Figure 3. Taxonomy of social reading platforms

Type of cultural artefact addressed by subsequent communication. Using social reading platforms to discuss and share opinions within a community, not only *books* but also *eBooks*, *audio books* or *other* cultural artefacts (e.g., public reading by authors, music or films) can be focused.

Type of communication. First, platforms allow people to write and share a review —separated from the book text itself—and to engage in subsequent discussions on specific books (*mediated discussion on a book—change of medium*). Second, providing a dynamic margin on the page of a book, allows a close discussion on books. The composition of multiple comments forms a review (*immediate discussion on a book—in the margins*) [8].

Realisation of subsequent communication. Social interaction related to social reading can be shaped by the theoretical concept of subsequent communication. It defines communication that is directly attached to the book [7, 11]. People directly write a review on a book (*primary thematisation—writing a review*) or they comment on reviews of other people (*secondary thematisation—comment function*). Further, numerical ratings (e.g., star, heart or thumb ratings) both for the book in general (*primary thematisation—like statement*) or for reviews or comments of other people (*secondary thematisation—like statement*) can be made. In addition, *book clubs* allow the structured discussion on books, offering different types of application (e.g., discussion on a chapter is only possible/open, after everyone read the chapter or at any time, readers are allowed to write comments to each chapter). For instance, authors or publishers can initiate a book club for a selected book. Interested people can participate—sometimes restricted by application procedures or number of participants—after having read the book. Thus, the initiator of the book club can start the discussion on the book, providing a structured selection of themes (e.g., by chapters of a book) that have to be discussed, resulting in multiple reviews and comments. The initiators get customised, structured feedback and the participants can engage in clear discussions, to communicate their feelings and evaluations about what they read. Moreover, people are supported to address additional literary themes, using a *discussion forum* and sometimes *direct text work (visual marks)* on books (e.g., use of text marking, bookmarks) is possible.

Assistance for subsequent communication. While writing a review, some platforms *directly* provide a *prescribed structure of a review* (e.g., reviews' title, short summary, positive and negative issues, resume) and/or *directly propose elements* that might be *discussed* (e.g., writing style, story of the book, figures). In contrast, both for *structure* and *elements general instructions* that are not simultaneously provided while writing a review are possible (e.g., first entry of a discussion forum that explicates how a review can be structured). In addition, *writing rules and tone* (e.g., rules of courtesy as avoiding swear words and personal insults, observance of spelling), *general assistance* for dealing with the platform and its characteristics (e.g., FAQ document, an introductory learning unit after registration) and a *categorisation of reviews* (e.g., verified sale) are provided. Moreover, some platforms allow *exporting* the text of subsequent communication.

Off-topic communication. Further, off-topic communication (i.e., communication without direct relation to literary themes) [7] can be performed on *officially provided places*. For example, some platforms provide an independent discussion forum or support exchange of messages between people (e.g., via chat or pin board).

System-based roles. To receive content on a platform and to participate in discussions on books, several system-based roles are established [7]. People can read content (e.g., reviews, discussions in book clubs) (*reader*) and participate in discussions as *reviewers*, mostly after registration. Further, people can register as *author*, *blogger* or *moderator* with special rights (e.g., generation und control of book clubs).

Identity customisation. People can create a virtual identity, to be noticeable for others in order to get an idea of each other, and to build an important foundation for trust [7]. Their virtual identity can be customised via an user profile (*general user or specific user profile*), several forms of *status information* (e.g., number of received "likes", rank measured by number of reviews and their helpfulness assessed by others), *activity overview* (e.g., reading statistics, wish list of books) and *linkage to other users* (e.g., "following" users, finding "friends").

Provided link to other communities. Further, the connection to other communities, offering links to *social media* (e.g., connection with Facebook account, social media button) or *personal sites and blogs* (e.g., link to book blog) can be provided.

Registration for the platform. To take part in discussions and to make use of all functions, a *free registration* can be required. Sometimes, a platform might be a more "closed system", providing access to a selected number of people (e.g., after invitation) (*conditional registration*).

Visibility of content. The general public is able to read, and therefore, to receive the whole content, presented on a platform (*completely public*). However, sometimes the visibility of content might be partly restricted to public (*partly public*) (e.g., author profiles are visible, whereas visibility of reviewer-profiles depends on registration) or only visible for a closed community (*not public*).

Social media intelligence. Aiming to collect, monitor, analyse, summarise and visualise data of the platforms, social media intelligence is integrated (*available*) [33]. For instance, a similarity function provides similar users within the community that are sometimes called "book neighbours". Further, similar authors or books are recommended that support the selection of further books.

Transaction offerings. Platforms directly support purchasing a book (*direct sales*) or guide people by an *affiliate link* to an external online-shop that, in case of purchase decision, financially supports the platform. Besides, *peer-to-peer transactions* allow exchange of cultural artefacts (e.g., "buy, exchange, gift forum").

Financing of the platform. To finance a platform, several activities are addressed by providers. *Personalised advertising* (e.g., newsletter, press advertising) or *usage analysis* to contribute to market and opinion research and to improve services are sample activities. To do so, external services are frequently used (e.g., Google Analytics). Further, *campaigns with publishers* (e.g., book club initiated and controlled by publishers, free copies) or *user fees* are possible financial sources.

Reviewer gratification. Next to more social gratifications of society (e.g., presentation and confirmation of peoples' own reading quality, belonging to a community) [11], some reviewer gratification can be derived from the platforms. People can have *fun and tension*, participating in specific games (e.g., writing competition, riddles), they can gain *symbolic,* (e.g., status enhancement because of users' activities), *monetary* or *material gratification* (e.g., draw of books).

Author gratification. Besides, authors benefit as they *directly interact with readers*, receiving immediate feedback. Also, *monetary gratifications* are possible.

4.2 Types of Social Reading Platforms

Following the cluster analysis method (Section 3), we identified four clusters. Each cluster has a different focal point along the dimensions and characteristics of social reading platforms. As the characteristics within a dimension are collectively exhaustive, the results can be read as percentages. Moreover, the absolute frequency of each characteristic is presented. For example, 100% of the social reading platforms in Cluster

1 support mediated discussion on a book as type of communication. In sum, the majority of platforms (9/10) supports such a mediated discussion (Figure 4). The darker the colour of a cell, and therefore, the higher the percentage of a characteristic within a dimension, the more it is shaping a cluster. Next, we present the clusters, highlighting the most typical characteristics of each cluster and utilising demonstrative examples.

Cluster 1—manifold discussions within a bonded community. The *mediated discussion on books* has been changed by digitalisation. Providing manifold *realisations of subsequent communication*, people interested in literature—especially *reviewers and authors*—can engage in meditated discussions, to communicate their feelings and evaluations about what they read. For instance, book clubs that allow a structured discussion on books, enable authors a *direct exchange with readers*, resulting in immediate feedback. To encourage collaboration and exchange, platforms provide various *assistance for subsequent communication*. Further, discussions on books are directly related to a bonded community. Therefore, users are closely linked, providing *customised identities* and expanding communication by non-literary themes (*off-topic communication*). In line, people benefit from specific games related to having *fun and tension*, from *material* (e.g., draw of books) or *symbolic gratifications* (e.g., on LovelyBooks users get "dog-ears" for their activities on the platform). Further, *affiliate links* and *peer-to-peer transactions* are provided. To reach many people, a lot of content is *visible for public* and only *free registration* in order to participate is required. For financing a platform, *personalised advertising*, *usage analysis* and *campaigns with publishers* are used.

Cluster 2—assessment of books to support purchase decisions. Offering *direct sales* transactions, platforms allow people to write reviews and numerically rate several (e.g., star ratings) *types of cultural artefacts*. Although secondary thematisation is allowed, manifold discussions between people—as they are observed in Cluster 1—are not focused (e.g., no official interaction between readers and authors). In line, less *assistance for subsequent communication* is provided and identity customisation is restricted to the users' own characteristics (*specific user profile*, *status information*, *activity overview*) without special interest in linkage of users (e.g., *no off-topic communication*). Besides, the visibility of content is *completely public* and reviewer can benefit from *symbolic*, *material* or *monetary gratifications* (e.g., users win a book voucher after writing a review on buecher.de). Moreover, *personalised advertising* and *usage analysis* are used to finance the platform.

Cluster 3—immediate discussions on books within a closed community. Providing a dynamic margin on the page of an *eBook*, allows *immediate discussions on books*. Only after invitation of *moderators*, *reviewers* can register (*conditional registration*) and participate. Consequently, the content is *invisible for public*. Engaging in discussions, *book clubs*, private *discussion* groups and *direct text work (visual marks)* can be used. To do so, several *assistance for subsequent communication* is provided (e.g., prescribed structure and proposed elements). Besides, next to *personalised advertising*, *usage analysis* and *campaigns with publishers*, also *user fees* are introduced as financial sources.

Figure 4. Results of the cluster analysis

Cluster 4—hybrid discussions on books, related to sales and monetary gratification. Both *mediated* and *immediate discussion on books and eBooks* can be performed by several roles (*reader*, *reviewer*, *author*, *blogger*). In consequence, multiple *realisations of subsequent communication* are available. To offer a diverse view on literary themes, and therefore, to contribute to various discussions, *personal* *literary sites* and *blogs* are linked. In addition, people can *directly buy* books. If the purchase decision has been influenced by a certain users' comment, she or he will receive *monetary gratification* (Mojoreads).

5 Limitations, Discussion and Future Directions

Before discussing selected issues and possible research directions, we acknowledge the limitations of this study. First, our investigation is limited to the selected German social reading platforms and the general validity of our sample cannot be guaranteed, although the developed taxonomy fulfils the ending conditions. However, as Germany is one of the largest European markets in terms of publishers' turnover [16], it provides a useful starting point for our research. Further, we would argue that our results provide a useful characterisation of platforms and the derived types already indicate major differences, underlining the heterogeneity between social reading platforms. Second, the identification of dimensions and characteristics is based on our own decisions and interpretations. To contribute to the robustness and the reliability, two researchers independently analysed the platforms and subsequently consolidated their results. Third, the number of types of social reading platforms is affected by the interpretation of the dendrogram. Although we followed established approaches (Ward's method, K-Means method), another number of clusters might have influence on the results.

Despite the mentioned limitations, we believe this study to be an important first step in investigating how the digitalisation changes the literary culture. For reasons of space limitations, we discuss selected issues and present possible research directions below.

Derive implications for design features of social reading platforms. Analysing social reading platforms, various characteristics and four types have been identified. Considering further platforms, not only non-German social reading platforms but also platforms of a wider field (e.g., related to scientific literature), may support verifying or extending our results. In addition, the taxonomy provides a foundation for other representations (e.g., derivation of a data model) that might function as a detailed basis for comparison of platforms and further developments (e.g., derivation of new characteristics that could not be found in the investigated platforms). Besides, based on our findings researchers are provided to derive design features for social reading platforms, contributing to the design of review systems [34] in general as well. For instance, various realisations of *assistance for subsequent communication* exist. Sometimes a guideline for writing reviews (structural hints, proposed elements) is separately provided on a platform, whereas also direct instructions while writing a review are provided. Hence, it would be interesting to analyse the influence of such different forms of assistance on reviews. Doing so, the content and structure of reviews should be analysed and compared to the proposed guidelines, leading to enhanced and novel proposals for assistance that might support the manifold, detailed discussion on books. In line, as online reviews influence purchase decisions [35, 36], and economic outcomes, also publishers, authors and book sellers can benefit.

Engage in social reading intelligence. Regarding the selected social reading platforms, almost all of them provided *social media intelligence* (9/10) to derive actionable information from social reading activities. For instance, similarity functions provide similar users within the community that are sometimes called "book neighbours". Further, the majority of platforms performs *usage analysis* (9/10) in case of market and opinion research and improvement of services. As the digitalisation will lead to novel reading realities and discourses [4], adopted or new tools and algorithms are required to analyse the changed form of socialisation of reading. "Social reading intelligence" presents great potential with important practical relevance. For instance, content that emerges within multiple realisations of subsequent communication could be analysed. Making use of this knowledge, for example, the impact of book clubs on sales—similar to effect of reviews on sales [37]—might be investigated.

6 Conclusion

In order to develop a taxonomy of social reading platforms, we carried out an initial literature review, collected social reading platforms, analysed the findings and built a taxonomy that *structures* various *characteristics that are provided by social reading platforms*. Performing a cluster analysis, we discovered four types of platforms: (I) manifold discussions within a bonded community, (II) assessment of books to support purchase decisions, (III) immediate discussions on books within a closed community, (IV) hybrid discussions on books, related to sales and monetary gratification. Based on the findings, we discussed selected issues and possible future research endeavours.

Overall, our findings contribute to the ongoing research in digital transformation in creative industries. Based on the taxonomy, both research and practice are supported to derive implications for future social reading platforms. Researchers are, for example, supported to position and redesign their platforms or research results, and to identify gaps that need to be addressed by future endeavour. Practitioners (book sellers, publishers), for instance, can be informed within the wide range of social reading platforms, to compare, refine and develop further platforms. In addition, users (e.g., readers, reviewers, authors) are supported to make an informed decision concerning the selection of a social reading platform as they receive an overview of platforms.

Abstract. Digitalization has a broad impact and the risk of external disruption is omnipresent throughout all industries which also applies to IT consulting firms. One response to this threat is to understand better the determinants of how value is created during the joint work on an IT project. Although previous literature offers valuable starting points for explaining value co-creation, no previous research synthesizes service provider and client perspective in a comprehensive model and empirically explains the co-creation of IT consulting service value. We build on the service-dominant (S-D) logic as the fundamental meta-theory and evaluate our deductively derived structural model based on 113 collected responses from IT consulting projects using structural equation modeling. Our major finding is that IT consulting service value only seems to be determined by consultant capabilities. Our findings provide new insights for S-D logic and service science literature and potential for future research.

Keywords: Value, Value Co-Creation, Service-Dominant Logic, Service Science, IT Consulting Services

1 Introduction

Digitalization has begun to change the rules of competition in many industries. The risk of disruption is omnipresent, and the digital transformation is on everyone's lips which is why organizations need to reconsider and to adjust their business models to remain competitive [1]. In this quest for digitalizing existing business models, creating new ones, or transforming existing services and processes, organizations often draw upon the knowledge of consultancies as external knowledge providers and transformation agents with specialized skills and resources to manage their digital transformation [2]. This way, organizations closely interact with IT consulting firms to achieve business value from such co-creations. In the same vein that regular organizations feel pressured to remain competitive, so do IT consulting firms [3]. While their fundamental business model has not changed for many decades, IT consulting firms are currently facing major

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

challenges. First, the IT consulting industry is strongly tied to the global economic situation, which means that in times of recession and resulting budget cuts at the clients' organizations, consulting assignments flatten out [2]. Second, IT consulting services are mostly labor intensive and require highly skilled and trained consultants. Particularly in the field of digitalization, IT consulting firms are in a 'war for talents'. Third, the billing model based on daily or hourly rates promotes overstaffed and protracted offerings which nowadays will be realized by clients through their increased experience with consulting offerings. Forth, the client organization's necessary shift to a more customer-centric view is also valid for consulting firms. The increasing experience of the clients with consulting services reinforces this major challenge once again [2]. Furthermore, the progress in digitalization paved the way for digital platforms (e.g., Comatch) in the consulting business that broker between supply (of highly qualified freelance consultants who formerly worked for large consultancies) and demand (organizations of different sizes requiring external advice). In addition, digital platforms offer organizations the opportunity to individually assemble their consulting team, so that the competition continues to increase [4].

To overcome the mentioned challenges, it is also for IT consultancies more essential than ever before to understand their customers' needs and IT literacy as well as to place the clients' requirement at the center of their activities and create value for them. Only a deeper understanding of which determinants drive the client's overall value enables ideal collaboration and co-creation settings and ultimately increases or at least maintains the IT consultancies' sales and profits and is beneficial to the client [2]. Therefore, both parties need to join their forces and individual capabilities. Surprisingly, empirical results on the underlying mechanisms between IT consulting firms' service provisions and client value are scarce. We connect to the research streams of service quality and customer satisfaction which is grounded in marketing literature and based on the distinction of technical and functional quality to measure customer satisfaction [e.g., 5, 6]. This research stream also includes approaches to measures service quality and satisfaction with the SERVQUAL instrument [7] and was adapted and used in information systems (IS) literature [e.g., 8, 9]. However, also the adapted IT-SERVQUAL instruments could not overcome the existing criticism [e.g., 10, 11].

The advent of the S-D logic can be considered as the most impacting shift in marketing and service science literature from a firm- and goods-centric to a customer-centric perspective [12-14]. Within the last years, research studies applied the S-D logic on various disciplines, e.g., service recovery [e.g., 15], service innovation [e.g., 16, 17-20], retailing [e.g., 21], tourism [e.g., 22], and IS [e.g., 23, 24-27]. Furthermore, S-D logic also impacted the service science research stream which is, in particular, relevant for us. The fundamental unit of analysis is service system, such as IT consulting service. Thus, we consider S-D logic as a meta-theory [25, 28] in which we theoretically ground our work, and we embed our work in service science.

We subsequently analyze existing quantitative-empirical studies in research streams which might be helpful for us. Although there are previous empirical IS studies applying SERVQUAL [e.g., 8, 9], they take an outdated firm- and goods-centricity and they focus on customer satisfaction (instead of value). Most literature on the meta-theory of S-D logic are conceptual contributions: First, the conceptual study of

Grönroos and Ojasalo [29] conceptually distinguish between customer-induced and provider-induced contributions to explain service productivity. While we second their suggestion that the service provider and the service recipient create the service in interaction, we disagree with their view that service productivity can be measured solely based on financial measures. Breidbach et al. [18] draw upon the S-D logic and investigate innovations in professional service firms, acknowledging a customer-centric perspective. Furthermore, Tallon [27] framed his study in a service science context and investigated the impact of business and IT strategy on firm performance. While both contributions provide valuable thoughts of value co-creation in a service system, their underlying objective differs.

The Work of Barrutia and Gilsanz [23] who examine electronic service quality and value in a business-to-consumer (B2C) e-commerce context inspired us. They state that "both consumer expertise and electronic service quality directly and positively affect value perception" [23, p.231] and incorporated a consumer and firm resources in their model. Whereas their model and the incorporation of consumer and form resources serve as a valuable starting point, the investigated B2C-service cannot be compared with the more complex IT consulting services. Concluding, all previous works neglect certain parts central to our research objective: they focus on B2C-relationships, the underlying objective differs, and/or the investigated services are not applicable and transferable to IT consulting services. Hence, no validated quantitative-empirical model synthesized service provider and client capabilities in a business-to-business (B2B) service system. To address this research gap, we investigate the following research question: Which factors determine the IT consulting service value considering both consultant and client capabilities?

2 Theoretical Foundations

We ground our research in the S-D logic of Vargo and Lusch [12] as "philosophical foundation" [28, p.19]. With the occurrence of S-D logic, the dichotomy of goods and services is overcome. Vargo and Lusch [12, p.2] define service "as the application of specialized competences […] through deeds, processes, and performances for the benefit of another entity or the entity itself". Hence, goods represent the distributing mechanism for services because service is the fundamental unit of exchange [12, 13]. Taking this into account, S-D logic assumes that "all economies are service economies" [12, p.10] and "enterprises cannot deliver value, but only offer value propositions" [13, p.7] which leads to an enhanced client role.

Moreover, S-D logic, as a meta-theory, can be seen as a theoretical foundation for service science [30]. Maglio and Spohrer [28, p.18] state that the "service-dominant logic may be the philosophical foundation of service science, and the service system may be its basic theoretical construct". Service science also focusses both on mutual interaction between the service provider and its customers in which specialized competences, such as knowledge and skills (operant resources), are exchanged and posits that a service "is a process of applying the provider's competences (knowledge and skills) for the benefit [value] of, and in conjunction with [value co-creation], the customer" [31, p.361]. In this framing, service systems are the basic unit of analysis and are defined "as value-co-creation configurations of people, technology, value propositions connecting internal and external service systems, and shared information (such as language, laws, measures, and methods)" [32, p.72].

2.1 Value Propositions, Value Co-Creation, and Value

The term value proposition is widespread in research as well as in practice. However, scholars realize that the term is yet poorly defined [17], also in the initial work and later revised works of S-D logic [14]. Lusch et al. [33] describe value propositions as a service provider's promise in which value-in-exchange is linked to value-in-use. Similarly, Grönroos and Voima [34, p.145] consider value propositions as "promises that customers can extract some value from an offering". However, the actual assessment of whether the service provision contributes to the client's value in future use can only be made by the client. Therefore, a service provider cannot guarantee an initial value contribution [17], but only make suggestions as to how the client can generate value through the use of the service. Barrutia and Gilsanz [23, p.232] which state that service provider and service recipient "simultaneously access, adapt, and integrate resources to create value for themselves and others" and assume that value is always co-created.

2.2 Consulting and Client Capabilities

Consulting service is defined as a time-limited achievement with the goal of defining, structuring, analyzing, and solving specific business problems interactively with the client [35]. Due to the interactive service provision and the knowledge-intensive industry and in line with Grönroos and Ojasalo [29], it is essential to consider both consulting and client capabilities in the value co-creation process. Furthermore, service science differentiates between operant (intangible, continuous, dynamic) and operand resources (tangible, static resources). We defined operant resources as those that act on operand resources [13]. Within consulting services, the fundamental unit of exchange is operant capabilities, such as knowledge and skills [36]. Thus, we solely focus on operant resources. To ensure a high consulting value, both parties should provide particular skills within the project. Both parties need certain types of expertise, such as social expertise, technological expertise, and functional expertise to maximize the consulting service value. In addition, consultants also need industry expertise and innovativeness to achieve high-quality results. However, IT consultancies can only provide value propositions which consist of their overall skill set. Thus, we integrate IT consulting quality as an operant resource in the consultant capabilities. IT consulting quality represents the overall perception of various underlying factors. Summarizing, the above outlined different types of expertise, as well as the consultant's innovativeness, contribute to the IT consulting quality which in turn contributes to the overall IT consulting service value.

Similar to the consultant capabilities, the client needs to provide a particular social, technological, and functional expertise. However, the client also needs specialized skills to handle the provided service [37]. A client who works on a time-limited project with consultants needs to understand how to work together with a consultant [38]. Hence, we consider the past experiences made while working with consultants as an operant client resource. Furthermore, an IT consulting service will only contribute to a client's value if the client has the ability to recognize the provided value and external information, as well as transform, assimilate, and apply it [39]. Thus, the client's required skills contribute to its absorptive capacity which in turn contributes to the overall IT consulting service value. Additionally, we hypothesize that the collaboration of both parties is an additional important determinant that contributes to the overall consulting service value and displays the co-creation of the consultant and the client. A prerequisite for consulting services is the exchange of knowledge and information between the consultant and the client as well as a trustworthy and courteous way of collaborating [40]. These social resources comprise for instance interpersonal trust, know-how exchange, relationship proneness, and social skills. We suggest that each of the parties' social expertise determines the collaboration quality which in turn directly influences the overall consulting service value.

3 Conceptual Development

After having described the theoretical foundations and identified previous works related to consulting service value, we now derive our hypotheses to explain the value co-creation between IT consultancies and clients. Our research aims at explaining and measuring consulting service value by both client and consultant capabilities. Therefore, we built on Oesterle et al. [41] in which we deductively derived a preliminary conceptual model. Whereas the previously published article served as a valuable starting point, we modified the previous model by including the concept of absorptive capacity [39] and by extending the model with additional antecedents. Investigating the value co-creation in the consulting industry, we focus on the project-level and examine the consulting service value that emerges from the mutual work of an IT consultancy and its client on a project level. As introduced in our theoretical foundation, we follow the distinction of Barrutia and Gilsanz [23] and integrate both client and consultant capabilities to capture the co-creation process within the consulting industry. We incorporate collaboration quality as an additional determinant of our dependent variable. Our dependent variable is the consulting service value which is the overall assessment of multiple factors (monetary and non-monetary) and emerges during the use of the provided service [23].

The first determinant that influences the consulting service value is collaboration quality which in turn is influenced by consultant and client capabilities. It refers to the extent to which at least two entities of the IT consultancy and the client worked jointly and coordinated together [42]. Thus, collaboration consists of personal interactions and relations between consultants and clients as well as collaborating aspects like respect and friendliness [43]. The better these qualities, the stronger are the ties between a consultant and its client, and thus, a higher value emerges [44]. Hence, we hypothesize:
H1: Collaboration quality has a positive impact on IT consulting service value.

3.1 Consultant Capabilities

The consultant should provide high consulting skills to address all relevant tasks in a structured and comprehensible way as well as practical research techniques applicable to the specific project. We define IT consulting quality as the extent to which a consultant has expert knowledge in required project skills such as systematic approach, statistical analysis, project and change management, development of surveys, or software engineering [45]. The necessary consulting skills can vary in each project. It is the consultant's task to assess which skill set is best for the project to achieve a high consulting service value. Hence, we state:

H2: IT Consulting quality has a positive impact on IT consulting service value.

Furthermore, the IT consulting quality depends on the consultants' industry knowledge. Consultants with high industry expertise better understand the specific needs of the client and have a thorough understanding of how business is conducted in the client industry [46]. We define industry expertise as the extent to which a consultant possesses expert knowledge in the domain of the client. We hypothesize:

H3: Industry expertise has a positive impact on IT consulting quality.

Moreover, consultants also need technological expertise. Especially in light of the ongoing digitalization, there are only a few consulting projects which do not include technology issues which stresses the importance of consultants possessing technological skills. The contracting of a consultant seems to be an easy way for clients to get access to new technologies. We define technological expertise as the extent to which a consultant possesses expert knowledge in technology and related areas [47] which facilitates the overall IT consulting quality. We hypothesize:

H4: Technological expertise has a positive impact on IT consulting quality.

Consultants also need functional expertise to complete consulting projects successfully. Consulting projects require a heterogeneous set of expert knowledge. We follow the definition of Hoffman [48, p.85] who defines a functional expert as "one who has special skills or knowledge derived from extensive experience with subdomains". Hence, we hypothesize:

H5: Functional expertise of the consultant has a positive impact on IT consulting quality.

Within the consulting industry, clients rely on consultants to figure out new ways of dealing with a specific issue. Especially in the light of the digitization of services, a certain level of innovative approaches is necessary. We define innovativeness as the degree to which consultants provide an innovative and novel service and are able to influence the client organization positively [49]. Hence, we hypothesize:

H6: Innovativeness of the consultant has a positive impact on IT consulting quality.

Finally, we define social expertise of the consultant as "interpersonal perceptiveness and the capacity to adjust one's behavior to different situational demands and to effectively influence and control the responses of others" [50, p.1076]. This conclusion also remains valid in a B2B context. Within a consulting project, there are various types of actors with different kinds of expertise and attitudes. Hence, the consultant must cope and collaborate with all of them to successfully complete the project. Thus, social expertise will facilitate the quality of the collaboration and furthermore contribute to

the IT consulting quality. Therefore, we hypothesize:
H7: Social expertise of the consultant has a positive impact on IT consulting quality.
H8: Social expertise of the consultant has a positive impact on collaboration quality.

Summarizing, we hypothesize that the determinants introduced above positively influence the client's perception of the overall IT consulting quality.

3.2 Client Capabilities

We now introduce the client capabilities through which the consulting service value emerges. Some determinants of the client capabilities are similar to the consultant capabilities but are assessed from the client's perspective (social, technological, and functional expertise). Also, we include the determinants experience with consultants and the client's absorptive capacity.

Absorptive capacity is a firm's ability to identify, assimilate, transform, and apply valuable external knowledge [39] which is also applicable to consulting services. The client has to be able to identify, assimilate, transform, and apply the consultant's external knowledge (as seen by the client) to create value. Therefore, we hypothesize:
H9: Absorptive capacity has a positive impact on IT consulting service value.

The client's social expertise, while similar to the consultant capabilities, takes the client's perspective. According to Ferris et al. [50, p.1076], social expertise is defined as the "interpersonal perceptiveness and the capacity to adjust one's behavior to different situational demands and to effectively influence and control the responses of others". In the same vein, client employees have to work jointly together with consultants. These skills will also help clients to conduct business with consultants jointly and absorb the provided solutions. Hence, we hypothesize:
H10: Social expertise of the client has a positive impact on collaboration quality.
H11: Social expertise of the client has a positive impact on absorptive capacity.

Like the consultant's technological expertise, also clients need to provide technological expertise. Otherwise, the client does not have the abilities to absorb the externally provided knowledge [47]. The client needs technological expertise to evaluate if the provided service is applicable and valuable. Therefore, we propose:
H12: Technological expertise has a positive impact on absorptive capacity.

Like the consultant's functional expertise, the client needs to understand all functional aspects of the project and provide expert knowledge. Due to the interactive service provision, the client requires these skills to assess if the externally provided service fits into the client company and is beneficial [51]. Hence, we conclude:
H13: Functional expertise has a positive impact on absorptive capacity.

Besides, we also integrate the determinant experience with consultants which we define as the extent to which client project members have developed empirical knowledge based on past interactions with consultants. This determinant is vital for clients since it reflects the learning process of how to interact, govern, judge, and transform the relationship with consultants [38]. Hence, we hypothesize:
H14: Experience with consultants has a positive impact on absorptive capacity.

4 Research Method

To analyze our model, we opted for quantitative-empirical methods for our research project because of their advantage regarding statistical generalization [52] and used structural equation modeling. The online questionnaire had the advantage that respondents were more likely to state their true unbiased opinion compared to a face-to-face interview. To empirically validate our theoretical model, we had to develop a suitable survey instrument.

4.1 Construct Operationalization

While existing measurement scales served as a good starting point, we had to adapt them in wording, language, and formality. In the cases that no suitable measurement scales were found or did not fit to our context, we developed additional items. After a first analysis of the initial item pool, we shortened our long-list and continued with the resulting item pool. After having adjusted the raw items in several rounds, we conducted two rounds of card-sorting procedures proposed by Moore and Benbasat [53] to assess the construct validity. In the first round, we achieved a satisfying overall hit ratio of 82.96%. However, the spread of the continuum was quite broad, so that we had to sharpen and to elaborate on some construct definitions and items. After a thorough revision of the items with the lowest scores and the highest cross-loadings and the construct definitions, we conducted a second round of card-sorting procedure. With an overall hit ration of 95.14% in the second card-sorting round, the score of the revised measurement model was satisfying.[1] After having successfully developed the measurement instrument, we conducted a pre-test with 20 participants (researchers, consultants, clients) which showed no need for further action. We measured all items with a seven-point Likert scale ranging from 'strongly disagree' to 'strongly agree'.

4.2 Data Collection

Having developed our survey instrument, we proceeded with the data collection. Our target population were consultants and employees who were jointly working on an IT project or an IT-related project. We used the convenience sampling approach when we approached potential participants in our professional business networks with an individual email including a personalized link for participation. The invitation contained a short description of our research endeavor as well as the assurance that we will handle all gathered data confidentially. The survey period lasted four weeks. The survey was provided in English to apply to a high number of participants. All participants answered the complete questionnaire and therefore, assessed own capabilities, the project partner's capabilities, the collaboration quality, and the consulting service value according to their perspective.

[1] We provide the final measurement model online: https://www.dropbox.com/s/e687qo8gcte6ja5/WI2019sub.pdf?dl=0

487 participants were invited, and 113 fully completed the questionnaire. Of the 113 participants, 67 were consultants and 46 clients and were mainly located in the German-speaking area. Most of the projects had one to five full-time equivalents and also one to five consultants working on the project. The client participants can be mostly assigned to higher management, and the consultant participants were mainly senior consultants or above. The client role within the projects can be considered as project managers and can be assigned to the area of IT. Most of the client participants were from the consumer goods industry (21.7%), followed by the financial service industry (19.6%), and manufacturing (15.2%). Regarding the consultancies, 59.7% were IT consultancies, followed by IT management consultancies (14.9%). 47.8% of the participants had a relationship above two years with their project partner.

5 Data Analysis and Results

First, to assess our measurement model, we tested for unidimensionality, internal consistency, indicator reliability, convergent validity, and discriminant validity [54, 55]. To measure unidimensionality, we conducted an exploratory factor analysis (EFA) using SPSS 20 with a principal component analysis in combination with the Varimax rotation. All of the identified factors had an Eigenvalue above 1.0 and loaded on their corresponding factor. We dropped one item of each of the constructs *functional expertise* and *absorptive capacity*, not meeting the threshold of 0.600 [56]. After these corrections, all factor loadings were above 0.600 and unidimensionality was shown. Furthermore, we tested our measurement model for internal consistency. We calculated Cronbach's Alpha (CA) and composite reliability (CR). Both CA and CR values of all constructs were above the threshold of 0.800, suggesting a high degree of internal consistency [57]. Furthermore, we checked our measurement model for indicator reliability. Therefore, all indicators should be greater than 0.707, and significant at the 0.05 level, which was the case for our data [57]. To assess convergent validity, we checked the average variance extracted (AVE), which should be higher than 0.500, which also applied to our data. Finally, we tested for discriminant validity. We calculated the Fornell-Larcker criterion [58], the heterotrait-monotrait ratio (HTMT) [59], and checked the cross-loadings [57]. Assessing the Fornell-Larcker criterion, all constructs had the highest correlation with themselves.[2] Furthermore, all constructs had an HTMT ratio below the threshold of 0.850 [59]. The cross-loadings also met the requirement to have the highest correlation with its corresponding construct. Hence, we conclude that the discriminant validity of our measurement model is given.

After having discussed the measurement model, we focused on the structural model by assessing path coefficients and coefficients of determination (R^2 values). To check our model for significance, we applied the Bootstrap procedure [57] with 5,000 subsamples. As we only considered completed questionnaires in our analysis, we did not have to cope with missing values. Figure 1 presents our findings showing R^2 values, path coefficients, and the level of significance.

---

[2] We provide the Fornell-Larcker Criterion online: https://www.dropbox.com/s/e687qo8gcte6ja5/WI2019sub.pdf?dl=0

Eight of our fourteen hypotheses could be confirmed on the 1%- or the 5%-level of significance and have weightings higher than 0.200 [57]. The coefficients of determination (R^2) indicated how much variance of a latent variable was explained by its preceding constructs [54]. Chin [57] distinguished between three groups of coefficients of determination (R^2): $R^2 \geq 0.670$ could be considered as substantial, $R^2 \geq 0.330$ as moderate, and $R^2 \geq 0.190$ as weak. Based on this classification, our structural model explained a moderate amount of variance of our dependent variable.

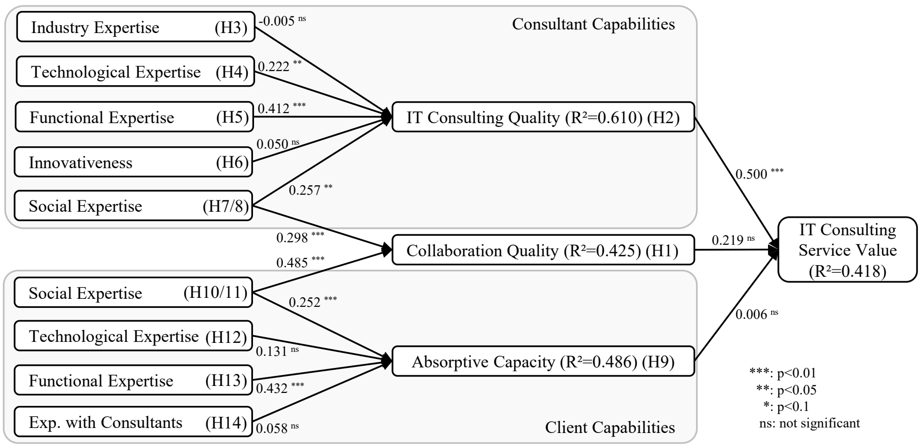

Figure 1. Assessment of the structural model

6 Discussion

Within the meta-theory of S-D logic and the service science research stream, there are numerous theoretical contributions and some qualitative-empirical studies. The number of quantitative-empirical studies which draw on the co-created emergence of value is surprisingly scarce. In this light, our major finding is that consulting service value only seems to be determined by consulting capabilities, while client capabilities, in contrast to our conceptualization, do not show any significant influence on consulting service value, neither in the overall data set nor in the subsamples. These results contradict the limited number of quantitative-empirical studies which suggest that service providers and their clients jointly co-create value. These studies, however, do not focus on a B2B service system [23], do not explain consulting service value but different dependent variables, such as loyalty, or do not focus on the consulting industry but other industries, such as hospitality [22]. As all these previous quantitative-empirical studies provide support for the co-creation of value within a B2C context, we argue that these service beneficiaries are always individual persons who have a high intrinsic motivation to co-create value and thus may have a higher priority to extract value from the service system. At a business level, the obtained value does not directly affect a tangible individual [60] which is why we propose that the client's intrinsic motivation in a B2B service system is lower than in a B2C service system. To the best of our knowledge, there is no previous quantitative-empirical study in a B2B service system that found support for the applicability of value co-creation.

Whereas IT SERVQUAL [8] as a measuring instrument for service quality relies on the gap model and focuses on how the service is delivered, our measurement model is not based on the disconfirmation paradigm. Thus, we concur with the various criticisms [10, 11] concerning both theoretical and operational aspects of the instrument. A second study is a conceptual model to explain customer satisfaction without an empirical validation [6]. Our empirical results provide support for their assumption that the functional expertise of the consultant positively contributes to service quality, which we included as IT consulting quality. IT consulting quality, as already briefly mentioned above, is a strong and significant determinant of consulting service value in our study, which means that IT consulting quality, such as addressing tasks in a structured and understandable way as well as providing the right project skills, contributes to the overall consulting service value. This result is in line with previous research [23]. Focusing in more detail on what IT consulting quality determines, our data show support for some of our hypotheses. We found support for our hypotheses that technological expertise (H4) and functional expertise (H5) are needed to provide a high IT consulting quality. Also, consultants need functional expertise to fully understand all facets of the project and apply their specialized skills to the actual problem. Hence, they can proceed their consulting competences. Next, we hypothesized that the IT consulting quality is influenced by the social expertise of the consultants (H7). The more a consultant possesses personal skills which help to direct its actions from an individual to a common action orientation, the higher is the IT consulting quality. Our data shows support for the hypothesis.

In contrast to our conceptualization, we also need to reject a few hypotheses. We hypothesized that consultants need to possess specific industry expertise that they leverage in projects for the success of the project, i.e., have a thorough understanding of how business is conducted in the client industry (H3). Our data shows no support for this hypothesis, and we reason that consultants and clients consider themselves smart enough to work in any given industry and context so that industry expertise is not viewed as a relevant determinant of IT consulting quality. Furthermore, we hypothesized that consultants need a certain degree of innovativeness to be able to provide unique and problem-solving solutions to the client (H6), which, however, is not supported by our data. This result is surprising, and we can only assume that there was no need for highly innovative solutions in the projects in our dataset or the client wanted standardized solutions.

Finally, we hypothesized that collaboration quality positively influences consulting service value (H1), which we cannot confirm. This finding is quite surprising. We posit that the value of the consulting service is determined by the mutual interaction and hence, the co-creation within the service provision. Especially in knowledge-intensive industries such as the consulting industry, mutual interactions of the service provider and the service recipient concerning information exchange and communication openness seem to be important. However, contrary to our hypothesis and based on the empirical findings, the relationship between collaboration quality and consulting service value is not supported. We assume that this non-significant relationship (H1) depends on the incorporated different types of consulting project types. Whereas consultants can provide some IT consulting projects with a low collaboration level (e.g., IT strategy projects, IT audit), some others need a high collaboration level (e.g., IT implementation, IT transformation).

Summarizing, our data set does not support one of the main assumptions of S-D logic, the co-created determination of value in the domain of IT consulting services. It seems as if the consulting industry is still service provider-centric, not only in the perception of the consultants but also in the perception of the client. Our findings show consulting capabilities solely determine the consulting service value.

7 Conclusion

With our work, we set out to empirically identify determinants which explain the emergence of co-created value in consulting relationships from both the perspective of IT consultancies and clients. To achieve this objective, we adopted and further developed a conceptual model [41]. Our key contributions are twofold. First and foremost, our study showed that consulting service value is determined by consultants only, neglecting any influence of the client. Second, the consultant's functional, technological, and social expertise mainly predict IT consulting quality.

Before we conclude this paper by outlining our recommendations for future research and by highlighting our contributions to both theory and practice, we briefly discuss our study's limitations. Our study only focuses on perceived value, which can be considered as a key determinant of consulting service success. Success in that respect may also be influenced by additional factors such as price, political connections, and sales capabilities which, however, is beyond the study's scope. Furthermore, the participants completed the whole survey, i.e., also the assessment of own capabilities which could be biased, and thus, participants might have overestimated them. This bias could be minimized by collecting matched pairs.

Regarding the next steps, we will follow a dyadic data analysis approach [61] to overcome the possibly biased self-assessment of the participants. Within the dyadic analysis, clients will evaluate their consultants and vice versa on a project level. Through this measurement, it will be possible to get an objective judgment of the incorporated consulting and client capabilities. Thus, we will obtain more profound insights. To account for the particularities of the consulting domain, we aim to strengthen our statistical analysis by carrying out multi-group comparisons. Especially, multi-group comparisons regarding the different IT consulting project types may lead to new insights on the underlying mechanisms.

Keeping the limitations in mind, our results contribute to both theory and practice. Our contribution to the research stream of service science is the advancement of the theoretical discourse on value emergence by providing an empirically validated theory. Furthermore, we account for the value co-creation model in a service system which is the fundamental basis of analysis in service science. Our study indicates that value co-creation in an IT consulting service system is still service provider centric. The fact that our data do not support the co-creation of value provides new insights into a service system as well as foster the discussion of the meta-theory S-D logic.

From a practical point of view, we provide meaningful insights to both consultant and client organization. IT consultancies may learn which determinants lead to a high consulting service value and can be used internally for human resources development purposes. In addition to consultancies, our results equip clients with information which determinants matter most in the selection of a consultancy to maximize the value they gain from contracting a consultancy.

Abstract. Service modularity has been proposed as a possible solution to the dilemma between the customer-driven thirst for individualization and the standardization ambitions of service providers. However, current modularization methods that intend to support the corresponding transformation process remain mostly on a conceptual level with little real-life application. Therefore, we develop the Modularity Canvas – a generic framework for the structured information capturing and identification of potentials for advancing towards a modular service architecture. The artifact is developed following the Design Science Research Methodology. The results include the artifact itself and first insights from five demonstration workshops at industrial service providers from contract logistics, wind energy and automotive engineering sectors. The contribution of the paper lies in the deeper understanding of what dimensions need to be considered when preparing service providers for their move towards a modular service architecture.

Keywords: Service modularity, canvas, framework, modularization method, design science

1 Introduction

In business-to-business (B2B) markets, customer requirements are highly individualized and complex, meaning that the same service value proposition cannot be offered twice to different customers without profound alteration [1]. However, growing competitive pressure also forces B2B service providers to constantly search for cost efficiency improvements by standardizing their resources and processes. In this regard, the concept of service modularity has been proposed as a viable solution to the dilemma between individualization and standardization [2].

A modular system is comprised of smaller parts (i.e., modules) with standardized interfaces and clearly defined functionalities, features, or values, which can be designed, improved and exchanged independently, yet function together as a whole [3]. This way, the provider can try to maximize external variety (i.e., the number of possible variants due to configuration possibilities), while minimizing internal variety

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

(i.e., a finite and manageable amount of service elements or modules). Although the concept of modularity has been successfully established in the context of software engineering [4] and manufacturing [5], recent academic discussions on service modularity have often remained on a conceptual level with little evidence for practical adoption [6]. Although there exist several service modularization methods in the academic literature [7], it seems that these are not acknowledged by practitioners, which can be partly ascribed to their abstract and conceptual nature. Nevertheless, it is especially the field of services, in which the concept of modularity is expected to further accelerate [8, 9]. Moreover, recent works also conceptualize service innovation as a "recombination of resources" [10, p. 380] and strongly rely on ideas related to the concept of service modularity.

Against this background, the objective of our research is to develop a framework that service providers can use to create visual models of their status quo in service provision and to identify potentials for developing towards a modular service architecture. We name this framework the Modularity Canvas. Similar to the very popular Business Model Canvas, the Modularity Canvas intends to offer a "shared language for describing, visualizing, assessing, and changing" [11] service modularity in organizations. Our development process follows the Design Science Research Methodology (DSRM) proposed by Peffers et al. [12]. The paper presents our results after the first four stages of the DSRM (namely *1. Problem Identification*, *2. Objective Definition*, *3. Design and Development*, and *4. Demonstration*), leaving the further stages of *5. Evaluation* and *6. Communication,* as well as possible design iterations, for our upcoming research activities. The Modularity Canvas focuses on the very first phase of information capturing at the beginning of a modularization initiative, before service modules are defined. This phase has been identified as being under-researched and not well covered with method support [7]. The theoretical contribution of the paper lies in the deeper understanding of the dimensions (both on a strategic and operational level) that need to be considered when preparing service providers for their move towards a modular service architecture.

The remainder of this paper is structured as follows. Next, we give a brief background on service modularity, canvases, and ontologies, followed by a section on our research approach. We present the artifact in Section 4 and report on our demonstration workshops in Section 5. Section 6 gives a summary and an outlook.

