscheidungen treffen bzw. inwieweit sie ihre Entscheidungen überblicken können [32–35]. Der Beitrag der IT-Sicherheit für die Verbraucherinformatik besteht darin, ein breites Verständnis zu Sicherheitstechniken und der algorithmischen Analyse großer, heterogener Datensätze (etwa basierend auf dem Tracking von NutzerInnen zu Werbezwecken) zu liefern. Umgekehrt besteht der Beitrag der Verbraucherinformatik für IT-Sicherheit darin, die gesellschaftspolitischen, ökonomischen und sozio-kulturellen Annahmen und Implikationen dieser Mechanismen unter die Lupe zu nehmen und eine evidenzbasierte Grundlage zum Verbraucherhandeln zu liefern (vgl. bspw. Studien zum *Privacy Paradox* [34]). Ferner hilft eine, die politische Ökonomie aufgreifende Verbraucherinformatik dabei, die Ergebnisse gesellschaftspolitisch einzuordnen, um die populäre Fehlannahme zu vermeiden, dass VerbraucherInnen kein Interesse an Datenschutz hätten.

2.2 Die VerbraucherInnen im Blickfeld der Kultur- und Sozialwissenschaften

Neben den dargestellten Kernforschungsfeldern finden sich zusätzliche Anknüpfungspunkte zur existierenden, interdisziplinär verfassten Verbraucherforschung in weiteren Forschungsbereichen, in denen ebenfalls zunehmend die Digitalisierung thematisiert wird:

Die **Rechtswissenschaften** stellen eine wichtige Säule der Verbraucherforschung dar. So wird z.B. VerbraucherIn im Bürgerlichen Gesetzbuch definiert, als „*jede natürliche Person, die ein Rechtsgeschäft zu einem Zwecke abschließt, der weder ihre gewerblichen noch ihrer selbständigen beruflichen Tätigkeit zugerechnet werden kann*" (BGB § 13). Diese Definition bietet analytisch eine gute Grundlage, etwa Phänomene der *Shareconomy* begrifflich zu fassen. Dabei macht es z.B. aus technischer Perspektive keinen Unterschied, ob eine VerbraucherIn ihre Privatwohnung im Urlaub über eine Internetplattform zum Wohnen anbietet oder ob dies durch ein Immobilienunternehmen geschieht. Deshalb wird meist beides vermischt. Aus sozio-kultureller als auch rechtlicher Perspektive handelt es sich jedoch um zwei strikt getrennt zu betrachtende Vorgänge.

Das Kartell- und Wettbewerbsrecht hatte schon immer eine große Bedeutung für den Verbraucherschutz. Insofern ist es nicht verwunderlich, dass Beiträge zur Verbraucherinformatik gerade aus diesem Bereich kommen. Mit der MTS-Kraftstoff-Verordnung

[36] wurden bspw. erstmals digitale Verbraucherinformationsdienste beschrieben und festgelegt: „die Verbraucherinformation, insbesondere die Darstellung, darf nicht irreführend und dadurch geeignet sein, die Entscheidungsfreiheit der Verbraucherinnen und Verbraucher […] zu beeinträchtigen“ [36]. Interessanterweise findet sich kein Pendant hierzu im Bereich der Lebensmittelsicherheit

Die **Psychologie** stellt mit der Werbe- und Wirtschaftspsychologie [37] eine weitere Säule der Verbraucherforschung dar. Deren Erkenntnisse werden insbesondere von der Marketingforschung aufgegriffen, um das Kaufverhalten zu verstehen, zu analysieren und zu gestalten. In neueren Studien lassen sich hierbei zwei sich ergänzende methodologische Strömungen erkennen: Auf der mentalen Ebene versucht z.B. das Neuromarketing die kognitiven Prozesse bei der Bildung von Konsumintentionen präziser zu erfassen [2]. Auf der Verhaltensebene versuchen z.B. neuere *Data Science-Ansätze*, Muster im Verhalten der Masse von VerbraucherInnen zu identifizieren [38]. Daneben postuliert die in der HCI-Forschung aufgegriffene Bedürfnispsychologie [17], dass die Gestaltung der Hauswirtschaft und der Alltagspraktiken nicht allein nach Effizienzkriterien betrachtet werden sollte, sondern dass es den Menschen in der Gesamtheit seiner Bedürfnisse zu betrachten gilt.