2 Research Background

2.1 Service Modularity

The research on service modularity is still considered to be in its infancy [6]. Pekkarinen and Ulkuniemi [2] were among the first to apply the concept of modularity to business services and highlighted the multi-dimensional nature of service modularity. Ever since, service modularity has attracted the attention of researchers from different academic fields such as marketing, information systems (IS), engineering, and even psychology [6]. The expected benefits of service modularity include, amongst others, efficiency benefits for the service provider [13], economies of scale and scope [14], the reusability of service elements for future offerings [15], as well as flexibility and faster development cycles [16]. Besides provider-related benefits, modular customization is also believed to directly improve the service experience and the loyalty of customers [17]. To leverage such benefits, Carlborg and Kindström [15] outline different modular strategies based on a distinction between four service types with different process characteristics (rigid vs. fluid) and different customer roles (passive vs. active).

In order to support the transformation process of a service provider from a rather monolithic towards a modular service architecture, scholars have been focusing on the design of appropriate methods. Depending on the underlying service paradigm [18], these methods were either transferred and adjusted from the domain of products [19], developed specifically for services [16], or reflect a simultaneous modularization of products and services due to their inseparability and joint value-creation [20]. A synopsis of existing methods for service modularization is provided by Poeppelbuss and Lubarski [7], who systematize them along, first, an idealistic modularization process (Figure 1) and, second, different types of modular structures. Further pertinent works include the iterative guideline FAMouS for architecting modular services [21], and a list of three trade-offs that are to be tackled when translating modularity into a functional set of design choices for professional services [22].

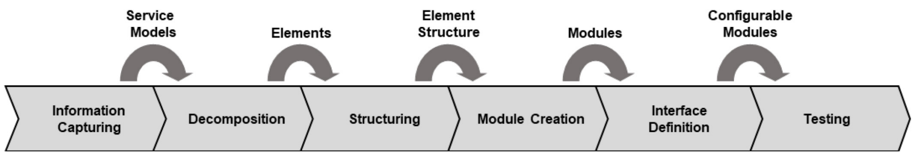

Figure 1. Phases of the modularization process [7]

However, there is little empirical evidence that these strategies and methods have actually been adopted in practice; apart from information given about the testing environments and case studies presented within the papers themselves [5]. In fact, very little is known about whether and how practitioners actually conceptualize and document modular service architectures at all. We see three explanations for this issue. First, the majority of existing modularization methods oftentimes make unrealistic assumptions or define ambitious prerequisites such as the existence of an already decomposed service portfolio or a clear assignment of required resources to operational service processes. Second, due to the academic origin of many modularization methods, they tend to remain on an abstract level and provide rather generic recommendations only. For instance, the FAMouS framework for architecting modular services [21] does not provide practical details on how to actually perform the steps such as “identification of elements” or “analysis of elements”. Third, existing works mostly approach service modularization from the strategic perspective of variety management and disregard the interrelationships with operational sales processes and the quotation process in particular. IT requirements for implementing and communicating a modular service portfolio in marketing and sales activities are hardly discussed, although modular architectures can enable the use of online configurators and so-called configure-price-quote (CPQ) software. Hence, we assume that practitioners cannot determine easily how their organization can benefit from the concept of service modularity and, more importantly, where to start with their own modularization initiative.

2.2 Canvases and Ontologies

Inspired by the worldwide success and great acceptance of the Business Model Canvas (BMC) [11], both in academia and practice and across various disciplines, we decided to use a canvas representation for visualizing the intended framework. A canvas representation is a concise, easy-to-understand, easy-to-use, and visually appealing overview of the key components required for a specific subject area. One of the first canvases developed in an academic setting was the Strategy Canvas evaluating a company's position within its respective industry based on pre-defined factors of competition [23]. Almost a decade later, the BMC became a role model of how a canvas can have a major impact on both the theoretical discussion and practical application of designing business models. Ever since its introduction, it has been used by various consulting agencies and was further extended and modified to fit specific purposes, including the Service Business Model Canvas [24], for instance.

The BMC was initially presented as a business model ontology [25]. Following Uschold and Gruninger [26], an ontology provides a shared understanding and conceptualization of a domain of interest that can be used as a unifying framework to facilitate knowledge sharing and re-use, as well as inter-operability between different organizational entities and systems. An ontology provides a conceptual framework for modeling domain knowledge and it is specified in the form of definitions of representational vocabulary. While Osterwalder [25] also worked on a formal representation of business models with an own XML-based language, the BMC, as it is known today, mainly offers an informal framework, which is to a large extent "expressed loosely in natural language" [26, p. 6].

Similarly, the Modularity Canvas that we present in this paper is supposed to help organizations in creating a shared understanding of their current service architecture and to derive actions to achieve a (more) modular service architecture thereof. Opposed to previous frameworks that cover the whole modularization process, it mainly addresses the initial phase of modularization initiatives in organizations. Hence, the Modularity Canvas covers the *Analysis* phase of the FAMouS framework of Dörbecker and Böhmann [21] and the *Information Capturing* phase of the classification framework of Poeppelbuss and Lubarski [7] (Figure 1), both of which emphasize the key role of the initial phases for the overall modularization initiative.

3 Methodology

Consistent with Osterwalder [24], we consider the development of the Modularity Canvas and its underlying ontology to be subject of design science and, hence, follow a corresponding research approach. Following the distinction between different artifact types (constructs, model, method, and instantiation) by March and Smith [27] and Osterwalder's [24] categorization, the different fields of the Modularity Canvas can be considered constructs, and the actual canvas is a model (i.e., the ontology). Our research process follows the DSRM by Peffers et al. consisting of six phases [11]:

1. Identify Problem and Motivate: We extracted the research problem and the motivation for the development of the Modularity Canvas from the current literature on service modularity (section 2) as well as through a pre-study with representatives (mainly managing directors and heads of sales) from industrial services providers in the contract logistics and wind energy sectors [28]. In this pre-study, we conducted 17 semi-structured expert interviews. The interview results show that most of the providers face challenges to display the full spectrum of their services in a structured and understandable way to their customers. This is partly due to the heterogeneity of their service offerings, but also due to the concerns of losing the personal touch towards their customers. However, the majority of the interviewed partners also sees the quotation process (i.e., the preparation of the quotation document containing how and at what price the provider will solve the customer's problem) as a current pain point and a possible area for improvement. They indicate that the preparation of the quote is often made from scratch costing too much effort and time. They further point to the issue of not well-integrated IT systems and a proliferation of spreadsheets, for which the management of master data is obviously a problem. From the interviews, we generally see a relatively poor adoption of the service modularity concept in practice. The experts confirm that the conceptual ideas and methods from academia are hardly known and not used. Therefore, we identify the need for a lightweight and easy-to-use tool in the form of a canvas, as the BMC has shown that a tool of this kind can be valuable to both practice and academia and achieve widespread adoption. As the Modularity Canvas must especially support the early phase of modularization initiatives, which is not well covered by existing method support [7] yet, we also consider a canvas representation as particularly useful. It can guide workshop discussions, which are common in the early phases of such initiatives.

2. Define Objectives of a Solution: As the Modularity Canvas is supposed to support the early phase of modularization initiatives; it is required to support the capturing and visualization of information about the status quo, the search for modularity potentials, and the definition of directions for improving variety management and the quotation process. It is not supposed to support the actual definition of service modules, for which many methods already exist [7]. As the canvas will be used in workshops with board markers and sticky notes, it must offer structure and flexibility alike. This means that it has to provide guidance during discussions and to direct the participants' focus to important aspects and their interrelationships, but also to offer the freedom of annotating notes wherever needed. Further guidance should also be provided for the interpretation of the canvas (e.g., how to identify potentials for designing modular service offerings from the status quo as depicted in the canvas).

3. Design and Development: The findings from our pre-study [28] indicate that there are two layers of service modularity that need to be considered, which include the strategic variety management and the operational quotation activities in sales.

Hence, the Modularity Canvas and its underlying ontology must correspond to these two layers. In order to further populate the two layers, we relied on existing academic literature (e.g., with regard to the dimensions of services offerings) and concepts prevalent in practice (e.g., configure, price, quote, CPQ). We give the detailed reasoning for the corresponding fields in the artifact description in the next section.

4. Demonstration: For demonstrating its usability, we utilized the Modularity Canvas in workshops with five German industrial service providers from contract logistics, wind energy and automotive engineering sectors. We gathered qualitative feedback from the participants concerning the workshops, the Modularity Canvas as a central tool of the workshops, and the documentaries that we provided to them after post-processing the workshop results. We were provided with valuable insights that we will address in a further design iteration of the Modularity Canvas.

This paper presents the current version of the artifact as used in the demonstration workshops. The DSRM further includes the two steps of *5. Evaluation* and *6. Communication*, which we plan to conduct in our upcoming research activities.

4 The Modularity Canvas

The Modularity Canvas provides a framework that organizations can use to create visual models for describing the rationale of how they manage service variety and modularity on a strategic level, and how they organize their corresponding operational quotation process. It comprises eleven fields that correspond to the underlying ontology of service modularity, which we will justify in the following.

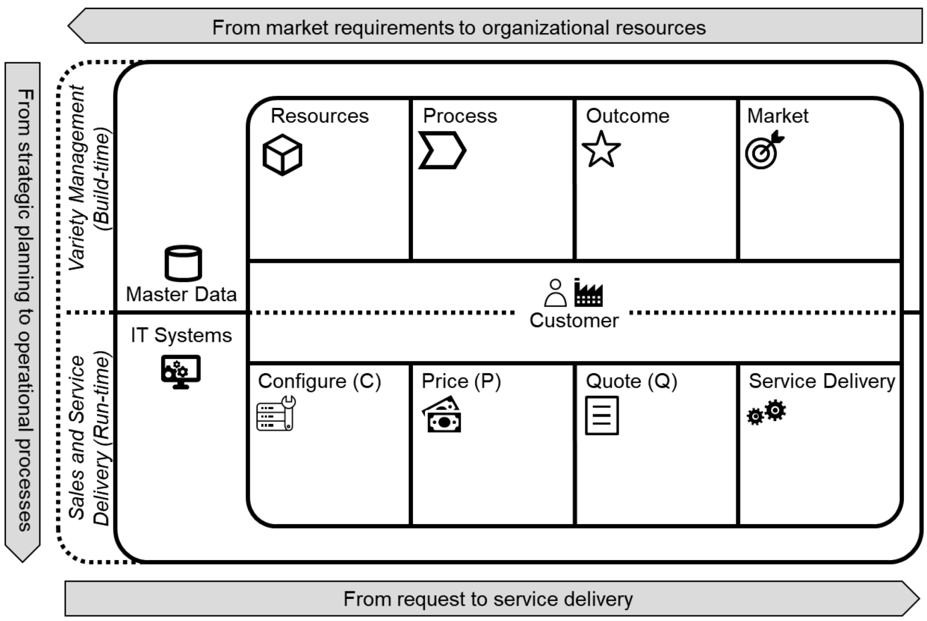

Figure 2. Modularity Canvas

The canvas representation of this ontology (i.e., the Modularity Canvas; Figure 2) comprises two layers: The upper layer focuses on *Variety Management*, which reflects strategic decisions about the modular service architecture made at *build-time*. The lower layer comprises the operational *Sales and Service Delivery* processes at *run-time*. The central field of *Customer* connects the two layers. They are surrounded by the two fields of *IT Systems* (supporting the operational processes) and *Master Data* (defining the service catalog or architecture and its elements).

The recommended order for capturing the status quo about the service architecture in workshops is starting with the strategic layer in the upper right corner, moving from market requirements to organizational resources, moving from the upper to the lower layer, and then moving from the request for quote to service delivery. However, if issues in the operational quotation process are the actual trigger for the modularization initiative, it can also be meaningful to start with the lower, operational layer first. Table 1 gives examples of guiding questions that are supposed to stimulate the workshop discussions when filling out the Modularity Canvas.

The *upper layer* is structured along the four steps towards a strategic service vision according to Heskett [29] and Pekkarinen and Ulkuniemi [2]. These four steps also correspond to four dimensions frequently used to describe service offerings [30, 31]:

1. Identification of target market segments (*Market* dimension),
2. Development of service concepts to address targeted markets' needs (*Outcome* dimension),
3. Codification of an operating strategy to support the service concept (*Process* dimension), and
4. Design of a service delivery system to support the operating strategy (*Resource* dimension).

The *Market* dimension depicts in how far the organization promotes its service offerings to specific market segments or even individual customers instead of an undifferentiated (one-size-fits-all) approach. Becker et al. [30] motivate the need for a distinct market dimension by the fact that service offerings require value co-creation with customers, and, thus, a particular fit with their specific demands. In our canvas, this field is supposed to capture in how far marketing communications and sales activities differentiate between market segments and even individual customers (e.g., through different customer interfaces and sales channels [2]). Correspondingly, the range of different interfaces and channels as well as the set of approaches used for market segmentation and customer insight analytics are noted down here.

The *Outcome* dimension captures the value proposition that the organization offers, which is typically represented by service concepts or product models [30, 31]. Such service concepts and product models comprise a definition of the service contents and a superordinate structure in terms of a service catalog or portfolio [31]. Here, the canvas captures the range of services that are offered and in how far the service portfolio has some structure, or even a modular architecture. The traditional literature on product modularity typically centers around this dimension when parts or components of a product are divided into modules that can be easily interchanged and replaced, while service modularity has been recognized as a more complex, i.e., multi-dimensional concept [2].

The *Process* dimension focuses on the activities performed by the service provider as well as the customer as an external factor to generate the outcome. “Whereas product models map *what* a service does, process models describe *how* the outcomes of a service are achieved” [31]. Here, the canvas captures in how far service delivery processes are broken down into standardized or customized sub-processes and how the process design allows for quick and flexible responses to varying customer requirements [12].

Table 1. Examples of guiding questions

Canvas field	*Guiding question*
Market	How are different customer segments addressed with service variants?
Outcome	Which service variants exist?
Process	Which process variants exist?
Resource	Which different resources are used?
Master Data	How are the variants represented in the master data?
Customer	How does the customer influence the variance of marketing activities, outcome, processes and resources? What interactions with the customer happen during the quotation process?
IT Systems	Which application systems support the quotation process?
Configure (C)	How is the service offering composed as a response to a request for a quote?
Price (P)	How is the price of a bundle of service modules determined?
Quote (Q)	How are quotation and contract documents designed?
Service Delivery	To what extent is information exchanged between sales and service delivery?

The *Resource*[1] dimension depicts the configuration of the service delivery system. The service delivery system defines how the resource base is organized, including human resources, equipment, organizational units, and supply chains for service delivery; and in how far the resource configurations can be flexibly adjusted depending on specific service cases. In this regard, Pekkarinen and Ulkuniemi [2] refer to the term “organizational modules” that provide standardized ways to organize a service provider’s internal and external resources for maximum efficiency. As examples for internal resource modules, they identify teams for specific customer segments or competence areas. Examples for external organizational modules include subcontracting, the use of hired labor, and alliances.

[1] With regard to this dimension, Bullinger et al. [31] refer to a “structure dimension”, whereas Becker et al. [30] name it “potential dimension”. In their textual explanations, however, both refer to the *resources* required to deliver a service or value bundle, so we opted for the term *Resource* dimension.

The decisions made on this upper layer are typically reflected by the *Master Data* in the organization's IT systems, including customer master data (Market), service and product master data, catalogs, or portfolios (Outcome), process definitions and job instructions (Process), as well as employees, assets and further organizational master data (Resource). The corresponding field in the canvas is supposed to capture what master data is available and how it is managed (including the collection, quality assurance, and distribution throughout the organization).

The master data is used by *IT Systems* to support the operational activities at the lower layer, which typically involve online shops and configurators, customer relationship management (CRM) and enterprise resource planning (ERP) systems, e-mail applications, as well as spreadsheets and desktop tools. The systems in use are captured in the corresponding field of the canvas. As the two fields *Master Data* and *IT Systems* surround the other fields on the two levels, it is recommended to depict which master data is available for which service dimension and which system is used for which phase of the lower layer.

The phases on the *lower layer* are also structured into four fields. The first three fields on the *lower layer* comprise the configuration (C), pricing (P) and quote generation (Q) activities that accompany the operational sales process, which can be supported by so-called CPQ software applications [32].

In the *Configure* phase, the service offering is specified or configured based on customer needs. This can happen from scratch, by adjusting similar specifications from the past, or by already using available service modules. The activities in this phase are typically carried out by a sales clerk relying on her/his discussions with customers about their needs. The feasibility of the specification/configuration has to be assessed and ensured, which may also lead to discussions with internal experts. In case of online configurators, the user can define her/his configuration based on existing modules through a web-based frontend as a self-service.

In the *Price* phase, the sales clerk calculates a price for the specification/ configuration of the service and additional parameters using the pricing engine of a software (or simply a spreadsheet tool, which is very common in practice). Depending on the industry and market environment, the pricing strategies to be implemented by the pricing engine can vary from rather simple cost-based and linear strategies, where the price of the specification/configuration can be determined from the prices as defined for single service components or modules, to more complex competition-oriented and demand-oriented pricing strategies.

In the *Quote* phase, a document with the configuration and the calculated price is generated, which is ready for transmission and presentation to the customer. This document may include additional explanations, illustrations, alternative configurations and options, as well as appendices and disclaimers. The quote document sent to the customer will typically also be stored in the CPQ, CRM or ERP system and/or archived in a document management system.

The *Service Delivery* phase starts when a settlement between the service provider and the customer is achieved. At this point, responsibilities and information are typically transferred from sales to other operational units within the organization. Although this phase typically is much longer and more intensive compared to the previous three phases, the details of service delivery are not in the focus of the Modularity Canvas. This field is mainly intended to capture in how far specifications and documents from sales determine the service delivery process and in how far these are revisited, e.g., for monitoring and controlling purposes, or for learning from service delivery for future sales activities or revising the service catalog.

Finally, the *Customer* field is in the center of the Modularity Canvas, as we consider customers to have an influence on all the surrounding fields. We expect the organization to make strategic decisions on service variety and modularity with their target customers in mind. Moreover, customers may also provide impulses to overthink and advance existing resource configurations, process definitions, service offerings, as well as sales channels and communications. Obviously, they are also involved in the operational processes in sales from request to quote, and, finally, as an external factor during service delivery.

5 Demonstration

For demonstrating the utility of the Modularity Canvas, we conducted workshops with five German industrial service providers from contract logistics, wind energy and automotive engineering sectors who were interested in advancing their service architecture and sales processes (Table 2). In order to incorporate different views on variety management and the quotation process, the workshops involved two to five members from various departments of each company (e.g., CEO, service portfolio managers, sales managers, IT system architects).

Table 2. Companies at which demonstration workshops took place

ID	*Industry*	*Offered services*	*Firm size (employees)*	*Revenue (million €)*
L1	Logistics	Packaging logistics, contract logistics, project business	200	18
L2	Logistics	Sea, air, and ground transportation; packaging, warehouse management	50	20
W1	Wind energy	Manufacturing of wind turbines, maintenance of onshore and offshore power plants, grid development	8000	5500
W2	Wind energy	Personnel leasing, technical services, technical training	400	5
A1	Auto-motive	Engineering services and consulting projects in the automotive industry	150	20

The half-day-workshops were conducted on-site of the respective company following a pre-defined agenda. Before discussing and filling out the actual Modularity Canvas, the agenda also included a first capturing of objectives and challenges in variety management and the quotation process. While the company members provided input to each of the Modularity Canvas fields (see exemplary notes in the right column of

Table 4), we as researchers acted as moderators and recorders. Hence, we were responsible for steering the discussions along the different fields of the canvas and tracking time. Figure 3 gives some impressions of how the Modularity Canvases looked liked at the end of the demonstration workshops.

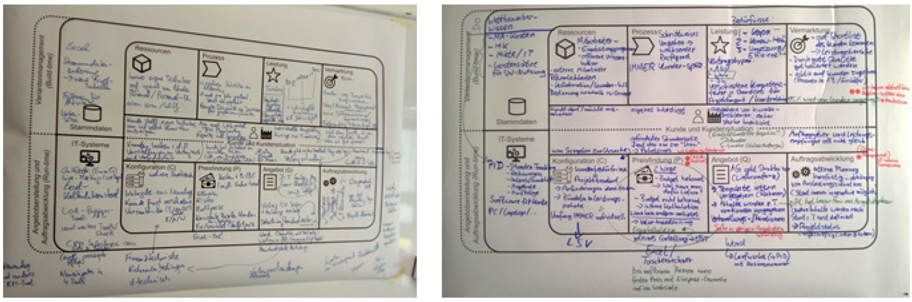

Figure 3. Impressions from the workshops with W1 (left) and A1 (right)

Table 3. Objectives and challenges of workshop companies

ID	*Objectives and challenges of workshop companies*
L1	• Price depends on the solvency of the individual customers • There is a strong motivation to introduce modular services in order to avoid to lag behind the already modular competitors • Knowledge needed for creating a quote exists solely in an employee's head
L2	• Prices are highly volatile (especially in sea transportation) • Completely different quotation processes per business unit • Time losses due to the back-and-forth communication with the customer
W1	• Business is strongly dependent on uncertainties in legislation • Service is offered according to the customer's technical knowledge • New services are identified in a provider-driven, not customer-driven, manner • Service packages are manually composed with no IT-support except for Excel files
W2	• Clear price structures with little room for negotiation • Pursue a clear expansion and internationalization strategy • First standardization approaches (e.g., unified quotation documents) • Rudimentary use of IT
A1	• Low number of highly powerful customers • Strong integration into the customers' development processes • Size of service offerings grow from single tasks to whole development projects • Tenders are fully adjusted to customer requirements, no service catalog with standardized services at the service provider

We conducted post-processing sessions after each workshop in order to discuss the contents of the Modularity Canvases and finally derive modularity potentials that we communicated to the participating companies together with a commented photo documentary of the workshops. We provided a summary of our observations relevant for developing a modularization vision and roadmap (see Table 3 for some excerpts for the five companies). We also explained our ideas for target visions and modularization potentials that we had derived from the status quo as captured in the Modularity Canvas (see Table 5 for an exemplary extract, here specifically for W1).

Table 4. Exemplary insights from the demonstration workshop at W1

Canvas field	*Guiding question*	*Exemplary notes in the Modularity Canvas from the demonstration workshop at W1*
Market	How are different customer segments addressed with service variants?	No differentiation or segmentation, but very different customers ranging from farmers to large-scale investors.
Outcome	Which service variants exist?	Three different packages (from basic to full-service), which can be fully customized.
Process	Which process variants exist?	Planned yearly servicing, unplanned incidents.
Resource	Which different resources are used?	External resources: cranes and ships.
Master Data	How are the variants represented in the master data?	Complex Microsoft Excel files. Changes in master data result in new, updated Excel files.
Customer	How does the customer influence the variance of marketing activities, outcome, processes and resources?	Customer provides own technicians (human resources) in order to absorb expertise.
	What interactions with the customer happen during the quotation process?	Iterative and long-lasting contract negotiations.
IT Systems	Which application systems support the quotation process?	Microsoft Outlook, Excel-based calculation and process tools, additional CRM system Salesforce.com, MS Sharepoint file sharing for projects.
Configure (C)	How is the service offering composed as a response to a request for a quote?	Initiated from wind turbine (physical product) sales, customer enquires about different service packages (e.g., different durations, basic vs. full-service).
Price (P)	How is the price of a bundle of service modules determined?	Cost plus calculation (not value-based), consideration of error rates, risks, and market prices.
Quote (Q)	How are quotation and contract documents designed?	Initial quote draft of 3-5 pages, later on: 50 pages contract plus 100 pages appendices.
Service Delivery	To what extent is information exchanged between sales and service delivery?	Defined handover-process to order processing department (offices next door) and project reviews.

We gathered qualitative feedback from the participants concerning the workshops and the Modularity Canvas as a central tool directly at the end of each workshop. In follow-up phone calls, we further asked them for feedback concerning the documentaries provided, including our ideas and recommendations. This feedback was generally positive as the participants appreciated the workshops, which in many cases offered them a new perspective on their own organization; and they also valued the potentials that we identified and explained.

The workshops and post-processing meetings allowed us to reflect on the Modularity Canvas. While the capturing of the status quo with the Modularity Canvas in the workshops seemed to be efficient, we realized that the derivation of the individualized potentials for modularity and the formulation of an overarching modularization strategy is not straightforward and requires a more systematic approach in addition to the canvas, which is currently lacking. Consequently, a design iteration that complements the canvas with a method (or guidelines at least) for more systematically deriving modularity potentials needs to be initialized before the artifact can be evaluated in a broader context.

Table 5. Identified modularity potentials at company W1

Target vision per layer	*Modularity potential*	*Potential actions*
Variety management: "Module catalog covers all customer demands"	• Launch of a modular service catalog • Communication of the modular service catalog to customers	• IT-supported modeling of the module catalog for integration into ERP system • Launch of online configurator
Quotation process: "Accelerated process with integrated IT support"	• Acceleration of processes • Increased understanding of customers • Internal selection support (click & choose) • Reduction of data input into different tools	• Integration of CPQ tool into the ERP system • Simplification of quotation documents

6 Conclusion and Outlook

With the Modularity Canvas, we present a novel artifact that can help organizations create visual models of their status quo in service modularity and identify improvement potentials. It is intended to support the initial phase of modularization initiatives in organizations when the status quo of variety management and quotation processes are captured and analyzed before the actual service modules are defined [7].

The motivation for this research was the limited adoption of the service modularity concept and corresponding methods in practice although a pre-study with experts pointed us to issues with variety management and quotation processes [27]. As it is of a similar complexity like the BMC, we expect our canvas to be a useful and appropriate tool for practice. From an academic perspective, this research also suggests a novel ontology of service modularity that includes both the strategic level of variety management and the operational level of the quotation process. Hence, this ontology offers a new and more holistic perspective on the service modularity concept apart from modularization methods and high-level conceptualizations that have dominated recent academic discussions.

While the general feedback on the current version of the Modularity Canvas from the demonstration workshops was positive, we realized that the derivation of specific modularity potentials and improvement measures during post-processing was not easy. We therefore plan to complement the canvas with a set of guidelines for systematically deriving modularity potentials. Once this is achieved, we also plan to conduct the DSRM steps *5. Evaluation* and *6. Communication*. Following March and Smith [26], the evaluation of the canvas will be directed towards criteria like completeness, simplicity, understandability, ease of use, as well as its fidelity with real world phenomena. The evaluation will most likely take place in a field study [33] together with a consulting company. Using the customer network of this consulting company, the Modularity Canvas will be applied in further real-life business contexts. In such settings, the consulting company will take the role of the moderator and we as researchers will be able to observe the workshops and to record the results. We expect that, with the increasing sample size, further design iterations are possible, leading to potential adjustments of the artifact's structure and improving its usefulness. Once no further adjustments are observable, the artifact together with practical insights will be *communicated* to various stakeholders in academia and practice.

Towards a Conceptualization of Capabilities for Innovating Business Models in the Industrial Internet of Things

David Soto Setzke[1], Tom Rödel[1], Markus Böhm[1], and Helmut Krcmar[1]

[1] Technical University of Munich, Chair for Information Systems, Munich, Germany
{setzke,tom.roedel,markus.boehm,krcmar}@in.tum.de

Abstract. The emergence of Internet of Things (IoT) technologies offers promising value potentials for industrial manufacturers based on the combination of smart products and data-driven services. At the same time, many incumbent firms experience a threat to their traditional value proposition and are challenged to innovate and reconfigure their existing business models. However, many of these traditional manufacturers lack or are unaware of the required capabilities for successfully reinventing their business model using IoT technologies. We therefore adopt the lens of dynamic and operational capabilities and conduct an empirical analysis of organizational capabilities required for successful IoT-enabled business model innovation (BMI). Through an exploratory, qualitative study based on interviews with decision makers in industrial manufacturing companies and experts in practice-oriented research institutions, we identify eleven distinct dynamic and operational capabilities. Our findings provide useful insights for research and practice and advance the understanding of enablers in IoT-enabled BMI.

Keywords: Digital Transformation, Industrial Internet of Things, Dynamic Capabilities, Operational Capabilities, Business Model Innovation

1 Introduction

In recent years, the Internet of Things (IoT) received enormous attention in academic literature as well as industry practice and still remains a promising research area [1]. The emergence of IoT technologies and their application in the industrial context, also known as the Industrial Internet of Things (IIoT), changes competitive dynamics by erupting traditional market boundaries between industrial manufacturers, software providers, and technology start-ups [2, 3]. Traditional manufacturers are challenged to generate new value propositions through data-based services and predictive solutions [4] which often requires adaptation of existing business models [5]. The German automotive supplier Bosch, for example, uses IoT technologies to enable customers of its fleet management system to identify potential problems in advance and to analyze the driving behavior of individuals [4]. However, such change brings along numerous challenges and has major implications for incumbent firms [3, 6]. While traditional

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

manufacturers possess critical industry knowledge, they most likely face substantial skill gaps when it comes to IoT and related business model innovation (BMI) [2, 6]. Besides a lack of technological expertise in areas such as IoT infrastructure, data analytics, and software engineering, industrial manufacturers are required to rethink existing business model components and to implement new approaches towards customer relationship management, sales, and collaboration with technology providers [3]. All in all, the IoT constitutes an exogenous technological change to which industrial manufacturers need to react by adapting their business model in order to capture the value potential and to secure future competitiveness [7].

Existing academic work on IoT-enabled BMI is still young and little is known about how the change in business models actually occurs. Most notably, there is a missing perspective on how to overcome the identified challenges and barriers of IoT-enabled BMI. In fact, based on our assessment, current literature fails to analyze enablers of IoT-enabled BMI and to conceptualize relevant organizational capabilities. There is thus a strong need to better understand the complex underlying processes and drivers of successful IoT-enabled BMI. Overall, existing research does not clarify the nature of required organizational capabilities for IoT-enabled BMI. In this paper, we present a conceptualization of eleven organizational capabilities that are required for IoT-enabled BMI. We identified these capabilities through an exploratory approach involving semi-structured interviews with decision makers in the German manufacturing industry and experts in practice-oriented research institutions. In the following, we introduce our understanding of IoT-enabled BMI and organizational capabilities that we applied in our exploratory research.

2 Theoretical Background

2.1 IoT-enabled Business Model Innovation

Despite a large body of research, existing theory still misses a common understanding about both business model (BM) and BMI [6, 8]. Therefore, it is essential to define both concepts in the context of our study. Business models are described as "mental models" [9] that represent the underlying architecture of a firm's overall business [10]. The concept focuses on the underlying organizational structures, processes, and resources that enable value creation [9] and defines "[…] the manner by which the enterprise delivers value to customers, entices customers to pay for value, and converts those payments to profit" [11]. According to Foss and Saebi [8] BMI encompasses "[…] designed, novel, nontrivial changes to the key elements of a firm's business model and/or the architecture linking these elements". Following Tesch, Brillinger and Bilgeri [2], in the context of our study this includes both "the 'modification, reconfiguration and extension […] of existing business models' (business model development) as well as the design of 'fundamentally new and sometimes disruptive' business models (business model design)". Furthermore, we refer to BMI using IoT technologies as IoT-enabled BMI.

Literature on IoT-enabled BMI can be grouped into three major research streams. The first stream focuses on the analysis of business model patterns and frameworks for the IoT and identifies new patterns such as remote usage or condition monitoring [1, 4, 12-14]. While many studies analyze the influence of IoT on specific business model components and describe underlying changes [12, 13], other studies do not focus on single organizations but take a broader view on the overall IoT ecosystem by analyzing the interaction and collaboration of different players [14]. Second, a group of studies analyzes the process of IoT-enabled BMI itself [2, 6]. For instance, Tesch, Brillinger and Bilgeri [2] apply a stage-gate model to IoT-enabled BMI and identify a semi-structured, iterative process. Moreover, current literature builds on processes identified in product development research, such as innovation stages in the process of IoT-enabled BMI [6]. Third, an emerging stream of literature analyzes challenges and barriers in IoT-enabled BMI [4, 6, 15]. Thereby, challenges are analyzed from both a technical and business perspective [6]. Manufacturers require new capabilities to incorporate software, data analytics, and data-based service offerings [2, 15]. All in all, companies need to develop capabilities to master both technology and business-related challenges in order to successfully implement IoT-enabled BMI [4]. However, current research is missing a close analysis of such organizational capabilities.

2.2 Organizational Capabilities

In this paper, we conceptualize organizational capabilities as dynamic and operational capabilities. The concept of dynamic capabilities was first introduced to better address the characteristics of today's volatile business environments and markets [16, 17]. They are described as "higher-order organizational capabilities" [18] that enable incumbent firms to modify existing capabilities, organizational structures, and even company culture [7, 18, 19]. The framework refined by Teece [20] distinguishes three basic dimensions of dynamic capabilities and differentiates the underlying organizational processes into the classes of sensing, seizing, and reconfiguration. Sensing capabilities encompass the organizational ability to discover opportunities related to technological developments as well as changes in customer requirements and the overall market [20, 21]. Seizing capabilities mainly encompass processes related to organizational value generation as well as new product development or service innovation [20]. Reconfiguration capabilities are based on processes for the alignment and realignment of organizational assets in order to meet new requirements [20]. These capabilities can address organizational topics such as decentralization or co-specialization and encompass critical processes of organizational knowledge management [20, 21].

Existing literature argues for the need to differentiate between different levels of hierarchy of organizational capabilities in order to reduce confusion about the concept and to eliminate its "tautological feel" [22]. Therefore, we distinguish two main classes of organizational capabilities: Dynamic capabilities and operational capabilities [23, 24]. Operational capabilities, also described as ordinary [16] or zero-level capabilities [17], encompass the operational function of a firm and enable the value proposition of a business model [22]. They are responsible for the execution of daily business operations and can be described as "how you earn your living" capabilities [17, 22]. In contrast, dynamic capabilities represent “how you change your operational routines” capabilities [22].

2.3 Dynamic Capabilities as Antecedents of Business Model Innovation

Several scholars regard dynamic capabilities as internal antecedents and drivers of BMI processes [8, 25]. Dynamic capabilities are integral to BMI as they enable firms to design and implement effective new business models [20, 25]. In addition, BMI requires strong dynamic capabilities as it involves a complex process of organizational and strategic renewal [19]. Besides strong sensing capabilities to realize the need for change, seizing capabilities are required for the modification and redesign of existing business models [19]. However, Leih, Linden and Teece [19] argue that capabilities for organizational reconfiguration and actual implementation of the business model are most critical, as BMI processes affect organizational boundaries, internal structures, and even company culture. Several authors build on the dynamic capabilities framework to advance theory on enabling capabilities. Mezger [18] conceptualizes BMI itself as a “distinct dynamic capability” and identifies corresponding organizational routines and processes. He uses the original framework by Teece [20] to disaggregate BMI dynamic capability into the dimensions of sensing, seizing, and reconfiguring capabilities. Thereby, “business model sensing” capabilities enable opportunity recognition by monitoring competition, market developments, and changes in industry-wide business models [18]. “Technology sensing” capabilities allow for a systematic assessment of technological possibilities and the exploration of new ideas. Seizing capabilities comprise innovation activities for the design and configuration of business models. Actual business model implementation is realized by reconfiguring capabilities that facilitate the realignment of operational capabilities and resources [18].

3 Methodology

We apply an exploratory, qualitative research design based on interviews with knowledgeable experts from the field to explore and describe the phenomenon of IoT-enabled BMI. We argue that the complex and highly context-specific nature of organizational capabilities is well-suited for the use of qualitative research methods. This approach allows us to generate rich theoretical insights from complex organizational decisions and processes. Further, the present study draws on evidence from multiple organizations to include several perspectives on the researched phenomenon. In the following, we describe our approaches for data collection and analysis in more detail.

3.1 Empirical setting

Regarding our industry interviews, we apply an industry focus on German small and middle sized enterprises (SMEs) in machinery and plant engineering to control for industry, regional, and strategic context [18]. The German industry is characterized by many highly specialized SMEs that contribute large economic value. Although many of the firms are global market leaders in specific segments, their positions are threatened by ongoing commoditization of machinery and by new competition arising from outside of the traditional manufacturing industry [26]. Thereby, most SMEs in machinery and plant engineering represent typical product-oriented manufacturers that are now challenged to innovate their business models [13, 26]. In addition, SMEs are likely to possess fewer resources as compared to industrial giants such as GE. Thus, they might lack sufficient capacities to react to technological change appropriately. The European Commission defines SMEs based on staff headcount and either turnover, or balance sheet total [27]. Thereby, a company qualifies as SME if it does not have more than 249 employees and its annual turnover does not exceed 50 Million €. However, many firms of the so-called "Mittelstand" in German machinery and plant engineering do not meet these requirements. Therefore, we apply the broader definition of SMEs provided by the Institute for SME research in Bonn to our company sample. Consequently, we also consider companies where the majority of company shares is hold by up to two natural person or their family members, given that these shareholders are active in the executive board [28].

We use theoretical sampling [29] to identify appropriate organizations for the empirical analysis. The objective of the selection process was to identify SMEs in the industry that already engage in IoT-enabled BMI and that experience the related transformation towards product-service combinations. We conducted an online search, using information from industry association websites and trade journals, to identify promising manufacturers for our research approach. We then gathered more specific information on single companies based on their corporate websites, product and service portfolios, and related press articles. In total, we contacted 50 individuals of 37 different companies, from which 17 executives replied. Some of them declined participation due to reasons of confidentiality, time pressure, or lack of experience. Eventually, we were able to schedule interviews with representatives from seven different SMEs. Our sample comprises six machine manufacturers and one electrical component supplier. All SMEs are headquartered in Germany but are present on international markets and often conduct global operations.

3.2 Data collection and analysis

In total, we conducted eight qualitative interviews with industry experts on IoT-enabled BMI. Seven interviews represent conversations with representatives of manufacturing firms. Thereby, we performed one interview per organization with each one executive. Moreover, we conducted one additional interview with an industry expert from a renowned research institution at the beginning of the data collection process. The interview was not firm-specific and rather explorative. We used the insights to generate a first understanding of IoT-enabled BMI in machinery and plant engineering and to further refine our interview guideline. **Table 1** represents an overview of all conducted interviews and the respective interview partners. Thereby, all interviewees were required to have at least three years of industry or research experience and, in the case of manufacturing organizations, to hold a managing position, preferably senior management, in research and development, business development, or product and innovation management.

Table 1. Overview of interviewed experts (M = manufacturing organization; R = research institution)

ID	*Expert role*	*Business sector*	*Founding year*	*Number of employees*	*Sales turnover*
M1	Head of Business Development	Packaging machinery and solutions	1869	2.500	€ 835 Million (2017)
M2	Senior Business Development Manager	Packaging machinery and solutions	1922	2.250	€ 350 Million (2017)
M3	Head of Product Engineering	Raw material processing and recycling machinery	1969	400	€ 100 Million (2017)
M4	Chief Information Officer	Environmental simulation and welding machinery	1913	8.200	€ 1,2 Billion (2017)
M5	Head of Digitalization	Packaging machinery and solutions	1961	5.065	€ 1 Billion (2017)
M6	Head of Machinery Solutions	Electrical component supplier	1850	4.700	€ 740 Million (2017)
M7	Head of Process Engineering	Water processing and machinery	1989	220	€ 19 Million (2016)
R1	Research Expert on Digital BMI	Research institution	1995	25.000	n/a

The interviews were recorded and transcribed afterwards. We used Qualitative Content Analysis as introduced by Mayring [30] to evaluate the transcribed expert interviews. While the initial categories were derived directly from the text basis using an open coding approach, we developed the main categories in close relation with existing theory on organizational BMI capabilities [18]. Challenges encountered by the organization on their way to IoT-enabled BMI constitute the basis of our category system. Thereby, a challenge comprises a situation that is described as being problematic and relatively new to the firm. Moreover, it cannot be solved with existing organizational processes, but requires management attention and dedicated investments. In addition, the challenge must not be firm-specific but can be transferred to the context of other organizations. The coding itself was conducted separately for each case study in order to allow for within-case analysis before aggregating the results. We then used existing literature on organizational capabilities to develop main categories for the identified challenges. The main categories group similar findings and allow us to identify critical capabilities for IoT-enabled BMI.

4 Organizational Capabilities for IoT-enabled BMI

We propose a conceptualization of IoT-enabled BMI organizational capabilities to link our findings to extant literature. We apply the lens of dynamic and operational

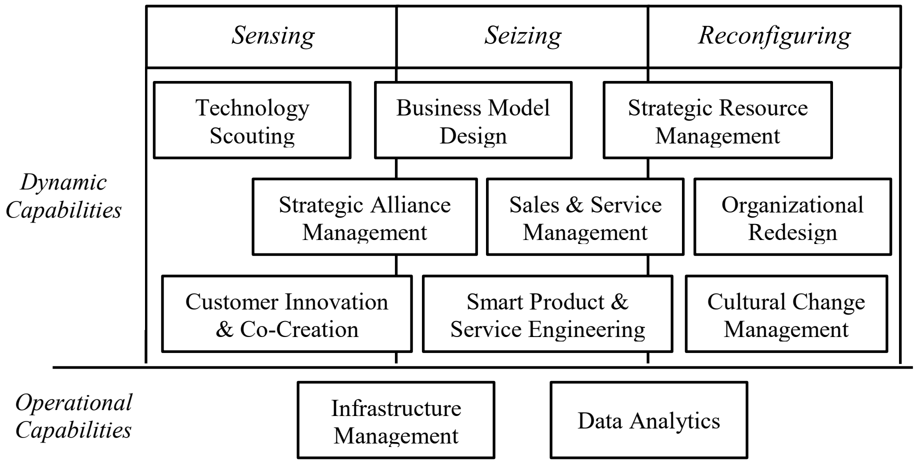

Figure 1. Conceptualized organizational capabilities for IoT-enabled BMI

capabilities to interpret our findings and group them according to the three dimensions of sensing, seizing, and reconfiguring dynamic capabilities [20]. Moreover, we use the concepts of dynamic and operational capabilities to distinguish between different types of organizational capabilities and the level of hierarchy on which they operate. Figure 1 presents our theoretical model that integrates the empirical findings into existing theory on BMI capabilities. We do not interpret the identified dynamic capabilities as purely sensing, seizing, or reconfiguring since they are often based on intertwined processes that relate to more than one capability dimension. Therefore, we interpret the three dimensions rather as a continuum and allocate identified dynamic capabilities in accordance to their main function and purpose. Furthermore, the model does not imply a strict chronological order. Although sensing capabilities are clearly needed at the beginning of the innovation process, the process of BMI is of iterative nature [2].

(1) Technology Scouting: A key challenge described by interviewees from all organizations in our sample is the understanding of IoT as a technology itself. Moreover, companies need to track the trends in technology development and assess the potentials of current IoT technologies. They first need to identify and then test appropriate solutions for the implementation within the own business environment:

> "*To a certain degree we are confronted with a real flood of suppliers. […] Consequently, there are incredibly many service providers and suppliers of IoT technologies that are entering the market. And […] it is a big challenge to […] identify the right technologies that are appropriate for the own use case.*" (M5)

This underlines that without a critical assessment at the beginning of the BMI process, companies will not be able to fully leverage the potential of IoT technologies and establish them at the foundation of their new business models. The capability "technology scouting" guides the evaluation process and increase the overall understanding of the technology itself.

(2) Infrastructure Management: Another challenge is the establishment of infrastructure that enables interconnection. Manufacturers need to install the required sensor technology on the machinery and establish network connections. Thereby, data and network security are highly important and need to be assured at all time:

"*Usually, our clients have their internal networks which are secured and protected. This is a major topic nowadays. Network security. But you have to access these networks. You have to access the client's network from the outside to do your job and this a major technical challenge"* (M7)

This also includes important decisions with regards to infrastructure for data storage, data processing, and data utilization. Many SMEs in machinery and plant engineering have no or little experience when it comes to sensor technology and IT security. Therefore, Infrastructure Management represents a critical IoT-enabled BMI capability. It encompasses the ability to establish and manage the required IoT-infrastructure for data generation and data-based value creation.

(3) Data Analytics is another organizational capability that is required to address the challenge of IoT technology as an enabler of BMI. It constitutes the capability to generate customer value from machine and process data, and to develop related software applications for data-based services. Therefore, organizations need to expand their existing skills in software engineering and build up critical expertise in areas such as big data or data science:

"I believe that one challenge that many companies face is to extensively collect data, to retrieve this data, to analyze it, and to draw the right conclusions in order to generate value for customers and for themselves." (M3)

(4) Business Model Design: Besides technology-related capabilities to implement IoT technologies as the necessary foundation, actual business model design is a key challenge. Organizations need to map business opportunities and define the corresponding use cases. This includes the design of new value propositions to meet emerging customer demands and to clearly segment existing and potentially new customer groups. Altogether, business model design depends on entrepreneurial processes which enable the exploration of new value propositions. Key decision makers need to promote the idea of recurring revenues and design appropriate revenue models. We therefore propose the organizational capability of Business Model Design that enables the organization to identify IoT-enabled value propositions and to design the corresponding BM. The capability is based on a systematic process for the exploration of new value opportunities and use cases. It is required to challenge the existing

business models and to implement a systematic and strategic approach towards business model design:

"*Well, everyone has already heard at one point about leasing or predictive maintenance. But to systematically list 80 different business models and to analyze what fits to our company, that has not happened in the beginning. It was all very casual and rather informal"* (M1)

(5) Strategic Resource Management: The implementation of IoT-enabled BMI and the development of related organizational capabilities depends largely on the right resource endowments. Companies that engage in IoT-enabled BMI need to identify critical know-how and develop it within the organization:

"*I also think that we should develop a lot of these competencies internally and not source them from the outside. Because at the moment it is quite difficult to foresee which competencies will be most critical for our future business."* (M6)

This also emphasizes the need for qualified employees. Many organizations are highly dependent on specialists that bring required know-how into the organization. Several companies in our sample have mentioned challenges with regards to the location of their headquarters that are often situated in rural areas. Besides the lack of know-how, the allocation of resources to innovation-related activities in addition to the current operations represents a key challenge, especially because most of the companies from our sample face exceptional good order positions and are working at full capacity. Our proposed capability allows companies to manage internal competition for resources and to pursue BMI activities without affecting ongoing operations negatively. Moreover, it encompasses the ability to identify areas of expertise that are best developed internally in order to gain competitive advantage in the long run.

(6) Customer Innovation & Co-Creation: Customer relations represent another main challenge faced by our sample organizations. On the one hand, industrial manufacturers require a certain level of openness to collaborate with customers and consider their input for product and service innovation. They need to understand the value of such co-innovation and establish the processes for collaborative innovation. However, this often contradicts the traditional mindset of SMEs in machinery and plant engineering. Many organizations have been very critical towards open innovation in the past and now face difficulties to open themselves and promote a new understanding of their clients as valuable business partners:

"We agree that it is important to understand customers more as partners. In my opinion that is inevitable for the survival in global competition." (M3)

(7) Sales & Service Management: Our interviewees have pointed out the necessity to adapt existing marketing and sales processes. They need to create new ways on how to approach the client in order to demonstrate the value of data-based IoT services. The responsible sales teams need to understand the business value arising from software

applications as well as smart services and integrate the idea of recurring revenues in contrast to onetime sales. They also have to convince clients of the new value proposition and overcome customer concerns with regards to data privacy:

"Consequently, we have to change the way we approach our clients and how we are selling our solutions. So far, our machinery has never been online. We sold pure offline machinery that is usually located at […] storages at client site […]. This has never been an issue for them. Actually, they are very sensitive when it comes to external data and network connections, especially data sharing." (M5)

Moreover, the sales system needs to internalize a new understanding of services and digital products. In accordance with new revenue models, a shift from a product-centric towards a service-centric sales system might be required. We propose IoT Sales & Service Management as another capability to address the challenges at the front end of the IoT business model. This capability allows to market IoT-enabled products and services appropriately by reconfiguring established sales processes and by designing appropriate IoT sales and service strategies.

(8) Strategic Alliance Management: Many traditional manufacturers in machinery and plant engineering have only recently started to engage in open discussions on market and technological developments. In fact, some of them have never built on external solutions before to realize their product offerings. That is why they need to promote an integral organizational openness towards external collaboration:

"I am convinced that only those companies will succeed in IoT-enabled BMI that engage in strategic alliances. This means to cooperate with others along the value chain, with regards to data usage and data processing, if necessary with competitors [...]. Only if these networks are created, which by the way is totally untypical for German machinery and plant engineering, […] success […] will be possible." (M1)

We propose that organizations need to develop Strategic Alliance Management capabilities to collaborate with external partners and networks in order to complement their existing capabilities. Moreover, they need to establish organizational processes that help to identify potential partners and to build up strategic alliances.

(9) Smart Product & Service Engineering: The value creation itself represents another major challenge. IoT-enabled BMI affects existing product innovation processes that so far are mainly oriented towards the development of physical products and add-on services such as repair and maintenance. Established product engineering processes are often not appropriate for the development of smart, digital products. Moreover, companies need to develop and implement a new understanding of a value creation that is based on machine and process data:

"Many organizations have no experience when it comes to data-based services. […] For example, if you do not sell machinery anymore but provide operator models you have to abandon the idea of onetime sales and implement processes for lifecycle-

services and recurring revenues. But this requires a huge shift in mindset with regards to value creation." (R1)

Therefore, we propose Smart Product & Service Engineering as an essential organizational capability for IoT-enabled BMI. It enables the organization to redesign existing product and service engineering processes and to develop smart products and smart services for data-based value creation.

(10) Organizational Redesign: Both scope and complexity of the organizational implementation of IoT-enabled BMI represent major challenges for our sample companies. Besides the necessity to redesign many critical organizational processes, nearly all organizational departments are affected by business model change. This emphasizes the need for a comprehensive transformation process that incorporates all organizational departments. Such complexity of implementation likely overwhelms traditional industrial manufactures:

"Another point is that we realized that the whole topic around digitalization, transformation, changing market requirements, and organizational culture involves such high complexity that we feel overwhelmed and that very likely we are not able to cope with this transformation on our own, organically." (M2)

Although all of the identified organizational capabilities enable organizations to reconfigure organizational processes, we propose a distinct capability of Organizational Redesign that allows to reconfigure organizational structures and support processes as well as to reallocate responsibilities to organizational units.

(11) Cultural Change Management: Many of the above-mentioned challenges and capabilities already point out the importance of a change in organizational mindset. Thereby, organizations not only need to challenge their existing business models, but also need to realize the importance of change in the first place. Despite current favorable market conditions, they need to take notice of the developments in the industry and raise overall awareness and openness towards change:

"It is also a very comfortable position to just say and acknowledge something could happen. I mean our order books are so full and the situation at the moment is just heavenly." (M4)

Organizations need to develop a certain organizational mindset that allows them to observe changes in market and technology and to initiate first actions. We therefore propose Cultural Change Management as an organizational capability that enables manufacturers to induce and manage cultural change throughout the organization. Thereby, it promotes a culture that values exploration and raises the openness towards IoT-enabled BMI.

5 Discussion, Contributions, and Limitations

The findings from our qualitative study support our understanding of dynamic capabilities derived from existing literature. They encompass a collective activity that enables organizations to systematically modify its operating routines [31]. We also find evidence for the key role of top management in the reconfiguration process [32]. Moreover, the empirical findings show the importance of sensing, seizing, and reconfiguring dynamic capabilities for IoT-enabled BMI [20]. In order to cope with technological change such as the emergence of IoT technologies, organizations need to reconfigure their existing resources as well as operational capabilities and establish new organizational processes [7]. Several of our identified capabilities could also be applied to general BMI (e.g., Business Model Design or Technology Scouting) or to data-driven BMI (e.g. Data Analytics), i.e., BMI based purely on the use of data analytics. However, capabilities such as Smart Product & Service Engineering go beyond the mere collection and analysis of data. While data-driven business models focus on "acquisition of data, its subsequent aggregation, the analysis of data […], and actions that are triggered" [33], we argue that IoT-enabled business models can be interpreted as an instance of data-driven business models that focus on more specific aspects such as enriching physical products with digital services [1]. However, future research could further explore how IoT-enabled BMI differs from more general data-driven BMI.

Our study contributes to literature on dynamic capabilities to advance theory on enabling factors in BMI [8]. Thereby, our set of organizational capabilities confirms the relevance of previously identified dimensions of dynamic capabilities in BMI research. Furthermore, we reduce the abstractness of the dynamic capabilities framework [5] by analyzing the underlying processes and providing a conceptualization of concrete capabilities.

The proposed findings have several important implications for industry practice and managerial decisions. In essence, SMEs are required to undertake a systematic assessment of their existing organizational capabilities and to define a set of capabilities required for their individual BMI aspirations. Key decision makers in the organization need to realize the need for change and interpret the value opportunities of IoT technology accordingly. IoT-enabled BMI very likely affects the entire organization and requires organizational redesign and restructuring. One key insight for managers is the necessity of cultural change. Leadership needs to promote an overall organizational openness towards external exploration and to overcome traditional thinking. Overall, we believe that our conceptualization of capabilities assists practicing managers in making informed decisions about the required investments in capability development and in reflecting on IoT-enabled BMI in general. Thereby, the practical implications are not limited to SMEs in machinery and plant engineering.

Our findings are not free from limitations. First, our model does not represent a complete set of capabilities and several capabilities might overlap to some degree or depend on each other (for example Organizational Redesign and Cultural Change Management). Organizational capabilities are highly context-dependent, and every incumbent firm faces different capability endowments [16]. Therefore, there is no definite set of key capabilities and our findings need to be interpreted within the given organizational context of a firm. Although we propose that our proposed capabilities lead to successful IoT-enabled BMI, we do not measure the interrelation with firm performance nor do we provide any evidence of a positive effect of the realization of our capabilities on actual BMI implementation. In fact, we argue that a capability-based conceptualization of IoT-enabled BMI alone cannot explain successful IoT-enabled BMI and superior performance since many factors need to be taken into account for an analysis of firm performance [16]. Furthermore, while exploratory, qualitative research approaches offer great potential to add new perspectives and extend existing theory, our relatively small expert sample limits the generalizability of the findings [29].

As mentioned in section 3.1, our empirical settings is focused on German SMEs in machinery and plant engineering in order to control for industry, regional, and strategic context. Furthermore, we believe that these SMEs are, due to their limited resources, under high pressure to build up relevant capabilities and thus represent an interesting context for our study. On the other hand, our identified capabilities could also be specific to SMEs in our chosen context while capabilities for large corporations or companies in other regions could be different. Strategic Alliance Management, for example, could be less critical for large corporations due to their extensive sets of existing resources. We regard our results as a first step towards an exhaustive conceptualization of capabilities for IoT-enabled BMI and invite other researchers to verify, extend, or adjust our set of capabilities by replicating our study in different contexts.

6 Conclusion and Opportunities for Future Research

The emergence of IoT technologies brings along new business opportunities in industrial manufacturing. However, IoT-enabled BMI constitutes a highly complex transformation process and implicates severe challenges [6]. Thus, the main purpose of this paper is to advance research on organizational capabilities that are required to master the challenges of IoT-enabled BMI. We identify several dynamic and operational capabilities that represent enablers of IoT-enabled BMI. Overall, organizations are required to assess their existing capability endowment and strategically invest in IoT-enabled BMI capabilities to seize the value opportunities of the Internet of Things in industrial manufacturing. Thereby, our empirical findings contribute to understanding key enablers and antecedents in BMI [25]. Finally, they outline a promising field for future research on IoT-enabled BMI.

IoT-enabled BMI in industrial manufacturing offers a promising area for future research in both information systems and strategic management literature. Especially the concepts of BMI and dynamic capabilities require additional empirical studies to advance existing conceptualization and overall understanding. While we present a rather aggregated view on different capabilities, future studies could focus on distinct capabilities and analyze underlying processes and resources in detail.

Furthermore, future research could include large-scale, empirical studies with longitudinal design. Such studies would allow observing the entire process of IoT-enabled BMI and could provide important insights on performance outcomes and the interrelation of different organizational capabilities. In addition, studies applying a retrospective analysis on success cases could provide interesting benchmarks and contribute to a comprehensive understanding of IoT-enabled BMI.

Abstract. Companies expect significant long-term gains in efficiency and productivity through digital transformation (DT). New ways of combining products, processes, and data-driven services, as well as new business models emerge. However, the rapid development of the DT leads to constraints regarding its realization. Barriers hinder companies to realize possible advantages out of DT. If firms promptly recognize potential barriers, they can reflect upon these challenges and can take well-coordinated countermeasures. Social, technical and socio-technical problems address different stakeholder and ask for specific solutions. Therefore, our study aims at developing a taxonomy for barriers to DT to enable researchers and practitioners to identify and classify existing barriers. For deriving the dimensions and characteristics, we collected data by conducting 46 semi-structured interviews with experts and enriched these by looking at the literature on DT barriers.

Keywords: Barriers, Digital Transformation, Taxonomy, Qualitative Research

1 Introduction

The increasing digitalization affects the industry and industrial processes [1]. A second machine age is announced to describe significant impacts of technology on the way of working [2]. Digital transformation (DT) is understood as the "use of new digital technologies (social media, mobile, analytics or embedded devices) to enable major business improvements (such as enhancing customer experience, streamlining operations or creating new business models)." [3] It is regarded as a major change in business and society [4] and is often described as an ongoing process [5]. One implication of digital transformation (DT) is the overall digitalization and cross-linking of the value creation process [6] as information and communication technologies merge with production processes. Digital transformation marks the whole business and must be taken up by the enterprises' strategy [7]. As DT affects people, processes, and products on all levels [2], it implies more than just an application of technology. Because of these overall implications, enterprises expect significant long-term gains in

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

efficiency and productivity by applying DT [4]. New ways of combining products and services [6] as well as new business models such as digital platforms emerge [8, 9].

Even though significant benefits are expected, many firms still struggle to realize transformation potential due to different barriers [10]. Only every sixth company in Germany has a high willingness for digital transformation [11]. So, the adoption of digital innovations is very faltering. Understanding present obstacles to planning countermeasures is critical. The rapid development of the digital transformation in companies leads to problems regarding the realization because of the development, diffusion, and implementation of new digitalized processes face many difficulties [12]. These difficulties or barriers (terms are used synonymously here) are understood as something that stands in the way of the realization of a project or the like and cannot be mastered without further ado.

The barriers to innovation approach [13] is often used to identify barriers and group these. Regarding DT, lists of barriers in specific technological contexts and different industries already exist [14, 15]. However, comparing and analyzing these to come to an overall view is still difficult. Taxonomies, which show dimensions and their characteristics, enable researchers and practitioners to understand, communicate and apply research findings in a more comprehensive way than lists. They help to "[…] structure or organize the body of knowledge" [16]. Describing taxonomies of barriers to DT are still missing. Thus, the goal of our study is to derive a taxonomy of DT barriers to contribute to the barriers literature. Different dimensions which can explain and classify these barriers are identified and analyzed. Categorizations help to generalize and lead to a better understanding. Therefore, the research question is: How can barriers to digital transformation be categorized into a taxonomy?

As the domain lacks theoretical foundation [17], we expect a qualitative approach to be useful to gain insights on barriers. On a broad database of 46 semi-structured interviews, we empirically derive the taxonomy in accordance with the procedure from Nickerson [18]. We use the collected material to develop a theoretical frame [19] which assists with overcoming the barriers. Results from the literature on DT barriers is also used to enrich the understanding.

For our study, we follow a holistic view. Digital transformation is said to transform whole value chains [6] which leads to a paradigm shift in business and focuses on the organization, rather than technological challenges [20]. Many researchers concentrate on distinct technologies or departments to describe the changes. As DT is still ongoing and many enterprises are at the beginning of the digital change, holistic approaches that regard the whole process of value creation are rare.

In the next chapter, we will define the term digital transformation and give an overview of existing classifications as well as barriers to DT literature. The methodology is presented in the third chapter. Afterward, the taxonomy is deduced from the interviews. Results from an evaluation and an outlook are shown. Finally, this paper highlights the contribution and describes limitations.

2 Related Work

As the field of DT is still rather new and many areas, that are touched by this, do exist, there is a certain need to classify and sort correlated phenomena. Several approaches exist, that set up classifications in distinct fields of DT research such as technologies (like cloud computing and big data) [21], digital strategies [17, 22, 23] as well as product and service enhancements [24–26]. Other researchers concentrate on the technology focus such as system architectures [27]. Furthermore, there is research on correlated topics like legal and regulatory frameworks [28] and DT research (methods) [29]. Taxonomies for certain industries also exist [30, 31]. These taxonomies help to structure the field of research on DT which is necessary because this is still a growing topic missing theorization [17]. Researchers already examined the positive aspects of DT success and developed a taxonomy of benefits [32]. We consider a systematic reappraisal of the opposite side of DT, which are the barriers that hinder a successful transformation, as a further valuable approach to understand DT. Thus, we regard the structured development of a taxonomy from a hindering point of view as important to identify, structure and overcome existing barriers to DT. Recently the research area of barriers is still dominated by unstructured lists which are hard to compare.

One of the first approaches to identify barriers is a study by Piatier from which the barriers to innovation approach has arisen [13]. Different classifications of barriers came up in literature since the approach was formulated. Often, these are differentiated in internal and external which are further subdivided. Internal barriers include resource-related, management-, time-, culture- and systems-related as well as human-related challenges. External barriers are subdivided into supply-related, demand-related and environmental-related [33]. The classification between internal and external has been proven as useful in many studies in different contexts [34, 35]. D'Este et al. [36] differ between revealed barriers describing the process of innovation and deterred barriers meaning the obstacles from adopting an innovation. In a study of Coad et al. from 2016 [37] items for four different barrier factors were used in a questionnaire: cost, knowledge, market, and regulation. Another differentiation has been pointed out in firm-related, project-related, product-related, and market-related factors [38]. This study also highlights the second side of the coin regarding barriers – success. Often success factors are described as the opposite from barriers. Success is more often in the center of research compared to the negative side of barriers [39]. Critical success factors are defined as "those few things that must go well to ensure success" [40]. The approaches are closely related to the adoption theory which deals with either adopting (success) or rejecting (failure) IT [41]. Although there is a long-lasting tradition of barrier research, a homogenous classification or guideline to describe barriers is still missing.

Especially in the dynamic field of digital transformation, classifications need to be developed. First studies identifying barriers in this context recently arise. The closely related "challenges" of DT are discussed in different approaches. These are, for example, strategic, organizational and cultural as well as implementation related [42]. Technical and market relevant challenges like time to market also exist [43]. Bilgeri and Wortmann [14] identified 16 barriers to innovation in an IoT context. They could highlight that DT also leads to new barriers referring to the knowledge of the people. The topic regarding business models is analyzed by different authors [14, 44]. Dremel [15] found six barriers to big data analytics for the automotive industry. In the context of the development of digital services through innovation contests, specific barriers like difficulties in finding competent team members are discussed [45]. So far, actual findings were valuable but they are generated in specific contexts. The results remain at a very detailed level and hardly allow systematic guidelines for action to be developed. They are heterogeneous and hard to compare, because they are often randomly compiled lists focusing on distinct aspects. Holistic approaches dealing with DT in a broader sense [46] are rather rare. We emphasize a certain need to characterize, describe and compare barriers to DT to be able to overcome these. A taxonomy is the first step to do so.

3 Method

As "fast-changing phenomena are difficult to investigate solely through the use of traditionally privileged methods” [47], it seems appropriate to conduct qualitative research in the context of DT. 46 interviews build the base for our study. In a first round, data from 30 participants were gathered. To check theoretical saturation [48], we gathered data from 16 more participants. Because no further impulses could be collected from the new data, we assessed the data set as useful for our purposes. We preceded the interviews in 31 different enterprises in varying industries. We aimed for a broad sample to be able to capture common base between different industries [49]. The taxonomy will be useful for a broad range of situations. Therefore, a purposeful sampling method was applied [50]. The selection criteria included a necessary affiliation of the interviewees to projects or departments explicitly dedicated to digital transformation in their company. All of the enterprises already implemented digital technologies successfully or/and were involved in digitalizing their processes and products. The dominant industries were automotive (7 companies) with mostly original equipment manufacturers (OEM) and agriculture (8 companies) with mostly agricultural machinery manufacturers (AMM). The length of the interviews ranges from 15 to 91 minutes with an average of 43 minutes. The interviewees are between 26 and 58 years old. Two interviewees are female and the rest male. All have German as mother tongue. Therefore, the interviews were conducted in German and mostly at the interviewee’s offices. Table 1 gives an overview of the participating interviewees. Industries, an identifier for case companies (to be able to associate the statements from interviews with the companies) and their role in the supply chain are shown. Many interviewees provided knowledge from the perspective of a user, producer and customer of digital products or services. The interviewees from the agricultural sector, for example, use digitalized production processes, sell machines with digital abilities and digital interfaces, and they buy digital services for big data applications which they use for their products and production processes.

All interviews were recorded, transcribed and translated for research purposes. An interview manual was used including (1) an introduction regarding digital transformation in general (including the understanding of the topic from the interviewee's perspective), (2) questions on the actual situation of DT and related barriers (including situations of success, frustration, emphasized support, and barriers), and (3) a subsumed report of three major barriers to DT.

Table 1. Overview of Interviewees

Industry	*Case*	*Role*
Automotive	Au1- Au7	OEM; supplier; service provider
Agriculture	AC1-AC8	AMM; food producer; farmer
Plastics Industry	P1-P3	processing chain; manufacturer
Steel Industry	SI1-SI3	processing chain
Other Manufacturing	OM1-OM4	engineering; cosmetics
Services	S1-S3	service provider; facility mgmt.; software solutions
Consulting	C1-C3	consultant

For the development of the taxonomy, we combined the approach according to Nickerson [18] with a qualitative content analysis [51]. We specified "meta-characteristics" by reading relevant literature regarding the field of barrier research. They serve as a guideline for the deduction of objects (Steps 4e – 6e) from the empirical material gained from the interviews. We used empirical data as the main source to develop the taxonomy. However, results from the literature were used to complement the understanding. The steps from Nickerson as well as our application for this study is shown in Table 2.

As an approach, we mainly used the empirical-to-conceptual procedure to gain insights on the characteristics (C) first. Afterward, we clustered the obtained characteristics according to dimensions (D). We openly coded the interviews [52] to iteratively develop a well-prepared database. We used the online-tool QCAmap for coding the material. Statements about barriers to DT and similarities regarding the structure and possible characteristics of the barriers were searched for. We sequentially adjusted the research for a simultaneous collection of data and analysis. All authors were permanently involved in the research process of data generation and analysis. Thus, making it necessary to discuss the coding in which the coders disagreed to come to an inter-coder agreement [51]. This led to a repetitive induction and discussion of concepts [53]. The cross-fertilized relationship between analysis and data generation as well as the development of the taxonomy led to a complex process of iterative revisions [54]. The research process was characterized by a comparative method [52] to deduce logical and consistent categories of barriers to digital transformation. Besides the data from the interviews, we included corresponding research streams for the development of the taxonomy. These also implied a conceptual-to-empirical iteration which complements the procedure.

Table 2. Development of the Taxonomy

Step by Nickerson	*Application of Steps*
Step 1: Determine meta-characteristic	(1) who is affected by the barrier; (2) major implications; (3) next steps for barrier
Step 2: Determine ending conditions	Going in iterations; no new, merged or split D or C in the last iteration; at least two Cs under every D
Step 3: Choose approach	Mostly empirical-to-conceptual
Step 4e: Identify (new) subset of objects	Coding of barriers and/or identification of barriers from literature
Step 5e: Identify common characteristics and group objects	Check context of barriers in interviews and/or look for characteristics in literature
Step 6e: Group characteristics into dimensions to create (revise) characteristics	Name dimensions independently and discuss within researcher group
Step 7: Ending conditions met?	Check independently by all authors; only if all agree, the process ends

Nickerson does not intend the last step of our research approach. Finally, we evaluated the taxonomy on the base of a qualitative interview. We chose a sample of ten interviewees and asked the interview-partners to apply the taxonomy with the help of a self-chosen case example. Afterward, we asked for an assessment and explored additional dimensions. The sample consisted of practical users (mainly IT consultants) and researchers in the field of DT. None of the participants was involved in the constructive analysis of the model or the creation of the taxonomy. As the sample of ten is rather small, we regard the evaluation as ongoing.

4 Taxonomy of Digital Transformation Barriers

During our research procedure, we deduced nine different dimensions (Table 3) that help to describe and explain the barriers to DT. The dimensions provide none or just parsimonious overlapping.Some dimensions are slightly connected (e.g., effect and duration). Characteristics describe dimensions. They explain the quality of the barriers. Some dimensions seem obvious to describe barriers to DT (e.g., stakeholder, impact and IT integration). Others needed a careful analysis and interpretation of the context (such as visibility, nature, solvability, duration, effect, recipient). Any dimension alone can be used to cluster or group existing barriers. However, the interplay of dimensions delivers a multi-focal view of the problem. The taxonomy helps to find out who is actually affected by the barrier (stakeholder, impact), what are the major implications (IT-integration, visibility, nature, solvability, integration) and what is the possible future of the problem (duration, recipient). Furthermore, we try to align the dimensions to related research streams.

Table 3. Taxonomy of DT Barriers

Dimension	*Characteristics*		
Stakeholder Who emphasizes the barrier?	individual	organiza- tional	environ- mental
Impact Which level does the barrier impact?	internal		external
IT-Influence How strong is the influence of IT?	social	socio- technical	technical
Visibility How obvious is the barrier?	hidden		visible
Nature What does the stakeholder sense?	standing by	fear of	lack of
Solvability What is the actual status of the problem?	low		high
Effect How huge is the effect on development?	no	slow	stop
Duration How long will the barrier last?	short-term	long-term	permanent
Recipient Who may solve the problem?	inner circle		outer circle

Stakeholder. The dimension stakeholder shows who emphasizes the barrier. The differentiation between the stakeholder groups is inspired by Coad et al. [37] who concentrated more on the level of who/what is affected. The stakeholder is not necessarily the person who expresses the barrier. Barriers often result from a lack of adoption. Adoption proceeds on different levels [55]. The level of impact is therefore related to the individual [56], the organization [57, 58] or the surrounding environment [59]. “Especially the internal employees. They are left alone. They do not know how they can handle this on their own.” (AC8) The characteristic organizational implies the core-enterprise as well as corporate networks for development and knowledge transfer. “It is all about cooperation. If data are not shared, the [digital transformation] won’t be a success.” (Au2) Customers [43] and suppliers (“The more change, the more risk to fail. That is, what the customer realizes” (Au3)), but also governmental or other third party organizations are subsumed with the term environmental.

Impact. Barriers to digital transformation do not only affect the stakeholders themselves but their surroundings as well [13, 34]. It is a question of where the barrier occurs. Therefore, we identified two contrasting forms of impact. The internal view, including employees, departments or the whole company, can hinder the pervasion. Internal change resistance [60], fear of high investments [36, 45] or lack of skills [61] proceed here. "We have a change in skills needed.” (Au5) However, digital transformation also implies the blur of borders and forces cooperation on a business level. “Network integration will be the biggest problem.” (AC1) Therefore, often external partners, customers, suppliers or others are also affected [8]. “Soon the digital transformation will change the market from buying things to using data. This will affect the suppliers.” (C2) Still, enterprises complain about the non-existence of legal standards. Using their market power, companies can develop quasi-standards in the new markets of DT. “Currently, in the software development, enterprises define the interfaces. […] I expect problems of norming occurring in the future." (OM2) Due to blurring borders, “internal” might mean more than just one company, e.g. in the evolvement of innovation networks [62].

IT-Influence. Digital transformation is to some extent a process of IT adoption [15] to achieve success [63]. Hence, barriers to DT can affect different stages of human-computer interaction caught between technical, socio-technical and social barriers. The pure technical barriers often result from a lack of technical standards [64], security aspects [65], and integration to the existing system environment [66]. “That is the problem. Digital transformation means: to work in a big general store with hundreds of different technologies and solutions.” (Au2) Furthermore, the access to network technologies slows down the DT. “One problem is the lack of network speed at specific locations.” (Ac1) The socio-technical implications refer to the knowledge of the workers and the way the technology is used [67]. “They left the people on the shop floor alone. That reduces the quality. There was no one left, who cared for the problems because they were all in front of their computers.” Moreover, the clear social implications are triggered by the DT but relate more to social effects like the fear of unemployment [2]. “Yes, I guess, many workers are afraid, that digitalization of works implies the loss of the workplace.” (AC8)

Visibility. This dimension describes how obvious a barrier is for third parties. Reasons for the hiding of barriers differ. The fear of repercussions, avoiding conflicts and even anxiety of job loss and harassment play an important role [68]. Especially barriers that rely on personal problems and estimations are slightly invisible. “Often the people do not tell. However, they are afraid.” (S2) Talking about barriers increases visibility. Furthermore, technical problems can be hidden and only appear when they accumulate. However, visibility is dependent on the observer. What is obvious for one group may be hidden from the other. Visibility, as well as existing barriers, can be very dynamic. "You cannot predict when the feeling of employees regarding the project changes, but suddenly it does.” (C2) Visible and invisible barriers have also been observed in case studies in research [69].

Nature. To understand what the stakeholders perceive and what they sense eases the later solvation. We differentiate three manifestations: standing by, fear of and a perceived lack of. The transition between these characteristics is often seamless. At an early stage of change for innovation, people and organizations prevent from changing existing structures. This behavior can be named resistance to change or the desire to stand by and can also be found in innovation research [70, 71]. “Possessive thinking, traditional role administration, […] they hinder the process.” (Au5) Many barriers also result from deficiencies. “The lack of standards is one of the major barriers to network integration. Moreover, of course, the habit of interdisciplinary co-working.” (Au5) For many enterprises, the implied investment and the lack of free capital plays an important role. “Initially it is expensive, and we do not save money at first glance.“ (Au1) Moreover, we detect a large group of unspecific fears that hinder the successful digital transformation. “There is much diffuse fear. Diffuse is important in this context.” (Au5)

Solvability. Solvability describes the actual status of the problem or barrier. Do the subjects of the obstacle consider the impediments as solvable or not from the current status? The classification of a barrier within this dimension might change over time as the status of its solvability might change. There are for example barriers that are (from the actual time of consideration) not solvable, such as standardization of interfaces and legal policies [72]. “From my point of view, we suffer from deficits of the technology. To name it: we have striking lack of standards.” (C1) Then again, other problems are more easily to solve, such as missing skills. “We need to […] train future skills.“ (SI1)

Effect. It is important whether the barrier has the potential to lead to massive interferences of an enterprises’ DT. We gradually distinguish the effects regarding how massive the barrier affects the DT process. Some implications seem to be negligible while others may stop the digital transformation process. A missing legal base for the use of data and the interconnection of firms can harm the DT of a company’s network [73]. “There is no improvement in sight. We realize that some things like works council, data protection statements massively brake the development.” (S2) Otherwise, barriers like a lack of technology acceptance from a few employees are threatening but not existential. “We worked with the employees. We went there and took a look at the situation. Why didn’t it work? Moreover, we included them in the development process.” (P3) There are also several research contributions dealing with the nature of technology acceptance [56, 71] and ways to handle [74].

Duration. The estimation of the duration of the barrier is also necessary to consider for the future planning of DT. The length of the barrier may influence strategic planning [10]. “What are we doing? We have to change as an organization. Moreover, this is difficult: to change the whole business model.“ (AC2) Many interviewees see the DT mainly as a long-term challenge: “There is still a lot to do to find the right solutions.” (Au4) Research about DT maturity may help to assess the duration of change processes [72]. We chose the dimension duration rather than a dimension that aims at the processual aspect including different states of adoption (suggested by Henriette et al. [42]). We consider the differentiation of adoption stages as less applicable, as the stages are often overlapping and they differ even within the enterprises as rollouts often proceed in several steps.

Recipient. Considering there is a possible solution for the barrier, it is central to understand who may solve the problem. We differentiate the inner and outer circle [75]. While the inner circle reflects the changing organization, its parts, and partners, the outer circle comprises legal institutions and governments. It is often up to the people to foster the DT. “I like to join community meetings. […] We share knowledge, and we exchange views.” (AC2) We assume that there will often be a group of people and institutions who remove barriers [42]. The overcoming of barriers is seldom limited to individuals. Schools (“It is a major barrier: the skills. IT should start in school.” (AC8)), governments (“The biggest barrier is the whole legal thing.“ (Au2)), and the people have to work together. „And it is due to the people, the organizations, and institutions beyond our organization like trade associations to become friends with the whole topic.” (Au5)

5 Discussion and Future Research

The evaluation of the model confirms the usability of the taxonomy. None of the respondents had a problem naming a barrier for DT and describing the problem using dimensions and characteristics. Using a 4-point-Likert-scale (very useful, useful, not useful, annoying), most respondents rated the model as useful or very useful for identifying, describing and discussing the barriers. However, the taxonomy is considered only slightly useful to find solutions. The group of consultants requested more space for solutions (e.g., for the resources needed to solve the problems) and the way to communicate the barrier. The group of researchers suggested further gradations for the characteristics. All respondents confirmed the high usability for the discussion of barriers. It will be part of future research to find out how the taxonomy can be used to identify barriers within DT projects. The taxonomy can be enhanced with dimension regarding the salvation of problem. Since the evaluation is not yet complete, we aim for future research at questions like: Which industry-specific adjustments of the taxonomy have to be made? How can the identification of barriers promote the formulation of a DT strategy [10]?

By using this taxonomy, one can develop a profile of any barrier which can help to overcome these challenges. For example, a wide discussed barrier to DT is the fear of losing jobs [2] which is often emphasized internally by individuals. It is a social barrier which is in many cases not visible to others. This could also mean that the solvability is complicated. It could affect others and last permanently. The inner or outer circle could be responsible for salvation. These interpretations of the barrier are not fixed. They depend on the company and the specific barrier that hampers DT. So, the taxonomy is useful in practice, if it is applied by companies to identify characteristics of barriers and thus be able to find solutions. In this example, employees would need to be educated about further projects and their impacts.

Though we carefully conducted this research, there are still limitations to our work. Even though the holistic view implies advantages regarding the usefulness of the taxonomy, it is also a limitation because the object of analysis is broad. Moreover, the qualitative approach implies limitations by nature as results could be due to the sample and subjectivity of the researchers. We tried to minimize this by coding interview data independently and discussing results in iterative rounds. Furthermore, the sample was chosen broadly to cover many different opinions. Besides this qualitative approach, it could be very fertile to quantify the characteristics of the dimensions. Moreover, it could be of great value to combine the findings of this study with case studies focusing on the overcoming of barriers. The evaluation and quantitative verification of the taxonomy is a call for additional research in this area.

6 Conclusion and Contribution

Any barrier in the field of DT leads to a slow down or complete termination of the digital change in enterprises. It is of great importance for research and practice to understand barriers to digital transformation. Different lists of barriers already exist in research but it is hard to comprehend those. To understand the barriers from a broader perspective, we developed a taxonomy that implies dimensions and characteristics of these to describe and classify barriers. The taxonomy consists of nine dimensions. Each of them answers questions on barriers to DT. Potential barriers can be classified by using each dimension of the taxonomy. Then, the characteristics can be used to describe barriers more in detail. The taxonomy was the result of a research process that orients towards Nickerson`s approach [18]. The findings of this study rely on the base of a qualitative analysis of 46 semi-structured interviews. To ensure the quality and validity of our conclusions, we enriched the results by further research on barriers.

The first and still ongoing evaluation of model proves the usability of the model so far. The structured taxonomy helps to identify, describe and discuss barriers to DT in research and practice. The taxonomy can foster the creation of a knowledge base for the ongoing process of DT [4]. Practitioners can use the taxonomy to understand and detect obstacles of DT as well as deduce action plans for a successful transformation. If firms can reflect upon their challenges, countermeasures can be taken.

Our approach builds upon the barriers to innovation literature by integrating barrier types like internal and external barriers [33] but adding new dimensions like visibility and solvability to structure barriers. Researchers in the field of barriers to DT research [e.g., 14, 15] can use the taxonomy to classify the identified barriers. Future findings can easily be aligned with actual and further research and connections can be discovered. We hope to foster the discussion on the understanding and structuring barriers.

Ambidexterity in Service Innovation Research: A Systematic Literature Review

Verena Wolf

Paderborn University, Department Wirtschaftsinformatik, Paderborn, Germany
verena.wolf@upb.de

Abstract. Increased interconnectedness of multiple actors and digital resources in service eco-systems offer new opportunities for service innovation. In digitally transforming eco-systems, organizations need to explore and exploit innovation simultaneously, which is defined as ambidexterity. However, research on ambidextrous service innovation is scarce. We provide a systematic literature review based on the concepts of ambidexterity, offering two contributions. First, research strands are disconnected, emphasizing either exploration or exploitation of service innovation, despite an organizations' need to accelerate innovation cycles of exploring and exploiting services. Second, a new framework for ambidextrous service innovation is provided, inspired by the dynamism and generative mechanisms of the ontologically related concept of organizational routines. The framework adopts the perspective of a mutually constitutive relationship between exploring new and exploiting current resources, activities, and knowledge. The findings remedy the scattered literature through a coherent perspective on service innovation that responds to organizations' needs and guides future research.

Keywords: Exploration, Exploitation, Service Innovation, Organizational Routines, Ambidexterity

1 Introduction

Digital transformation is a buzzword [1], which describes "a technology-induced change […] that includes both the exploitation of digital technologies to improve existing processes, and the exploration of digital innovation" [2]. Digital technologies, i.e. devices that process a binary computational code and smart technologies, i.e. interconnected devices that share information and interact with its users and other devices [3], provide opportunities for innovative services [4]. A service is designed through a collaborative process by integrating knowledge and skills (operant) and tangible resources (operand) that provide value to actors in a service system [5]. A fundamentally new process or service offering—either in addition to current services or as change in the delivery process—is defined as a service innovation (SI).

The complexity and rapid speed of changing markets and technologies [6] increase competition as well. Organizations need to accelerate cycle-times of exploring new SI and exploiting them efficiently [7]. The management of dual capacities of exploring

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

and exploiting is defined as ambidexterity [8]. Exploration is associated with radical SI to attain progress in changing service eco-systems [8]. However, new edgy services may not always be appealing to customers or take time to unleash their full potential, which can be risky for organizations [9]. While exploring SI, organizations need to exploit existing services through continuous improvement and increasing the efficiency of service processes [8]. Organizations like MySpace, studyVZ, or Vine that only focused on exploitation without exploring new value-adding features for their service portfolio have experienced declining user numbers and finally had to shut down their businesses. These cases demonstrate that organizational ambidexterity is an important capability in dynamic and digitally transforming service eco-systems [10].

Whilst organizations need to focus on exploring and exploiting SI simultaneously, research on SI is getting increasingly extensive and dispersed [11]. Previous literature reviews have pointed out that SI encompasses different aspects, such as New Service Development, Service (Systems) Engineering, and Service Management [6]. However, an integrated view on ambidextrous SI seems to be scarce [12], motivating our research question: "*To what extent are exploration and exploitation of SI covered in research?*"

The paper offers two main contributions. First, we identify a disjunction of SI literature with articles either focusing on exploration or exploitation. Second, we provide an integrative conception of the different research strands that uncovers the fundamental mechanisms of SI. We derive three propositions from a conceptual analysis and develop a framework for ambidextrous SI. The framework builds on dynamism and generative mechanisms, inspired by the concept of organizational routines—hereafter referred to as routines only. Routines are "recognizable patterns of interdependent actions, carried out by multiple actors" [13]. SI and routines are ontologically related since both are performed by multiple actors, are composed of some recognizable patterns of activity, and are endogenously changing. Further, the paradox of simultaneous competing pressures for exploration and exploitation activities has already been resolved in routines literature [6], helping to understand ambidexterity in SI as well and thereby, remedying the disjunction in SI literature.

The paper unfolds as follows: In Section 2, theoretical foundations of SI and ambidexterity are provided. Section 3 justifies the systematic literature review as research method. In Section 4 the results from the literature review are described and presented in a concept matrix. Section 5 continues with the discussion of insights resulting from the concept matrix. We derive three propositions that are used to develop a framework, which unifies scattered SI research through ambidexterity. The paper is concluded in Section 6 with the contributions to research, implications, and limitations.

2 Theoretical Foundations

2.1 Service Innovation Research

Service science is the study of service systems [14], which focuses on the co-creation of value within complex constellations of integrated resources, leading to innovative services [14, 15]. A service system is the basic unit of analysis [14], which describes "a configuration of people, technologies, and other resources that interact with other service systems to create mutual value'' [16]. Value emerges through the use and application of resources within a service system [5]. SI emerged as a new concept during the 1980's in service science research [17]. At the same time, New Service Development research emerged in the Anglo-American literature. Soon thereafter, Service Engineering arose in Germany as another research stream that adopted approaches from product engineering to design a value proposition in a structured way [18]. Whereas Service Engineering encompasses models, methods, and principles to design individual services, Service Systems Engineering describes the design and development of another basic unit of analysis, i.e. service systems as integrated conglomerates of services, products, and information technology [16, 19]. SI, New Service Development, and Service (Systems) Engineering emanate from different research disciplines, but are often used interchangeably [20].

There are two alternative views for conceptualizing value and value creation, which are referred to as "value-in-exchange" and "value-in-use" [15]. Value-in-exchange refers to the output or distribution of service, focusing on a goods-dominant logic (GDL) view [15]. Value-in-use is defined in service-dominant logic (SDL) by describing that value is determined by a user's consumption [21]. Value is co-created jointly and reciprocally by multiple actors through the integration of resources and application of competences [15]. Hence, value evolves differently in exploring and exploiting products and SI. In the light of SDL, we refer to service as "the application of specialized competences (knowledge and skills) through deeds, processes, and performances for the benefit of another entity or the entity itself' [5].

In a digitally transforming eco-system, organizations need to engage in accelerating cycles of SI to expedite growth, improve quality of services, satisfy customer needs, and to be competitive [17]. SI describes both, a change of an existing value-proposition or a design of a new value-proposition [22]. This includes the configuration or reconfiguration of resources within a service system [23]. Innovation does not only create value for an organization, it also changes the eco-system in which an organization operates [9]. Hence, SI needs to be distinguished from an invention, since an invention has no inherent value [9].

The process of SI can be planned, as an outcome of development activities or emerge from an individual's actions [24]. A multitude of methods for planning and developing innovative services have been proposed [18]. Whereas initial methods suggested sequential or linear aligned steps to develop innovative services, more recent models rather propose iterative patterns for service design [17, 18]. Other research focuses on managerial frameworks with a focus on different resources, information, and knowledge for SI [4, 12, 17, 22, 23].

2.2 Ambidextrous Organizations in Digital Transformation

Organizations need to adapt to a changing eco-system and technological change [25], which causes conflicting requirements. On the one hand, organizations have to achieve innovation through the exploration of new competencies [26]. On the other hand, they have to be efficient by exploiting their current capabilities [26]. In early research, the activities of exploration and exploitation have been seen as an incompatible trade-off [27]. However, focusing only on exploration will lead to low returns, whereas organizations that engage only in exploitation will eventually become deprecated [28].

More recent research introduced the concept of ambidextrous organizations. Ambidexterity refers to an organization's ability to be adaptive to changes for long-term success (*exploration*) whilst reducing variance and leveraging existing resources and capabilities efficiently (*exploitation*) [28]. Exploration and exploitation need to be well-balanced for the current continuance and future viability of an organization [25].

Until the late 1990's, ambidexterity was used to describe dual structures in organizations [29]. Some units of the organization were focused on searching and (re-) combining resources to achieve variation, while other units were employed for efficient alignment of organizational structures [26]. Ambidexterity was conceptualized as a temporal sequencing of exploitation and exploration [8]. However, in fast changing eco-systems, a periodically change by adapting new strategies and structures is ineffective [30]. Organizations need to engage simultaneously in exploitation ensuring current viability and devote sufficient attention to exploration to ensure the future viability [31]. In recent research, contextual ambidexterity has become prevalent, which is manifested in specific actions of individuals in organizations [29]. Contextual ambidexterity is the capacity to simultaneously demonstrate exploration and exploitation in each entity of an organization [29]. Since digital transformation requires removing organizational silos that work autonomously from other units [32], contextual ambidexterity is a crucial capacity of organizations. Thus, organizations continuously streamline current business activities and engage in innovation activities [8].

3 Research Method

The systematic literature review on SI is based on the methodological guidelines by Webster and Watson [33] and vom Brocke et al. [34]. We refer to Cooper's [35] taxonomy to cover a sufficient and representative degree of SI research (*Figure 1*) [34]. The focus is on both, methods and theories of SI since they are mutually constitutive. The goal is to gain a better understanding of the central concepts and thereby, identify issues and suggesting areas for further progress in the SI literature [35].

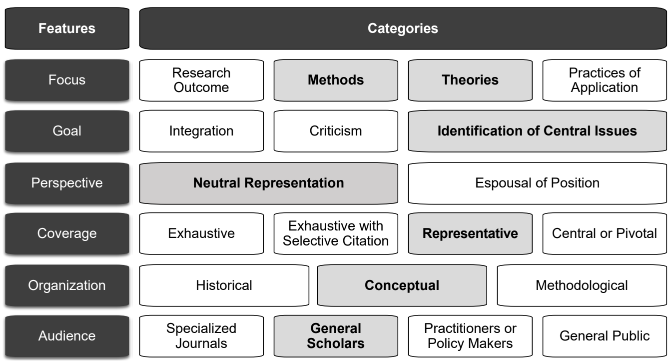

Figure 1. Positioning the Literature Review [35]

The perspective adopted for this literature review is neutral to provide a realistic representation of the current literature. A representative coverage of the literature by discussing the characteristics of SI makes the sample illustrative for a larger group of literature [35]. Although the audience of the review focuses mainly on IS scholars, we address researchers in service science, too. We conducted an iterative process for our literature search by defining and re-defining a search string and query structures through the course of the study. We started with scanning the literature to identify key terminology and synonyms. Since SI, New Service Development, and Service (Systems) Engineering emanate from different research disciplines, whose terms are often used interchangeably [34], we added the terms to our search string (see *Table 1*).