Einen weiteren Zweig stellen die **Haushaltsökonomik** und die **Ökotrophologie** dar, die nicht beim einzelnen Subjekt, sondern beim Haushalt bzw. den Alltagspraktiken als primäre Analyseeinheit ansetzen [39, 40]. Der Haushalt wird als Mikrosystem verstanden, das in Makrosysteme wie Gesellschaft und Kultur eingebettet ist, zugleich aber auch ein eigenes intimes Beziehungsgeflecht besitzt [39]. Aus diesem Verständnis analysiert die haushaltswissenschaftliche Verbraucherforschung z.B. Formen der Arbeitsteilungen, etwa bei der Kindererziehung, dem Finanzmanagement, der Verrichtung der Hausarbeit oder der Ernährung [41]. Durch das Smart Home verändert die Digitalisierung zum einen Gegenstände im Haushalt [11, 42, 43], zum anderen verändern sich durch Smart Services die Versorgung des Haushalts mit Produkten und Dienstleistungen [44]. Nicht zuletzt trägt die Digitalisierung mit dazu bei, dass sich Lebensstile und Haushaltsstrukturen selbst wandeln. Hier scheinen sich haushaltsorientierte und verbraucherinformatische Ansätze gegenseitig befruchten zu können.

Die **soziologische, politische** und **kulturanthropologische Verbraucherforschung** macht ferner auf politische, sozio-kulturelle und gesellschaftliche Dimensionen des Konsums aufmerksam [45–48]. Hierzu gehört auch die Frage, wie sich kollektive Interessen von VerbraucherInnen bilden bzw. diese sich (digital) organisieren [49]. Ferner verweisen kulturwissenschaftliche [50, 51] und soziologische Studien [52][53] auf die Historizität und Sozialität von Bedürfnissen. Der jeweilige sozio-ökonomische Kontext ist dabei zentral, so dass Fragen nach der Gestaltung und der Bedürfnisbefriedigung nicht isoliert von den herrschenden Marktmechanismen betrachtet werden sollten [54]. Insbesondere gilt es sich kritisch mit den Wachstumslogiken heutiger Marktwirtschaften auseinanderzusetzen [55], zu deren Prinzipien bspw. das vorzeitige Veralten von Konsumgütern im Sinne zielgerichteter Obsoleszenz [56] genauso gehört wie das Wecken von Bedürfnissen im Allgemeinen [57]: *„Der moderne Verbraucher ist kein Genussmensch, der seinem freien Willen folgt, sondern ein zwanghafter Käufer, zum Konsum getrieben, weil die Zukunft des Kapitalismus davon abhängt“* [57]. Insbesondere die mikroperspektivischen Studien der Kulturanthropologie stehen indes solcherlei deterministischer Zuspitzung mitunter entgegen. So verweisen sie abweichend auch auf die pluralen Logiken alltäglichen Verhaltens, auf individuelle und kollektive Sinnkonstruktionen, die eben nicht zwingend marktförmig sind, sondern sich kapitalistischen Imperativen z.B. auch bewusst oder unbewusst widersetzen, sie symbolisch unterlaufen und bottom-up zu verändern suchen [58–60] .

3 Leitbilder und theoretische Grundlagen

„Das Bild des ‚mündigen Verbrauchers' ist populär in Wissenschaft und Politik. Mündigkeit im Sinne von Kompetenz, Informiertheit und Entscheidungsautonomie ist eine zentrale Annahme herrschender wissenschaftlicher Erklärungsmodelle. Doch diese Modelle werden inzwischen als realitätsfern kritisiert. Von vielen Seiten wird gefordert, realistische Annahmen über das Verbraucherverhalten zu treffen. Denn erst dann könnten Möglichkeiten und Grenzen mündigen Konsums sinnvoll analysiert werden." [61]