Table 1. Search String

("service" OR "service system" OR "services" OR "service science") AND ("innovation" OR "innovate" OR "innovativeness" OR "innovating" OR "invention" OR "creation" OR "create" OR "engineering" OR "design" OR "designing" "development" OR "develop" OR "new" OR "novel" OR "configuration" OR "configure" OR "organization" OR "organizing" OR "management" OR "process" OR "technique" OR "value cocreation" OR "value co-creation" OR "value proposition" OR "outcome" OR "resource" OR "exploration" OR "explore" OR "exploitation" OR "exploit")

Major contributions are published in leading journals and some conference proceedings [33]. Hence, we started by scanning the table of content and performed key word searches within these publications. The journals and conference proceedings were selected interdisciplinary, originating from the IS and Management discipline and were ranked as A+, A, or B according to the "VHB-JOURQUAL 3" ranking. Then, we extended the search within literature databases of AISeL, ProQuest, EBSCOhost, Google Scholar, Science Direct, and Web of Science. Afterwards, we conducted a backwards and forwards search to identify additional articles [33]. In total, the search yielded 1,145 articles. Duplicates were removed and articles that did not adhere to the following criteria were excluded: written in English, published in peer-reviewed scholarly journals or conference proceedings, address the focus mentioned in the taxonomy[1], and are available in full-text. Then, we performed an analysis of the title, keywords, abstract, and browsed the papers to identify, which articles are relevant for our review, leading to a sub-sample of 51. Lastly, we excluded research that was ranked lower than B level, narrowing down the literature to a final sample of 25 articles.

We followed the sequential model for structured content analysis by Mayring [36] to code the data. We filtered interesting aspects from the literature by using criteria and sub-criteria derived from theory [36]. Ten concepts were identified for which we defined coding rules [36]. Three researchers coded the articles independently. An initial inter-coder reliability [37] was achieved by calculating the average pairwise percent agreement ($A_0 = 0.815$), Fleiss' Kappa ($\kappa = 0.711$), average pairwise Cohen's Kappa ($\kappa = 0.712$), and Krippendorff's Alpha ($\alpha = 0.711$). Since all values exceed the critical value of $\alpha_{min} = 0.667$, sufficient congruence between the coders can be assumed.

[1] We excluded articles with GDL approach, such as product-service-systems that emphasize a transfer of physical items or temporary access to resources.

4 Conceptual Analysis of the Service Innovation Literature

To present a systematic review of SI literature, we compiled a concept matrix, which is presented in *Table 2*. The matrix is built on two main constructs of ambidexterity theory: exploration and exploitation. The main properties of exploration and exploitation are derived from ambidexterity literature, which are then clustered into three dimensions of service science: potential, process, and outcome [38] to guide the derivation of sub-concepts for analyzing the literature on SI more in-depth.

First, the potential of SI can be grounded in the intention of a new *strategic focus (1)* or *operational leverage (2)*. The potential for exploration is manifested in strategical positioning to gain a sustainable competitive advantage [39] while the exploitation potential is based on leveraging existing services by enhancing efficiency, productivity, or the service itself by changing its value proposition [10]. Second, the process of exploration and exploitation involves the use of resources, such as intellectual resources, organizational resources, technologies, and other assets [44]. Exploration is associated with search and *acquisition of resources (3)*, which are new to an organization or the strategic intent to newly combine internal and external resources to design innovative services [10, 20]. In exploitation the emphasis is on leveraging, adopting, and *reconfiguring resources (4)* that are already prevalent in an organization to capture opportunities in SI and extend existing services in day-to-day work [10]. In this regard, ambidexterity describes the ability of organizations to simultaneously exploit existing resources, and explore new resources for SI [59]. Exploration will require disruption and a *path-breaking approach (5)* by abandoning established services [41] to generate a new value proposition [59]. As opposed to exploration, exploitation is *path-dependent (6)*, since improvements and incremental innovation evolve from existing knowledge and routine-based experience [60]. Through the performance of task and activities new opportunities can emerge that trigger variations of the current services [61]. Third, exploration and exploitation often create divergent outcomes [61]. Even though both are important for the viability of an organization, exploration will rather lead to a *radical innovation (7)* whereas exploitation is associated with *incremental innovations (8)*, e.g. as improvements or extensions of service [30]. The focus of the paper is another concept of the analysis, in which we consider the articles that emphasize the design of an innovative *service system or value proposition (9)*. We also analyze whether *technology (10)* is mentioned in SI.

Some of the analyzed articles propose a framework that structures SI through a configuration of resources and use of organizational capabilities [22, 23, 39, 41, 43–45, 49–52, 55, 56]. An integrated framework that adheres to the opportunities of digital transformation is offered by Lusch & Nambisan [50]. Their framework is based on SDL and treats SI as a collaborative process occurring in actor-to-actor networks, in which individuals interact within a service eco-system [50]. Lusch & Nambisan [50] include service platforms, which enhance the efficiency and effectiveness of SI by de-coupling and re-combing resources to generate new value propositions. Thereby, technology can act as an operand resource—on which an operation is performed to produce an effect [5]—for supportive or enabling purposes and as an operant resource—that acts upon operand resources [5]—by creating novel opportunities for resource integration [50].

Teixeira et al. [57]	x	x	x	x					SYS	x
Yu & Sangiorgi [58]	x	x	x	x					VP	

Abbreviations: VP = Value Proposition, SYS = Service System

The third element of the framework is value co-creation by integrating existing resources of the service provider and the customer. Russo-Spena & Mele [55] extend the idea of co-creation by introducing the five "Co-s" model, which includes: co-ideation, co-valuation, co-design, co-test, and co-launch. Each "Co-" represents a phase of the innovation process resulting from dynamic and on-going interactions among resources, actions, and a group of actors who are interrelated via a dense network [55].

Other articles propose a linear approach [42, 46, 53, 54, 57] with discrete or consecutive steps or iterative approaches with multiple repetitions of the involved activities [7, 18, 48, 58] for developing innovative services. Ojasalo & Ojasalo [7] develop a lean SI model for iteratively designing a new service through several improvement rounds until it is implemented. Each iterative cycle results in a minimum viable service that is deployed for customer feedback [7]. A different iterative approach is provided by Beverungen et al. [18]. The authors suggest an agile method that incorporates the recombination of internal and external resources to design an innovative service system [18]. The method is based on three phases: service system analysis, service system design, and service system transformation [18]. Each cycle of service system design results in a viable prototype that is either further improved or implemented [18], similar to agile methods in software development.

The conceptual analysis of the literature reveals three insights. First, previous research has mostly focused on either exploration or exploitation of SI. Few papers comprise sub-concepts of both, exploration and exploitation, e.g. in papers that are suggesting to use known and unknown resources for SI. Second, almost all articles consider technology as enabler for the design and delivery of innovative services. Only two articles provide a framework for designing and adopting an innovative service without explicitly addressing technology, neither as resource nor as an opportunity [52]. Third, most articles focus on creating, improving, or managing a value proposition and do not take a service system perspective. Only six articles consider a socio-technical system that comprises people, technologies, and other resources for value-creation.

5 Discussion

5.1 An Integrated View on Service Innovation

From the conceptual analysis we derive three propositions that describe how an integrated view of SI can be achieved. We acknowledge that exploring and exploiting SI are discussed as isolated concepts in the analyzed literature. However, exploration and exploitation should not be treated as a paradoxical tension or sequence of separate phases, but rather as continuum [61]. Ambidexterity theory provides a theoretical foundation that is already manifested in new product development [4]. However, exploring and exploiting SI requires a different approach, since services are designed through co-creation of value by multiple actors [23], integrate the knowledge and skills of multiple actors [5], and provide value through (temporary) access to resources (*value-in-use*) instead of acquisition (*value-in-exchange*) [23].

Our conceptual analysis reveals that SI can arise from both, strategic intent and operational activities. The constructive design of an innovative service is an exploratory process, aiming to design a new value proposition [63]. Managers can trigger innovation top-down through exploration by crafting a vision or strategy on how to design new services. Then, the services are implemented in daily work and become efficient [43]. Continuously adapting and improving services by using existing resources, knowledge, and processes refers to exploitation [20]. Employees have the knowledge needed to perform and improve services [22]. Further, they know the preferences of customers, which they can use to develop new services [22]. Employees can also deviate autonomously from a current service offering if they are faced with

unforeseen incidents, such as conflicts, resistance, specific customer requests, or the inability to carry out a service [22]. By adapting service to overcome constraints, incremental innovation is achieved, which may increase efficiency, effectiveness, or improve other organizational aspects [59]. Ultimately, strategic decisions for exploration are rooted in an organizations' resources and activities that are exploited [44]. Whereas, exploration promotes an organization's long-term viability, exploitation is indispensable to ensure short-term viability [61], resulting in our first proposition:
Proposition 1: Service innovation is a continuum of exploring new and exploiting current resources, knowledge, and processes.

The conceptual analysis also reveals that technologies create both, opportunities and challenges for SI [10]. On the one hand, this implies that technology and rapid-innovation contexts can generate strong pressure for organizations to introduce innovative changes in a value-proposition [6]. On the other hand, a new value proposition can be explored through deliberately searching and acquiring technological resources, which are then translated as a technological option into a value proposition, e.g. as a self-service [43]. Technology can offer an infrastructure that provides communication, collaboration and/or computing capabilities to support innovation [64] and thus, serve as enabler for service processes [4], e.g. web-based services such as shipment tracking of a postal office or online streaming services. Further, it can be adopted for exploitation by incrementally changing the value-proposition, e.g. through customization, as new ways for customer interaction, or by service extension [43].

While the importance of technology for SI is emphasized in many articles, the role and use of technology is divergent. Often, technology is used as an enabler providing the infrastructure, neglecting the innovation potential that is inherent in technology [4]. The continuous development and launch of new digital and smart technologies, such as smartphones, artificial intelligence, or big data trigger the design of innovative services creating a first-mover-advantage. Therefore, we propose that:
Proposition 2: The acquisition and configuration of technology offers a dual potential, as enabler and as trigger of SI.

SI is mainly studied by focusing on designing or enhancing value propositions, in which consumers participate in the development of service through co-creation of value [5]. However, against the backdrop of digital transformation new perspectives on value creation are needed [46]. A service system's perspective helps to understand SI comprehensively [23]. A service system incorporates resources, e.g. technologies and multiple actors that are connected by a value proposition and shared information [15]. Actors develop innovative services through a collaborative process of sharing and accessing these resources within value networks, i.e. service system configurations [23]. For example, Airbnb has designed a service system by leveraging technology and using the properties of their users as resources to provide customers a new innovative value-proposition. Thereby, Airbnb has become the largest global lodging company and brand today for cheap and efficient traveling without owning any properties [65]. A service system perspective can remedy the disjunction of research in exploring and exploiting SI, constituting our third proposition:
Proposition 3: A service system perspective provides a unified research perspective for service innovation.

5.2 Ontology of Ambidextrous Service Innovation

As exemplified in *Table 3*, most articles emphasize that SI is achieved through the interaction of multiple actors (e.g. client and provider, producer and co-producer, or a network of employees or customers). The process of interaction among multiple actors to co-create value is manifested in recognizable patterns of activities [66]. The analyzed articles provide explicit patterns—presented as frameworks, guidelines, methods, or models—that can be used by actors to explore and exploit SI.

Table 3. Exemplary Definitions of Service Innovation

Author	Definition
Breidbach & Maglio [23]	"Service innovation is service system reconfiguration. […] A service system is composed of multiple entities that interact to cocreate value."
Patricio et al. [54]	"Service innovation can be defined as a new process or service offering that is put into practice by an organization, and is adopted by, and creates value for one or more actors in a service network."
Rubalcaba et al. [22]	"A service innovation can be the outcome of innovation networks in which different agents cooperate to coproduce a service-based innovation result."

In addition to a formalized pattern of SI, the interaction between multiple actors can lead to variation in a value-proposition [66]. Employees can leverage and adapt existing services autonomously or as co-creators of value in cooperation with customers, e.g. to remedy inefficiencies in service provision [22]. Further, employees provide knowledge to elicit the formalized design of a new service. This interdependency can be described as generative mechanisms of adapting existing and experimenting with new patterns of activity to achieve SI. The involvement of multiple actors, the presence of recognizable patterns, and the generative mechanisms of exploration and exploitation mirror the concept of routines [66]. Routines are defined as "recognizable patterns of interdependent actions, carried out by multiple actors" [13]. Hence, SI and routines share the same ontological basis [66]. Further, theories to solve the dilemma of simultaneous competing pressures for exploration and exploitation activities have already been framed in routines literature [6]. From routines' theory, we derive insights on the reinforcing processes of exploration and exploitation for ambidextrous SI.

Routines are effortful accomplishments that are continuously and endogenously changing [13]. The dynamism of routines stems from two components that are recursively related: ostensive and performative aspects. The ostensive aspects represent the schematic form of a routine, whilst the performative aspects embody the actual enactment of the routine that is carried out by specific people, at specific times, and in specific places [13]. Ostensive and performative aspects form a mutually constitutive relationship, in which the ostensive aspects enable and constrain the desired performance of a routine whereas the performance of a routine creates and recreates the ostensive aspects [13]. Hence, an incremental variation in the performance can lead to a change of the ostensive aspects and consequently alter the overall routine. Analog to routine's theory, we emphasize a constitutive relationship of exploration and exploitation in SI, as illustrated in *Figure 2*.

The exploration of a new value proposition constitutes the basis for providing innovative services efficiently. Exploration enables and constrains exploitation in day-to-day work (1). In turn, multiple actors who exploit SI in their routines help to create and recreate the exploration of innovative services (2). This perception is in line with *proposition 1*, that SI can be described as a continuum of exploring new and exploiting current resources, knowledge, and processes.

In routine theory, external changes, e.g. a new technology, can induce the need to transform a routine by changing the ostensive aspect [67]. A radical, path-breaking, and strategic transformation of a routine in response to changes in an eco-system refers to the exploration of new routine patterns. Employees can also deviate in their performance from a standard routine by integrating external resources in their daily work or through reflective self-monitoring, which both refer to exploitation [13]. Likewise, actors are searching and acquiring technologies to explore new innovative services (3). The effect of technology that is radically new to the organization is mainly disruptive (4). When multiple actors are exploiting SI, they can also reconfigure a service (5) by selecting and integrating existing technology to adapt the value-proposition (6). These findings are in line with *proposition 2*, stating that the acquisition and configuration of technology offers potential for both, as enabler and trigger of SI.

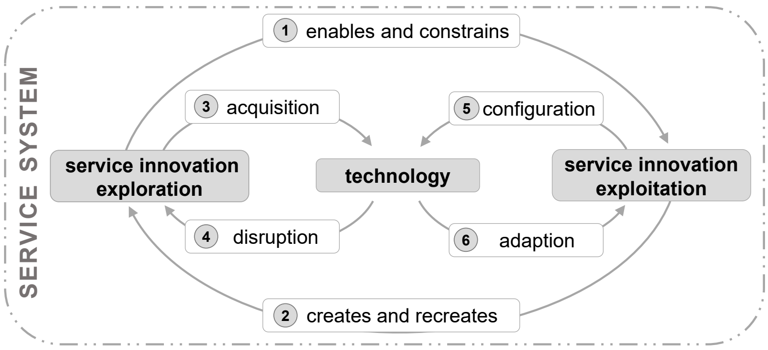

Figure 2. A Systematic View on Ambidextrous Service Innovation

Finally, routines are generative and continuously emerging systems with internal structures and dynamics [68]. A routine represents the interplay between ostensive and performative aspects, the role of artefacts (e.g. technology, rules, and methods), and interaction of multiple actors in shaping these dynamics [68]. By taking a system's perspective, internal dynamics of convergence and divergence among the elements within the system can be observed [68]. Likewise, SI can be viewed as a system (7) that consists of different resources, i.e. people, technology, organizations, and shared information [23]. Within a service system, multiple actors create and co-create mutual value through interaction by sharing and accessing resources [23]. A systematic approach is in line with *proposition 3*, stating that a service system perspective provides a unified research perspective for SI. The findings are summarized in a systematic and unified framework of ambidextrous SI. The framework provides an ample perspective on SI that is characterized by endogenous change. Thereby, the identified gap between distinct strands of research in SI is remedied.

6 Conclusion

Digital transformation provides opportunities for developing innovative services, but also challenges organizations to accelerate innovation cycles of exploring and exploiting new services. The capacity for exploring innovative services while simultaneously exploiting them efficiently is defined as organizational ambidexterity.

Based on a systematic literature review, this paper offers two main contributions. First, despite the need for organizational ambidexterity in practice, we identify that literature on SI consists of two strands of research focusing either on exploration or exploitation. Second, a framework for ambidextrous SI is provided that remedies this disjunction of exploration and exploitation in research. The framework is based on the dynamism and generative mechanisms of routines by adopting the perspective of a mutually constitutive relationship between exploring new and exploiting existing resources, activities, and knowledge. Thus, exploration of innovative services enables and constrains exploitation in day-to-day work. In turn, SI that is exploited in day-to-day work of employees can create and recreate the exploration of innovative services. The framework provides a systematic approach that incorporates technology as an opportunity for designing new and improving existing services. We develop a systematic view on ambidextrous SI that provides a coherent perspective on SI in research and adheres to the demands of organizations, which need to accelerate innovation cycles of exploring and exploiting services simultaneously.

Limitations of this study refer to the coverage of literature that is representative instead of exhaustive. In fact, we only considered peer-reviewed journals and conference proceedings that were published in English. Further, even though inter-coder reliability surpassed the critical value, we cannot assure that other researchers might come to a different assessment of the concepts.

Researchers can use the framework as impetus or guidance to study SI rather as a continuum instead of two distinct concepts. We are eager to see whether our findings can be extended to a broader set of literature and if there are synergistic effects between exploration and exploitation. Our framework can serve as guideline for organizations that can use, test, and assess our theoretical findings in different SI scenarios. Further, we would like to encourage future research to develop theories and methods for ambidextrous SI that take a system's perspective in order to meet organizational demands in a digitally transforming service eco-system.

Design and success factors of an online solution for cross-pillar pension information

Christopher Krug[1]

[1] FOM University of Applied Sciences, Essen, Germany
mail@christopher-krug.de

Abstract. As the European Commission notes, the importance of individual pension components is increasingly shifting from state provision to private provision, as most European states can only guarantee basic provision for retirement age instead of guaranteeing the continuation of a person's standard of living. This development requires transparent information for citizens on the composition of their pensions, as this is a prerequisite for taking responsibility for their old-age provision themselves. Digital solutions such as apps offer the possibility of bundling the various sources of an old-age provision in one system and showing them to the individual citizen at a glance to make individual pension needs and possibilities of influence understandable. This research-in-progress paper reflects the current state of research in a study that examines the success factors of digital retirement provision information in a pan-European context.

Keywords: Pension information, Digital Transformation, Financial Literacy, Pension Literacy

1 Introduction

Due to a pan-European decline in the level of statutory pension entitlements, the responsibility for adequate old-age provision is shifting from the state to the individual citizen [1-3]. Old-age provision in the member states of the European Union (EU) is based on the three pillars of statutory, company and private old-age provision and thus company and private pension provision become more important [1].

To be able to take on this responsibility, it is essential that individuals understand the development of their old-age provision, so they can find out about their pension needs and act accordingly [1-3]. In most EU Member States, however, there is a lack of an appropriate information medium to enable citizens to do so, as cross-pillar entitlements are difficult for non-professionals to understand due to complex information and effects like money illusion [2-4]. In consequence, this makes a significant contribution to the fact that many citizens are uncertain about their pension situation and do not pay enough attention to it [4-6].

The advantages over traditional media regarding data consolidation, simplification, and personalization offer potential for the digital transformation of pension information to solve this issue. Existing implementations, however, like in Denmark or Sweden,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

focus strongly on country-specific issues and thus cannot be transferred to other countries [3]. Hence, the European Commission (EC) recommends the implementation of an overall digital solution for comprehensive pension information, which considers the different pillars as well as the free movement of workers [1], [7]. In this study, which is still in progress, the success factors of such a solution are evaluated.

2 General State of Research on Pension Information

At present, citizens are confronted with a wide variety of sources of pension information, like previous employers or different EU countries [8]. Figure 1 shows which individual service providers the user is currently facing and what added value is generated by a cross-pillar pension information medium.

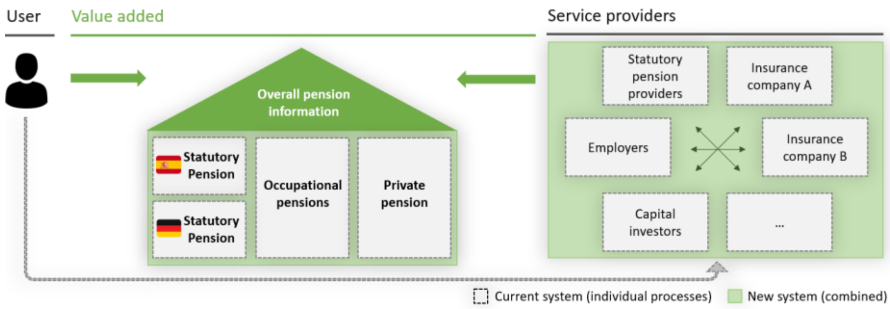

Figure 1. Pension information service system

Increasing the transparency of pension information and bringing together the various pillars is a highly contemporary topic, what is reflected in the number of current working papers and studies on the need for a cross-pillar retirement provision information medium [1], [4], [7-11]. However, the corresponding publications are regularly backed by private sponsors or public organizations. Current scientific research regarding the success factors of pension information, however, relates primarily to the individual pillars like, for example, the statutory pension [3], [12-16].

3 Research Approach

As outlined, the EC, among others, is proposing a digital solution for cross-pillar pension provision for its member states. This research work aims to determine the success factors of such an overall information medium, which is to be considered pan-European and inter-organizational.

In order to create the basis for achieving this objective, an application concept for a cross-pillar information solution has been developed. Since there is hardly any existing literature that specifically addresses the requirements of cross-pillar pension information, the concept is mainly derived by results of expert interviews, in addition to a literature review and a comparison of existing solutions in Denmark and Sweden.

To validate that the concept meets the requirements of the experts, it was prototypically implemented mainly via the application framework Angular and provided via a public domain, so the experts were able to evaluate the implemented solution in a second survey. Table 1 shows the framework data of both surveys.

Expert interviews	Phase 1 – Requirements	Phase 2 – Validation
Number of experts	12	7 (all of them also participated in phase 1)
Heterogeneity	High; experts from all three pension pillars as well as politics and science	Medium; experts from sciences and the second and third pension pillar
Structuring	Semi-structured	Structured
Cognitive interest	Attitudes and information	Information
Role of the interviewer	Active	Electronic, non-personal conduct of the survey
Interview situation	Symmetrical	Asymmetric (in favor of the interviewer)

Table 1. General data of the expert interviews

The second phase of expert interviews also serves as a pre-test before the conduct of end-user-focused experiments. According to the Design Science Research (DSR) approach of Hevner et al., the application design is broken down into several artifacts to strengthen the significance of this prospective end-user evaluation [17]. The findings of this evaluation will be analyzed and iteratively integrated into the concept.

In the first step of end-user evaluation, it is necessary to examine whether the basic application concept also meets the requirements of end users. Due to the complicated information situation and a high demand for a digital solution in Germany, German users are used for the first step. After a successful first evaluation and iterative revision of the concept, an end-user evaluation with other European users will take place. This evaluation is planned to be carried out in Spain and Italy, since the pension composition is different than in Germany, due to the lower relevance of the second pillar.

4 Current State of Results

The developed concept consists of a set of 12 functional, 11 non-functional requirements and a technical design. The functional requirements include: *(1) registration & identification; (2) overview of pension claims; (3) interfaces to pension providers; (4) a detailed view of pension modules; (5) merging claims for planning purposes; (6) input of forecast variables; (7) insight into personal data; (8) input of personal data changes; (9) further information insight; (10) contact options; (11) monitoring; (12) demo access*. The non-functional requirements mainly cover the framework conditions of the solution, such as access with as few barriers as possible and high usability. The technical design covers a first system design in the form of a web application with three-layer architecture and drafts for each of the layers. Specifically, these are a) an information architecture based on a mobile-first approach for the presentation layer, b) process designs for the application layer and c) a design for the data layer, including an entity relationship diagram for all pension-relevant data.

The expert interviews and the pretest carried out via a prototype implementation of the concept confirmed that the concept fulfils the experts' requirements. The prototype included all non-functional requirements as well as the functional requirements 1-10 on the presentation layer. Furthermore, basic functions were implemented on the application layer, e.g. for adding/changing/deleting pension entitlements. With regard to the interview results, it should be emphasized that the feasibility of cross-pillar information is supported by the providers of all pillars, with most of the experts taking the view that the respective other providers would be opposed to a cross-pillar solution. Also, the obstacle to data protection, for example, is assessed as solvable, insofar as data are only transferred on-demand and end-to-end to the respective user. Automatic data provision is identified as a first, decisive success factor, which requires a uniform identification of the users, e.g. via tax ID or social insurance number, as it exists in most European countries. When asked how the experts would assess the concept without fulfilling this success factor, it was judged to be less effective, but still an improvement over singular information media. This assessment supports the relevance of a cross-pillar information medium, which will be further deepened by the end-user evaluation.

5 Conclusion

This paper presents the basic methodology as well as the main results of the research work so far. Due to the focus of this research-in-progress-paper, the basics, in particular, represent only a small part of the research object, which opens up numerous further research fields. Thus, critical elements for pension information, such as the individual service providers will take on a more significant role in the final research.

The first evaluation showed that the requirements of experts from different pillars could largely be combined in one application, for which initial success factors and challenges could also be identified. In the next steps, these initial findings will be incorporated into the user-centred evaluation at a national and pan-European level as well as into the iterative development of the concept following the DSR approach.

A Frugal Support Structure for New Software Implementations in SMEs

Nivedita Agarwal[1], Martin Schymanietz[1], Albrecht Fritzsche[1]

[1] Friedrich-Alexander University Erlangen-Nürnberg, Institute of Information Systems, Nuremberg, Germany
{nivedita.agarwal,martin.schymanietz,albrecht.fritzsche}@fau.de

Abstract. During software implementations, budgetary and human resource constraints often make it difficult for small and medium sized enterprises (SMEs) to provide and maintain the required support. To overcome these constraints, this study describes a frugal support structure (FSS) to orchestrate available resources and to involve users as suppliers and co-creators of contextualized information. The FSS is conceptualized as a system that enables interaction and collaboration between the actors involved by using extant communication infrastructure wherever possible, systematizing and centralizing knowledge created and ensuring overall resource and time efficiency. Adopting a design science research process, development of the FSS combines a literature review and practical insights. Evaluating the challenges and benefits of FSS, the findings indicate that user involvement is necessary not only for contextualized and accessible support but to make support structures more frugal and sustainable in the long term.

Keywords: Software implementations, frugal, design science, user involvement, SMEs

1 Introduction

Software implementations have always interested IS scholars because of their high-risk and high-reward characteristics [1]. When introducing new software solutions, organizations commonly invest significant resources in change management practices and support structures to facilitate employees' gradual transition to the new business processes [2]. Unlike larger incumbents, resource-constrained small and medium-sized enterprises (SMEs) may find it challenging to support such transitions [6], as evidenced by the low success rates and sluggish adoption of new software in SMEs [1-2], [6].

Previous research on software implementations shows that post-project measures such as training, online support and IT help desks account for almost 90% of the total cost of implementation [6], [10]. Limited financial capacity, low human capital and fragmented governance structures [15] make it more difficult for SMEs to offer and sustain these employee supports over time. However, as the literature confirms, the importance of these support structures for successful software implementation [1], [6], SMEs must balance the costs against the benefits of the new software, making it important to explore more resource-efficient and sustainable alternative supports.

Although user involvement is widely acknowledged as a critical factor for successful software implementation [17], it is rarely a feature of existing support structures [6], [19-20]. The limited attempts to facilitate user involvement have emphasized social structures such as advice networks and peer-to-peer collaboration [6], [19-20], which are said to provide contextualized information and better accessibility than traditional support structures (TSS). As this is a relatively new area of IS research, there are no clear design principles and little consensus in relation to the benefits of these social support structures in different organizational contexts [6]. The present study describes the design of one such structure to enhance user involvement, with particular reference to new software implementation in SMEs.

SMEs commonly face financial and human resource constraints, and a frugal approach is necessary to ensure the efficient utilization of available resources. The frugal approach involves developing cost-effective and accessible solutions by making creative use of resources at hand [21]. We argue here that involving users as consumers, suppliers and co-creators of information will be more cost- and time-efficient. To that end, the present study describes the design of frugal social support structures for SMEs to facilitate creative orchestration of available resources for higher benefits. In designing a frugal support structure (FSS) for SMEs and evaluating its benefits as compared to TSS, we addressed the following research question:

How can frugal support structures orchestrate available resources and influence user adoption within SMEs to overcome specific organizational constraints during IS implementation?

To design and assess the proposed FSS, we adopted the conceptual lens of service-dominant (S-D) logic, which specifies principles for the creative orchestration of interactional resources, including tangible (technological) and intangible resources (knowledge, skills and competencies) by structuring, bundling or leveraging these for competitive advantage [40]. Adopting a design science research (DSR) approach, the subsequent empirical study conceptualized the proposed FSS in terms of S-D logic, followed by ongoing evaluation of the effects on user adoption as compared to TSS. The study was conducted in collaboration with a German SME from the IT sector currently undertaking multiple new software implementations. Drawing on links between the principles of S-D logic and the frugal approach, we focused on user involvement and co-creation. As well as contextualizing S-D logic in a resource-constrained setting, the study describes design guidelines for FSS development and provides evidence of the tangible benefits of a frugal approach to software implementation.

The remainder of this article is structured as follows. After introducing the theoretical foundations of S-D logic, we go on to discuss the frugal approach. We then describe our methodology, which is based on design science research (DSR), along with insights gathered and iterative development and demonstration of the FSS. Following an explanation of the evaluation phase, the article ends with contributions and conclusions.

2 Background

2.1 S-D logic

In contrast to goods-dominant (G-D) logic, which is grounded in a "push" philosophy, S-D logic is based on a user-centric "pull" philosophy and focuses on value co-creation [23], emphasizing process and the exchange of services [24]. On this view, value is co-created by combining the unique resources (e.g., knowledge, skills) of the actors involved (e.g., employees, partners, suppliers, firms, customers) [25], and traditional goods become a mere vehicle for the exchange of value [26].

S-D logic combines tangible and intangible resources that are internal or external to the actors, referred to as *interactional* resources [23]. Technology and knowledge are important types of interactional resource; while technology provides necessary infrastructure, knowledge and specialized skills serve as the fundamental unit of exchange [26]. Actors orchestrate these interactional resources to help each other [26]. S-D logic has four meta-theoretical foundations: actor-to-actor networks, resource liquefaction, resource density and resource integration [24]. Altogether, they provide a strong conceptual basis to address the increasing challenges of systems design and implementation in the digital economy [27]. An actor-to-actor network includes all the relevant actors serving variously as producers, suppliers or users as potential co-creators of value. Resource liquefaction is the decoupling of information from users or technologies and enabling information sharing. Resource density specifies the mobilization of resources in terms of space, time and actors; density is optimized when contextually relevant information is shared in the most effective and efficient way. Resource integration is based on the fundamental idea that resources are less useful in isolation and must be combined with other resources to yield higher value [24].

2.2 The Frugal Approach

Derived from the Latin word *frugalis*, the concept of *frugal* has local equivalents around the globe, such as DIY in the US, Jugaad in India, Zizhu in China, Jua Kali in Africa and système d in France [29]. Scholars have defined frugal innovation as a bottom-up approach to innovation that creates accessible and affordable solutions for resource-constrained customers [30]. Beyond mere de-featuring or remodeling of existing solutions, frugal is a problem-solving approach to innovation whose underlying principle is to "do more with less" [34] – that is, to develop solutions with a higher performance-to-cost ratio [36]. Based on a clean-slate approach, frugal innovation involves re-designing the whole development process to eliminate unnecessary costs, yielding resourceful and easy-to-use solutions [30], [34], [36]. These simple, low-cost, high-benefit, local-focused, scalable, mass-market solutions are designed for the harsh conditions that prevail in emerging markets, responding to the unique needs of customers living in resource-constrained areas. As well as identifying core values and avoiding needless costs, the frugal approach is driven by the concept of *inclusivity* – involving users as suppliers – which is widely discussed in the literature as a means of overcoming particular local constraints [31]. In the context of information systems, frugality is defined as a "*system which is developed and deployed with minimum resources to meet the pre-eminent goal of the client*" [42]. Watson et al. [42] highlighted ubiquity, uniqueness, unison and universality as the four drivers of frugal information systems.

A parallel is often drawn between "bricolage" theory [33] and frugal innovation because of the shared focus on the efficient utilization of resources [40]. While the theoretical foundations of frugal innovation remain contested, the approach is gaining momentum in both developing and developed regions. In developing countries, cost-effective and accessible innovations are needed to overcome extreme conditions and existing resource constraints [36]. In developed countries, companies are turning to frugal innovation in response to changing environmental conditions that include resource scarcities and changing demographics. In light of the close link between the frugal approach, bricolage and inclusivity, we argue here that S-D logic – and especially the fundamental principles of resource density and integration – are highly relevant in resource-constrained contexts. On that basis, the proposed FSS employs S-D logic to design supports for new software implementations in resource-constrained SMEs.

3 Design Science Research

In designing the proposed FSS, we followed the approach of Peffers et al. (2006), who described a design science research process (DSRP) model for iterative building and evaluation of the given artefact [35]. To begin, DSRP specifies the problem by combining insights from a literature review and practical experiences. Having identified the problem, the requirements and objectives of the proposed artefact are then specified. By means of an iterative process, the design is further developed, demonstrated and evaluated in the given context. Finally, the built artefact is communicated to the wider world.

In the present case, this approach was adopted to design and implement an FSS for a German SME (around 250 employees) in the IT sector, which was undertaking several new software implementations to achieve a common cloud-based IT infrastructure. The systems to be implemented included a new intranet, a novel travel management tool, MS Office 365 and a mobile device management system. While some of these were sourced from external vendors, some were developed in-house and required different support structures. Given the challenges of supporting the new IT strategy with limited resources, the company was looking for an integrated and efficient support structure, so providing an appropriate context for our research.

3.1 Problem Identification and Motivation

Literature Review

In a literature review of support structures for software implementations, peer-reviewed journal articles published after the year 2000 were searched across three databases (AIS, EBSCOhost and Science Direct) using the following search stream: ("software introduction" OR "software launch" OR "project launch" OR "project implementation"

OR "Enterprise Resource Planning System*" OR “Enterprise System*" OR “ERP” OR "change management") AND ("user adaptation" OR "effective use" OR “post-implementation” OR “pre-implementation” OR “support” OR “job stress” OR “impact on employees” OR “satisfaction" OR “knowledge management” OR “shakedown phase” OR “learning” OR “acquisition” OR “sense-making” OR "community platform" OR “communities” OR "software agent" OR “collaboration”). Appendix 1 summarizes the 33 articles selected to capture the benefits and challenges of existing support structures as a concept matrix [36]. Largely influenced by ERP implementations, the extant IS literature discusses five primary types of support structure (see Appendix 1), and the benefits and challenges of each are discussed next.

Training. In different forms (e.g., one-on-one, group, online), training is the most widely adopted support structure for new software implementation. Hands-on experience [37-38] and didactic knowledge transfer during training have been shown to impact significantly on user adoption [28]. While recent research links the convenience of online training to higher user acceptance [38-39], it also highlights some associated challenges [6], which include lack of contextual information, high cost and being time bound.

Online Support. Offering real-time support for users, this includes access to manuals, help files and, in some cases, online chat with technical advisors. Users can retrieve information regardless of location or time. However, like any knowledge management database, this type of support must be updated regularly. As well as being human resource-intensive, it lacks the contextual information that users need [6].

Peer-to-peer/Advice Network. This approach involves direct interaction among users with the goal of seeking or giving advice [6]. These networks commonly involve informal exchanges between actors [22], often fellow employees; benefits include ease of access, prompt responses and context-specific knowledge, which means that the information received is often more understandable and more readily applied [6].

Top Management Support. Usually seen as a more intangible support, this relates to resource provision and making the new software visible within the organization [11, 13-14, 16, 18]. Open communication and alignment of software implementation with company objectives have been shown to impact positively on user adoption [11]. However, because of its intangible nature, this kind of support is difficult to realize and is often overlooked [1], [7-9]

IT Helpdesk. Like online support, an IT helpdesk aims to provide generic support to users by facilitating access to manuals or other reference material as an intermediary between software provider and user [22]. Offering mainly technical assistance, this approach fails to provide contextual information; it is also time-consuming, as users must raise an IT ticket each time and then wait for assistance.

Aside from a consistent lack of user involvement, the literature review reveals distinct challenges for TSS in terms of timeliness, resource intensiveness and contextualization of information. While some recent research has sought to demonstrate the benefits of user involvement in the form of advice networks, further exploration is needed. The review also shows that support for new software is currently offered primarily during the pre-implementation phase. In contrast to the strong emphasis on training and top management support, there has been little exploration of other forms of support to promote user involvement, such as peer-to-peer or advice networks. Although it has been identified as a critical factor for successful implementation, the issue of user involvement has been largely ignored. The review also reveals a lack of comparative studies of these support structures in terms of their individual cost and time effectiveness and their impact on user adoption.

Expert interviews

To integrate insights from the literature with practical understanding and for increased relevance [5], expert interviews and discussions were conducted around software implementations at the selected German SME [45]. The company, which was involved in multiple IT rollouts, was selected through convenience sampling [46]. SMEs are of great relevance to the present study for a number of reasons. First, SMEs are of great importance to Germany's economy, accounting for 35.3% of the total revenue of German firms and employing 58.3% of workers who pay social insurance contributions [43]. Additionally, SMEs often lack the financial and human resources of large firms and have different governance structures [16, 44]. To assess the SME's requirements, the authors conducted three detailed interviews and held discussions with key actors, including IT support and project management teams. We also participated in kick-off workshops and introductory sessions for the new software systems. In addition to monthly discussion meetings with the project manager, three further interviews were conducted with other relevant actors. All the interviews were recorded, transcribed and coded with QDA software. The research partner also granted us access to their internal portals to observe user adoption.

The SME started its transformation journey by rolling out off-the-shelf ERP software. Purchased from an external vendor, this software streamlines and integrates business processes across departments such as finance, marketing and sales. As an off-the-shelf product, there is little or no possibility of customization, and the provider offers only standard tutorials and limited training. Thirty lead users (department heads) were selected by the company for initial training, and they were then expected to support further roll-out in their respective departments. Within the company, one project manager was responsible for the entire roll-out and was the single point of contact for end users. Communication between lead users and the project manager mainly involved email exchanges and personal meetings. In the absence of a common communication platform or forum, the project manager often spent a lot of time answering repetitive questions from both lead and end users. The project manager was supported by an IT service desk managed by one full-time employee. For every support requirement, users had to raise a ticket and wait for manual confirmation of the estimated time. As well as being time-consuming, this process was inefficient in terms of utilization of available resources.

In parallel to ERP implementation and the Office 365 initiative, the company also introduced new software for travel and mobile device management. Supported by the same project team, the company continued to struggle to offer adequate support to end users. Interviews with the project team and management highlighted budgetary and human resource constraints and the lack of centralized knowledge management initiatives. While acknowledging the need for user involvement and bi-directional communication, the interviewees expressed resistance to doing so because of the anticipated effort and cost, highlighting the need for a frugal solution that makes best use of extant communication infrastructure wherever possible.

Requirements of a Frugal Support System

Based on the literature review and the practical insights gleaned from the case study, we identified eight main requirements for FSS development on the basis of existing infrastructure. They can be broadly categorized as either conceptual or operational. The conceptual requirements are based on information gathered from the literature on frugal innovation and S-D logic while the operational requirements derive from the research setting.

Conceptual requirements:

1. To facilitate user involvement, a frugal support structure needs to identify the relevant actors.
   Research on frugal innovation emphasizes co-creation with end users and bottom-up development of solutions [32]. This aligns with the S-D logic perspective, which focuses on value co-creation involving all of the actors involved [25]. For that reason, it is important to identify all relevant actors, including end users, lead users and project and IT teams.
2. To increase the interaction between actors, a frugal support structure must establish an actor-to-actor network.
   According to S-D logic, actor-to-actor networks blur traditional provider-seeker relationships and enable co-creation [24]. It is crucial to activate or develop a network that enables the identified actors to exchange their knowledge in order to co-create value for themselves and others. This feature of peer-to-peer sharing is expected to enable the required flexibility and will provide contextual information to FSS.
3. To be cost-effective, a frugal support structure must be based on a universal and modular architecture that facilitates efficient utilization of interactional resources.
   Frugal innovation is about developing cost-effective solutions [36] and a universal platform to overcome the friction of technology incompatibilities [42]. In software contexts, a modular architecture enables the dynamic combination, replacement or replication of available resources.
4. A frugal support structure needs to mobilize and orchestrate resources to increase efficient utilization.
   According to both frugality and S-D logic, it is important to be resourceful as well as liquefying or mobilizing resources. Apart from acquiring and bundling of resources, the literature indicates that orchestration also involves leveraging resources through strategies such as mobilizing or modularizing [4]. This avoids additional costs for setting up isolated applications and ensures the best combination of mobilized resources for a given situation.

Operational requirements:

5. A frugal support structure should combine or provide a common interface for all new software introductions.
   Our interactions with the research partners confirmed that support for different software implementations should be integrated and centralized, as a common interface and consistent navigation makes access smooth and easy to understand. One-time authentication should be implemented to prevent additional hurdles.
6. For value co-creation, a frugal support structure should provide tools for collaboration, as well as distinct but connected communication channels.
7. For knowledge management, users need to be able to easily share and store the information generated.
   Collaboration tools and communication channels must be provided to facilitate both value co-creation and knowledge management. Facilities for sharing and saving user-generated information will co-create a common knowledge base that can be (re)used in certain scenarios.
8. To be time-efficient, a frugal support structure needs to be accessible anytime and anywhere.
   The structure needs to be lightweight and accessible regardless of time and location. It should be able to take account of the urgency level and offer the required support within a specified time.

3.2 Objectives of the proposed solution

Based on the literature review, frequently experienced challenges for TSS include a lack of contextual information, high costs, and time and resource inefficiencies (e.g., in relation to training, online support, IT helpdesk). Advice and peer networks, though better, are not necessarily seen as formal support structures. Based on the frugal and S-D logic approaches, the following objectives were formulated for the proposed FSS to overcome the limitations of TSS and to encourage user involvement. The objectives summarized in Table 1 reflect requirements identified from the literature and from practical insights.

1. Enable interaction between multiple actors through collaborative tools/communication channels
   The solution should enable the establishment of a network that includes all relevant actors and facilitates interaction between them – for instance, by means of a platform that supports both synchronous and asynchronous communication.
2. Provide a centralized and structured self-sustaining system
   The solution should provide a structure that helps actors to find what they are searching for, based on the establishment of communities and/or groups focusing on similar topics. These communities/groups should be managed by the actors themselves.

Table 1. Objectives of the intended frugal support structure

	Objective 1	Objective 2	Objective 3	Objective 4
Description	Enable interaction between multiple actors through collaborative tools/ communication channels	Provide a centralized and structured self-sustaining system	Ensure efficient knowledge management	Ensure resource and time efficiency
Underlying characteristics	R1: Facilitate user-involvement R2: Increase interaction between actors R6: Provide tools for collaboration	R5: Single /common Interface R8: Easy access	R7: Tools for knowledge management	R3: Cost-effective & resource efficient R4: Mobilization of resources

3. Ensure efficient knowledge management
   To facilitate the integration of actors' resources, the solution should support knowledge sharing and should be accessible 24/7. The solution should be overarching – that is, it should provide support across an extensive range of use cases within a single structure.
4. Ensure resource and time efficiency
   In line with the concept of frugality, the solution should be based on existing software and should support modular extension for resource efficiency. Additionally, the system should motivate users to provide solutions within a certain time limit.

3.3 Design and Development

The FSS was developed in four recursive iterations. The first design consisted of a draft based on the literature review and the interviews. Subsequently, a clickable mock-up was created using Atlassian software. In the third iteration, that mock-up was ported to the company's intranet portal. Focusing on the ERP implementation, a special group was created on the intranet website, with customized video tutorials and documents. However, the technical limitations of the platform in terms of collaboration tools and communication media meant that opportunities for user involvement were minimal. For that reason, the fourth iteration incorporated the Microsoft (MS) Teams platform to enable the envisioned support structure. As part of the Office 365 bundle, this digital platform provides a common environment for the formation of actor networks and for co-creation. The design requirements were then implemented on the platform.

3.4 Demonstration

The final design of the FSS on the MS Teams platform, which was available to the whole company, is shown in Figure 1.

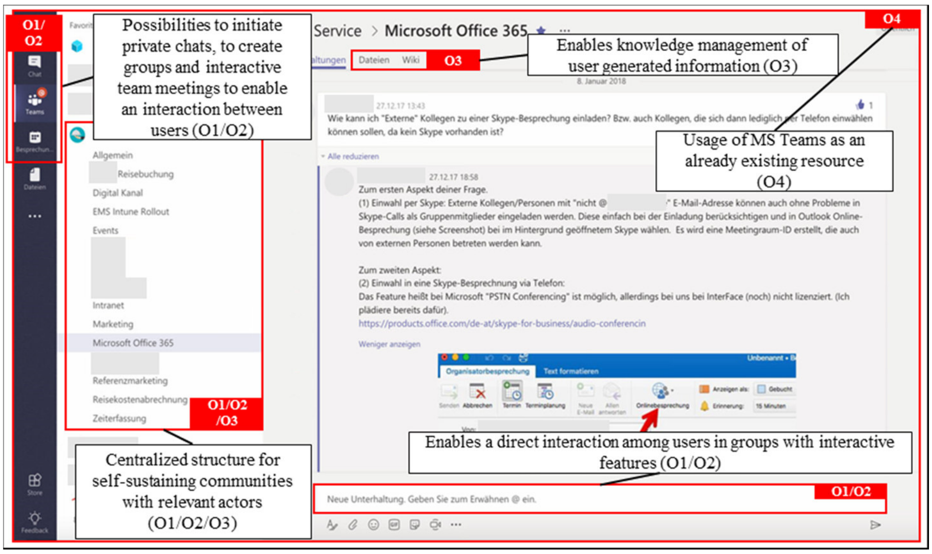

Figure 1. Frugal support structure in MS Teams

3.5 Evaluation and Communication

Evaluation of the FSS was based mainly on the analysis of usage metrics [36] as summarized in Table 2. Analysis of the log files showed that the new FSS was accessed by 163 of the approx. 250 employees from different departments, enabling them to interact and collaborate (Objective 1). Of these, 82 could be regarded as active users of MS Teams and were classified as publicly active, privately active or a combination of both. While only five users were only publicly active (i.e., their posts were accessible to all registered users), 15 employees were solely privately active, using only features like private chat messages to communicate. However, the largest group (62) used both private and public channels to interact with their colleagues. On average, publicly active employees created 34 public posts and 200 private chat messages per user (Objective 1).

The interaction between the different users for support reasons was organized in self-sustaining groups within MS Teams and was used by the employees to ask different questions, concerning the travel booking procedure, mobile device management, MS Office 365, time keeping, intranet, digital services or other general issues (Objectives 2&3). This area was frequently used by 27 users that created a total amount of 244 posts that could be divided into 200 on topic and 44 off topic posts. The employees asked 67 questions in this support structure and 61 of these were answered by other employees. On an average, three posts were created for each of the question asked on the platform.

The analysis of the resource availability showed that 46% of the users just seek information and 32% of them only responded to open questions. Nevertheless, 22% of the active users in the support area took both roles and searched for information as well as pro-vided useful comments on posted problems. While the traditional, ticket-based support clocked a response time of around one week, the frugal support system was able to respond to 90% of the posted questions/problems in less than one week time. Out of which, 73% of questions were answered within one day and 46% in less than two hours, validating a huge reduction of the standard response time through the FSS (Objective 4). However, it emerged that each of the support channels for travel booking, MS Office 365, etc. had one specialist who answered to the maximum number of questions. For example, for travel booking 39% of the posted questions were answered by a single specialist and in case of mobile device management the response from the specialist was as high as 83% of the posted questions.

Table 2. Summary of evaluation

Objective #	Achieved through…
1	•establishment of a wide and active user base •possibilities to communicate on a public and private level
2	•structured groups for different service topics
3	•knowledge sharing among users through their interaction
4	•usage of already established software •increase of response time in case of requests

4 Discussion

To assess the ability of frugal support structures to orchestrate available resources to address specific organizational constraints during IS implementation, the study included a design science research project. This revealed that establishing a frugal support structure can be related to the meta-theoretical foundations of S-D logic. The development of actor-to-actor networks fosters co-creation of value, both dyadic (between information seeker and support channel expert) and at extended network level, where other regular platform users try to help each other [3]. The platform itself supports liquefaction of resources through digital decoupling of single-user knowledge, making this information available to every member of the support structure [24]. High resource density is enabled by response rates that are achievable only by rapid mobilization of actors who can provide the relevant knowledge [4]. Finally, the frugal support structure helps to integrate resources through recombination of existing resources (in this case, IT infrastructure and knowledge), ensuring a level of utility for the whole organization beyond that of isolated resources [24].

The findings confirm that frugal support structures can be systematically developed to support the management of software implementation in SMEs or other settings where there are limited resources for training and change management. At the same time, the present case illustrates that frugal support structures are necessarily diverse and must be designed to ensure that implementation maximizes the potential benefits in each case. Further research on the management of online platforms is needed to devise suitable intervention strategies for increasing traffic and productivity on the platform.

5 Conclusion and Contributions

This article proposes a frugal approach to enhance existing support structures for new software introductions in resource-constrained SMEs. The findings confirm the close links between the frugal approach and S-D logic, where users and their knowledge are the most widely available resource, and value is co-created through integration of the actors' resources. The study confirms that user involvement is crucial, not only in overcoming the challenges of existing support structures but to make support structures more frugal and sustainable in the long run.

To date, the frugal literature has focused on emerging markets and on bottom-up product development approaches, neglecting the developed world, especially in the context of information systems and software implementation. This study is among the first to explore the application of the frugal concept to information systems in developed markets. Using the principles of S-D logic in combination with the frugal criteria of being resourceful and user-driven, the study suggests guidelines for developing a frugal support structure for software implementation. The findings contribute to the S-D logic and frugal innovation literatures. While past research applied S-D logic to the development of efficient customer networks and marketing business solutions [23], the link to frugal innovation contextualizes S-D logic in resource-scarce settings. Along with design principles for developing a frugal support structure, the study clarifies how interactional resources (such as technology) can act as enablers for the development of frugal solutions in developed world settings. Both of these new insights invite further research. From the IS perspective, this study also contributes to the research on software implementation, and in particular to the issue of user involvement, providing evidence of its tangible benefits in the post-implementation process, which remains largely unexplored in the existing literature.

Abstract. Driven by increasing amounts of data and by emerging technologies to store and analyze them, companies adopt Big Data Analytics (BDA) to improve their innovativeness and decision-making. However, adopting BDA across the company in the sense of an insight-driven organization (IDO) is challenging, since it influences the entire company and requires an organizational change. Despite mature knowledge, approaches that provide concrete methods for structuring the company-wide adoption of BDA to fully exploit the benefits of BDA and to reduce the risk of its failure are still missing. Following action design research, we developed and evaluated a method for structuring the company-wide adoption of BDA in a concerted research effort at a German bank. Based on knowledge of BDA and the roadmapping approach, the method structures the adoption along the BDA capabilities. We illustrate how companies can define a target state, identify gaps, and derive a BDA roadmap.

Keywords: Big Data Analytics, Roadmapping, Action Design Research.

1 Introduction

Inspired by big players, such as Google and Amazon, companies increasingly adopt Big Data Analytics (BDA) as an approach to utilize big data and advanced analytics for delivering value, improving efficiency, and establishing competitive advantage [1], [2]. The rapid growth of data generated by social media like Facebook and Twitter, as well as emerging information technologies (IT) like the Internet of Things, advance this trend [2], [3]. Additionally, the market increasingly offers more mature and powerful tools to source, store, and analyze big data, which lay the foundation for adopting BDA. Considering its technological capabilities and the associated high expectations, it is not surprising that BDA is – meanwhile – considered as a game changer, due to its operational and strategic potential [1]. Thereby, adopting BDA across the whole company instead of only using it within individual projects is considered as more beneficial since companies that use BDA as a competitive differentiator, – defined as insight-driven organizations (IDOs), – tend to perform better in terms of financial and operational results [4], [5]. They are champions in implementing BDA and improving the speed and quality of action through data-driven decisions [4], [5].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

However, a company-wide adoption of BDA is challenging as it requires a long-term evolution [3], involves different stakeholder groups, impacts various levels of the enterprise architecture, and needs high investment amounts [6]. Due to this complexity, a structuring approach is important to coordinate the individual measures, taking into account the dependencies in terms of content and time. Prior research has already revealed factors that may be relevant for a structured adoption of BDA. For example, [7] address the need for a clear vision of what companies want to achieve and a roadmap to reach the target. [4] concretize that companies should define the business challenges, identify the organizational changes needed, and derive a roadmap. However, they do not show how companies can apply this procedure. Furthermore, prior studies recommend the development of BDA maturity or capability models that allow companies to assess their current state regarding the required capabilities [8]. However, they fail to illustrate how these models can be used for a coordinated company-wide adoption of BDA. Finally, [5], [9] advise companies to start with seed or lighthouse projects for a few use cases to gain initial experience with BDA, encourage collaboration, and create awareness. Thereby, they do not consider the long-term changes. Thus, despite addressing important issues, approaches that provide concrete methods for structuring the company-wide adoption of BDA are still missing. In order to contribute to this research gap, we study the following research question: *How can developing a roadmap assist in structuring the company-wide adoption of BDA?*

In order to answer this question, we adopt action design research (ADR) and develop a method that aims to assist companies in structuring a company-wide adoption of BDA. In line with ADR, we develop and evaluate our method in a concerted research effort at a German bank [10]. The paper is organized as follows: Section 2 contains a brief overview of the related research. After introducing our methodology in Section 3, we describe our method's design in Section 4 and evaluate it in Section 5. We conclude by discussing implications, limitations, and directions for future research in Section 6.

2 Background and Related Work

Since our research is motivated by a concrete problem in practice, we have first discussed their needs with the end-users to achieve an in-depth understanding of the problem, and then researched the literature for appropriate methods to solve it. Therefore, this section provides a brief overview of the work related to BDA as the main content of the project and to roadmapping as one possible concept to approach the solution of the problem. As already recommended by prior research (e.g. [4], [7]), we focus on roadmapping to structure the adoption of BDA since it allows to define a target state, to identify gaps, and to derive and prioritize measures to reach the target state.

2.1 Big Data Analytics (BDA)

Prior research states that developing appropriate BDA capabilities can help companies to successfully adopt BDA in order to become an IDO. Thereby, studies define different BDA capabilities. For example, [11] identify culture, data management, and skills as the main dimensions of a BDA capability, whereas [1] define BDA infrastructure, personnel, and management capability as the key components. [8] identify thirty four generic capabilities, which they assign to eight capability fields (e.g. customer relationship management, strategy development, and transformation competence). Thereby, they state that the relevance of the capabilities might vary, depending on the scenario. Despite differences about the identified components and the level of granularity, all studies have a multidimensional perspective and address the need to develop BDA capabilities to successfully adopt BDA. Further, [4] provide an approach that could be the first step toward a BDA maturity model. They consider people, processes, and tools as the necessary building blocks for BDA and define three levels of BDA capability: aspirational, experienced, and transformed. Whereas aspirational organizations focus on process efficiency or process automation to cut costs, experienced organizations aim at optimizing their organizations by developing new ways to use BDA. Transformed organizations (i.e. IDOs) focus on using BDA as a competitive differentiator to expand their market position [4]. During the transformation, BDA expands from use in only selected business units toward organization-wide adoption [4], [9]. Further studies highlight the need for managing transformation effectively [5] and structuring it by defining a clear vision, identifying required changes, and deriving a roadmap to achieve the target state [4], [7]. Since the company-wide adoption of BDA might require a long-term evolution, companies can start with lighthouse projects for selected business units to gain initial experience with BDA [5], [9] and provide initial results by using prototyping.

2.2 Roadmapping

The roadmapping approach is a widely used management concept for supporting strategy and innovation [12]. It has been widely adopted at various levels of granularity from product to industry sector and also across various industries [6], [12]. Thereby, roadmaps can be used to communicate visions, to explore the development of the business and its components, to coordinate activities and resources, and to monitor progress [12], [13]. They also enable the alignment of different functions and perspectives within an organization, particularly business and technology [12]. The roadmaps are also very flexible and scalable, and can be customized to suit different strategic and innovation contexts [14]. The most general approach delivers a framework that addresses three key questions: 1) Where do we want to go? 2) Where are we now?, and 3) How can we get there? [12]. The first key question refers to the definition required for a target vision, the second one aims at covering the gaps between the status quo and the target vision, and the third one includes identifying, as well as structuring, the measures for achieving the target vision. The roadmap architecture consists of two dimensions: 1) timeframes, as well as 2) layers and sub-layers [12]. Timeframes are usually the horizontal axis and include short-, medium-, and long-term perspectives, as well as the past and vision. The layers and sub-layers are usually the vertical axis and show different levels of a hierarchical taxonomy. Since roadmaps can be used at various levels of granularity, the roadmap architecture should be customized to suit the aims and scope of the contemplated effort [12].

3 Research Method

In order to answer our research question, we relied on Action Design Research (ADR) to build, intervene, and evaluate our method. ADR involves the construction of an artefact, its intervention in the organization, and its evaluation by means of a concerted effort [10]. The developed artefact reflects, therefore, not only the theoretical precursors and the researchers' intent, but also the users' influence in organizational contexts [10]. Using ADR enabled us to design and fine-tune our method such that we could provide both academic insights and practical value. We implemented the four ADR stages. According to the first stage, – problem formulation, – we studied the research gap in the existing knowledge and outlined our research question in the introduction [10]. The second stage involves building, intervention, and evaluation activities. During this stage, we designed and evaluated our method at a German bank. In the third stage, – reflection and learning, – we continuously reflected on our method's design and analyzed the intervention results in context of our method's goals by integrating the feedback received from practitioners and end-users. In the fourth and last ADR stage that aims to formalize the learning gained throughout the project, we identified general insights about activities and techniques (cf. introducing our method below). In order to ensure that our method includes the relevant attributes and elements needed to design a new method, we further relied on the mandatory method components provided by [15] as shown in Table 1.

Table 1. Mandatory Method Components [15]

	Name	*Description*
Attributes	(A.1) Goal orientation	Methods must strive for achieving specific goals
	(A.2) Systematic approach	Methods must include a systematic procedure model
	(A.3) Principles orientation	Methods must follow general design guidelines and strategies
	(A.4) Repeatability	Methods must be repeatable in different contexts
Elements	(E.1) Activity	Task that creates a distinct (intermediate) output
	(E.2) Technique	Detailed instruction that supports the execution of an activity
	(E.3) Tool	Tool (e.g. method) that supports the application of a technique
	(E.4) Role	Actor that executes or is involved in the execution of an activity
	(E.5) Defined output	Defined outcome per activity (e.g. artefact, documents)

4 The Method Design

4.1 Design Principles

In line with ADR, we derive design principles for our method [16] from the existing theory and knowledge gained during the project [10]. As detailed above, a company-wide adoption of BDA is challenging as it affects various levels of the enterprise architecture and involves different stakeholder groups [6]. Thus, the company-wide adoption of BDA needs a clear vision of the target state, as well as a concept to capture the status quo, and to identify the changes needed to reach the target [4], [5], [7]. Thereby, a BDA capability model can provide guidance on which capabilities an organization should develop to become an IDO [4], [8]. This leads us to define the following design principle: *(DP.1) The method should allow for a precisely defined target state to be achieved by the adoption of BDA and identification of measures to close the gaps between the status quo and the target state. It should further take into account BDA capabilities needed as well as various levels of the enterprise architecture and stakeholder groups.* Besides, organizations also need guidance on how to proceed to reach the target state [4], [7] by prioritizing and structuring the identified measures [6] to coordinate the initiatives with regard to limited resources and predecessor-successor dependencies. As the company-wide adoption of BDA requires a long-term evolution [3] and high investments [6], definition of milestones might help to reevaluate and terminate the transformation project, if necessary. We therefore define the following design principle: *(DP.2) The method should allow for prioritizing and structuring the implementation measures according to the BDA capability developed by them and to the time of their implementation. It should further enable defining the milestones for reevaluation.*

4.2 Method Procedure Model

In keeping with [15], our method consists of activities (E.1), each of which includes techniques (E.2), tools (E.3), roles (E.4), and output (E.5) as summarized in Table 2. Our method comprises three activities: defining the target state, identifying and prioritizing the gaps, and deriving a BDA roadmap. Although tools can be defined as IT tools only, we use a broader definition of [15], [16] and focus on tools that support the application of one or more techniques.

Activity 1: Defining the target state

Technique: According to [12], activity 1's purpose is to address the question "Where do we want to go?" and to define the target state to be achieved by the adoption of BDA. First, the method user needs to define a target vision to have a common understanding of the target state. For companies that aim at using BDA as a competitive differentiator, becoming an IDO can be an appropriate target vision. In order to avoid a target vision being almost unattainable or only achievable with a great deal of effort, the method user can derive a second target vision as an intermediate step positioned between the status quo and an IDO. Furthermore, the intermediate step might allow a reevaluation of the targets and even a termination of the project, if necessary. Based on the defined target vision, the method user should define requirements that need to be fulfilled at the target state and group them according to appropriate dimensions to conceptualize the target state. Later on, these dimensions will be visualized as layers in the BDA roadmap. Since development of BDA capabilities can be an appropriate way to become an IDO, we recommend that selected BDA capabilities be used as roadmap layers. After conceptualizing the target state, the method user should operationalize it by breaking down the requirements into fields of action and group them into roadmap layers or sub-layers. The number of sub-layers should meet the appropriate degree of granularity. While too many sub-layers lead to a very detailed and overloaded roadmap, too little sub-layers would make it difficult to derive effective measures to close the gaps [12]. We recommend deriving a maximum of 5 – 8 sub-layers for any layer [12].

Tool: We recommend that all the activities of our method should be based on the roadmapping as a structuring approach [12] and techniques such as brainstorming and moderated group discussions [15] to generate and evaluate ideas. In order to derive layers and sub-layers of the roadmap, the method user can base on BDA capability models (e.g. [1], [8], [11]).

Roles: In order to carry out all activities of our method, we recommend that a project team, which can consist of internal and / or external experts in BDA and developing roadmaps, be assigned. The project team prepares and moderates discussions, interviews, and workshops. They also consolidate and analyze the input, and provide outputs. Since management support is a well-known success factor for projects with high transformation potential like the company-wide adoption of BDA [4], [6], activity 1 involves (senior) managers who are familiar with the organization's strategy.

Output: Activity 1's output is the target state(s) as well as fields of action grouped into layers and sub-layers.

Table 2. Overview of Method's Activities and Elements

Activity	*Technique*	*Tool*	*Role*	*Output*
Activity 1: Defining the target state	Define the target state based on selected dimensions	Roadmapping, BDA capability model, discussion	(Senior) Managers, project team	Target state, layers, sub-layers, fields of action
Activity 2: Identifying and prioritizing the gaps	Capture the status quo, identify and prioritize the gaps	Semi-structured interviews, fulfillment-importance matrix	Stakeholder, (senior) managers, project team	Fulfillment-importance matrix with prioritized gaps
Activity 3: Deriving a BDA roadmap	Derive and structure measures to close the gaps	Roadmapping	(Senior) Managers, project team	BDA roadmap with structured measures

Activity 2: Identifying and prioritizing the gaps

Technique: Consistent with [12], activity 2 aims at addressing the question "Where are we now?" as well as identifying and prioritizing the gaps between the status quo and the target state. In the first step, the method user needs to identify the experts who can give input on the derived fields of action (cf. *Roles* below). In the next step, they need to collect quantitative and qualitative data for further analysis to identify and prioritize the gaps by, for example, using the tools described below.

Tool: We recommend using semi-structured interviews [17]. The method user can include selected follow-up questions that match with the interviewees' areas of expertise to gain more insights. They can also include overarching questions to bring out the interviewees' expectations concerning their perceived challenges and opportunities regarding the company-wide adoption of BDA. In order to assess the status quo of fields of action in terms of their relevance and degree of fulfilment, we recommend using five-point Likert scales with 1 = irrelevant / not fulfilled at all and 5 = highly relevant / completely fulfilled. For identifying and prioritizing the gaps, the method user can adapt the fulfillment-importance matrix, which slightly resembles a mirrored version of Gartner's Magic Quadrant [18]. Therefore, they need to assign the fields of action according to their assessment of the matrix's four quadrants: "Invest!", "Manage Excellence!", "Reprioritize! or Disinvest!", and "Ignore!". The fields of action in the "Invest!" quadrant are the most important gaps and need to be closed by moving the associated requirements to the "Manage Excellence!" quadrant.

Roles: We recommend that the project team prepares, conducts, and analyzes the interviews. In order to gain sufficient information for a comprehensive report on the status quo, experts from different management layers and stakeholder groups should be interviewed (e.g. IT, finance, risk management, and sales departments). If necessary, the project team should consult the (senior) managers to identify the appropriate experts. Internal experts from projects with a similar focus (e.g. data quality projects) as well as external experts (e.g. consultants) that accompany these projects can also be interviewed. Each interview should be conducted by at least two project team members to avoid subjective interpretations of the answers.

Output: Activity's 2 output is a fulfillment-importance matrix with prioritized gaps.

Activity 3: Deriving a BDA roadmap

Technique: Following [12], activity 3 aims at addressing the key question "How can we get there?", as well as identifying the measures to close the gaps and structuring them in a roadmap. Method user should derive the measures and assign them according to the roadmap's sub-layers and layers. In terms of timeframe, the measures need to be structured according to their short-, medium-, and long-term perspective. Since the company-wide adoption of BDA requires a long-term evolution [3], a BDA roadmap might have a timeframe that spans over several years. Thus, the method user should consider intertemporal and scheduling interactions between the measures [6].

Tool: For identifying appropriate measures to close the gaps, method user can rely on knowledge about IDO, BDA, and BDA capabilities as well as brainstorming and discussions within the project team. For the latter, method user should be aware of limitations of relying on existing personal knowledge of the involved practitioners. A close collaboration between researchers and practitioners can help to reduce this bias if an intensive and reflective discussion process is ensured to combine the perspectives and insights from researchers and practitioners. For structuring the measures, we recommend deriving a roadmap as an established planning tool [12]. Thereby, the layers and sub-layers are based on the BDA capabilities derived in activity 1. The timeframe includes short-, medium-, and long-term perspectives.

Roles: The project team derives the measures to close the gaps from the literature, structures them in a roadmap, and evaluates the results with the (senior) managers.

Output: The output is a BDA roadmap with structured measures.

5 Evaluation

5.1 Case Study Setting

We conducted our study in the strategic department of one of the leading universal banks in Germany. Since the banking industry is exposed to increasing innovation pressure through changing client behavior [19] and new market players like FinTechs [20], financial service providers need to innovate their current value delivery and interactions with clients [21] through providing data-driven services, for example. As a financial service provider, the case-study bank particularly had a large volume of client data such as details on repayment behavior and outstanding loans or credit lines. However, the bank failed to systematically get value from its data and it also failed to provide data-driven services to its clients. Thus, the bank aimed at adopting BDA across the whole company to develop it towards an IDO and to capture BDA potentials like strengthening innovative power and improvement of decision-making. However, the bank faced various challenges for this project. For example, a lack of end-to-end processes, a lot of manual work involved in the processes and thinking in silos led to frequent breaks in information flows. In addition, the bank had a partially outdated IT architecture and outsourced IT. Finally, the bank put a lot of effort into regulatory-driven projects and thus had rather limited human and financial resources for innovation projects. This led to a lack of awareness for innovation projects in general and for a company-wide adoption of BDA in particular.

The objective of the case study was therefore to develop a method for structuring the company-wide adoption of BDA to shift the company toward an IDO. Thereby, the head of the strategy department and the CIO, who recognized the market relevance of BDA, were looking for a method that would allow them to show the potentials of BDA to create awareness and to include the entire organization as well. With regard to the challenges highlighted above, the new method should consider various perspectives (e.g. people and processes) to enable including different stakeholder groups and levels of the enterprise architecture. Since the board of directors would have to approve the new initiative, the new method should also allow to assess what exactly they want to achieve with the company-wide adoption of BDA, what the status quo looks like and how they aim to achieve the target state. Due to the high complexity of the project, the new method should provide guidance in covering which adoption measures are necessary, how long the adoption will last, whether there are dependencies between the measures and which resources will be necessary for their implementation.

The project team consisted of five academic members from the authors' institutions (two research fellows and three professors) with expertise in developing digital roadmaps and in the financial services industry. In addition, the project team included four members of a consulting company (two consultants and two senior consultants) with BDA expertise and experience in regulatory-driven projects conducted at the case-study bank. The head of the strategy department and his assistant were also part of the team. The external project team's role was to prepare and conduct workshops, as well as interviews, and to develop the BDA roadmap. The project lasted three months in total. The external team members mostly worked in the back office and were on site for workshops, interviews, and other meetings. The external project team predominantly worked three to four days a week on the project and spent the rest of the time synchronizing with colleagues who were working in similar areas.

5.2 Method Application

Activity 1: Defining the target state

In order to create a common understanding of the target vision, we first discussed the meaning of an IDO with the head of the strategy department and the CIO. Thereby, we defined an IDO as follows: An IDO anchors data-based decision-making processes throughout the company and classifies big data as a core capability with the aim of making value-creating insights available at the right place and at the right time. According to the feedback of the bank end-users, we derived a second target vision as an intermediate step on the way from the status quo to an IDO to take into account the current challenges of the bank (e.g. a lack of resources and awareness). Since a company-wide adoption of BDA requires high investments, this step was also defined as a milestone for reevaluating the targets and the project to adjust the resource allocation or to determine the project, if necessary. In order to better express the focus of both target visions, we named them "Lab" and "Factory". Following the recommendations of prior research (e.g. [4], [5], [9]), the target vision "Lab" aimed at using BDA in selected business units – mostly in the form of lighthouse projects, – which should serve as enabler of strategic corporate goals. The target vision "Factory" focused on a group-wide use of BDA as a competitive advantage and unique selling proposition in an IDO context. In the next step, we conceptualized the target states by deriving the roadmap layers based on five BDA capabilities of strategy, people, process, data, and technology. Since a company-wide adoption of BDA influences different levels of the enterprise architecture, the BDA capabilities should be oriented at these levels. With this in mind, we first drew up a list of possible BDA capabilities based on literature research and selected the most important ones for the bank in a workshop with the head of the strategy department. For example, developing strategy and people capabilities might help to increase company-wide awareness for BDA, whereas process capabilities would allow accelerating innovation and decision-making processes. Since BDA requires an excellent handling of data and advanced technologies to collect, store and analyze it, the bank finally needed to develop data and technology capabilities. In close collaboration with the head of the strategy department, we assigned the defined target visions to the layer strategy. We then derived requirements to be fulfilled at the target states and grouped them into the remaining layers as summarized in Table 3. Thereafter, we specified the requirements by breaking them down into the fields of action and grouping them into roadmap sub-layers. In sum, we derived twenty four fields of action (e.g. specialists, research environment, idea generation, and agility) and seven sub-layers (team structure, broad knowledge, innovation process, project management, data quality, data access and trust, and toolkit). Due to the challenges described above, several fields of action aimed at improving innovation processes (in particular increasing their speed) and promoting interdisciplinary collaboration to counter silo thinking.

Table 3. Target States at the Case-Study Bank with Selected Requirements

Layers	*"Lab"*	*"Factory"*
Strategy	Use of BDA in selected business units in the form of lighthouse projects which serve as enabler of strategic corporate goals	Group-wide use of BDA as a competitive advantage and unique selling proposition in the sense of an IDO
People	Specialists in selected functions	Specialists in all functions
Process	Focus on lighthouse projects to create awareness	Integration into daily processes
Data	Data standardization within the lighthouse projects	Data lifecycle management
Technology	Focus on visualization software	Use of advanced BDA tools

Activity 2: Identifying and prioritizing the gaps

We conducted eleven semi-structured interviews with heads and members of different departments (e.g. finance and IT), as well as internal and external experts involved in regulatory-driven projects (e.g. AnaCredit and BCBS#239). The interviews followed the fields of action defined in activity 1. In close collaboration with the head of the strategy department, we excluded the strategy capability from the questionnaire, because it was defined through the target visions. Each interview was conducted by at least two external project team members and lasted roughly one hour. The interviewed experts answered the questions for each field of action and assessed the relevance, as well as degree of fulfilment, on a scale of 1 to 5 with 1 = irrelevant / not fulfilled at all and 5 = highly relevant / completely fulfilled. We also included follow-up and overarching questions to gather qualitative data for further analysis.

In the next step, we aggregated the quantitative results for each field of action and assigned them to quadrants of a fulfillment-importance matrix as shown in Figure 1. According the five-point Likert scale, we defined the quadrants of the fulfillment-importance matrix by interpreting fulfillment values less than or equal to 3 and importance values less than 3 as low. We treated all fields of action located in the "Invest!" quadrant as gaps with a high priority and the fields of action assigned to the "Manage Excellence!" quadrant as gaps with medium to low priority. Based on our analysis, there were no fields of action assigned to the "Reprioritize! or Disinvest!" and "Ignore!" quadrants. This is reasonable, because evaluating the fields of action with practitioners and end-users in activity 1 already ensured that the most relevant fields of action were identified, also considering the organizational idiosyncrasies. We further evaluated the matrix by analyzing the qualitative insights from the follow-up, as well as overarching questions, and discussing our results with the head of the strategy department. Our first result was that the bank did well in a few central topics of the company-wide adoption of BDA, since many fields of action were located in the “Manage Excellence!” quadrant. For example, the bank made an effort to establish a data quality awareness within regulatory-driven projects. Most interestingly, the fields of action located in the “Invest!” quadrant were distributed almost equally across the four BDA capabilities. Therefore, deriving a BDA roadmap as a purely IT-driven effort would have neglected a substantial share of the relevant gaps. The gap analysis revealed that the first step was laying the foundations for an IDO by, for example, establishing a team of specialists, introducing an explicit research environment, and adopting basic technologies. On this basis, the bank could then begin with the more culture-oriented shift toward an IDO by focusing on generating innovative ideas, agility, and speed when it comes to the implementation of ideas.

Figure 1. Fulfillment-Importance Matrix at the Case-Study Bank

Activity 3: Deriving a BDA roadmap

We derived measures to close the gaps based on the literature review, as well as discussions with the head of the strategy department and the CIO. In the next step, we structured the measures in the BDA roadmap in terms of sub-layers and timeframe-dimensions. We also delivered a comprehensive documentation with a detailed description of each measure. For anonymization reasons, Figure 2 shows only a high-level BDA roadmap with selected measures structured into five layers (i.e. strategy, people, process, data, and technology) and three timeframe-dimensions (i.e. short-term phase 1, medium-term phase 2, and long-term phase 3). The target vision "Lab" should be reached at the end of phase 2, and the target vision "Factory" at the end of phase 3. Thereby, the planning reliability and granularity of measures are greatly reduced in phase 3 due to its long-term focus. We also included phase 0, which indicates the project start in the current year, as well as two evaluation loops at the end of phase 1 and phase 2 as a reevaluation or termination option.

In order to reach the target "Lab", within phase 1 and phase 2, we structured the measures aimed at creating BDA awareness and initiating a data-driven culture via lighthouse projects. These measures include, for example, recruiting internal and external specialists, as well as providing a research environment and technologies to carry out initial lighthouse projects. Further, measures like conducting lighthouse projects, providing the first prototypes through agile methods, and design thinking should foster idea generation, organizational agility, and speedy ideas implementation. The measures in phase 3 aimed at closing the gaps to reach the target vision "Factory". Measures like organization-wide training programs in BDA or agile (innovation) project management approaches should ensure innovativeness and speed. Organization-wide data quality measures need to enable a high-quality data as basis for BDA. Further, measures like the implementation of a data lake architecture and a central sandbox should provide a flexible and scalable technological base that e.g. allows for adopting various BDA technologies. In close collaboration with the head of the strategy department, we also included strategy-related measures in our roadmap (e.g. change management, as well as strategic alignment between BDA measures and ongoing IT and regulatory-driven projects).

	Start Phase 0	**Lab** Phase 1 (short-term)	Phase 2 (medium-term)	**Factory** Phase 3 (long-term)
Strategy	• Change management: Promoting agility & innovation, embedding BDA in corporate culture, developing a CoE for BDA • Strategic alignment: Closely interlinking BDA and IT roadmaps as well as regulatory projects			
People	Set-up of the BDA transformation project • Kickoff • Detailed planning • Concretization of the roadmap • Preparation and start of initial measures	• Internal and external specialists • Trust through lighthouse projects	• Individually training programs • BDA goal for middle management	• Training programs for specialists • Company-wide education programs
Process		• Agile project methods • Simplified administrative processes	• Innovation management for BDA • Explicit BDA process	
Data		• Mirrored database • Program for data quality	• Data integration within the pilot areas • DQM in the pilot areas	• Enterprise data framework • Company-wide DQM
Technology		• Software for the lighthouse projects • Prototypes for lighthouse projects	• Software deployment process • Lighthouse projects	• Cloud for high-performance analysis • Systematic adoption of new technologies

Completion & evaluation of first 2 lighthouse projects

Figure 2. High-Level BDA Roadmap at the Case-Study Bank

5.3 Method Evaluation

Regarding the evaluation of design artefact, we can state that the new method that we co-developed and applied at a German bank provides an initial proof-of-value, since it fulfills the requirements of the bank outlined in Section 5.1. In particular, the new method enabled the bank to structure the company-wide adoption of BDA by deriving a roadmap that considers various perspectives (i.e. strategy, people, process, data, and technology) and prioritizes measures to close the identified gaps. Furthermore, the end-users evaluated the new method as understandable and practicable. Moreover, the board of directors accepted it and the bank has already started initiatives to implement first projects proposed in the roadmap. From a more abstractive point of view, our method fulfills the content and domain-specific requirements defined by the two design principles (DP1 and DP 2) in Section 4.1. According to DP1, our method allows defining one or more target states and their operationalization by considering selected BDA capabilities as shown in activity 1. In activities 2 and 3, it enables identifying gaps and deriving measures to close these gaps by involving different stakeholder groups (e.g. through interviews). Finally, the new method considers various levels of the enterprise architecture when defining the layers and sub-layers of the BDA roadmap. According to DP 2, our method allows prioritizing and structuring the implementation measures in a BDA roadmap as illustrated in activity 3. It also enables considering dependencies between individual measures and defining the milestones for the project reevaluation. Finally, our method meets general requirements for a new method because it contains the mandatory method components summarized in Table 1. In terms of goal orientation, our method aims at structuring the company-wide adoption of BDA. As for principles orientation, our method is geared toward two design principles derived from the literature and fine-tuned with practitioners and end-users within an ongoing method evaluation by incorporating requirements outlined in Section 5.1. Repeatability and systematic approach are achieved by describing the method procedure model in detail and demonstrating its applicability at the case-study company.

Regarding the evaluation of design process, our method design follows the seven ADR principles. Within the first stage, we followed the ADR principle of practice-inspired research by illustrating that practice pays a lot of attention to BDA adoption. As for the ADR principle of theory-ingrained artefacts, our method bases on the existing knowledge related to BDA and roadmapping. During the second stage, we followed the ADR principles of reciprocal shaping and mutually influential roles, as well as authentic and concurrent evaluation by co-developing and evaluating our method in an iterative manner with the practitioners and the bank end-users. Through a continuous reflection on our method's design within the third stage, our method does not only reflect the preliminary design, but also the organizational shaping, as well as the practitioners' and end-users' feedback, thereby meeting the ADR principle of guided emergence. For example, activity 1 initially included defining one target state. After an evaluation with the bank end-users, we added the opportunity of defining more target states including a short explanation when it might be useful. In the fourth stage, we followed the ADR principle of generalized outcomes by providing general insights about activities for structuring a company-wide adoption of BDA.

6 Conclusion

In this study, we investigated how organizations can structure the company-wide adoption of BDA. Using ADR, we developed a new method for structuring the company-wide adoption of BDA by deriving a BDA roadmap. Based on knowledge of roadmapping and BDA, our method includes three activities: 1) defining the target state, 2) identifying and prioritizing the gaps, and 3) deriving a BDA roadmap. Consistent with ADR, we developed and evaluated our method in a concerted research effort at a German bank.

Our work contributes to both research and practice. From an academic perspective, we enrich the body of knowledge related to BDA by linking the concept of BDA capabilities with the roadmapping approach when developing a new method for structuring the company-wide adoption of BDA. In particular, we show how companies can develop a BDA roadmap by considering BDA capabilities. Furthermore, we extend prior research on BDA capabilities by applying the concept of BDA capabilities to a concrete use case and illustrating how this concept can help to structure the company-wide adoption. Thus, our work can serve as a starting point for developing BDA maturity models and investigating their application in practice. Practitioners can use our method as a guideline for structuring the company-wide adoption of BDA. They can customize our method by extending our dimensions based on the BDA capabilities or by using other dimensions. Moreover, our research might help to develop company-individual methods for structuring other complex efforts like innovation and business transformation projects.

Our research has limitations that can serve as further starting points for future studies. First, we derived a customized BDA roadmap and noticed a lack of holistic BDA capability models that can be addressed by further research. Further, our method focuses on deriving a BDA roadmap as a planning tool and neglects the implementation phase. Research based on successfully carried out but also failed BDA adoption projects could be helpful for ex post analyses of success factors and development of key performance indicators to manage the adoption. Developed and evaluated at a German bank, our method is to a certain extent company-specific. Nevertheless, many aspects of our method can be generalized. As in our case, organizations should ensure a multidimensional view of the BDA adoption. Our experience also corroborates the importance of a close collaboration between strategy department, IT department, and business units, as well as the roadmap alignment to ongoing IT and regulatory-driven projects. Conducting further case studies might provide further valuable insights and outline possible differences along industries or the type of adoption projects. Despite its limitations, our research postulates a method for structuring the company-wide adoption of BDA and serves as a basis for further research aimed at closing the outlined research gap.

Abstract. Despite being acknowledged for playing a pivotal role in facilitating innovations in the digital age, there is a lack of research on the multifaceted role of digital innovation actors. This paper provides a systematic, multi-disciplinary literature review on innovation actors in a digital and non-digital context. Based on a search of 149 high-quality journals and conference proceedings, we identified 110 articles as relevant and categorized as well as synthesized the knowledge on innovation actors' role and organizational antecedents in a digital and non-digital context. We find an increasing focus on innovation actors' role in user communities in a digital context. Moreover, literature on organizational antecedents puts a stronger emphasis on allocating resources to innovation actors outside the organization. By analyzing extant research we provide a comprehensive summary on current knowledge and outline opportunities for future research on digital innovation actors.

Keywords: Digital Innovation Actors, Organizational Antecedents, Literature Review, Digital Innovation, Digital Age

1 Introduction

Digital technology has given rise to a radically new type of innovation [1]. These digital innovations have been conceptualized as "carrying out new combinations of digital and physical components to produce novel products" [2, p.725]. The transformation in the nature of innovations' outcome has not only manifested itself in more heterogeneous knowledge [3], and an increased importance of network effects [1] but has also given rise to a more distributed agency [4]. Consequently, a new set of digital innovation actors with distinct proficiencies has emerged [1].

The innovation management literature has acknowledged the importance of innovation actors early on by pointing out their key role in innovation development: "A new idea either finds a champion or dies" [5, p.84] and "successful innovation […] require a special combination of entrepreneurial, managerial and technical roles" [6, p.59]. Innovation actors are defined as stakeholders who promote an innovation vigorously through the various stages of the development process against resistance and by taking risks [5–8]. Existing reviews in innovation management [e.g., 7, 9]

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

have considered the concept of innovation actors through the perspective of their particular subdiscipline, without considering the new materiality of digital innovation.

In a digital context, a number of studies with various research foci have explored digital innovation actors' roles and organizational antecedents [e.g., 10, 11]. However, literature reviews that synthesize the current state of knowledge on digital innovation actors are very scarce so far [12]. Thus, existing reviews focus on digital innovation, but neglect to consider literature on innovation actors [e.g., 13, 14]. Moreover, no comprehensive literature reviews exist that explore fundamental differences in innovation actors' roles and organizational antecedents in a digital and non-digital context. Changes in innovation actors' roles and organizational antecedents that are caused by the distinct materiality of digital technology are unclear so far [1, 3]. With the rising importance of digital technology and the increasing prevalence of digital innovation such research is important. Organizations can only identify innovation actors and promote them by creating fitting organizational conditions, if innovation actors' roles in a digital and non-digital context are sufficiently clear [15].

Literature acknowledges this gap and called for future research to explore innovation actors' roles in a digital context by acknowledging "the complexity of how their actions interact with, and can be shaped by, a wider change process" [12, p.108]. Therefore, we explore the following two research questions:

RQ1: What are distinct roles of innovation actors in a digital and non-digital context?
RQ2: Which organizational characteristics promote or hinder innovation actors in a digital and non-digital context?

In a nutshell, this research article provides a comprehensive literature review on innovation actors' roles and organizational antecedents in a digital and non-digital context. By presenting an in-depth analysis of four subdisciplines and synthesizing findings from an individual and organizational perspective, this literature review offers the opportunity to build a thorough understanding of innovation actors. Based on differences in digital and non-digital innovation literature, we also identify gaps in existing research and provide practical implications.

The paper is structured as follows. While the next section outlines the methodology, section 3 describes the findings of our content-based analysis. Next, we discuss our results with implications for theory and practice and identify avenues for future research. Finally, we delineate our study's limitations.

2 Methodology

With respect to the methodology, a narrative literature review [16] was performed following a systematic and transparent methodology based on Paré et al. [17]. For the purpose of assuring the findings' quality, our search process compromised six steps adopted from Rowe [18]: selecting research questions, choosing sources, creating a search string, applying methodological and practical screening criteria, categorizing and reviewing literature's findings as well as synthesizing the results.

First, we selected a research question (see section 1). In a second step, we chose the sources for our literature search by opting for leading journals in four subdisciplines, information systems, organization and human resources, business administration as well as technology, innovation and entrepreneurship to account for the interdisciplinary nature of the research theme. A meta-ranking (Journal Quality List [19]), which incorporates 12 different journal rankings (e.g., Financial Times 50 Ranking 2016 or German VHB-JOURQUAL3), was used to evaluate the publication outlets. The 149 selected publication outlets were classified as leading journals in the majority of these rankings and include among other outlets the AIS Senior Scholars' Basket of 8. When considering, for instance, the German VHB-JOURQUAL3 we included all journals, ranked in the categories A+, A or B. The literature search was restricted to the time frame 1995 to 2018, because the year 1995 marks the beginning of the Internet commercialization, characterized by the elimination of the last restrictions on its commercial use [20]. This acknowledges innovation actors' high importance for digital innovation development [21] and enables us to draw a comparison between a digital and non-digital context.

In a third step, we created and utilized an extensive search string within the selected journals including five keywords: innovation, championing, level of analysis, characteristics and context. As depicted in Table 1 each keyword was covered by a variety of search terms, including synonyms as well as corresponding adjectives and verbs. To cover innovation actors comprehensively as well as systematically and to limit prepossessions on the research topic, we chose a broad range of synonymous and overlapping search terms to characterize innovation actors who promote innovation. We consolidated activities, such as brokering and promoting to cover innovation actors' roles in both a non-digital (e.g., innovation champions [8]) and digital context (e.g., lead users [10]). Moreover, we consider innovation actors both from an individual and organizational perspective.

Table 1. Search string

Keyword	*Search terms*
Innovation	("innovat*")
Championing	("champion*" OR "promot*" OR "boundary spann*" OR "broke*" OR "recombin*" OR "cataly*" OR "sponsor*" OR "corporate entrepreneur*" OR "blog*" OR "challeng*" OR "use*" OR "develop*" OR "influenc*")
Level of Analysis	("individ*" OR "personal*" OR "user*" OR "human" OR "employee") OR ("organi?ation*" OR "network*")
Characteristics	("characteristic*" OR "behav*" OR "attribute*" OR "trait*" OR "propert*" OR "qualit*" OR "capabilit*" OR "structure*" OR "culture*" OR "factor*" OR "requirement*" OR "variable*" OR "element*" OR "competence*" OR "nature*" OR "personalit*")
Context	"digital"

At least one search term related to each keyword had to appear either in the title, the abstract or the subject terms in order to be considered relevant for our literature review. Accordingly, a complete search string was generated. Next, a literature search was executed by using this search string and a meta-search engine, based on 202 different databases, such as EBSCO Business Source Complete, and containing all relevant 149 publication outlets. We ran our search both with and without the search term “digital” to cover both a digital and non-digital context. In the search, 1178 research articles were identified as potentially relevant.

In a fourth step, we screened the potentially relevant research articles grounded on five methodological and practical criteria. The examined articles had to (1) include a research methodology, (2) address aspects of the innovation process, (3) analyze an actor championing innovation, (4) adopt an individual or organizational perspective, and (5) not focus on the macro level. First these filtering criteria were applied to the title, abstract and keywords resulting in a reduction of the relevant research articles to 270. Second, the full text was screened, which led us to 85 relevant research articles. Following Webster and Watson [22], we then performed a backward (i.e., reviewing older literature quoted in the relevant papers) and a forward search (i.e., reviewing sources that quoted the article) to include all literature sources on innovation actors, which resulted in 25 additional research articles. Overall, the final sample consisted of 110 relevant papers.

Fifth, we categorized and reviewed literature’s findings. We covered innovation actors both from an individual and organizational perspectives by categorizing the content of the research articles into (1) (digital) innovation actors’ roles and (2) six dimensions of organizational antecedents. The different roles of innovation actors were derived in an iterative and inductive process. To analyze literature on organizational antecedents systematically, we adopted a categorization from prior research [23–25] that has found these six organizational characteristics[1], structure [24], human resource (HR) practices [25], culture & climate [24], resource allocation [24], knowledge management [24], and strategy [24], to influence organizational innovativeness. Finally, we synthesized literature’s findings, as elaborated in the following section (step 6).