Die Anfänge des Konsums als Verbrauch von (Handels-)Gütern findet man spätestens seit der Etablierung des Ackerbaus und der Viehzucht. Treiber dabei waren vor allem die darauf einsetzende Vermögensbildung, die Etablierung des Handels, sowie die zunehmend auf Dauer gestellten Arbeitsteilungen und die Ausbildung von Rechtssystemen [62]. Die modernen VerbraucherInnen heutiger Form existieren aber erst durch die Ausdifferenzierung des modernen Wirtschaftssystems, bei der Produktion, Distribution und Konsumption zunehmend eigenständische Bereiche darstellen. Durch die starke Trennung von Berufs- und Privatleben zeichnete sich das eigene Heim zunehmend auch durch die Funktion aus, die bei der Lohnarbeit verausgabte Arbeitskraft zu regenerieren. Der private Konsum wurde hierbei maßgeblich hinsichtlich der Befriedigung physiologischer Elementarbedürfnisse wie Nahrung, Schlaf, Wärme, etc. verstanden [63]. Mit Einsetzen der Massenkonsum- und Überflussgesellschaft in den westlichen Nationen haben sich vormals elitäre Konsumpraktiken in der Breite etabliert, wobei gleichzeitig Fragen der Freizeitgestaltung, der Mode und des Stils in den Vordergrund rückten [64].

Diese Ausdifferenzierung moderner Konsumgesellschaften bildet damit die Folie einer interdisziplinär verfassten Verbraucherforschung, die sich durch eine hohe Themenvielfalt auszeichnet und zunehmend auch IT-Themen, Daten-Sicherheit und Datenschutz betrachtet [65, 66]. Innerhalb dieser Vielfalt lassen sich aus Sicht der Verbraucherinformatik zunächst drei besonders relevante Strömungen identifizieren: die markttheoretische, konsumtheoretische und praxistheoretische Verbraucherforschung.

3.1 Markttheoretische Verbraucherforschung

Die klassische Verbraucherforschung hat das Markthandeln von VerbraucherInnen zum Gegenstandsbereich. Der Mensch wird dabei als *Homo Oeconomicus* aufgefasst, der jedoch unter Bedingungen mangelnder Markttransparenz und nicht perfekter Märkte agieren muss. Aus den festgestellten Mängeln werden dann meist ordoliberale

Empfehlungen zum Schutz der VerbraucherInnen abgeleitet [67]. Zunehmend werden auch spieltheoretische Modelle zu ungleichen Macht- und Informationsverteilungen zwischen den Marktteilnehmern herangezogen [68] sowie transaktionstheoretische Überlegungen zu den Kosten der Informationsbeschaffung und -verarbeitung [69]. Meist sind VerbraucherInnen aufgrund von Asymmetrien in einer schwächeren Position, woraus sich auch ein besonderer Schutzbedarf ableitet, der seinen Niederschlag z.B. in diversen Verbraucherschutzgesetzen und -verordnungen findet [70]. Es ist deshalb nicht verwunderlich, dass Verbraucherinformationen einen Schwerpunkt der Verbraucherforschung darstellen.

Aus Sicht der VerbraucherInnen lassen sich die Informationen in die drei Kategorien Such-, Erfahrungs- und Vertrauenseigenschaften unterteilen. Diese Informationen können dabei entweder freiwillig bzw. aufgrund rechtlicher Regelungen vom Hersteller stammen oder von Verbraucherinstitutionen und Verbrauchermedien [71]. Die Digitalisierung führt zum einen zu einer Verbreiterung der Quellen und der Kanäle, über die sich VerbraucherInnen über Produkte informieren können. Zum anderen werden die Kosten und der Aufwand zur Informationsbeschaffung gesenkt. So können VerbraucherInnen sich z.B. auf Vergleichsportalen, in Nutzerforen oder über Soziale Medien informieren bzw. sich über ihre Erfahrungen mit Produkten und Dienstleistungen austauschen. Die Kosten der Informationsbeschaffung lassen sich dabei durch Ansätze wie elektronische Kassenzettel weiter senken, da hier VerbraucherInnen nicht jedes einzelne Produkt abscannen müssen, um sich durch Apps wie Barcoo, Codecheck oder fTrace Informationen zum Produkt zu beschaffen [30, 72, 73]. Einen weiteren Trend stellen mobile Verbraucherportale [74] dar. Diese stellen nicht nur Informationen zu Preisen und Eigenschaften von Produkten zur Verfügung, sondern ermöglichen darüber hinaus den Austausch von Erfahrungen und Bewertungen [75].

Offen ist jedoch die Frage, inwieweit und unter welchen Bedingungen es hier zu einer Verschiebung des Kräfteverhältnisses zugunsten der VerbraucherInnen kommt, denn es zeigt sich das zusätzliche Informationen nicht automatisch dazu führen, dass VerbraucherInnen besser informiert sind [76]. So stellt das Positionspapier des *Verbraucherzentrale Bundesverbands* [77] eine Reihe von Forderungen an Vergleichs- und Buchungsportale, um deren Neutralität bewerten zu können. Dazu zählt insbesondere die Gewährung von Transparenz über Geschäftsmodelle, erhaltene Provisionen und den Einfluss und die Gewichtung der Bewertungskriterien bei Produktvergleichen. Hierbei bewegt sich die Wissenschaft stets im Spannungsfeld unterschiedlicher Interessen, wie dies z.B. die Untersuchung zu Vergleichsportalen im Auftrag durch die Verbraucherzentralen [78] als auch im Auftrag von *verivox* [79] exemplarisch zeigt.

In der Verbraucherforschung findet in den letzten Jahren auch eine verstärkte Diskussion zur evidenzbasierten Verbraucherpolitik statt, bei der auch verhaltensökonomische Ansätze aufgegriffen werden [76, 80, 81]. So stehen meist an kognitiv-emotionale Verhaltensweisen ansetzende Maßnahmen im Vordergrund des Interesses, wie z.B. eine verbraucherfreundlichere Regelung von *Opt-in-* und *Opt-out*-Klauseln, welche die Trägheit von VerbraucherInnen berücksichtigen [43]; oder die Gestaltung von Produktinformationsblättern, die die kognitiven Fähigkeiten und emotionalen Verhaltensweisen von VerbraucherInnen beachten [58]. Hierzu gehört explizit auch die Frage nach der visuellen, interaktiven Gestaltung von Verbraucherinformationen und der Aneignung von Informationssystemen durch VerbraucherInnen. Denn die Erkenntnisse der Verhaltensökonomie können sowohl im Sinne der VerbraucherInnen als auch gegen ihr Interesse genutzt werden [82].

3.2 Konsumtheoretische Verbraucherforschung

Konsumtheoretische Ansätze setzen nicht bei der Kaufentscheidung, sondern beim Konsumverhalten an. Belz und Birhatz [70] sprechen hier davon, die klassische Verbraucherforschung um eine zweite Säule zu erweitern. Neben einer verbraucherfreundlichen Marktordnung gilt es auf das Verbraucherverhalten unter dem Leitbild der Nachhaltigkeit einzuwirken. Bei der konsumtheoretischen Forschung wird häufig auf verhaltenspsychologische Handlungstheorien [84] sowie psychologische Bedürfnistheorien [85, 86] Bezug genommen. Der private Konsum wird zum einen in Bezug auf physiologische Elementarbedürfnisse wie Nahrung, Schlaf, Wärme etc. betrachtet [63]. Zum anderen werden die erweiterten, sozialpsychologischen Bedürfnisse und der symbolische Konsum untersucht, der sich in der Massenkonsumgesellschaft in der Breite etabliert hat [64]. Hierbei zeigt sich, dass die Befriedigung der Individualbedürfnisse in der Masse zunehmend in Konflikt mit der ethisch-normativen Forderung einer nachhaltigen Gesellschaft geraten.

Ein Schwerpunkt der neueren Forschung liegt deshalb auch auf der Frage, welche Faktoren für ein nachhaltiges Verhalten verantwortlich sind. Neben utilitaristischen Faktoren, z.B. monetären Anreizen, spielen hier soziale Normen im Sinne der Theorie des sozialen Vergleichens [87] als auch eine persönliche, internalisierte Moral im Sinne der *Norm-Aktivations-Theorie* [88, 89] eine Rolle. Das Ziel verbraucherpolitischer Intervention besteht deshalb nicht nur im Schaffen finanzieller Anreize, sondern auch darin, soziale und persönliche Normen zu aktivieren. Dies geschieht beispielsweise durch Aufzeigen der Folgen (nicht) nachhaltigen, fairen oder solidarischen Handelns, durch Verantwortungszuschreibungen oder Appelle zum Eingreifen. Hierbei ergeben sich enge Bezüge zu den oben genannten *Eco-Feedback*-Systemen und der an VerbraucherInnen orientierten Umweltinformatik.