3 Analysis

In the following, we first analyze innovation actors’ roles (individual perspective). Next, we outline our findings on organizational antecedents, characteristics that facilitate or hinder innovation actors’ innovativeness (organizational perspective). Figure 1 illustrates our theoretical framework based on our categorization schema.

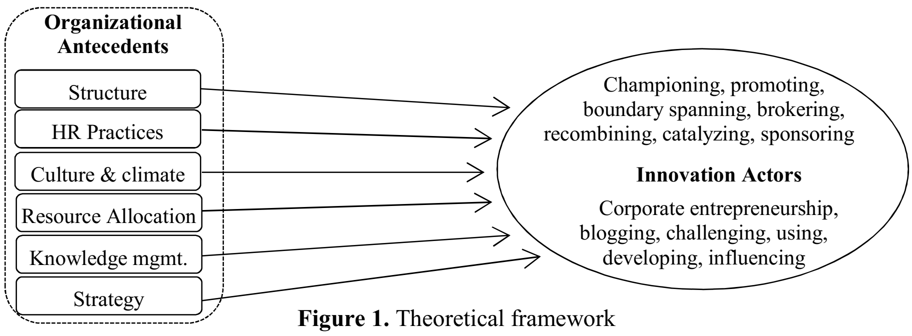

Figure 1. Theoretical framework

[1] A table depicting the definitions of the different categories can be accessed here: https://bit.ly/2ToX7cS

3.1 Roles of Innovation Actors

Innovation Actors in a non-digital context. Our analysis showed that we can distinguish between a number of innovation actors in a digital and non-digital context. The innovation champion constitutes one of the earliest identified innovation actors [5], who promotes an innovation vigorously through the various stages of the development process against potential resistance by taking risks [e.g., 6, 8]. Innovation champions have been described as motivating their innovation team [e.g., 26], inspiring others with their vision [e.g., 15], transferring information and knowledge [e.g., 27], connecting with others and building networks [e.g., 26], bringing different actors in the organization together [e.g., 28] and gaining management support [e.g., 8]. Besides the innovation champion, further types of innovation actors[2] have been identified as summarized in the following table.

Table 2. Roles of Innovation Actors in non-digital and digital context

Roles of Innovation Actors	*Exemplary Sources*
Innovation champion – Innovation actor who promotes an innovation vigorously through the various stages of the development process against potential resistance by taking risks. [6, 27] (Synonym: *process promoter*)	*Non-digital:* [8, 28] *Digital:* [29]
Corporate entrepreneur – Innovation actor who creates a new venture or initiates renewal or innovation within an existing organization by combining four competencies: inventing, brokering, championing and sponsoring. [30]	*Non-digital:* [31, 32] *Digital:* [33, 34]
Sponsor – Innovation actor who holds a managerial position and uses his or her formal power to support an innovation by supplying or obtaining resources, lending legitimacy or giving advice. [6, 27] (Synonym: *power promoter*)	*Non-digital:* [30, 35] *Digital:* [11, 36]
Boundary spanner – Innovation actor who is responsible for the interaction of an organizational unit or organization with its environment. [27, 37] (Synonym: *relationship promoter*)	*Non-digital:* [35, 37] *Digital* [38]
Knowledge broker – Innovation actor who facilitates information flows by transferring knowledge important in the innovation process between otherwise unconnected actors. [39]	*Non-digital:* [39, 40] *Digital:* [41]
Lead user – Innovation actors on the user side who detects problems, generates ideas for improvements to existing products and subsequently carries out modifications to generate an innovative product. [10, 42]	*Non-digital:* - *Digital:* [43, 44]

Innovation Actors in a digital context. The roles of innovation actors described above are also mentioned in a digital context. At the same time, digital technology gives rise and puts special emphasis on two roles, lead users and sponsors. Lead users have been shown to drive innovations from a user perspective in a digital context [e.g., 10, 43]. They communicate and collaborate with other (lead) users in user communities via digital platforms or technologies and apply their own knowledge and

[2] Even though roles of innovation actors have been characterized extensively in the literature, we only focus on the most frequently mentioned activities characterizing innovation actors. Therefore, the cited references only represent a selection of the research articles that we considered in the analysis overall.

knowledge exchanged with other users to advance products and drive innovation [e.g., 42]. A purely user-specific role of innovation actors has only been enabled by the distinct characteristics of digital technology. Moreover, literature in a digital context puts a stronger emphasis on the role of sponsors. Especially the new organizational role of the chief digital officer, one type of sponsor, has gained considerable significance, as these innovation actors in management positions drive an organization's digital transformation and champion digital innovation [e.g., 11].

3.2 Organizational Antecedents

We now analyze how idiosyncratic characteristics of an organization influence and shape innovativeness of digital and non-digital innovation actors following the framework depicted in Figure 1. All findings are summarized in Table 3[3].

Structure. As an organizational antecedent to innovation actors' effectiveness in a non-digital context organizational structure has been widely studied. A high degree of centralization in decision-making and a high degree of formalization of behavior through rules and procedures have been found to form barriers for non-digital innovation actors' emergence and effectiveness [e.g., 37, 45]. In contrast, a low degree of vertical differentiation, i.e. the existence of few hierarchical levels, and structuring an organization into teams and based on projects, an aspect of horizontal differentiation, enhances non-digital innovation actors' activities [e.g., 30].

These findings for the non-digital context are in line with evidence found in a digital context. Thus, Ansari and Munir [43] find that organizations need to move from a structure characterized by hierarchy and control to a structure that enables collaborative and interactive innovation with digital innovation actors in user communities. In addition, digital innovation research also focuses on other aspects of organizational structure. For instance, digital innovation actors in high hierarchical positions can only champion innovation effectively if their role is defined clearly and in alignment with other executive positions [e.g., 11, 36].

HR Practices. With respect to HR practices, research in a digital or non-digital context shows similar findings but addresses distinct types of innovation actors, respectively. When focusing on performance appraisal, sanctions due to failed innovation projects are likely to impede the emergence of non-digital innovation actors. Contrarily, rewards compensating innovation actors for innovation success enhance their emergence in a non-digital context [e.g., 32, 45]. However, non-digital literature disagrees whether performance appraisal should be based on innovation-promoting behavior [30] or innovation accomplishments [45]. Digital innovation research finds that performance appraisal needs to also compensate digital innovation actors in user communities for innovation success monetarily [e.g., 46] or through non-financial measures, such as recognition or rewards [e.g., 10, 44] to enhance

[3] In Table 3 different organizational characteristics are considered from the perspective of drivers only. As elaborated, for some of these factors only the counterfactual relations with innovation actors have been explored. In the illustration in Table 3 we inversely code barriers in order to display drivers.

digital actors' activities. Additionally, Tumbas et al. [11] point out the importance of defining key performance indicators for all executives driving digital innovation.

On staffing practices non-digital innovation literature remains largely silent and only proposes hiring employees with distinct personalities [e.g., 30] to spur innovation actor's emergence. In a digital context, hiring employees with high experience inside and outside the organization is found to be positively associated with innovation-promoting behavior [e.g., 41]. When considering a group of digital innovation actors that work together to advance an organization's innovation projects, Van Laere and Aggestam [29] propose that a diverse group of individuals who possess complementary skills, knowledge, and social networks should be hired to enhance digital innovation actors' effectiveness. Additionally, in digital innovation processes that incorporate a user community hiring leaders of the community as gatekeepers between community and organization can enhance innovation promotion within the user community, because these gatekeepers moderate the exchange and simultaneously maintain the boundaries between community and firm [e.g., 44].

Training employees is another aspect of HR practices that has been shown to be positively associated with innovation actors' emergence and effectiveness in both research streams [e.g., 31, 37]. While non-digital literature generally focuses on employees, in a digital context the training of external users is also beneficial for the emergence of digital innovation actors [e.g., 44].

Culture & Climate. Non-digital literature finds that a culture supportive towards innovation [31, 32] is positively associated with innovation actors' activities. Both digital and non-digital innovation research agree that a long-term outcome orientation of the business culture [e.g., 30, 34] as well as culture tolerant of failure [e.g., 10, 31] and risk rewarding [e.g., 32, 47] encourage (digital) innovation actors' emergence and effectiveness. Additionally, in a digital context organization's culture needs to adapt to external users' participative role in the innovation process to encourage the emergence of innovation actors in user communities [e.g., 43]. Going one step further, Parmentier and Mangematin [44] find that organizations need to work towards identity convergence of user community and organization by sharing identifying elements and building common values embedded in products and services.

Resource Allocation. The non-digital literature on resource allocation's influence on innovation actors presents a positive effect of provisioning financial resources and time to pursue innovation [e.g., 32], as well as management legitimization to use existing resources or networks [e.g., 47]. In a digital context, the availability of digital technology can promote, and limitations to technological capabilities can hinder innovation actors' promotion of innovation [e.g., 33, 48]. If no formal allocation of resources towards digital innovation occurs, a lack of internal control benefits digital actors' effectiveness, because it allows the diversion of funds and employees [e.g., 34]. Additionally, literature on digital innovation emphasizes allocating resources to the innovating user community. The provision of tools for innovation-promoting activities as well as support towards the community (e.g., through community events) can enhance digital innovation actors' emergence [e.g., 10, 44].

Table 3. Organizational antecedents of non-digital and digital innovation actors

Category	*Non-digital innovation actors*	*Digital innovation actors*
Structure	Low centralization and formalization [e.g., 37, 45] Low vertical differentiation [e.g., 30] Horizontal differentiation into teams [e.g., 30]	Structure enabling collaborative and interactive innovation [e.g., 43] Definition and alignment of role on executive level [e.g., 11, 36]
Human Resource Practices	Existence of rewards, but no sanctions [32, 45] Performance appraisal based on innovation-promoting behavior [e.g., 30] or innovation accomplishment [e.g., 45]	Monetary compensation [e.g., 46] or non-financial rewards for digital innovation actors in user community [e.g., 10, 44] Definition of key performance indicators on executive level [e.g., 11]
	Hiring employees with distinct personalities [e.g., 30]	Hiring employees with high experience inside and outside organization [e.g., 41] Hiring diverse group of individuals with complementary skills, knowledge and social networks [e.g., 29] Hiring leaders of community as gatekeepers [e.g., 44]
	Training of employees [e.g., 31, 37]	Training of external users [e.g., 44]
Culture & climate	Culture supportive towards innovation [e.g., 31, 32] Long-term outcome orientation [e.g., 30] Culture tolerant of failure and risk rewarding [e.g., 31, 32, 47]	Long-term outcome orientation [e.g., 34] Culture tolerant of failure and risk rewarding culture [e.g., 10] Adaption of culture to users' participative role [e.g., 43] Identity convergence of user community and organization [e.g., 44]
Resource allocation	Provision of financial resources and time [e.g., 32] Management legitimization to use existing resources and networks [e.g., 47]	Availability of digital technology and technological capabilities [e.g., 33, 48] Lack of internal control allowing the diversion of funds [e.g., 34] Allocation of resources to user community [e.g., 10, 44]
Knowledge Mgmt.	General learning orientation of organization [e.g., 31] Organizational support towards knowledge exploitation and recombination [e.g., 49]	Tools and databases supporting the sharing, exchange and creation of knowledge [e.g., 10, 50] Creation of interaction possibilities in user community [e.g., 10, 44] Sharing knowledge with external users [e.g., 10, 44]
Strategy		Effective IT governance structure [e.g., 36] Opening content to user community without losing control [e.g., 43, 44, 46]

Knowledge Management. With respect to knowledge management, non-digital literature is relatively silent and only proposes that a general learning-orientation in organizations [e.g., 31] and organizational support towards knowledge exploitation and recombination [e.g., 49] strengthen innovation actors' emergence and effectiveness. In a digital context, tools and databases that support the exchange and creation of knowledge promote digital innovation actors' effectiveness [e.g., 10, 50]. In innovation processes incorporating a user community, organizations can promote digital innovation actors' effectiveness by creating multiple possibilities of interaction (e.g., setting up discussion areas) to foster the exchange of explicit and tacit knowledge and by actively sharing knowledge [e.g., 10, 44].

Strategy. While non-digital literature is relatively silent on the role of strategy for innovation actors' emergence and effectiveness, digital technology poses new challenges that need to be addressed. Thus, for digital innovation actors on the executive level an effective information technology (IT) governance structure is a requirement for their effectiveness [e.g., 36]. In innovation processes involving a user community, organizations' optimal strategy to promote digital innovation actors' emergence incorporates opening (proprietary) content [e.g., 46] without losing control of the innovation outcome [e.g., 43, 44].

4 Discussion and Areas of Future Research

This research offers a comprehensive literature review on differences in innovation actors' roles (RQ1) and organizational antecedents (RQ2) in a digital and non-digital context. Theoretically, we contribute to literature by providing an in-depth analysis of research in four subdisciplines. By contrasting findings on innovation actors in a digital and non-digital context and taking both an individual and organizational perspective, our literature review offers insights into changes caused by the distinct materiality of digital technology and aims to close the identified gap in literature [12]. Based on our findings, we also provide recommendations and research questions for promising avenues of future research (see below).

Practically, we contribute to literature by offering organizations' management important insights into changes in innovation actors' roles due to the digital transformation. By synthesizing differences in organizational antecedents in a digital and non-digital context, we also enable organizations to provide adequate framework conditions to support innovation actors and enable the championing of innovation.

4.1 Roles of Innovation Actors

With regard to the roles of innovation actors (see subsection 3.1), our analysis shows that most roles of innovation actors hardly vary in a digital compared to a non-digital context. At the same time, research points to the rise of a new role, lead users in innovation collectives (i.e., user communities), and puts a higher emphasis on one role already known in a non-digital context: sponsors (e.g., chief digital officers) [11, 43]. The reason and importance of these changes remain unclear throughout existing literature. Furthermore, we observe that research on digital innovation actors' roles is rare, indistinct and ambiguous. Literature in a digital context rarely provides a characterization of innovation actors that goes beyond a description of innovation actors' behaviors and incorporates their knowledge, skills and personality profile.

Additionally, innovation actors show different degrees of homogeneity in a digital and non-digital context. Thus, innovation actors' roles in a non-digital context are characterized by similar behaviors and share common objectives (i.e., innovation champion and corporate entrepreneur) [27]. In contrast, innovation actors' roles in a digital context vary more greatly. While sponsors in a digital context, such as chief digital officers, are part of the management board [11], lead users can rarely influence organizations' strategic decisions [42]. At the same time, these heterogeneous, digital innovation actors are increasingly part of a group or innovation community [29, 42]. Since, the scarcity of research on groups of innovation actors in a non-digital context limits the implications that can be derived for a digital context, the characteristics and compositions of such groups offer another area for future research. By considering and combining the results on innovation actors' role, Table 4 integrates and concludes with recommendations for future research and proposes research questions.

Table 4. Research agenda for future research on innovation actors' roles[4]

Recommendation	*Selected research questions for future research*
Researchers should investigate innovation actors' roles in a digital context	**Why do new roles, such as lead users in innovation collectives, arise and why does the emphasis with respect to existing roles change?** How important are these changes for digital innovation?
	What characterizes digital innovation actors' knowledge, skills and personality?
	How do digital innovation actors' goals and motivation differ from those of non-digital innovation actors due to the rise of digital technology?
	How do innovation actors develop the skillset required for digital innovation?
Researcher should analyze characteristics and compositions of groups of digital innovation actors	**How can groups of innovation actors as well as their composition be characterized?**
	What are the factors enabling or hindering the collaboration of digital innovation actors in a group?
	Does artificial intelligence change the collaboration of digital innovation actors in innovation communities?

4.2 Organizational Antecedents

With regard to the organizational characteristics that enable or hinder innovation actors, our results reveal changes in organizational antecedents associated with the distinct materiality of digital technology. We find that literature focuses on different aspects of innovation actors' organizational antecedents in a digital compared to a

[4] All research questions in Table 4 and 5 were derived from the literature review's findings. Research questions in bold are discussed in detail in the respective subsection.

non-digital context. Digital innovation literature puts a stronger focus on the inclusion of innovation actors outside the organization (i.e., lead users), for example, by allocating resources and training these actors. Moreover, only a small number of articles examine organizational antecedents in a digital context [e.g., 33, 46]. These papers remain very generic and have mainly other research foci, so that organizational antecedents are only covered shallowly. Since organizational antecedents have been shown to play such an important role in enabling organizational innovativeness [e.g., 24], future research should explore a number of aspects in depth.

The existing literature on organizational antecedents in a digital context points in one direction: the digitization of work environments initiates change, which rapidly redefines the interaction of individuals and organizations. We observe that organizational boundaries are weakened as user communities play an increasingly important role. For instance, with respect to the organizational structure, literature finds that a structure enabling collaborative and interactive innovation not only inside the organization but also in user communities outside the organization is beneficial for digital innovation actors [43]. Similarly, in a digital context organizations not only need to create a culture internally but also have to establish a shared culture with the user community [44]. In the future, digital technology could lead to the dissolution of traditional organization structures towards virtual organizations with a loose accumulation of innovation actors and new forms of collaboration between them [1]. Challenges connected to these developments have not been addressed in existing literature so far.

Issues could, for instance, arise with respect to resource allocations to digital user communities. A virtual organization would not only need to provide appropriate IT infrastructure and resources to the digital user community, but also ensure the correct and targeted usage. Yet, the tracking of resources to secure efficient usage in a digital environment could prove to be more challenging as innovation actors would be scattered all around the world. Moreover, with the increasing heterogeneity of the innovation actors, the individual requirements to IT infrastructure might diverge [4], further adding to the challenge. Therefore, questions on how to allocate and use resources efficiently to avoid the waste of resources need to be explored in-depth in the future. Similarly, if innovation actors collaborate with organizations spontaneously using digital platforms in user communities, it will be difficult to track their knowledge and skills. Due to the nature of platforms, innovation actors will vary and their composition fluctuate [51]. As a result, knowledge becomes more tacit and fluid [3]. To face this challenge new knowledge management systems have to be created and new avenues for future research exist.

While we have discussed on a limited number of potential avenues for future research in the following, Table 5 integrates and concludes with more elaborate recommendations and research questions for future research on organizational antecedents.

Table 5. Research agenda for future research on innovation actors' organizational antecedents

Recommendation	*Selected research questions for future research*
Researchers should investigate innovation actors' organizational antecedents in a digital context:	**Why do organizational antecedents promoting or hindering digital innovation actors change due the rise of digital technology?** Do organizational antecedents that promote or hinder non-digital innovation actors also affect digital innovation actors? Which additional organizational factors could hinder the evolution and development of digital innovation actors?
Structure	**Which structure is required to enable collaborative and interactive innovation among digital innovation actors not only inside the organization but also in user communities outside the organization?** How can organizations establish such a structure?
Human Resource Practices	What are appropriate incentives to motivate digital innovation actors? How can HR departments identify digital innovation actors? How can non-digital innovation actors evolve into digital innovation actors? How can organizations support non-digital innovation actors in this endeavor?
Culture & climate	**How can organizations create a culture that supports digital innovation actors both inside and outside an organization in their endeavor to promote innovation?**
Resource allocation	**What are the requirements for appropriate IT infrastructure and resource allocation to digital innovation actors in virtual organizations?** **How can organizations promote efficient use of resources among heterogeneous innovation actors in innovation communities?** What are the diverging requirements of digital innovation actors with respect to IT infrastructure and resources?
Knowledge Management	**What are the requirements for organizations' knowledge management systems to track knowledge and skills of digital innovation actors in user communities?** How can organizations ensure an appropriate and complementary composition of innovation actors' knowledge and skills in user communities?
Strategy	How can organizations manage the strategic challenge of opening proprietary content to digital innovation actors in innovation communities without losing control of innovation outcomes?

5 Limitations of the Literature Review

After the preceding analysis and discussion of our findings we also acknowledge some limitations. The selection of publications of our review restricts the results of our analysis. The review is based on 149 publication outlets selected using a meta-ranking (Journal Quality List [19]), covering 12 different journal rankings. Although this selection ensures the high quality of our literature base, some relevant contributions, such as scientific books [e.g., 52] or whitepapers, may be missing in the review due to the restriction of our sample to peer-reviewed publications. Similarly, by limiting the time frame of our search to 1995 to 2018 we risk the exclusion of relevant literature. Since the concept of the innovation actors was first mentioned in 1963 [5], relevant research articles might have been published prior to 1995. However, we solve this problem by relying on backward search to complement our sample of the relevant literature [22].

Moreover, the coding and categorization of innovation actors' roles and organizational antecedents may have been subject to mistakes. Yet, since we relied on two independent coders, who followed an orderly and rigorous coding approach, the number of mistakes was kept to a minimum. Accordingly, a high reliability and validity of the findings of our analysis was secured [53].

Abstract. Digitalisierung und fortwährend steigende Anforderungen an den Servicedesk führen dazu, dass zur Unterstützung bei der Kommunikation mit Kunden zunehmend autonome Software-Agenten, sog. Chatbots, zum Einsatz kommen. Mit dem dadurch steigenden Automatisierungsgrad lassen sich Effizienzverbesserungen und Einsparpotenziale realisieren. Allerdings hängt die Akzeptanz der Chatbots bei den Kunden von dem durch diese wahrgenommenen Nutzen ab. Im Rahmen dieser Arbeit wird eine Methode zur Bewertung des Kundennutzens von Chatbots im Bereich des Servicedesks entwickelt und evaluiert, die sich eines domänenbezogenen Fragekatalogs und spezifischer Bewertungskriterien bedient. Dabei folgt die Arbeit dem konstruktionsorientierten Forschungsansatz mittels Design Science Research Process und konzentriert sich auf die Bewertung von Chatbots aus Kundenperspektive.

Keywords: Servicedesk, Chatbot, Kundennutzen, Bewertungsmethode, Evaluierung

1 Einleitung

Im Zuge der Serviceorientierung im IT-Management hat sich der Servicedesk unternehmensintern als zentrale Kommunikationsschnittstelle zwischen IT-Organisation und ihren Nutzern weitgehend etabliert [1]. Als Vorbild dienten Organisationseinheiten im Kundenservice von Unternehmen. Diese haben die Aufgabe, den Kontakt mit externen Endkunden zu professionalisieren und dadurch die Kundenzufriedenheit zu verbessern [2]. Im Bestreben, Kundenanliegen schneller und effizienter zu bearbeiten, dabei zugleich aber auch Kosten zu reduzieren, setzen Unternehmen in letzter Zeit verstärkt sog. Chatbots ein [3]. Diese Software-Agenten zeichnen sich durch ihre (begrenzten) Fähigkeiten zur Verarbeitung natürlicher Sprache aus und ermöglichen dadurch eine weitere Automatisierung der Kunden- bzw. Nutzerschnittstelle [4]. Dabei stehen großen Erwartungen an die Automatisierungspotenziale durch Chatbots seitens der Unternehmen nicht weniger große Vorbehalte seitens der damit konfrontierten Zielgruppe gegenüber. So lehnen laut einer Studie aus dem Jahr 2017 [5] ca. 70 Prozent der Deutschen die neuen Sprachassistenten ab. Als eine mögliche Ursache für diese Ablehnung liegt eine mangelnde Nutzenstiftung durch Chatbots aus Kundensicht nahe. Neben dem Risiko der mangelnden Kundenakzeptanz wird Unterneh-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

men das Erreichen ihrer Automatisierungsziele beim Einsatz von Chatbots auch durch das wachsende Angebot an Chatbot-Plattformen, Entwicklungsframeworks und Programmierschnittstellen sowie deren schnelle Weiterentwicklung zusätzlich erschwert [6]. Dadurch getrieben, sehen wir einen sich verstärkenden Bedarf, den tatsächlichen Kundennutzen von Chatbots festzustellen.

Ein Chatbot für den Einsatz im Servicedesk hat bestimmte Aufgaben zu erfüllen und Nutzerbedürfnisse zu befriedigen, die sich von denen anderer Chatbots (z.B. zur Wettervorhersage) unterscheiden. Die Evaluierung von Mensch-Computer-Dialogsystemen (hierzu zählen wir auch Chatbots) zielt seit dem Turing-Test von 1950 primär auf die Überprüfung der Intelligenz von Systemen mit Blick auf ihre Fähigkeit, Konversationen mit Menschen zu führen, ohne als Maschine erkannt zu werden [7], [8]. Aus Kundensicht ist diese Fähigkeit aber lediglich Mittel zum Zweck, nämlich durch Konversation mit einem Chatbot ein produkt- oder servicebezogenes Anliegen schnell und zufriedenstellend zu erfüllen.

Shawar und Atwell [9] haben verschiedene Evaluationsmethoden für Chatbots untersucht, die entweder aus Innensicht die Komponenten des Chatbots (Glass box evaluation) oder aus Außensicht den Chatbot als Ganzes (Black box evaluation) betrachten. Als Fazit wird betont, dass standardisierte Testverfahren ohne Berücksichtigung der jeweiligen Anwendungsdomäne und der damit verbundenen Kundenanforderungen wenig aussagekräftig seien. Insbesondere sollte sich die Bewertung nach der Lösungsqualität richten, die der Chatbot für eine ihm gestellte Aufgabe erzielt. Stoeckli et al. [6] untersuchen die Nutzenstiftung von Chatbots für abgegrenzte Nutzergruppen aus einer Functional-Affordance-Perspektive am Beispiel von Software-Entwicklungsteams. Functional Affordances (FA) repräsentieren die Möglichkeiten, die technische Artefakte bestimmten Nutzergruppen für deren Aufgabenverrichtung bieten. Damit abstrahiert dieser Bewertungsansatz gezielt von einzelnen Anwendungsfällen, um so grundsätzlichere Aussagen zum Chatbot-Nutzen treffen zu können. Dabei besteht ein enger Zusammenhang zwischen FA und den materiellen Eigenschaften des betrachteten Artefakts wie bspw. dessen konkrete Funktionalitäten (Features). Die eingenommene Perspektive stellt hier den Chatbot mit seinen feature-abhängigen Einsatzmöglichkeiten in den Mittelpunkt.

Demgegenüber nimmt der vorliegende Ansatz die Kunden- bzw. Nutzerperspektive ein und betrachtet den Chatbot als Blackbox, um so unabhängig von sich schnell verändernden technischen Implementierungen den vom Nutzer wahrgenommenen Mehrwert zu qualifizieren. Als weiteres Entwurfsziel für unsere Methode wird neben theoretischer Fundierung und hohem praktischen Nutzwert ein möglichst geringer Zeit- und Kostenaufwand für die Anwendung der Methode angestrebt. Einen vergleichbaren Evaluierungsansatz für Chatbots konnten wir in der bisherigen Literatur nicht finden.

Vor diesem Hintergrund geht unser Beitrag der Frage nach, wie sich der Kundennutzen eines Chatbots innerhalb der spezifischen Anwendungsdomäne Servicedesk systematisch bewerten lässt. Dabei liegt der Fokus auf Chatbots zur automatischen Beantwortung von Kundenanfragen. Als Ergebnis wird eine Bewertungsmethode vorgestellt, die durch eine fragebogengestützte Interaktion mit dem Chatbot Aussagen über dessen Nutzen aus der Perspektive des Kunden ermöglicht.

1.1 Abgrenzung der Begriffe Chatbot und Servicedesk

Der Begriff *Chatbot* (auch Conversational Agent [8] oder Virtual Assistant [10]) bezeichnet Software-Agenten, die in der Lage sind, mittels natürlicher Sprache Zug um Zug mit menschlichen Nutzern zu interagieren [9], also einen Dialog zu führen. Basierte die Intelligenz von Chatbots in der Vergangenheit meist auf regelbasierter Schlussfolgerung haben sich die Fähigkeiten durch neuartige Verfahren im Bereich maschinelles Lernen und Information Retrieval beträchtlich erweitert [11], [12]. Xu et al. [13] sehen in Chatbots eine vielversprechende Alternative zum herkömmlichen Kundenservice. Die Bedeutung von Chatbots im Kundenservice steigt durch ihr Potenzial als neuer, effizienter und automatisierter Kanal zur Kundeninteraktion, wobei Følstad et al. [14] auch darauf hinweisen, dass den Chatbots eine zunehmende Nutzung mobiler Messaging-Plattformen durch eine Vielzahl von Kundengruppen entgegenkommt.

Als Funktionseinheit einer Serviceorganisation besteht die Hauptaufgabe eines *Servicedesks* darin, den Kunden bei Problemen oder Anliegen im Zusammenhang mit bereitgestellten Services bzw. Produkte zu unterstützen [15]. Dazu fasst der Servicedesk sämtliche Mitarbeiter mit Support-Aufgaben organisatorisch zusammen und bietet den Kunden eine zentrale Kontaktstelle für Probleme und Anliegen aller Art (sog. Single point of contact). Für einen effizienten und effektiven Informationsaustausch mit den Kunden stehen typischerweise mehrere Kommunikationskanäle wie Telefon, E-Mail oder Web-Formulare zur Verfügung [1]. Damit werden eine effiziente und nachhaltige Bearbeitung der Kundenanliegen sowie eine möglichst schnelle Störungsbeseitigung angestrebt. Als „Gesicht der IT" zum Kunden liefert der Servicedesk einen wichtigen Beitrag zur Kundenzufriedenheit [16], [15]. Da der Servicedesk sehr personalintensiv ist, gerät er schnell unter Kostendruck. Gleichzeitig muss durch aktuelle Entwicklungen im Zuge von Digitalisierung und Industrie 4.0 für eine steigende Anzahl von Produkten und Services Support geleistet werden [1], [17]. Die Automatisierung des Servicedesks soll diese widersprüchlichen Anforderungen erfüllen. Schließlich erwarten die Benutzer ein immer besseres Nutzenerlebnis auf Basis eines wahrgenommenen Mehrwerts [18].

1.2 Forschungsmethodik

Der diesem Beitrag zugrundeliegende Forschungsprozess basiert auf einem konstruktionsorientierten Ansatz und folgt dem Design Science Research Process [19]. Nach Aufarbeitung des aktuellen Forschungsstands durch Literaturrecherche wurde als Artefakt eine Bewertungsmethode konstruiert. Die auf dem klassischen Turing-Test beruhende Loebner-Preis-Methode [20] diente dabei als Ausgangspunkt für eine weiterentwickelte, domänenbezogene Bewertungsmethode. Der jährlich vergebene Loebner-Preis, benannt nach dem Preis-Stifter Dr. Hugh Loebner, wurde 1991 erstmalig ausgelobt, um die Leistung von Software-Systemen in einem natürlichsprachlichen Mensch-Maschine-Dialog zu bewerten [21]. Beim Loebner-Preis handelt es sich um eine Blackbox-Evaluierung, für die seit 2014 ein standardisierter Fragebogen genutzt wird [20]. Die seit seiner ersten Durchführung immer wieder geäußerte Kritik am Loebner-Preis adressiert in erster Linie seine Eignung als Turing-Test [22], auch im Zusammenhang mit einer irreführenden Berichterstattung und Fehlinterpretationen in den Medien. Durch den Preis-Charakter besteht die Gefahr, dass durch einseitige Optimierungen und vordefinierte Reaktionen die allgemeine Aussagekraft der Bewertungsergebnisse verloren geht. Unabhängig von dieser Kritik eignet sich die Datenerhebung mittels standardisiertem Fragebogen für unsere Entwurfsziele und wird neben der grundlegenden Bewertungssystematik als Methodenelement übernommen.

Für die Konstruktion des Fragebogens wurden ausgehend von einer einfachen Konzeptionalisierung relevante Anforderungen für die Bewertung von Chatbots im Servicedesk aus der Literatur extrahiert und kategorisiert. Es folgte die Erarbeitung von Bewertungskriterien sowie eines Punktesystems zum Testen der Antwortqualität des Chatbot-Outputs. Parallel dazu wurden aus den Anforderungen Fragen für die Erstellung eines Fragenkataloges abgeleitet. Die Nutzung eines standardisierten Fragebogens ermöglicht die Erschließung der Kundenperspektive und eine gute Vergleichbarkeit der getesteten Chatbots. Aus den Bewertungskriterien und dem Fragenkatalog wurde ein Bewertungsbogen erstellt.

Die Entwicklung des Fragenkataloges beruhte zur Verbesserung der Objektivität auf der Anwendung einer Investigator-Triangulation, bei der nach getrennter Arbeitsphase die individuell entwickelten Fragestellungen inkrementell zu einem Gesamtkatalog vereint wurden. Mittels einer Testreihe mit fünf Chatbots erfolgte schließlich die Evaluation der Bewertungsmethode gemäß Design-Science-Prozess.

2 Entwurf einer Bewertungsmethode

Ähnlich wie Vasconcelos et al. [23] oder beim Loebner-Preis [20] wird die Annahme zugrunde gelegt, dass sich die Anforderungen an einen Chatbot dadurch testen lassen, dass ihm bestimmte Fragen gestellt werden. Der Chatbot wird unter der Einnahme der Kundenperspektive als Blackbox betrachtet, der ein bestimmter Input in Form von Fragen oder Bemerkungen übergeben wird und die daraufhin einen bestimmten Output generiert. Dieser vom Chatbot ausgegebene Output wird hinsichtlich seiner Qualität getestet und gibt so Aufschluss darüber, in welchem Ausmaß der Chatbot bestimmte Anforderungen erfüllt. Während der Loebner-Preis die Menschenähnlichkeit des Chatbots und Vasconcelos et al. [23] grundlegende Qualitäten der Gesprächsführung testen, strebt die hier entwickelte Methode die Bewertung eines domänenspezifischen Kundennutzens an. Damit unterscheidet sie sich in der eingenommenen Perspektive ebenfalls von der Bewertung des Chatbot-Nutzens für Programmierteams mittels Functional Affordances von Stoeckli et al. [6].

Die Konstruktion unserer Bewertungsmethode erfolgte in zwei Schritten: In einem ersten Schritt wurden ausgehend von einem grundlegenden Modell die für einen Chatbot im Servicedesk relevanten Anforderungen identifiziert. In einem zweiten Schritt erfolgte die Konzeption des eigentlichen Bewertungsvorgangs inklusive der Erstellung eines Bewertungswerkzeugs.

2.1 Identifikation wesentlicher Anforderungen

Die Grundlage für die Bewertungsmethode bildet das untenstehende Modell, welches das zu betrachtende System aus Kunde, Servicedesk und Chatbot beschreibt. Der Kunde äußert ein bestimmtes Anliegen, welches der Servicedesk aufnimmt und bearbeitet. Der Chatbot bildet das Interface zwischen Kunde und Servicedesk (siehe Abbildung 1).

Abbildung 1. Chatbot als Interface zwischen Kunde und Servicedesk

Das Vorgehen bei der Sammlung der Anforderungen an einen Chatbot für die Kundeninteraktion eines Servicedesks wird durch Abbildung 2 dargestellt. Dem Ausgangsmodell folgend, wurden Anforderungen aus den Zielen und Aufgaben des Servicedesks, aus allgemeinen Merkmalen kommerzieller Chatbots sowie aus den Kundenbedürfnissen abgeleitet. Die Anforderungen wurden in Anlehnung an Walker et al. [24] in die Kategorien Kommunikationsfähigkeit und Problemlösungsfähigkeit eingeordnet.

Um ein umfassendes Bild der Aufgaben im Servicedesk und ihrer Bedeutung für einen Chatbot zu erhalten, wurden die Anforderungen anhand der Komponenten des IT-Service-Managements – Personen, Prozesse, Technologie und Information – betrachtet [25]. Beispielsweise agiert der Chatbot an Stelle der Personen eines Servicedesks, so dass eine Bewertung daraufhin erfolgen sollte, wie gut er diese Aufgabe übernehmen kann. Wesentliche Aufgaben eines Servicesdesks (vgl. [16], [26], [27]) wurden den einzelnen Komponenten zugeordnet.

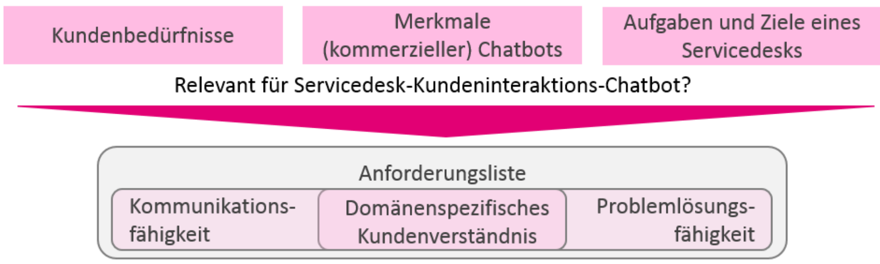

Abbildung 2. Ableitung der Anforderungen an einen Servicedesk-Chatbot

Anschließend wurden allgemeine Anforderungen an kommerzielle Chatbots [8] auf ihre Relevanz für Chatbots im Selfservice hin betrachtet. Hierzu gehört z. B. die Fähigkeit, mit Irritationen wie Rechtschreibfehlern oder Beleidigungen umzugehen sowie dem Kunden Feedbackmöglichkeiten anzubieten. Relevante Merkmale eines Chatbots aus dem Reifegradmodell von Smiers [28] wurden ebenfalls aufgenommen.

Um eine Bewertung des Kundennutzen ohne die Durchführung einer Nutzerbefragung zu ermöglichen, wurden die von Nielsen [29] entwickelten

Heuristiken in ihrer Übertragung auf Chatbots nach dem Vorschlag von Scott [30] verwendet. Demnach sollte ein Chatbot unter anderem schlanke Dialoge ermöglichen und dem User die Möglichkeit bieten, ungewollte Dialogpfade schnell wieder zu verlassen, ohne den gesamten Dialog von vorne starten zu müssen.

Als zusätzliche Anforderungen erschienen Datensicherheit [33] und Kontextsensitivität wesentlich. Durch die Kontextsensitivität ist der Chatbot in der Lage, den Kontext des Users in die Gesprächsführung mit einzubeziehen und sich dadurch z. B. auf den Ticketverlauf zu beziehen [31].

Die Verwendung der Kategorien Kommunikationsfähigkeit und Problemlösungsfähigkeit entspricht den beiden Hauptanliegen der Kunden eines Servicedesks:

- *Kommunikationsfähigkeit.* Die inhaltliche Qualität des Chatbot-Outputs zeigt sich in einem hohen Anteil an richtigen und passenden und zudem freundlichen und empathischen Antworten. Dem Bereich der Kommunikation werden auch die allgemeine Usability sowie Sicherheitsaspekte zugeordnet. Die Effizienz des Chatbot-Outputs zeigt sich in kurzen Antwortzeiten und einer möglichst geringe Anzahl an Dialogschritten.
- *Problemlösungsfähigkeit.* Zu dieser Kategorie zählen die Anforderungen, mit denen die Bandbreite und Tiefe der Problemlösungsfähigkeit des Chatbots bewertet werden. Sie repräsentieren das Spektrum an Kundenanliegen in der Domäne eines Servicedesks und bewerten die Fähigkeit des Chatbots, ein Kundenanliegen abschließend zu lösen, bzw. einen als Mehrwert empfundenen Lösungsgrad zu erreichen.
- *Domänenspezifisches Kundenverständnis.* Im Schnittbereich zwischen Kommunikation und Problemlösung ist das Verständnis der Kundenanliegen angesiedelt, die der Chatbot verarbeiten kann. Zum einen ermöglicht das Verständnis von Fachbegriffen und typischen Anliegen eine reibungslose Kommunikation, zum anderen ist dieses Verständnis die Grundvoraussetzung für eine Lösung des Anliegens.

2.2 Konzeption des Bewertungsvorgangs

Die Bewertung, inwieweit der Chatbot die Anforderungen erfüllt, erfolgt in der hier vorgestellten Bewertungsmethode anhand seiner Antworten. Zur Datenerhebung wurde ein standardisierter Fragebogen entwickelt, dessen Fragen unabhängig von den Antworten immer gleich gestellt werden. Zu jeder Frage gehört eine erwartete Antwort, die bestimmte Qualitätskriterien erfüllen soll. Die Kriterien für die Bewertung der Antwortqualität wurden in Anlehnung an die Kriterien der Loebner-Preis-Evaluation festgelegt [20]. Es werden für jedes Kriterium abhängig von der Güte der Antwort null, ein oder zwei Punkte vergeben. Die Kriterien wurden für unsere Zwecke wie folgt angepasst:

Relevanz. Relevanz meint die Erkennung der Themen, die dem Kundenanliegen zugrunde liegen (z. B. Vertragskündigung). Für die Vergabe von zwei Punkten wird von der Antwort erwartet, dass das Thema bzw. die Absicht des Kunden durch den

Chatbot vollständig erkannt wurde. Entsprechend wird ein Punkt vergeben, wenn das Thema nur teilweise erkannt wurde und null Punkte, wenn der Chatbot das Anliegen nicht erkannt hat.

Korrektheit. Korrektheit meint die inhaltliche oder logische Korrektheit einer Antwort. Bei Fragen, die eine Vielzahl von Antworten zulassen, meint Korrektheit die inhaltliche Passung zu der zugehörigen Frage. Durch die Korrektheit einer Antwort kann die Logikfähigkeit, das Gedächtnis und der Umgang mit unerwartetem Input getestet werden. Die Punktevergabe erfolgt analog zur Relevanz und bewertet das Maß, in dem die Frage richtig bzw. passend beantwortet wurde.

Lösungsgrad. Der Lösungsgrad sagt aus, in welchem Maß das Anliegen des Kunden gelöst wurde (vollständig, teilweise, gar nicht). Dies kann je nach Anliegen durch das Geben von Informationen, das Anstoßen von Transaktionen, eine Problemdiagnose oder die vollständige Problembehebung geschehen. Für die Vergabe von zwei Punkten wird von der Antwort zudem erwartet, dass sie vollständig autonom durch den Chatbot gegeben wurde (ohne Weiterleitung an menschlichen Agenten). Das Kriterium Lösungsgrad erfordert zu jeder Frage die Definition der erwarteten Lösung.

2.3 Auswahl der Anforderungen und Ableitung der Fragen

Zur Durchführung der Bewertung wurde ein Bewertungsbogen konzipiert. Für die Erstellung des Bewertungsbogens wurden jene Anforderungen ausgewählt, die mittels eines standardisierten Fragebogens überprüft werden können (siehe Tabelle 1). Weitergehende Anforderungen, für deren Test ein Dialogverlauf nötig wäre, wie beispielsweise die Anforderungen nach einer möglichst geringen Anzahl an Dialogschritten oder nach einer dialogbasierten Störungsdiagnose, sind für diese Art der Überprüfung nicht geeignet und wurden daher ausgeschlossen.

Zu jeder Anforderung wurde eine oder mehrere Fragen bzw. Aussagen abgeleitet. Die ausgesuchten Fragen repräsentieren Anliegen aus dem Bereich des Servicedesks. Gleichzeitig wurde auf eine möglichst branchenunabhängige Auswahl der Fragen geachtet. Durch branchenunabhängige Fragen kann die Methode auf Chatbots im Servicedesk verschiedener Branchen angewandt werden.

Mehrere Fragen wurden insbesondere aus Anforderungen mit einem weiten Spektrum möglicher konkreter Kundenanliegen abgeleitet. Ein Beispiel dafür ist die Anforderung „beantwortet Informationsfragen" der Kategorie Problemlösungsfähigkeit, aus der Fragen zu Produkten und zur Rechnung abgeleitet wurden. Unter anderem wurde auf diese Weise die Frage „Welches ist euer günstigstes Produkt?" formuliert. Die Betreuung von Produkten und Services ist eine Kernaufgabe des Servicedesks. Gleichzeitig lässt die Frage offen, welcher Art die Produkte sind, so dass sie branchenunabhängig gestellt werden kann. Die Ableitung der erwarteten Antworten zeigt die Übersicht in Tabelle 2.

Tabelle 1. Durch standardisierten Fragebogen testbare Anforderungen

1 Kommunikationsfähigkeit
1.1 Zugänglichkeit
• gewährleistet die Erreichbarkeit der IT-Organisation [26] • kann als einzige Kontaktadresse funktionieren [16], [20] • beherrscht mehr als eine Sprache [28]
1.2 Kundenbehandlung
• erhöht Kundenbindung durch persönliche Note [8], [24] • kommuniziert freundlich und wertschätzend (abgeleitet aus [26]) • kann auf die Stimmungen der Kunden angemessen reagieren (abgeleitet aus [26]), [28] • kann mit Beleidigungen umgehen [8] • erinnert sich an vorangegangene Äußerungen [9]
1.3 Usability
• ist robust gegenüber Tippfehlern und erkennt Synonyme (bzgl. alltäglicher Begriffe) [8] • ermöglicht Abkürzungen für versierte Kunden [30] • bietet Conversation Listening [28] • nutzt Links für weiterführende Informationen [8], [22] • nutzt vorstrukturierte Antworten zur Steuerung der Nutzererfahrung [30] • bietet leichten Zugang zur Bedienungshilfe [8], [24]
1.4 Sicherheit und Kontext-Sensitiv
• gewährleistet Vertraulichkeit der Daten [33] • ist kontextsensitiv [28], [25]
2 Domänenspezifisches Kundenverständnis
• kann auf die Absichten der Kunden angemessen reagieren (abgeleitet aus [26]) • versteht Begriffe der Kundendomäne (Fachsprache der Kunden) (abgeleitet aus [26]) • robust ggü. Tippfehlern, erkennt Synonyme (bzgl. der domänenspezifischen Begriffe) [8] • nimmt entgegen: Informations-, Beratungs-, Produktwunsch, Anmerkung, Kompliment, Beschwerde, Störungsmeldung, Nachfrage zu bestehender Störung [16], [19] • kommuniziert verständlich [30]
3 Problemlösungsfähigkeit
3.1 Problemlösung
• beantwortet Informationsanfragen [16] • gibt Informationen und Vorschläge bei Beratungswunsch (abgeleitet aus [16]) • löst bei Produktwunsch Bestellungen aus [20] • nimmt Beschwerde entgegen und leitet Behebung oder Eskalation ein [16] • verbindet im Ausnahmefall mit einem persönlichen Ansprechpartner [17] • findet Fehlerursache (durch Messungen) heraus [19] • macht Lösungsvorschläge [19]
3.2 Ticketbearbeitung
• eröffnet ein Ticket (registriert Ticket) [16], [19], [20] • prüft Störungsmeldungen auf Service Level (Priorisierung) [16], [19], [20] • leitet Ticket an die richtige Stelle weiter und stößt weitere Bearbeitung an [16], [19] • verfolgt Ticket nach [16], [19] • koordiniert nachfolgende Support-Einheiten [16]
3.3 Integration (Anwendungen, Webseiten, Services)
• kann relevante Information auslesen und anbieten (abgeleitet aus [26]), [28] • kann notwendige Transaktionen anstoßen (abgeleitet aus [26]), [28]

Tabelle 2. Beispiele der Anforderungen an eine Frage

Kriterium	*Anforderung/ erwartete Antwort*
Relevanz	Der Chatbot versteht, dass es um das Produktangebot geht.
	Der Chatbot versteht, dass es um das günstigste Produkt geht. (2 Punkte)
Korrektheit	Es wird das günstigste Produkt genannt oder die Antwort geht auf das günstigste Produkt ein. (2 Punkte)
Lösungsgrad (mit Beispielen für Definition der erwarteten Lösung)	
2 Punkte	Kunde weiß, welches Produkt das günstigste ist. Er bekommt die Information direkt als Antwort oder als Link auf die entsprechende Seite.
1 Punkt	Kunde erhält einen Link oder Hinweis zu Produktseiten, muss dort aber selber nach dem günstigsten Produkt suchen. Oder Kunde wird mit einem Mitarbeiter verbunden und erhält so weitergehende Unterstützung.
0 Punkte	Der Kunde erhält keine Informationen dazu, wie er die günstigsten Produkte in Erfahrung bringen kann. Der Kunde wird lediglich an die allgemeine Telefonnummer oder die Webseite verwiesen.

3 Anwendung der Bewertungsmethode

Die Anwendung der Bewertungsmethode erfolgt durch eine „Befragung“ des zu bewertenden Chatbots sowie anschließende Bewertung der gegebenen Antworten anhand der spezifischen Kriterien und wird nachfolgend näher erläutert.

Der Fragenkatalog und die Bewertungskriterien bilden die zwei Grundelemente der Bewertungsmethode. Der Fragenkatalog enthält die aus den domänenspezifischen Anforderungen abgeleiteten Fragen bzw. Äußerungen. Durch die Eingabe dieser Fragen werden die Kommunikationsfähigkeit, das domänenspezifische Kundenverständnis und die Problemlösungsfähigkeit des Chatbots getestet. Die Bewertungskriterien sind das Mittel zur Beurteilung der Antwortqualität. Hier werden das Verständnis des Inputs und die Korrektheit bzw. Passgenauigkeit des Outputs sowie das Maß der durch die Antwort erreichten Problemlösung bewertet. Für die Durchführung der Bewertung wurde ein strukturierter Bewertungsbogen entwickelt, dessen Aufbau am Beispiel des Ausschnitts in Tabelle 3 erläutert wird.

Die Tabelle zeigt alle relevanten Elemente des Fragebogens. Auf der linken Seite sind die Fragen in ihren jeweiligen Kategorien und Unterkategorien aufgeführt. In der Spalte daneben steht die Anforderung an einen Chatbot, welche mit der Frage (teilweise auch mehrere) geprüft werden soll. Auf der rechten Seite wird der Chatbot mit seinen Antworten dokumentiert. Dabei wird nach Vor- und Nachteilen des Chatbots unterschieden. In die Felder können allgemeine Feststellungen, die bei der Durchführung der Methode auffallen, eingetragen werden. Darunter werden die Antworten des Chatbots mit zugehörigen Beobachtungen (Beob.) eingetragen, die aus den Antworten allein nicht hervorgehen. Daneben folgt die Bewertung der Kriterien Relevanz (R), Korrektheit (K) und Lösungsgrad (L). Die Summe (S) der Einzelbewertungen wird am Ende berechnet und eingetragen.

Tabelle 3. Ausschnitt des Bewertungsbogens

Kategorie: Problemlösungsfähigkeit *Unterkategorie:* Problemlösung		*Vorteile:*	*Nachteile:*				
Frage	*Anforderung*	*Antwort*	*Beob.*	*R*	*K*	*L*	*S*
Kannst du mich zu euren Angeboten beraten?	Beratungs-wunsch			0	0	0	0
Welches ist euer günstigstes Produkt?	Informations-wunsch			0	0	0	0
Ich möchte mich über dich beschweren.	Umgang mit Beschwerden			0	0	0	0

R = Relevanz, K = Korrektheit, L = Lösungsgrad, S = Summe

4 Evaluation der Bewertungsmethode

Zur Evaluation im Rahmen des Design Science Research Prozesses wurde eine Testreihe durchgeführt und dabei die Bewertungsmethode auf mehrere Chatbots angewandt. Im Hinblick auf den angestrebten Einsatzzweck der Methode wurde zur Untersuchung von Bewertungsqualität und Zweckmäßigkeit eine Reihe von Evaluationskriterien festgelegt: a) Objektivität, Validität und Reliabilität dienten als Kriterien der Bewertungsqualität sowie b) Domänenbezug, Branchenunabhängigkeit, Technologieunabhängigkeit, Usability sowie die innere Ordnung der Fragen als Kriterien der Zweckmäßigkeit.

Um diese Kriterien zu überprüfen, wurden fünf geeignete Chatbots für die Durchführung ausgewählt: Lisa (O_2), Julia (Vodafone Kabel Deutschland), Digitaler Serviceassistent (Deutsche Telekom), Chatbock (Klarmobil) und Clara (Otto). Gründe für die Auswahl waren die Vergleichbarkeit der Funktionalitäten der Chatbots innerhalb einer Branche (Telekommunikation mit Lisa, Julia, Chatbock und Digitaler Serviceassistent) und zwischen zwei verschiedenen Branchen (Telekommunikation und Versandhandel mit Clara) zu überprüfen. Ebenso kann durch diese Auswahl die Branchenunabhängigkeit des Fragenkatalogs geprüft werden. Durch die Auswahl von Chatbock, der im Unterschied zu den direkt auf der Unternehmenswebsite integrierten Chatbots auf dem Facebook Messenger aufbaut, kann außerdem die Technologieunabhängigkeit des Fragebogens untersucht werden.

4.1 Ablauf der Evaluation

Bei der Durchführung der Evaluation wurde jedem Chatbot die Frage: „Welches ist euer günstigstes Produkt?“ gestellt. Diese Frage adressiert die Anforderung der Bearbeitung von Informationswünschen. Für jede Frage des Fragebogens wurde das im folgenden beschriebene Vorgehen durchgeführt:

Als erstes wurde dem Chatbot die Frage gestellt. Die Antwort des Chatbots wurde dann in das Protokoll eingetragen. Diese lautete bspw. beim Chatbot Julia: „Links zeige ich Ihnen unsere günstigsten Kabeltarife“ ergänzt durch eine Auflistung von vier Tarifen inkl. Hyperlink. In die Spalte Beobachtung wurde nun eingetragen, dass auf der linken Seite Links zu den jeweils günstigsten Tarifen angezeigt werden. Danach konnte mit der Bewertung begonnen werden.

Der Chatbot hat erkannt, dass sowohl Informationen zu Produkten (hier Tarife) als auch von diesen Produkten die günstigsten gewünscht waren. Die Bewertung der Relevanz wurde daher mit zwei Punkten vorgenommen. Nach Prüfung der Links konnte bestätigt werden, dass diese Tarife die jeweils günstigsten der jeweiligen Kategorie sind. Die Korrektheit wurde deshalb mit zwei Punkten bewertet. Für die Bewertung des Lösungsgrads wurde die in Abschnitt 3.4 beschriebene Anforderung herangezogen. Da der Nutzer durch die Antwort weiß, welches die günstigsten Produkte sind und direkt Links zu diesen vorfindet, wurde auch der Lösungsgrad mit zwei Punkte bewertet. Allgemeine Feststellungen während der Evaluation konnten in den Zellen Vor- und Nachteile dokumentiert werden. Das vollständig ausgefüllte Protokoll für die Frage „Welches ist euer günstigstes Produkt?” ist in Tabelle 4 dargestellt.

Tabelle 4. Evaluationsdurchführung

Kategorie: Problemlösungsfähigkeit *Unterkategorie:* Problemlösung		*Vorteile:* schnelle Reaktionszeiten	*Nachteile:*				
Frage	*Anforderung*	*Antwort*	*Beob.*	*R*	*K*	*L*	*S*
Welches ist euer günstigstes Produkt?	Informations-wunsch	Links zeige ich Ihnen unsere günstigsten Kabel-Tarife.	Links zu den Tarifen	2	2	2	6

Dieses Vorgehen wurde für jeden der Chatbots und jede Frage wiederholt. Dabei wurden die Chatbots nacheinander bewertet. Aus den Bewertungen der Chatbots und den Beobachtungen während der Durchführung wurden die im folgenden Kapitel dargestellten Evaluationsergebnisse abgeleitet.

4.2 Evaluationsergebnisse

Die Evaluation der Bewertungsmethode hat verschiedene Stärken und Schwächen der entwickelten Bewertungsmethode aufgezeigt. Diese werden nachfolgend anhand der Evaluationskriterien für Bewertungsqualität und Zweckmäßigkeit diskutiert.

Objektivität, Validität und Reliabilität. Die Objektivität der Methode ist dann sichergestellt, wenn diese unabhängig von äußeren Einflüssen durchgeführt werden kann. Die Methode ist in ihrer aktuellen Form nicht vollständig objektiv. Das liegt vor allem daran, dass die erwarteten Antworten in einigen Fällen nicht vorher definiert werden können, da nicht klar ist, welche Fähigkeiten die Chatbots im Detail haben. Die Güte der Antwort kann in diesen Fällen nicht eindeutig bestimmt werden, so dass die Bewertung vom subjektiven Eindruck des jeweiligen Prüfers abhängt.

Reliabilität bedeutet, dass eine Messung wiederholt werden kann und sich die Ergebnisse nicht oder erklärbar unterscheiden. Die Reliabilität der Methode ist gegeben, da es sich um statische Fragen handelt und der Chatbot in der Regel bei gleichen Fragen die gleichen Antworten gibt. Eine Ausnahme hiervon stellt die Weiterentwicklung des Chatbots dar. Diese kann aber anhand der Differenz zur vorherigen Messung bewertet werden.

Eine Bewertung ist valide, wenn sie tatsächlich das misst, was mit ihr gemessen werden soll. Einfache Anforderungen, wie die in Abschnitt 4.1 angeführte Frage, können valide getestet und bewertet werden. Die Bewertung der Kriterien bei diesen Fragen mit null bis zwei Punkten hat sich bewährt, da sie nicht nur Ja-/Nein-Bewertungen zulässt, sondern eine differenzierte Bewertung ermöglicht. Die geringe Anzahl an Bewertungsalternativen erleichtert dabei die eindeutige Bewertung.

Eine Bewertung komplexer Themen, die von einem Chatbot nur im Dialog gelöst werden können, kann mit der aktuellen Bewertungsmethode nicht durchgeführt werden, was die Validität der Methode einschränkt.

Für einzelne Anforderungen kann durch den Bewertungsbogen nur die Text-/ Sprachausgabe des Chatbots bewertet werden. Beispielsweise ist in Bezug auf die Vertraulichkeit der Daten der tatsächliche Umgang des Chatbots mit Personendaten nicht über die Benutzerschnittstelle feststellbar. Bei der Weiterentwicklung der Bewertungsmethode wäre demnach zu prüfen, ob Anforderungen mit einem sehr breiten Spektrum möglicher Kundenanliegen, wie z.B. die Anforderung „beantwortet Informationsanfragen“, weiter detailliert werden können, um Unschärfen in der Bewertung zu reduzieren.

Zusätzlich ist der Fakt zu beachten, dass sowohl Relevanz als auch Korrektheit Einfluss auf den Lösungsgrad haben. Versteht ein Chatbot die Frage nicht oder ist nicht in der Lage, eine korrekte Antwort zu liefern, wird er in der Regel weder bei der Relevanz bzw. Korrektheit noch beim Lösungsgrad Punkte erhalten.

Allgemeine Feststellungen, wie die Reaktionszeit der Chatbots, werden zwar in den Vor- und Nachteilen betrachtet, aber nicht bewertet. Dabei können gerade die hier festgestellten Eigenschaften des Chatbots erhebliche Auswirkungen auf den Kundennutzen haben. Um die Methode in dieser Hinsicht zu verbessern, können Erkenntnisse von Kuligowska [8] für die punktemäßige Bewertung von beobachtbaren Merkmalen einbezogen werden.

Domänenbezug. Der Domänenbezug konnte mit der Bewertungsmethode in der aktuellen Form nur teilweise erreicht werden, da typische Kundenanliegen im Servicedesk eine Dialogführung für ihre Erfassung und Bearbeitung benötigen.

Branchenunabhängigkeit. Die Branchenunabhängigkeit der Fragen konnte festgestellt werden. Dieses wurde durch die Auswahl von allgemeinen Fragen oder den Einsatz von Variablen (Bsp.: „Ich möchte mich über <Unternehmen> beschweren.”) in den Fragen sichergestellt. Chatbots aus zwei verschiedenen Branchen können dadurch in Bezug auf ihren Nutzen hinsichtlich typischer Servicedesk-Themen miteinander verglichen werden. Auch innerhalb einer Branche bietet die Methode Vergleichsmöglichkeiten.

Technologieunabhängigkeit. Mit Fokus auf die Technologieunabhängigkeit zeigte sich der Fragebogen in der Testreihe als ausreichend abstrakt, da die Nutzbarkeit des Fragebogens nicht durch die zugrundeliegende Technologie beschränkt wird. Aus Kundenperspektive muss der Nutzen unabhängig von der eingesetzten Technologie eintreten. Ergebnisse zu technologiebedingten

Nutzungsbeschränkungen des Chatbots können im Kopfteil des Fragebogens vermerkt werden (Bsp.: „Facebook-Account notwendig“ für den Chatbock).

Usability. Aus dem Blickwinkel der Usability zeigte sich, dass die Anwendung der Methode vergleichsweise wenig aufwendig ist. Für die Bewertung eines Chatbots wurden knapp zwei Stunden aufgewendet, technische Hilfsmittel sind nicht erforderlich. In einer der folgenden Iterationen zur Verbesserung der Methode soll dennoch versucht werden, die Anwendungszeit weiter zu verringern, etwa durch (Teil-)
Automatisierung.

Innere Ordnung. Die innere Ordnung der Fragen konnte durch die Zuordnung zu den Kategorien und Unterkategorien gewährleistet werden.

5 Fazit und Ausblick

In Beantwortung der Forschungsfrage ist eine Bewertungsmethode entstanden, die ausgehend vom fragebogenbasierten Vorgehen der Loebner-Preis-Methode die Spezifika eines im Servicedesk agierenden Chatbots integriert und dadurch die Nutzenbewertung eines solchen Chatbots durch den konstruierten Fragebogen mit zugehöriger Bewertungsmethode domänenspezifisch unterstützt.

Durch die systematische Erfassung der vielschichtigen Anforderungen an einen Chatbot als Grundlage zur Erstellung des Bewertungsbogens zeigt die Arbeit außerdem die Mannigfaltigkeit der von einem Servicedesk-Chatbot abzudeckenden Themenbereiche auf. Darüber hinaus konnte durch die Evaluation der Bewertungsmethode anhand von fünf Chatbots eine praxisorientierte Nutzungsmöglichkeit des erstellen Artefaktes aufgezeigt werden, die sich durch die Anwendbarkeit in verschiedenen Branchen sowie Unabhängigkeit von der technischen Implementierung auszeichnet.

Die aufgezeigten Beschränkungen des bisherigen Methodenentwurfs motivieren weiterführende Forschungsarbeiten mit dem Ziel, die Bewertungsmethode bspw. durch erweiterte Evaluation mit einer größeren Anzahl von Chatbots zu verbessern. Vorrangig sollte nach Möglichkeiten der Integration von Dialogverläufen in die Bewertung gesucht werden. Weiterhin sind Automatisierungspotenziale bei der Anwendung der Bewertungsmethode erkennbar, die zu einer Reduzierung des manuellen Aufwands führen könnten. Als reizvoller Ansatz wäre hier die Entwicklung eines Chatbots zur automatisierten Befragung des zu bewertenden Chatbots vorstellbar. Schließlich könnte geprüft werden, ob sich die Methode auch für eine reifegradbasierte Untersuchung von Chatbots erweitern ließe.

Understanding the Benefits of Agile Software Development in Regulated Environments

Jens Karrenbauer, Manuel Wiesche, Helmut Krcmar

Technische Universität München, Chair for Information Systems, Munich, Germany
jens.karrenbauer@tum.de, {wiesche, krcmar}@in.tum.de

Abstract. Agile software development has become increasingly popular in recent years. Applying agile methods, companies expect flexible planning, early delivery of the software product, and a continuous improvement of the development process itself. However, in regulated environments the use of agile development is not yet common practice. In such environments, various regulatory requirements apply which affect the software development process. This paper examines the use of agile software development in the regulated medical device industry and explores reasons for using agile methods although their use is limited. We interviewed agile software development teams in three different companies using semi-structured interviews. Using grounded theory methodology, we identify reasons why companies are using agile methods, even though problems and barriers exist. Our main achievement is the development of four categories, which describe the benefit of agile software development in regulated environments. These categories are master complexity, reduce effort, improve usability, and promote collaboration.

Keywords: agile software development, regulated environments, benefit of agile software development, medical device industry

1 Introduction

For some time, companies adopted agile methods, such as Scrum, within their software development process. Reasons for agile adoption are benefits such as flexible planning, early delivery of the software production, or a continuous improvement of the software development, which results in better quality software [1]. However, companies often find it difficult to implement agile methods due to challenges in the organizational, cultural, and human context [2]. In regulated environments, this is intensified by various regulatory requirements that must be met, while at the same time reacting flexibly to market or customer requirements is necessary [2].

One characteristic of regulated environments is the multitude of compliance procedures, regulations and standards that have to be considered in the software development process. There are various organizations and associations, such as the International Organization for Standardization (ISO) or the Food and Drug Administration (FDA),

14^{th} International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

which formulate specific requirements [3]. Furthermore, self-imposed requirements apply which are not mandatory for an industry, but which are generally recognized standards required by customers [4].

One example is the medical device industry, which is highly regulated. Companies that develop software for the US market must guarantee that their software complies with all FDA requirements.[1] For all stakeholders of these organizations, it is important to see that the system developed was designed safely and effectively for the intended purpose [6]. Breaching these requirements can quickly cause economic damage to a company [7]. For instance, a violation of regulatory requirements can lead to sanctions such as product recalls, product seizures or export restrictions [8].

A company in the medical device industry must, therefore, meet the challenge of reconciling the both existing and changing, strict regulations with the agile approach and at the same time constantly reducing development cost [2]. Thus, understanding why agile methods are used in regulated environments despite these barriers is important. This paper attempts to answer the following research question: *What are typical benefits of the usage of agile software development in a regulated environment?* To explore this question, we conducted 20 interviews with members of agile software development teams in three different companies from the medical device sector. Using the Grounded Theory Methodology (GTM) for data analysis, our main achievement is the identification of four categories, which describe the benefit of agile software development in regulated environments.

The remainder of the paper is structured as follows. In the next section, we provide a brief introduction of the background literature. This is followed by an introduction of our research approach as well as a presentation of the relevant cases. We then present our results and discuss the findings in detail. The paper concludes by highlighting the contributions that our study makes to research and practice.

2 Background

2.1 Agile Software Development in Regulated Environments

Agile software development methods became more and more popular in recent years. Different methods have been classified as agile, e.g. eXtreme Programming (XP), Crystal, Feature Driven Design, or Scrum. Scrum is one of the most widely used agile development methods in practice [3]. This method has been adopted in many sectors of the software industry. Companies expect flexible planning, early delivery, and continuous improvement of the development process [1]. Agile methods promise to reduce development time, increase product quality, and reduce development costs [9].

[1] The EU directives for medical devices are in a period of change. On 25 May 2017, the new European Medical Devices Ordinance (MDR) came into force with a transition period of three years. This imposes extensive new requirements on the clinical evaluation of devices [5] and assimilates the requirements of the FDA and EU.

Agile was originally intended to be used by small teams in non-safety-critical projects and in co-located environments [10] [11]. However, agile methods need to be tailored to suit the needs of different circumstances [12]. Agile has been adopted to other contexts, including virtual environments [13], global software engineering [14], complex systems or Capability Maturity Model (CMM) environments [15] [16], as well as regulated environments [3].

Especially in regulated environments scholarly research finds puzzling results regarding the use of agile methods. The main conclusion of [3] is that agile practices and regulated environments are not necessarily incompatible. Others say that agile practices are unsuitable and can only be used successfully in combination with plan-based methods [17]. Most of the literature recommends an adaptation of agile approaches (e.g. [9], [18], [19]), while some consider it is too early altogether to apply agile methods in such environments (e.g. [15], [20]). One possible explanation for these inconsistent empirical findings are different regulated environments with different focuses.

Table 1: Relevant laws and regulations in the field of medical devices with their impact on the process.

Law/ Regulation	*Comment/Impact*
Focus: Control instrument for demonstrating the safety and medical-technical performance of medical devices.	
EU Medical Device Directive (MDD), EU Medical Device Regulation (MDR) *[23] [24]*	• Define software as a medical device. • Divide medical devices into four classes which are used as the basis for the requirements to be implemented and the scope of an inspection by the authorities. • Require state of the art validation of the software, considering the principles of the software life cycle, risk management, validation and verification.
Focus: Software Life Cycle Processes for Medical Device Software	
AANIS/AAMI/DIN EN/IEC 62304 *[25] [22]*	• Requires activities and tasks within the software life cycle required for the safe development and maintenance of medical device software. • Requests a prior determination of what is expected of the software and subsequent proof that the use of the software fulfils these intentions without causing unacceptable risks.
Focus: Quality management systems for medical device manufacturers.	
ISO 13485, 21 CFR 820 *[26]*, *[27] [21]*	• Requires the development of internal policies and procedures describing the QMS. • Requires the creation of Standard Operation Procedures (SOP). • Requires the creation and documentation of a comprehensible software development process. • Low-level processes must be consistent with those at a higher level and provide a coherent and consistent approach across the organisation that meets regulatory requirements.
Focus: Application of risk management to medical devices	
ISO 14971 *[28] [22]*	• Calls for the introduction of systematic management of the risks associated with the development and operation of a medical device. • Requires consideration of product risks for patients, operators, others, and the environment. • Requires continuous monitoring of risks, even after delivery of the product.

2.1 Requirements for Agile Software Development in Regulated Environments

For the medical device industry, different laws and regulations apply with regards to the software development process. Various organizations and associations such as the ISO and the FDA, formulate and publish regulatory requirements for product development [3]. For the development of software this implies a need for high quality, security and reliability. Table 1 illustrates the most relevant laws and regulations for the EU and the US and provides more information about potential impacts of these requirements on the software development process.

The table shows that the specific regulatory requirements differ between the countries. These international standards and guidelines make the medical device software development process unique [21]. Especially the IEC 62304, which places demands on life cycle processes for medical device software, is recognized by many regulatory bodies around the world as the *gold standard* [22].

There are strict requirements for the reliability and traceability of the products and their development process in the medical device industry. From these specific requirements, general rules can be derived which apply in a regulated environment in general. Table 2 highlights these common requirements. For instance, quality is one of the most important characteristics that a process and its software must show. Additionally, it is imperative to plan the entire project, as well as document all the activities done. Companies adopting agile methods face barriers when complying to the agile principles, for example, a lack of documentation or up-front planning. [29] Also, there are different agile barriers for the development teams which have an impact on the performance. Examples are the occurrence of subgroups or the relationship of personality models [30] [31] [32].

Table 2: Typical examples of requirements in a regulated environment [2]

Topic area	*Description*
Ensuring quality	planning, implementation and proof of quality assurance measures [6]
Ex-ante planning	additional process steps (e. g., risk analysis or additional tests) [15]
Roles & responsibilities	mandatory roles (e. g., security expert or a quality manager) [33]
Documentation	extensive, development-related documentation (e.g. requirements documentation or test specifications) [8]

The impact of these requirements leads to different problems, for instance during the overall process implementation, during the transition to the testing phase, or within the documentation. For example, all tasks and activities must be completed before a release takes place (including a complete documentation). This also means, software cannot be delivered without a complete documentation [18]. Additionally, it is not worth to deliver small releases in short cycles as the additional work to be done is extensive. Also, the costs of refactoring will become quickly very high as soon as a change involves a re-verification and re-evaluation of the artifacts concerned [20].

Literature showed several examples for such problems, which redundant occur in this context. That is the reason why we want to clarify and understand the motivation and benefits for companies in a regulated environment to use agile methods.

3 Research Approach

To understand why agile is used in regulated environments requires a rich understanding of the field and yields several potential explanations. We, therefore, find an inductive, qualitative research design appropriate. We conducted 20 interviews in three different cases and used the GTM for data analysis. Based on the case studies and the results of the GTM, four categories which describe the benefits of agile software development in a regulated environment have been elaborated.

Table 3: Background information of the interviewees

				experience (years) in			*agile*

3.1 Research Method

For sampling our data, we chose a holistic multiple-case design, where we identified several distinct case organizations to be included in our sample [34]. We identified three companies, each of which is regarded as a separate case. A description of these cases is provided in the following.

In all cases semi-standardised interviews were conducted to collect data [35]. An interview guideline was developed which served as a basis for the interviews. This guideline included questions on known regulations, agile procedures used in the company, characteristics of the implemented active development process, and one's own opinion on existing conflicts. Additionally, we asked questions about the benefits and existing barriers of the usage of agile software development in the regulated environment. The aim was to interview each role of the agile software development team in order to gain a comprehensive picture of the benefits using agile software development methods in regulated environments [35].

We conducted 20 interviews. Each interview lasted between 40 - 90 minutes. Table 3 provides background information of all interviewees. After each interview, a theoretical memo was prepared to record our impressions and thoughts about the interviewee [36]. The interviews were transcribed and analysed with Atlas.ti.

For data evaluation and analysis we followed Grounded Theory Methodology (GTM) [37]. In the first step of the analysis, initial concepts were identified in the data. These were divided into categories (open coding). Concise and self-explanatory codes were used to create the categories. Next, the open codes were divided into groups by selective coding. Due to the large number of codes, we also worked with subcategories of the respective categories.

3.2 Cases

We identified three companies from the medical device industry which are already using agile methods within their software development process. The first case, INFUSE, is a software design house with experiences in the automotive, safety & security, aerospace, and medical device sectors. The project focuses on the development of software for an automatic infusion pump. The implementation of Scrum is close to the framework. Concurrent to the agile process, there is a risk management, a verification, and a configuration management process. Issues or requirements of the concurrent processes are given as requirements in the Scrum process. In our view, the company does not distinguish between regulatory requirements and product requirements as they want to use the opportunity of developing a high-quality software product.

The second case, XRAY, is a company in the dental industry. The interviews were based on the development of a software, which is used for the imaging of X-ray machines (image display, image enhancement). A special feature is that the software can be used as a variant with other imaging devices (e.g. industrial area). Currently, there are two agile Scrum teams working on this project. There are also many other roles involved, e.g. an Ergonomics Manager or a Requirements Engineer. At the start of a new project (or a new release) all requirements have already been defined. The whole software development process is very extensive and rigid. The interpretation of the existing regulations is always enforced strictly.

The third case, DATA, is a provider of products and solutions for ophthalmology, neurosurgery, dentistry and oncology. The software can be used to collect, process and archive data from their system as well as third-party devices. In addition, the data is prepared for the physician and the information is made available for diagnostics. The implementation of the Scrum framework at DATA is a pragmatic approach. Nevertheless, it takes them an average of one year until a new release takes place.

4 Results

4.1 Software Development Process in the Cases Applied

The three projects are similar at a high level. The same regulations apply to all three cases, since all software products are grouped in the same classification of medical devices (IIb). In addition, the same agile practices are predominantly used. In all cases the embedding of the software development process in a higher-level product development/medical product process took place and run as a V-model. For the software development they move into the agile process. After several iterations within Scrum, the agile process ends, and the V-model is completed with verification/system tests and other necessary activities. Table 4 provides an overview of the three cases.

Table 4: Comparison of the three cases

	Case A (INFUSE)	*Case B (XRAY)*	*Case C (DATA)*
Employees	190	1000	3000
Product	Software for an infusion pump	Software for the imaging of x-ray machines	Data Management System for Ophthalmology
Form of Software	Embedded	Stand-Alone	Stand-Alone
MD classification		IIb	
Runtime	- Started: 2012 - Scrum: Since 2014 - End: 2019	- Feasibility study: 2011 - Started: 2012 - Current version: 2.3	- Started 2008 - Current version: 4.2.1
Relevant regulations	ISO 13485, 14971, 60601, 62304, FDA	ISO 13485, 14971, 60601, 62304, FDA	ISO 13485, 14971, 60601, 62304, FDA
Team Size	Scrum-Team: 8 members (6 developer, 1 PO, 1 SM)	Scrum-Team: 12 members (10 developer, 1 SM, 1 PO)	Scrum Team: 4 members, 1/3 PO, 1/3 SM (PO & SM are shared with 3 other teams)
Used agile practices	Burn-Down-Chart, Code Ownership, Code Refactoring, Continuous Integration, Pair Programming, Mob Programming, Retrospective, User Stories,	Burn-Up-Chart, Code Refactoring, Continuous Integration, Pair Programming, Retrospective, User Stories,	Burn-Down Charts, Code Ownership, Code Refactoring, Continuous Integration, Pair Programming, Retrospectives, User Stories,
Agile strategies	- embedding agile in existing V-model based development - using agile as toolbox of different procedures - “mini-Vs” within each sprint		

In order to compare these cases, we need to take a deeper look into the processes and have, therefore, identified three main characteristics by using GTM which are handled differently. These characteristics are *implementation of requirements*, *documentation* and *final integration/system test*. Implementation of requirements means time and procedures for the implementation of requirements. Documentation describes the time and procedure of the documentation. Final integration/system test characterises the handling of these final tests. Table 5 compares the three cases.

Table 5: The software development process in the three different cases

	INFUSE	*XRAY*	*DATA*
Implementation of requirements	- user stories are partly defined in advance, or they are created dynamically parallel to the development	- strict modular processing of the various steps - requirements are defined and approved in advance	- development is based on the defined user story and the acceptance criteria - no formal specification in advance
Documentation	- documentation is usually made in parallel or after development	- without finalized documentation, the software may not be implemented.	- no current, formal documentation on the development is required - developers are free to decide how they want to document the development
Final Integration / System test	- a full system test is performed after the last sprint and before release	- a full system test is performed after the last sprint and before release	- there is no completely system test - final tests of the main operating functions take place

4.2 Benefits of Using Agile Methods in Regulated Environments

If one looks at the problems and barriers identified in the previous chapters, it is noticeable that these areas match the aspects that are considered as an incentive for the introduction of agile development methods. The coding of the data revealed four categories of motivation to introduce agile development methods. These four categories are *master complexity, reduce effort*, *improve usability*, and *promote collaboration*.

Master complexity

Software development and software itself have grown more and more complex in the previous decades. With new technological possibilities, increasingly complex systems found their way into medicine. In this context, agile methods help the software development team to deal with complexity-related issues such as compatibility with modules, integration with hardware, or handling all the regulations applying to the software development process.

In contrast to an agile approach, the classic V-model provides a complete definition of all requirements at the beginning. In the case of complex systems, this is sometimes difficult to implement, as the entire set of requirements must be described initially. If a V-model is used for software development today, it leads to additional efforts as existing developments have to be continuously changed. Regardless of the selected process model, an iterative procedure is required to master the complexity.

There are different possibilities how agile helps to master the complexity in a software development project. For instance, agile is suited very well if the definition of the final product is not quite clear at the beginning of the project: "*Actually, as soon as it becomes more complex and at the beginning is still a certain blurriness in the whole,* *then it is always helpful, even if it is only that I go through the first phases agile and iteratively." (INFUSE).* Additionally, iterative learning is nowadays almost indispensable for complex system development:

"*Mastering the complexity is in an agile team, where I don't have quite rigid requirements, and that has to be on the table in three years (...). But, I have a vision, and also the vision I adjust in my reflections constantly after a bit. Of course, I can't throw it all over the place, that there will be something completely different. Because then I produced for the trash can. But that it is just a matter of bringing a vision into the world and with the knowledge I learn about the iterations, that it really grinds itself so finely that in the end what I need really comes out.*" *(XRAY).*

Another point and what we already mentioned is, that complex software can no longer be defined completely in advance. The reason for this is the high uncertainty regarding the features to be developed, as well as the difficulty of understanding complex interdependencies in advance: "*I don't have the chance to initially describe all requirements, all interfaces in such a way that I can easily implement them.*" *(XRAY).* The following quote explains this in more detail:

"The whole world and technology and systems are becoming increasingly complex. This means that we are networked, all devices talk to each other, and the complexity is meanwhile on one level that it is not controllable in this classical process model topic, like also a V-model." (INFUSE).

The degree of complexity in such an environment became so high, that the traditional process models are no longer suitable: "*And that's why a big key of agility is that none of the very complex systems, no single person or individual, is able to describe the system in such a way that it is then processed by a team, and in the end what I really want, and need comes out.*" *(INFUSE).*

This illustrates how the use of agile methods helps software development teams to deal with complexity. In a regulated environment, an agile approach is relatively rigid, but still more dynamic than in a classical process model.

Reduce effort

An agile approach is far more efficient than a classic process model. It can help software development teams to reduce effort in a better way than classic process models do. Efficiency can be achieved by saving time (and thus increasing speed) or preventing waste (and thus reducing the number of tasks). Speed is an essential factor in software development. With agile methods and procedures, the development of the product begins earlier in the development process.

Generally, an agile approach is leaner than a classic approach and, thus, is better able to reduce effort in a software development process. In addition, a minimum viable product is usually available at an early stage: *"Because the agile is more like saying with the whole toolset, you start working much earlier on what the Minimal Viable Product is. That means you try to understand the problem much better, so you don't generate waste by specifying something that no one needs. And there is also such a bit of cultural change necessary." (INFUSE).*

Additionally, with an agile approach, it is possible to react and develop faster. This is a reason why companies are choosing this method: "*That was our main motivation* *to actually introduce agility. Namely to be able to react faster to changing market requirements in our process world as well, and in development." (DATA).* Also, traditional activities already planned are often not pursued further, resulting in unnecessary planning effort. In addition, requirements are often implemented in the software that are not required in the end. Software developers refer to this as "waste":

"[..] a motivation to originally introduce agility was that the predictability about what is the feature scope had nothing to do with what was then in the product requirement spec. So, there was something in it, but during the development period, it felt 50% completely different. And then it had made absolutely no sense to stay in this rigid process model now." (DATA).

"[...] and because he knows that, he defines what he thinks what will be needed in five years. The next big thing. And most of it is just over-specified. This means that you simply create a solution to problems that no one has." (DATA).

In summary, this means that in an agile environment only needed requirements are implemented: *"And then I have all the requirements that I want to implement, which I would not find with a classical approach. Because then I add insane things and have as requirements that no one really needs, and I would still forget a lot*." *(DATA)*. This, combined with regular feedback, leads to an efficient development process. Although mandatory activities for the provision of software must take place for a regulatory environment, these are, as expected, equally mandatory in a classical process model. The advantage in an agile environment is that the waste previously generated with conventional methods is no longer necessary, which reduces the effort and increases the efficiency in software development.

Improve usability

Even though some essential aspects of agile methods, such as early delivery or more flexible planning, are difficult to apply in a regulated environment, there are other facets that are beneficial and suitable for that environment. Software development teams can use these lean frameworks with a limited number of rules and specifications in various scenarios. Due to their simplicity, they are adaptable and can be combined with various agile and non-agile methods and procedures.

One example for the improvement of the usability is the fact that an agile approach leads to more innovation through employees. "*I can let the employees go, those who are normally motivated, they do it. And others, who are highly motivated, bring in more innovation and so on*." *(INFUSE).* Another example is the continuous process improvement which is very well supported by the Scrum framework. "*[...] the knowledge, and then contribute it back to the improvement process. So continuous process improvement. That's good." (XRAY)*. This is accompanied by regular feedback and adjustments which are carried out within the iterations. "*And what is definitely useful are the short iterations, where you quickly realize, ok, maybe we are on the wrong path after all, maybe we still have to readjust*." (*XRAY).*

Additionally, while using Scrum, it is possible to be nearer to the reality: "*And it's just the same, as always, the problems are actually always human. And that doesn't matter which process it is, you will always have that. Only the agile process helps us to be much more in reality than the waterfall process would do." (DATA)*. Last but not least, the documentation within a software development project is simpler than in a traditional process model: "*The documentation is easier to think through in the classic scrum, product backlog, product backlog item, test, idea, item, than in that (..), gives me a request and I turn you the request over, and then it is a test case." (INFUSE).*

Agile methods have several advantages which improve the usability within a software development process. Continuous process improvement is characteristic for an agile environment. This is particularly helpful in a regulated environment due to the existing rigidity and necessary additional activities. This includes providing regular feedback to stakeholders or the entire Scrum team, as well as promoting innovation in the development process by employees. A final point is the fact that an agile approach helps to develop realistically. With classic process models, development is a kind of black box for outsiders, as little feedback is given to the developers during development. Agile procedures provide transparency in the development process due to continuous feedback and a continuous target/actual comparison.

Promote collaboration

Agile methods promote collaboration between different roles and stakeholders within the software development process. Agile software development methods encourage an active collaboration between different stakeholders. This can lead to an increase in quality both in the process and the software product itself.

According to the interviews, the developers prefer to work in an agile environment rather than in a classical process model: "*[...] typically, it does not apply to all developers, but the developers prefer to work in this agile model rather than in a classic model. So, for me, the classic model in software development has simply outlived itself in any industry*." *(DATA).* Developing agile entails, a greater appreciation for the developers is shown because they work on their own responsibility and the team is organized independently: "*Many developers say they want to develop agile. That is the motivation. Then we can offer you whatever you need." (INFUSE)*. Active involvement is desired and enabled. This can be transferred from the team level to each team member.

Furthermore, external stakeholders can be involved in the process in Scrum: "*And then we* continued *to pursue this Scrum idea. Even if they're not on the team, just get them closer. So, they will be there on every Scrum-Day. And at the review meeting and see what's new." (INFUSE). "So, if you don't want to join the team and the same office, just get as close as possible and do as much as possible in small steps in the sprint." (XRAY).* Different roles and stakeholders are working closer together. An agile approach also increases employee satisfaction: "*Because the satisfaction is better after all, yes. Employee satisfaction is also important*." *(XRAY).* The team becomes more dynamic, more flexible and more efficient. The human component is a (success) factor and reason to consider agile developments in regulated environments.

To summarize, an agile approach supports working together with different roles and responsibilities. It is, therefore, suitable in a regulated environment as many stakeholders need to be involved and coordinated.

5 Discussion and Conclusion

The goal of this research was to shed light on the benefits and barriers of agile methods used for software development in regulated environments. The aim was not to find new agile practices, but to find the right fit for a regulated compliance context.

Our results confirm that software development in regulated environments emphasize quality assurance, ex-ante planning, additional roles, and documentation. Furthermore, our results show that organizations use agile methods in regulated environments to master complexity, reduce efforts, improve usability, and promote collaboration. Hereafter, we discuss our contributions, limitations and provide avenues for future research.

Our research contributes to the ongoing question why organizations use agile software development methods, given the strict regulations in compliance savvy environments [3]. Our results suggest that agile procedures, such as a project vision, do not only help mastering complexity of both software and hardware solutions that involve APIs and different stakeholders, but also support project planning by separating long-term and short-term planning in different mechanisms. Thereby, our results suggest that a good tailoring of the agile method leaves developers with a suitable methodology to work user-oriented and efficient, meet regulatory requirements [38] [39] as well as perform innovation projects [40].

Our results provide additional detail on how agile methods can be tailored to regulated environments [41]. We identified two different strategies, which we refer to as (1) embedding agile in existing V-model based development and (2) using agile as toolbox of procedures. When embedding agile in an existing plan-based environment, the agile part focuses on the development aspects and usually uses plan-driven approaches for testing and verification. When using agile as a toolbox to improve software development, we found that the teams developed what we refer to as mini-Vs within each sprint: A hybrid approach of combining agile and plan-based elements in each iteration.

Overall, we contribute to the literature on usability of agile methods by enhancing literature on scaling agile methods [42]. Our results provide evidence that agile methods can be successfully applied in regulated environments. We analysed three cases that tailored agile methods to their context by using agile procedures to organize daily work to foster collaboration and focus on user-centricity procedures to ensure usability and cope with complexity. The teams combined this with plan-driven elements for planning and interfaces, especially when complex hardware was involved.

Our study is subject to limitations. First, we selected teams that reported to actively use agile methods and, thus, we might have missed configurations where plan-driven approaches were enriched with agile elements. However, we examined three different cases and asked interviewees about the process, tailoring, and their experiences to ensure a broad perspective. Second, we focused on cases regulated by medical device compliance requirements. We argue that this is a typical regulatory environment but call for future research in different industries such as pharma, banking, and aerospace. Third, the focus of this paper is mostly on the benefits of agile software development in regulated environments. Drawbacks and problems were only touched briefly. We recommend for future research to also consider these aspects. Lastly, it is inherent to exploratory qualitative work that generalizing the results is challenging. For example, we derived our results from agile teams that used Scrum as agile method. Thus, they cannot be taken for granted for methods such as XP or lean. Further research should extend our theoretical sampling and examine other organization size and company context, including distributed teams and other agile methods. Research and practice would benefit from design science research that develops new artifacts, e.g., tools for agile teams in regulated environments or apply method engineering to develop a new development method for applying agile in such environments.

Overall, this research empirically illustrates the tailoring of agile methods for regulated environments. Our findings illustrate that regulated environments emphasize quality assurance, ex-ante planning, additional roles, and documentation. We show that organizations make use of agile methods to master complexity, reduce efforts, improve usability, and promote collaboration.

Abstract. In most organizations, employees commonly use mobile technologies including smartphones and tablets to complete their tasks. Therefore, many organizations have started to implement policies that govern the use of mobile devices such as Bring-Your-Own-Device (BYOD) policies, that allow employees to use private devices for work-related purposes, or Company Owned Privately Enabled (COPE) policies, which allow the use of organizational technologies for private purposes. Despite its relevance, there is only little empirical research that provides evidence on the effectiveness of specific policies, i.e., policies in favor of BYOD/COPE, policies that prohibit it, and no implemented policies. Based on survey data ($N = 381$), we provide initial insights in terms of the effectiveness of these policies. Our results indicate that policies indeed influence the degree of technology use. Policies in favor of BYOD/COPE are particularly effective. We conclude this paper by discussing our findings and derive several implications for theory and practice.

Keywords: IT Consumerization, BYOD, COPE, policies

1 Introduction

In modern organizations, it has become common practice for employees to use their personal technological devices or applications for job-related tasks. This use of consumer IT in the workplace, also known as "IT consumerization", represents a significant change in contemporary work life and has different benefits such as increased innovation, enhanced productivity, and a higher level of employee satisfaction [1]. A maturing body of knowledge has contributed to a better understanding of this development by investigating specific antecedents of IT consumerization [2] and its effects [3].

Although literature on IT consumerization has matured, it hardly investigates organizational aspects. This gap becomes most evident with regard to the effects of policy implementation and its impact on use behavior (see for instance [4]). From a practical perspective, this shortcoming is quite significant because policies are powerful instruments that allow organizations to influence their employees' use behavior (e.g., [5]). Therefore, it is important to provide empirical evidence on the usefulness and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

effectiveness of policies to derive implications and consult with organizations. Since there are two dominant options, namely Bring Your Own Device (BYOD) strategies [6] and Company Owned Privately Enabled (COPE) strategies [7], which are both equally important for organizations, a detailed analysis of their effectiveness would be most beneficial. Against this background, we seek to address this aspect with the following research questions (RQ):

RQ 1: How effective are policies in enhancing/reducing device use behavior?
RQ 2: Is there a difference between the effectiveness of BYOD and COPE policies?

In order to address our research questions, this paper is structured as follows: first, we review existing literature on IT consumerization to identify existing knowledge on the effects of policies in this field (section 2). Based on our review, we propose a research model that addresses this issue by hypothesizing differences in terms of policies and their impact on use behavior (section 3). In Section 4, we describe our methodological approach to address our objective. Thereafter, we present our analysis and the results (section 5). We discuss our findings in Section 6 and conclude by reflecting on the limitations of our study and by providing impulses for future research (section 7).