3.3 Haushalts- bzw. praxistheoretische Verbraucherforschung

Die neueren praxistheoretischen Ansätze [90, 91] setzen an den Haushalts- und Alltagspraktiken von VerbraucherInnen an. Die sozialen Praktiken im eigenen Haushalt sind demnach weniger durch explizite Rollen- und Prozessmodelle geregelt, als durch informelle Absprachen, subtile Aushandlungsprozesse und eingeschliffene Routinen und Gewohnheiten. Dies heißt aber nicht, dass der Haushalt als sozio-materielles Gebilde nicht auch Objekt einer rationalen Gestaltung sein kann, wie dies beispielhaft an der (arbeits-)ökonomisch gestalteten Frankfurter Küche nachvollzogen werden kann [92]. Häufig hat man es aber mit schleichenden, nicht gezielt rational gestalteten Veränderungsprozessen zu tun, wie z.B. der eher organischen Herausbildung der Couchecke [93]. Innerhalb dieses Forschungszweigs wurden unter anderem die Digitalisierung des Haushalts bzw. deren Schwierigkeiten exemplarisch am Beispiel der Gestaltung und Nutzung digitaler Haushaltsbücher untersucht [94]. Die ernüchternden Ergebnisse deuten an, dass verbraucherinformatische Ansätze sich stärker mit der Adaption von IT-Systemen auseinandersetzen müssen, d.h. wie diese angeeignet und in die häuslichen Routinen integriert werden (können) [95]. Einen Schwerpunkt stellen die Ernährungsweisen von VerbraucherInnen dar, die sich auf verschiedenen Ebenen durch die Digitalisierung wandeln, unter anderem durch die Art und Weise wie sich VerbraucherInnen über Lebensmittel und deren Zubereitung mittels digitaler Medien informieren, wie sie Kochen und Essen ästhetisch codieren und digital kommunizieren, wie Produkte über den Online-Handel beschafft werden und wie sich bspw. durch smarte Küchenmaschinen Esskulturen (beschleunigt) wandeln. Denn Haushalt und damit verbundene Lebensweisen werden durch die Digitalisierung selbst transformiert – und damit auch der Gegenstandsbereich der Verbraucherforschung.

In der neueren Verbraucherforschung werden deshalb vermehrt praxistheoretische Ansätze [90] aufgegriffen, um soziale Praktiken des Wohnens, Kochens, Kaufens, Vorsorgens etc. zu analysieren und zu verstehen [91]. Insbesondere werden hier Handlungen nicht als einzelne, diskrete und individuelle Einheiten betrachtet, sondern als sozial eingebettete, situierte, durch implizit-methodisches Wissen geleitete Praktiken verstanden. Sie bilden ein schwach-strukturiertes, dynamisches Geflecht, in dem sich die VerbraucherInnen bzw. der Haushalt als Forschungsgegenstand erst konstituieren [96]. Auf Basis dieses theoretischen Verständnisses haben Ganglbauer et al. [42] gezeigt, dass sich Ernährungsverhalten aus einem Komplex lose gekoppelter Praktiken des Einkaufens, Kochens und Essens zusammensetzt, deren wechselseitige Abhängigkeit es in der Gestaltung von Verbraucherinformationssystemen zu berücksichtigen gilt. Daneben kann man aktuell eine eher schleichende Aneignung intelligenter Einrichtungsgegenstände wie Küchenmaschinen, Staubsaugroboter oder Smart Speakers beobachten. Offen ist, wie diese neuen KI-Materialitäten die häuslichen Routinen und Praktiken verändern werden.

4 Zusammenfassung

„Verbraucherforschung ist Querschnittsforschung und in der Wissenschaft interdisziplinär verortet. Sie findet als nicht eigenständig abgegrenztes Wissensgebiet in den Sozialwissenschaften insbesondere in den Disziplinen der Wirtschaftswissenschaften, der Soziologie, der Politologie und in den Rechtswissenschaften statt wie auch in der psychologischen und medizinischen Forschung.“ [1]

Der kurze Abriss hat gezeigt, dass Verbraucherinformatik als Querschnittsforschung aus Sicht der VerbraucherInnen zu verstehen ist, die sowohl viele Anknüpfungspunkte zu den verschiedenen Gebieten der angewandten Informatik als auch zu den verschiedenen Gebieten einer interdisziplinär verfassten Verbraucherforschung aufweist. Das Ziel des Workshops „Digitaler Konsum – Herausforderungen und Chancen der Verbraucherinformatik“ ist es, verschiedene AkteurInnen und Disziplinen in diesem neuen Feld der Wirtschaftsinformatik zu vernetzen, um ein gemeinsames Verständnis dafür zu entwickeln, was geeignete Themenfelder, Theorien und Methodologien einer pluralen Verbraucherinformatik sein können (vgl. http://www.verbraucherinformatik.de).