2 Related Work on IT Consumerization

Today, it is common practice to use privately-owned technologies for work-related tasks or to use company-provided IT for private purposes. The blend of personal technological devices or applications and business IT is described as "IT consumerization" or "consumerization of IT" [8]. This development comes with distinct strategies that allow organizations to monitor this phenomenon: BYOD and COPE. While BYOD refers to employees' work-related use of private hardware devices (such as personal laptops, smartphones, or tablets), COPE refers to the personal use of corporate IT. A typical example of COPE is the dual use of company-provided technologies such as smartphones for professional and private communication. In contrast, using a privately-owned smartphone for both purposes is considered BYOD.

Literature on IT consumerization acknowledges the multiple perspectives on this phenomenon. For example, Harris et al. [1] and Köffer et al. [6] refer to three perspectives, namely the individual, the organizational and the market perspective. The individual perspective refers to how an individual handles personal IT that is brought to work and is used for work-related purposes [1]. The individual perspective on IT consumerization thus focuses on the ownership of an IT tool [6]. The organizational perspective on the other hand deals with governing the use of such private IT in official business settings. From this point of view, IT consumerization can be seen as both a threat and an opportunity [1]. Finally, the market perspective on IT consumerization focuses on the origin or target market of consumer IT [1]. This third perspective highlights that consumer market technologies gradually reach enterprises, thereby having an impact on the IT department and preventing the distinction between consumer and enterprise IT [6]. It is worth noting that those perspectives overlap and influence each other.

In order to identify literature that addresses our research questions, we conducted a structured literature review [9, 10]. We started with the Web of Science by searching for "IT consumerization" within the senior scholar basket of eight [11]. Moreover, we manually scanned the forthcoming section of each journal. This means that most current publications [12, 13] are also considered here. Since the initial search did only reveal two studies, we further consulted the AIS library, which yielded in 24 papers. Note that the search was conducted by means of a keyword search in the abstract without limitations regarding the publication year. Each of the 26 papers was read by at least one of the authors and classified into one of the three perspectives. We specifically took all research questions, the research design, and the data sample into consideration and analyzed the unit of analysis. Since the three perspectives are not distinct (i.e., they overlap), we used the dominant perspective as a criterion to which we assigned each paper. An overview is given in Table 1.

For instance, Junglas et al. [13] seek to "examine the effect of IT consumerization on innovative work behaviours" (p. 2). Since the main focus lies on the individual, we included this study in the individual perspective. Similarly, we included research that investigates the change of governance structures [12] in the organizational section. Studies that examine the market perspective such as Niehaves et al. [8] ("[w]hat areas of information systems are specifically affected by consumerization", p. 2) were categorized accordingly.

Table 1. Related work on IT Consumerization

Perspective	Focus	Typical research question	References
Market	"Origin or intended target market of the IT tool" ([6], p. 366)	"What areas of information systems are specifically affected by consumerization?" ([8], p. 2)	[8]
Individual	"Ownership of the IT tool" ([6], p. 366)	"Why do some employees choose novel and innovative consumer IT on their own while others continue to work with the existing enterprise IT?" ([14], p. 1)	[2, 3, 6, 13–23]
Organizational	"Permission to use private IT tools for work" ([6], p. 366)	"What conflicts does IT consumerization create for IT departments?" ([24], p. 4)	[1, 4, 12, 24–31]

Our review highlights that the primary focus of research on IT consumerization lies on the individual perspective, whereas the market perspective only seems to play a minor role. This indicates that the origin of an IT tool, which is the focal point of the market perspective, is not of crucial importance in current literature anymore. This trend seems rather natural due to the pervasive nature of consumer technologies today. In turn, this makes the distinction between consumer market and business market less important. Our review also shows that, while the organizational perspective on IT consumerization has expanded in general, there is not yet a lot of literature that addresses the subject of policies. If at all, policies in relation to IT consumerization are of secondary importance in the reviewed literature. Notable examples include a study conducted by Lüker et al. [4] who make an important contribution to the field by investigating the importance of IT consumerization policies. Similarly, Mokosch et al. [28] study how organizational structures affect individual behavior. This lack of research is very significant because policies are a fundamental aspect of workplace design and, therefore, influence individual behavior. Without empirical evidence that provides further insights into this relationship, it is challenging to justify the implementation of such policies. Against this background, we seek to expand existing knowledge on the role of policies by investigating the impact of different types of policies on individual use behavior based on a large empirical sample. Our underlying research model is proposed in the following section.

3 Research Model

It is commonly accepted that external factors such as organizational factors including policies have a major impact on technology use. This is a fundamental assumption in the technology acceptance literature (e.g., [32]) and has also been emphasized in literature on mobile devices [28, 33]. The link between policies and individual behavior has also received support in various fields. For instance, Richman et al. [34] show that there is a significant relationship between supportive work-life policies and an employee's engagement. Similarly, Moskowitz et al. [35] highlight that workplace smoking policies result in employees smoking less.

Surprisingly, in related literature on IT Consumerization, the link between policies and use behavior is somewhat ambiguous. On the one hand, there is an increasing amount of literature that shows that employees use their devices despite it being prohibited or at least not approved. This trend is commonly referred to as shadow IT (e.g., [36]). In fact, existing research suggests that individuals who seek to meet their job performance expectations willingly neglect IS policies [37]. Based on this stream of research, we can assume that policies might not yield the intended degree of effectiveness. On the other hand, current literature provides evidence that the type of policy indeed has a significant effect on use behavior. For example, Junglas et al. [13] show a significant relationship between permission to use and intended use behavior.

In order to investigate the impact of different policies in detail, we propose a research model that explicitly differentiates between three distinct types of policies: policies that allow BYOD/COPE, policies that prohibit BYOD/COPE, or a lack of policy (i.e., no policies are implemented).

Policies that allow BYOD/COPE. We generally assume that policies allowing BYOD/COPE have a positive impact on use behavior. This is in line with existing literature on IT Consumerization (e.g., [13, 28]). We specifically assume that a policy that is in favor of BYOD or COPE has a positive impact on the corresponding degree of technology use. In fact, current literature suggests that permission to use private technology at the workplace has a significant impact on the individual's decision to actually use it [13]. We assume that this relationship is stronger when organizations have a policy in place that is in favor of BYOD/COPE rather than lacking such a guideline. Therefore, we propose the following hypotheses:

Hypothesis 1a:	A policy that allows BYOD leads to a higher degree of (private) device use (for work-related purposes) than a lack of policy.
Hypothesis 1b:	A policy that allows COPE leads to a higher degree of (company-owned) device use (for private purposes) than a lack of policy.

In line with hypothesis 1a and 1b, we assume that there also is a significant difference between organizations that allow BYOD/COPE and organizations that prohibit it. Therefore, we hypothesize the following:

Hypothesis 2a:	A policy that allows BYOD leads to a higher degree of (private) device use (for work-related purposes) than a policy that prohibits BYOD.
Hypothesis 2b:	A policy that allows COPE leads to a higher degree of (company-owned) device use (for private purposes) than a policy that prohibits COPE.

Policies that prohibit BYOD/COPE. Based on the IT consumerization literature that investigates the prevention of security threats and non-compliant behavior (e.g., [4, 38]), prohibition policies are of major interest. Those studies suggest that awareness of prohibition policies as well as the possible cost of noncompliance effectively decrease the use of technology. This is also in line with more general literature on security compliance relating to deterrence theory. This theory suggests that the higher the cost of noncompliance (e.g., sanctions, privacy concerns), the more likely it is that employees comply with given policies (e.g., [39, 40]). Contrary to this assumption, literature on shadow IT proposes that employees tend to be pragmatic and care more about their job performance than about complying with IS policies [37]. Those types of behavior can be explained by the neutralization theory, which suggests that people use neutralization techniques to legitimize their misbehavior [41]. For instance, Silic et al. [42] show that the neutralization technique "metaphor of ledger" has a strong and positive effect on policy violation in the context of shadow IT. This technique is based on the idea that we compensate bad behavior (e.g. violating the policy) with good behavior (e.g., overtime) [42]. Considering both streams of research, we argue that the existence of a prohibition policy has a stronger effect than a lack of policy. Hence, we propose the following:

Hypothesis 3a:	A policy that prohibits BYOD leads to a lower degree of (private) device use (for work-related purposes) than a lack of policy.
Hypothesis 3b:	A policy that prohibits COPE leads to a lower degree of (company-owned) device use (for private purposes) than a lack of policy.

Combining the arguments mentioned above, we propose a model that compares different relationships between policies that govern different types of use behavior and the actual use (cf. Figure 1).

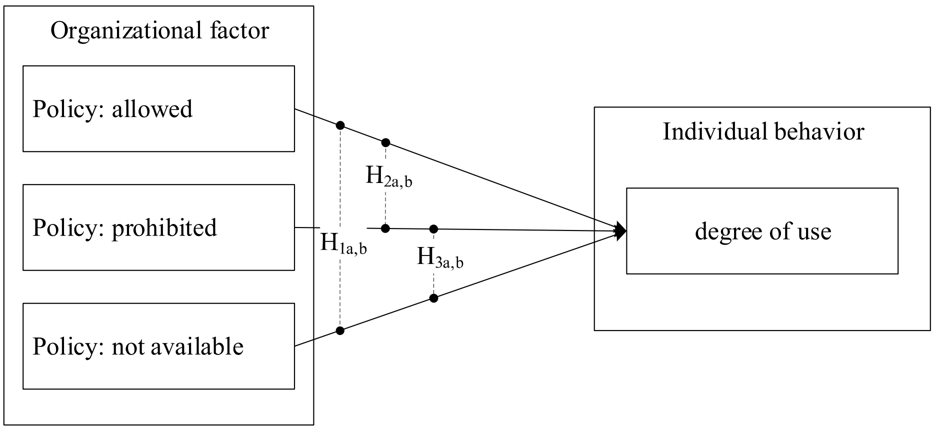

Figure 1. Research model

4 Methodology

This study is part of a larger project on IT consumerization and its impact on organizations. The focus of this study is related to the role of organizational policies and how they affect individual behavior. We collected data from 400 employees using computer-assisted telephone interviews (CATI). The participants were recruited from different local administrations in Germany that ranged from less than 50 employees up to 10,000. In order to create a representative sample, we selected 400 administrations out of the overall administration population. Responses with missing values relating to policies or use behavior were excluded, which yields 381 usable observations for this study. Table 2 provides a summary of the demographics. To measure the perceived skill in terms of technology use, the participants rated their IT skills ("How would you rate your IT skills…") on an ordinal scale ranging from "beginner" to "competent user" to "expert".

Table 2. Demographics, $N = 381$

Dimension	Classification	Percentage
Age	20-39	21.3%
	40-60	61.2%
	Older than 60	11.5%
	n/a	6.0%
Gender	male	67.4%
	female	32.6%
Skills	beginner	20.5%
	competent user	60.1%
	expert	19.1%
	n/a	0.3%

Whenever possible, we used established measurements. For BYOD and COPE use, we applied the device-related dimension of an established scale [2][1]. In terms of policies, we adopted an existing categorical [2] including "not allowed", "allowed", "missing". An overview is given in Table 3:

Table 3. Measurement Items

	Variable	Adapted Item	Scale	Source
BYOD	Use	I use private devices (e.g., laptop, smartphone) to complete work tasks.	7-point Likert scale	(adopted from [2])
	Policy	In my organization, the use of private devices to perform work tasks is …	"not allowed", "allowed", "missing"	(adopted from [13])
COPE	Use	I use the devices provided by the organization (e.g., laptop, smartphone) to complete private tasks.	7-point Likert scale	(adopted from [2])
	Policy	In my organization, the use of devices provided by the organization to perform private tasks is …	"not allowed", "allowed", "missing"	(adopted from [13])

[1] We also computed the analysis with the complete scale, including the use of internet accounts and the use of software [2] with sum scores. Since the results did not yield significantly different results, we only use one item for the subsequent analysis. Therefore, it is more in line with the objective of this study.

5 Data Analysis and Results

In order to investigate the hypotheses, the data analysis for each policy (i.e., BYOD and COPE) was conducted in three consecutive steps.

First, we applied a multiple regression in order to identify possible confounding factors. Therefore, we included gender, age, and skills as possible factors (i.e., predictors) of use in our regression models because these are commonly included in use-related research (e.g., [43]). The results of the BYOD regression model are significant in that they predict use and show that the three predictors account for 2.5% of the variance, $R^2 = .025$, F (3, 375) = 3.216, $p < .023$. We found no significant predictive power for the coefficients of age, $\beta = .063$, $p = .223$, and skills, $\beta = .057$, $p = .261$. However, the data shows that gender is significant, $\beta = -.124$, $p < .016$. The regression for COPE yielded similar results. The regression model shows that the three predictors account for 4.3% of the variance, $R^2 = .043$, F (3, 377) = 5.666, $p < .001$. Age, $\beta = .022$, $p = .663$, and skills, $\beta = -.021$, $p = .679$, do not significantly predict use while gender contributes to the model significantly, $\beta = -.020$, $p < .001$. Thus, the results indicate that gender has a confounding effect. Consequently, we include gender in our consecutive analysis.

Second, to analyze the effects of policies on the use of consumer IT, we applied an analysis of covariance (ANCOVA) including gender as a covariate. Table 4 shows the results that indicate a significant effect of BYOD policy on BYOD use after controlling for gender, F (2, 377) = 13.93, $p < .001$.

Table 4. ANCOVA results and Descriptive Statistics for BYOD Use by Policy and Gender

Type of Policy	BYOD Use			
	M	Adj. *M*	*SD*	*n*
Use prohibited	1.91	1.89	1.61	138
No Regulation	2.26	2.28	1.76	172
Use allowed	3.21	3.21	1.90	71
Source	*SS*	*df*	*MS*	*F*
Gender	24.44	1	24.44	8.26*
Policy	82.42	2	41.21	13.93**
Error	1115.58	377	2.96	

Note. *$p < .01$, ** $p < .001$

Similarly, Table 5 shows the significant effect of COPE policy on COPE use after controlling for gender, F (2, 377) = 17.43, $p < .001$.

Third, due to the statistically significant results, we carried out post hoc comparison analyses using Tukey's honestly significant difference (HSD) test to further examine the differences between the policies. For BYOD, the post hoc Tukey tests show that the "use allowed" policy ($M = 3.21$), no regulation ($M = 2.26$) and the "use prohibited" policy ($M = 1.91$) differ significantly at p < .01; the "use prohibited" policy and "no regulation" were not significantly different (see Figure 2). For COPE, the post hoc Tukey tests yield similar results. The "use allowed" policy ($M = 2.49$) differs significantly at p < .01 compared to "no regulation" ($M = 1.63$) and the "use prohibited" policy ($M = 1.40$); the "use prohibited" policy and "no regulation" were not significantly different (see Figure 2).

Table 5. ANCOVA Results and Descriptive Statistics for COPE Use by Policy and Gender

Type of Policy	COPE Use			
	M	Adj. *M*	*SD*	*n*
Use prohibited	1.40	1.41	1.11	195
No Regulation	1.63	1.64	1.21	116

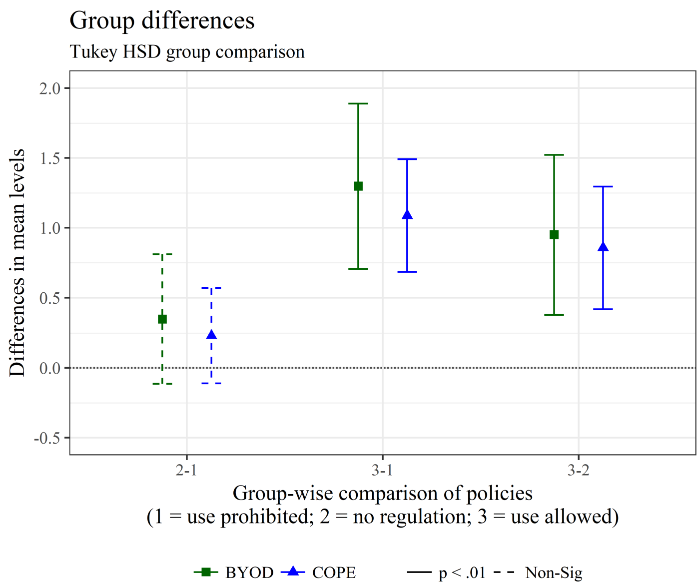

Figure 2. Group-wise differences

6 Discussion

Overall, our results indicate that BYOD and COPE policies can be compared in terms of their impact on individual use behavior. Therefore, our results hold for both types. We do recognize small differences between BYOD/COPE regarding their mean levels.

Specifically speaking, the differences between COPE policy groups are smaller than the differences between BYOD policy groups (see Figure 2). This indicates that the effect of BYOD policies is slightly stronger in terms of absolute values. We also conclude that the use of private devices for work related tasks (BYOD) is more common than using company owned devices for private purposes (COPE). In comparison, each BYOD policy type (i.e., "use prohibited", "no regulation", "use allowed") has a higher mean use than COPE policies (see Table 4 and Table 5).

The results also suggest that the hypotheses that a policy that allows BYOD/COPE leads to a higher degree of device use than a lack of policy (H1a, H1b) or a policy that prohibits BYOD/COPE (H2a, H2b) can both be supported. Thus, we can conclude that the implementation of policies in favor of using technology is an important tool for organizations to promote use. However, H3a and H3b, which are proposing that a policy that prohibits BYOD/COPE yields a lower degree of use compared to a lack of policy have to be rejected because no significant differences were detected. This does not necessarily imply that policies that prohibit use are not effective. Based on our data, this is rather due to a generally low level of use (BYOD – *M*: 1.91; COPE – *M*: 1.40). Consequently, we argue that no regulation reduces device use. As hypothesized in H1a and H1b, perceived risks may have an influence on whether a device is used or not in the case of no regulation. Since our findings were focused on the overall effect of policies and not on the individual antecedents of device use, we did not measure those factors. But we believe that those perceived risks are a valid explanation for these results.

Based on our insights, we derive several implications for theorizing. Most importantly, our results suggest that there are situations where there are no differences between an implemented policy and a lack of policy. Against this background, existing IT consumerization studies on policies could be examined in more detail. For instance, Lüker et al. analyze a compliant behavior related to different specified prohibition policies (loose vs. strict) [4]. Since they do not explicitly distinguish between a lack of policy and prohibition policies, their research can benefit from our results. Similarly, Junglas et al. show that policies have a significant impact on IT consumerization behavior [13]. Again, their study could be further expanded by investigating different types of policies.

Since the primary objective of this study is to investigate the effectiveness of different policies, this research has important implications for organizations. Most importantly, this study provides empirical evidence that the implementation of policies is effective. Therefore, organizations that are interested in increasing (or decreasing) their staff's use behavior (such as BYOD) can implement policies that follow their intended strategy. This is also in line with previous literature that investigates the relationship between organizational structures and individual behavior [28].

Based on our results, there is no significant difference between policies that prohibit use and a lack of policy. Hence, if organizations want to benefit from advantages related to consumer IT (e.g., innovation behavior [6] or performance [3]) they should implement policies that explicitly allow the use of private devices.

7 Conclusion, Limitations and Outlook

Based on a comprehensive review of the IT Consumerization literature, this paper addresses a gap by examining the effectiveness of distinct BYOD and COPE policies. The results show that policies generally are an important tool to influence the degree of use regarding BYOD and COPE. Above all, they highlight that if an organization is interested in benefitting from consumer IT (e.g., innovation behavior [6] or performance [3]), they should implement policies in favor of BYOD and COPE.

Not unlike any other study, this piece of research has its limitations, which, in turn, opens the door for future research. First, our results suggest that devices are used rather sparingly (see mean values). A possible explanation for this is our sample. In fact, there is a high proportion of older people (see Table 2). Since literature on digital divide suggests that older people play a pivotal role (e.g., [44]), future research should shed further light on the role of age. Second, this research builds on survey data. Based on our findings, further research could extend these efforts in terms of field experiments in order to go beyond self-reported indications. Third, our literature analysis is based on previous work on "IT Consumerization". However, there is more literature available that can be included by extending the keywords. For example, "Individual Information Systems" can be included to get a more comprehensive overview. Fourth, there might be situations where organizations force their employees to use private IT (e.g., gig economy). Hence, future research should also investigate how enforcement affects the degree of individual use behavior. Finally, the role of policies may differ across specific groups. Therefore, we suggest to further investigate this topic by acknowledging group differences such as industry versus government or large organizations versus small and medium sized enterprises.

Abstract. The current shortage of information systems (IS) specialists is leading to a strongly competitive labour market for the IT workforce. Technology companies need opportunities to prevent high replacement costs and knowledge loss by strengthening the affective organisational commitment (affective OC) of their employees. Using structural equation modelling, we investigate the influence of agile information systems development (ISD) on team members' affective OC. Our results demonstrate that agile project management (APM) positively predicts affective OC directly as well as indirectly via team members' job autonomy (JA) and their supervisors' support (SS). Our study gives empirical evidence on the relationship between agile ISD practices and affective OC and provides implications how to successfully leverage team members' affective OC. For practitioners, our research expounds why and how agile ISD is a suitable instrument to transform leadership culture within the company so as to raise affective OC beyond the IT workforce.

Keywords: Agile information systems development, affective organisational commitment, IT workforce, supervisor support, job autonomy

1 Introduction

Expenditure on IT is currently at its highest level and points to a new cycle of growth in the IT industry [1]. Consequently, the IT sector is now the strongest sector with respect to jobs in Germany, which is why IT professionals are in greater demand than ever before [2]. Simultaneously, the IT industry suffers from high labour fluctuation [3]. A current average turnover rate of 13.2% makes the software industry the unfortunate leader among all industries in this regard [4]. The consequences of turnover, such as high replacement costs and a significant loss of knowledge [3], indicate the need for measures that counteract the resignation of employees.

One main factor influencing turnover is organisational commitment (OC). Committed employees feel personally attached to their company [5], and therefore, they are willing to invest effort on behalf of the organisation [6]. To bind their employees, companies have to be attractive and convey values that employees regard as positive [7]. By introducing and living a culture within the company to which employees can

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

relate, they (the employees) identify with the organisation and satisfaction, engagement and performance increase [6].

Currently, a widely used method of sustainably modifying not only work processes but also values in the organisation is the introduction of agile information systems development (ISD). Using the concept of job redesigning, agile ISD practices influence job characteristics, as well as value constructs, and thereby, they change individuals' outcomes in terms of job satisfaction and motivation [8, 9]. We use this perspective of agility as a form of job redesigning to investigate the connection between agile practices and attachment by examining this question: "*What are the effects of agile project management (APM) practices on the affective OC of agile ISD team members*?"

We claim that agile ISD practices predict affective OC both directly and indirectly. First, agile practices interfere with values embedded within the organisation [10, 11], and consequently, they affect the value congruence and the identification of employees with the organisation. Second, by following the principle of self-organisation, agile ISD shifts responsibility to the team level, and at the same time, it provides a supervisor with the ability to support and protect the team in the face of difficulties [12, 13]. This rise of autonomy and supervisor support determines the commitment of employees to an organisation [14]. Using structural equation modelling, we aim to demonstrate the impact of agility both directly and indirectly on affective OC.

The paper is structured as follows. First, we explain the theoretical background research regarding agile ISD as well as affective OC. Second, we introduce the research model, as well as the hypotheses based on the literature review. Third, we describe the research method, as well as the study approach, and introduce the results of the structural equation model. Last, we discuss the implications and give further recommendations concerning affective OC in the context of agile ISD.

2 Theoretical Background

2.1 Agile Information Systems Development

Agile ISD is widely used in companies of various sizes and those belonging to various industries [15]. Within our paper, we define agile ISD as "the continual readiness of an information systems development method to rapidly or inherently create change, proactively or reactively embrace change, and learn from change while contributing to perceived customer value (economy, quality, and simplicity), through its collective components and relationships with its environment" [16]. The strength of agile ISD practices is decisive here: Agile approaches react to the challenges and needs of a fast-moving environment. By embracing change in projects, agility enables flexible planning, even when the scope of projects remains unstable [17].

At the employee level, agile ISD acts as an instrument for job design [8]. Agility improves team structures [18], reduces negative effects of subgroups [19] and influences job characteristics such as skill variety and task identity [8]. Furthermore, the ability to complete a whole task in the form of "user stories" leads to an increase in motivation, as well as ambition, to improve constantly [9]. Because of these factors, agile ISD influences the working processes of agile team members.

Agile ISD also causes an alteration in individuals' values and principles, changing the software development process fundamentally. In contrast to traditional development methods, agile ISD puts the focus on people and collaboration [11, 20]. Agile ISD trusts in self-organised teams that decide independently the extent and implementation of the requirements [21]. Equally, the supervisor assumes a coordinating and mentoring role [22]. This shift to flat hierarchies reduces cumbersome processes and makes agile teams faster and more efficient, allowing high-speed and top performance within the software development process [12, 13].

In our paper, we define an agile ISD team as a cross-functional team building and updating software, mostly using agile ISD practices and including members both focusing on delivering software as well as managing the team [8].

2.2 Affective Organisational Commitment

OC is "the relative strength of an individual's identification with and involvement in a particular organisation" [5] and consists of affective, normative and continuance commitment [23]. It is particularly important in the IT context as it has a great impact on turnover intention [38]. People with high productivity or fulfilment often perceive themselves as inseparable from their jobs. Consequently, their personal commitment to, and professional engagement with, the organisation for which they work is borne out [24].

Organisational culture and environment are strongly related to affective OC [25, 26]. The person–organisation fit and perceptions of congruence between worker and company sustainably influence employee commitment [27]. The more important values for an employee are reflected in the company the more the employee's commitment rises [28]. Therefore, the active management of embedded organisational culture and values has significant influence on retention.

Another essential point here is how decisions are made within the company. Informal culture and communication, as promoted within the context of an agile system, bind the team members in the form of an organisational family, and therefore, they foster OC [25, 26]. The empowerment to decide regarding work tasks gives an employee the opportunity to contribute to the success of the company, and consequently, it increases their interest in the enterprise's well-being [29, 30].

3 Research Model

The results of the literature review indicate the influence of agile ISD on affective OC beyond agile team members. In our study, we use our research model to investigate the impact of APM practices on affective OC. We hypothesise that APM practices influence affective OC in two ways. First, the impact happens directly through the embedding of positive, agile values into the organisation's processes, thereby affecting the person–organisation fit (H1). Second, the impact of APM practices occurs indirectly consequent to the change in leadership culture by affecting JA (H2a+b) and SS (H3a+b). **Figure 1** illustrates the research model.

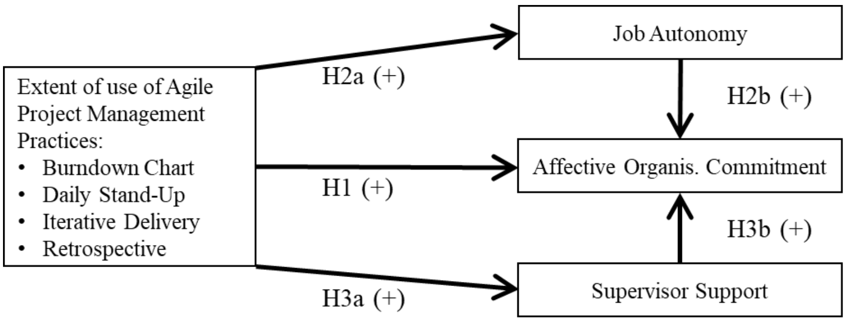

Figure 1. Research model

3.1 Direct Influence of Agile Practices on Affective OC

By promoting agile ISD within the company, the enterprise advocates positive agile values such as collaboration or customer involvement [10]. Retrospectives drive the team to constant reflection and at the same time improve the bond within the team. [31]. The principle of iterative delivery helps team members not only to see individual work packages, but rather to gain an overview of the entire development process [8]. Thus, an agile employee experiences a change at work under the umbrella of attractive and people-oriented values [20].

Agile values and principles play an essential role for agile teams. Williams [32] show that the majority of agile teams (65%) is not only committed to implementing agile practices, but rather to pursuing agile values. We suggest that this integration of agile values within organisational values influences the ways in which employees perceive their organisation. The advocacy of agile values in the company leads to an increased value congruence between employee and company, which implies an increased level of perceived person–organisation fit and supports identification with the enterprise [7, 33] , as well as OC [28]. Thus, we hypothesise the following: *H1: The use of APM practices positively influences affective OC of agile ISD team members.*

3.2 Indirect Influence of Agile Practices on Affective OC

JA, which is described as “the degree to which the job provides substantial freedom, independence and discretion in scheduling the work and in determining the procedures to be used in carrying it out” [34], has increased in the past few years within the IT sector . JA decentralises decision-making to those who actually carry out the work, and thus, it provides the team and the individuals with the flexibility to react faster to changes and unforeseen circumstances [15].

Self-organisation occurs at both the team and individual levels and is a decisive principle of agile practices [11, 13]. In accordance to [8] we suggest that agile methods support JA by combining the doing, the planning, and the controlling of the software development activities and providing the team with the possibility to manage a personal client relationship [8]. Furthermore, agility trusts in the self-coordination of teams and follows a shared decision-making approach [21]. Contrary to traditional software development, where managers delegate, coordinate and supervise work, agile teams are encouraged to organise work independently and make decisions jointly. This principle is, for example, followed by the agile practice of iterative delivery, which encourages team-based estimations regarding workload [35]. Thus, we hypothesise the following: *H2a: The use of APM practices positively influences JA of agile ISD team members.*

JA, as one dimension of intrinsic rewards, positively influences self-disciplined and commitment-driven behaviours. These behaviours are expressed by the presence of hard work, voluntary initiative and the support of organisational objectives [36]. Workers who are self-responsible for the organisation and the coordination of their work are more closely associated with the company.

Furthermore, employees who are challenged with self-organisation at work experience greater well-being and job satisfaction. This is because JA lowers stress, increases motivation and enhances work engagement [8]. Self-organised employees develop a personal interest in the well-being of the company, and consequently, commitment rises and turnover drops [29, 30]. Thus, we hypothesise the following: *H2b: JA positively influences affective OC of agile ISD team members.*

Although agile ISD calls for self-organisation, it does not mean that leadership has become obsolete. To maintain a functioning team, organisational guidance and particularly the support of supervisors are still needed [11, 12, 37]. Agile development requires a new, changed image of managers. Instead of trite adherence to hierarchy and micromanagement, agile ISD calls for management styles that foster the collaborative self-management of teams [37].

Studies already show the positive effects of this new form of leadership. Windeler, Maruping and Venkatesh [38] provide evidence by investigating 73 ISD teams in which empowering leadership contributes to a reduction in role ambiguity, role conflict and stress, and thus, the authors of that study determine that this management style is a suitable measure against technical risk factors [38]. Tyssen, Wald and Heidenreich [39] show that task and people-oriented leadership behaviours in temporary organisations, such as IT projects, are aimed above all at follower commitment in projects, thus having indirect effects on project success [39].

We consider this shift in management styles as beneficial and claim that the change to self-organisation in agile teams does not compensate the need for organisational support; rather, it enhances the perception of SS. By carrying out retrospectives, the team is able to detect problems more quickly and forward them to their supervisor. The use of burndown charts also allows ongoing and rapid feedback from the manager. Thus, we hypothesise: *H3a: The use of APM practices positively influences perceived SS of agile ISD team members.*

Organisational support is one essential key driver of affective OC [40]. By fulfilling socioemotional needs as affiliation and fostering the norm of caring, employees feel the obligation to improve performance and care about the organisation's welfare [41]. Consequently, employees perceive a higher level of satisfaction with their jobs and are more committed to their organisation.

SS, as one dimension of organisational support, reflects the connection between organisational support and affective OC [14, 41]. On the basis of the perceived identification of a supervisor with their organisation, managers act as organisational agents. Therefore, supervisors who appear to be valued by their organisation can highly influence the perceived organisational support of employees [14]. Consequently, we claim that the link between organisational support and commitment can also be transferred to the sub-dimension of SS. Due to flat hierarchies and close cooperation in agile ISD, we suggest that this effect might even be intensified and therefore, we hypothesise the following: *H3b: SS positively influences affective OC of agile ISD team members.*

4 Research Method

4.1 Study Design

Our study was conducted in cooperation with a German company operating in the automotive industry. The company employs approximately 130,000 workers, 4,500 of whom can be allocated to the IT function. The IT organisation strives for a holistic, agile approach, and therefore, it introduced company-wide agile practices in 2016.

We decided to perform the study with the aid of structural equation modelling (SEM). Because of the unestablished character of the theory and the occurrence of 2^{nd} order constructs within the model, we chose Partial Least Squares Structural Equation Modelling (PLS-SEM) over Covariance Based Squares Structural Equation Modelling (CB-SEM) and selected SmartPLS as the software tool [42, 43]. As a foundation for the procedure, we used the instructions of [43].

4.2 Participants and Data Collection Procedure

Due to restrictions, it was not possible to survey the entire IT department of the cooperating company and therefore we had to limit to a smaller target group. To capture a wide range of agile approaches, we intended to reach employees engaged in software engineering, with various degrees of agile experience and with different roles within the teams. On the basis of these parameters, we sent the survey to 380 potential candidates from different departments that use agile methods.

The survey achieved 172 responses, representing a response rate of 45%. The company in which the study was carried out works in close cooperation with external service providers because of which the company employs many people at managerial positions internally. It is, therefore, not surprising that around half of all respondents (52%) stated that they hold project managerial positions, such as Scrum Master Product Owner. The rest of the respondents were Business/System Analysts (15%), Software Developers (9%) and those in other positions (12%). In addition, 12% of all participants belonged to senior management. Most of the respondents had started to use agile methodology within the last 1.5 years (75%), while 6% had medium agile experience (1.5–3 years) and 12% had used agile practices for more than 3 years.

4.3 Measures

For the study, only established measures published in prior research with good quality criteria were chosen. To measure the extent of APM practices, we oriented on [8]. In order to investigate the most common agile practices we conducted a pre-survey within the company with 15 selected representatives from different divisions, with various roles and different degree of agile experience. The pre-survey revealed that iterative delivery (ID), daily stand-up (SU), retrospective (RE) and burndown chart (BD) were the most applied methods in the cooperating company (80 % of all respondents used ID and SU, 70 % used RE and 50% used BD), which is why we decided to integrate these practices in our survey. To assess JA, we used the scale from the job diagnostic survey by [34]. SS was measured using the five-item scale of [44]. For the assessment of affective OC, we used a scale from [45]. All items asked for the participants' agreement on a 7-point Likert scale, ranging from 1 (strongly disagree) to 7 (strongly agree).

4.4 Model Analysis

We built the structural equation model based on our research model. In accordance with [8], we defined the construct "APM Practices" as a reflective–formative 2nd-order construct, compounding burndown chart, iterative delivery, retrospective and daily stand-up. The other scales were modelled as reflective as proposed by the respective authors.

Following [46] and [47], we used a multilevel approach for assessing the structural equation models in order to analyse the added effects of agile practices on the suggested model. First, we modelled the direct effects of JA and perceived SS on the dependent variable affective OC (Model 1). Collectively, the manifest variables explained 24.2% of the variance of affective OC. When we included the agile practices (Model 2), the variance of affective OC increased to 26.9%. To test whether this increase was significant, we followed the instructions of [46] and calculated $f^2 = (R^2_{Model2} - R^2_{Model1})/(1 - R^2_{Model2})$. Afterwards, we performed a pseudo F-test ($f2*(n - k - 1)$)[1] [48]. The results indicated a significant change in R^2 ($F = 4.65$, df: 1, 130), which lets us conclude that the construction of the model is valid.

Subsequently, we evaluated the measurement model by conducting tests for internal consistency reliability, convergent validity and discriminant validity. The results of Cronbach's alpha, composite reliability and AVE can be found in **Table 1**. Cronbach's alpha of Retrospective, as well as composite reliability of Retrospective and Supervisor Support showed a critical value of > 0.95. However, in order to avoid losing informative value of the scales by deleting items, we decided to keep the scales as suggested and not to delete any items [43]. In addition, the outer loadings all exceeded the threshold of 0.7. Finally, the results of the cross-loading analysis demonstrated that all items loaded higher on the intended construct than they did on all other constructs, thus implying the construct's discriminant validity [49].

[1] * n = sample size, k = number of independent variables

Table 1: Reliability scores and AVE

		Cronbach's Alpha	Composite Reliability	Average Variance Extracted (AVE)
BD	Burndown Chart	.874	.923	.799
ID	Iterative Delivery	.835	.901	.752
RE	Retrospective	.964	.976	.933
SU	Daily Stand-Up	.891	.933	.822
JA	Job Autonomy	.904	.938	.834
SS	Supervisor Support	.947	.960	.827
OC	Organis. Commitment	.820	.880	.648

To examine the validity of our formative 2nd-order construct, we followed the guidelines of [43, 45]. The assessment demonstrated that all 1st-order constructs significantly loaded on the 2nd-order construct. We, therefore, conclude that the modelling of our 2nd-order construct is valid.

Finally, we investigated collinearity, the Q^2 and the R^2 values, to provide evidence for the validity of the structural model. The inner VIF values were all clearly beneath the critical value of 5 and left no indication for a strong correlation between the predictor constructs [43]. Likewise, all Q^2 values, resulting from the blindfolding procedure, exceeded the value of 0, and thus, they provided evidence for the predictive relevance of the model [43]. R^2 of affective OC (0.269) implied a low effect [50].

5 Results

The path coefficient analysis provided evidence for the positive impact of the use of agile practices on affective OC. First, the results show that agile practices significantly and directly influence affective OC (0.201, $p < 0.01$).

This indicates that agile team members are more committed to their organisation. Thus, H1 is fully supported. Furthermore, we found confirmation for indirect links from APM practices to affective OC. JA was significantly influenced by the use of APM practices (0.262, $p < 0.01$), and furthermore, it (JA) impacted affective OC (0.212, $p < 0.05$). These results imply that agile teams perceive more autonomy in their work processes, which consequently leads to a higher level of commitment. Therefore, both Hypotheses 2a and 2b can be supported. In addition, the analysis demonstrated the significant influence of agile practices on SS (0.217, $p < 0.01$) as well as that of SS on affective OC (0.282, $p < 0.01$). Agile team members accordingly feel more supported by their direct supervisors; consequently, affective OC rises. Thus, Hypotheses 3a and 3b are fully supported. The results of the path analysis can be found in **Figure 2**.

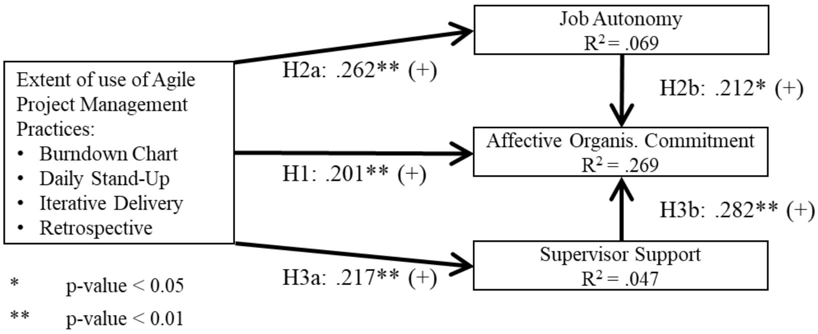

Figure 2. Path analysis results

6 Discussion

The findings of our study are in line with previous research [8, 35]. As with previous studies, we provide evidence for the existing conclusion that the extent of use of agile ISD practices positively predicts JA in agile ISD teams [8]. Furthermore, we reveal that team members of agile ISD teams gain high levels of support and empowerment from their supervisors [35].

We extend existing knowledge and provide insights that go beyond the results of previous research. When focusing on agile ISD practices, prior studies often investigated a particular practice, such as extreme programming or assessed agility, as a concept rather than investigating the extent of its use [51]. Most previous studies only investigated perceptions of work such as job satisfaction [8] and motivation [52]. The present study theorised and validated the effect of the use of agile ISD practices on JA, SS and affective OC. The results show that agile ISD practices have a direct effect on affective OC. In addition, affective OC is indirectly influenced by JA and SS. These additional insights provide several theoretical and practical contributions, which we explain in the following.

6.1 Theoretical Implications

The current research focuses on assessing the motivating and satisfying potential of agile ISD practices [8, 52]. Our theoretically conceptualized and validated research model is the first step in research on agile ISD to consider affective OC as a direct and indirect outcome variable and investigate how JA and SS predict affective OC. Thus, the contribution of our paper to existing literature is threefold.

First, our study contributes by theorizing and validating that agile ISD practices positively effects team members' affective OC. Analyzing the data with structural equation modeling, we show that there is a direct positive relationship between agile practices and affective OC in agile ISD teams. Thus, our paper extends existing knowledge on the effect of agile ISD practices on job perceptions of agile team members. The relationship between agile practices and team motivation was investigated by [52]. As well, Tripp, Riemenschneider and Thatcher [8] found that team members are more satisfied if agile ISD practices are used by showed that particular agile practices are related to job characteristics, such as skill variety and feedback. Therefore, we contribute to the agile ISD literature by indicating that in addition to increased satisfaction and motivation, team members are also higher committed to their organisation. By investigating affective OC in agile ISD teams, we also contribute to research on turnover of IS professionals in general [30]. Van Scotter and Motowidlo [36] found that affective OC is a valid predictor of employees' turnover intention. Existing studies often investigated teams using particular practices (such as Pair Programming [53]). This approach has gained critique as it does not assess the amount of use of agile practices, but rather the "high level concept of use of that method" [51]. Our study extends existing knowledge on agile practices as we measured the extent of use of agile practices, as suggested by [51]. In summary, we contribute to literature on agile by demonstrating that the extent of use of agile practices positively affects team members' affective OC.

Second, prior literature indicates that the extent of use of agile practices is positively related to team members' JA [8]. Our study replicates the findings in a conceptual manner [54] and shows a significantly positive relationship between the use of agile practices and team members' JA. As well, we found that JA positively affects affective OC in agile ISD teams. Based on previous literature indicating that self-organisation is a decisive principle of agile practices [11, 13], we theorized that the amount of agile practices positively predicts autonomy in agile ISD teams. The use of agile practices decentralizes decision-making to those who actually carry out the work, providing the team and the individuals with the flexibility to faster react to changes and unforeseen circumstances [15]. Thus, we argue that this principle of self-organisation is fostered when agile practices are used. As well, we theorized based on literature indicating that self-organised employees develop personal interest in the well-being of the company and, as a consequence, higher commitment [29], that JA predicts affective OC in agile ISD teams. Employees who are self-responsible for the organisation and the coordination of their work are more closely associated with the company. These theoretically derived effects have been proven within our study. Therefore, our study contributes to research as we replicate the results of [8] by indicating that the use of agile practices directly influences team members' JA. In addition, our results extend research focusing on affective OC [29] by revealing JA as a predictor of affective OC in agile ISD teams. Furthermore, the findings of our study extend prior literature on self-organisation and turnover such as [30] by providing evidence that JA significantly predicts affective OC in agile ISD teams. Moreover, our results also extend existing general literature on self-organisation of agile ISD teams such as [12], [13] and [22] by revealing that there is not only a direct effect of self-organisation on affective OC, but of JA on affective OC as well. In summary, we contribute to literature on self-organisation of agile ISD teams by providing evidence for a positive effect of agile practices on JA as well as a positive relationship between JA and affective OC.

Third, our study reveals that the use of agile ISD practices significantly influences team members' SS and this, in turn, predicts their affective OC. Hence, with an increasing amount of use of agile practices, team members gain more support from their supervisor. As a result, when perceiving themselves as being highly supported by their leader, team members feel more committed to the organisation. The present paper contributes to existing literature such as [55], who state that empowering leadership is crucial for project performance in agile ISD teams, by demonstrating that agile practices significantly affect team members' perceived support by their supervisor. agile Moreover, we contribute to existing knowledge such as [38], who find that empowering leadership is related to lower role ambiguity, role conflict and stress in software development, by showing that perceived SS is also positively related to affective OC. By fulfilling socioemotional needs as affiliation and fostering the norm of caring, employees feel the obligation to increase performance and care about the organisation's welfare [41]. In consequence, they are more committed to their organisation. Additionally, we extent literature such as [39], who found that people-oriented leadership behaviours in IT projects are aimed at follower commitment, by revealing that SS positively predicts affective OC. Summarizing, the present paper contributes to agile literature and psychological commitment literature by revealing that agile practices positively affect SS, which in turn is positively related to affective OC.

6.2 Practical Implications

In addition to theoretical derivations, our study also provides insights for practitioners. The results of the study demonstrate that agile ISD significantly influences not only work processes but also the well-being of IT professionals. By means of APM methods, it is possible to influence the perception of employees towards their company. Through striving for agile principles, an employee finds a common basis with their organisation and feels more connected to their company.

In addition, the results highlight the impact of leadership in empowered teams. The study proves that autonomy in agile teams by no means makes leadership obsolete but rather puts it at the centre of the scheme of things. The results demonstrate that JA and SS are of equal importance for an employee. This indicates the necessary shift in the current leadership culture. Supervisors must position themselves in a supportive and protective function to further encourage the self-organisation of their teams. This concept enhances the well-being of individuals and retains employees for the long term.

6.3 Limitations and Future Work

We want to emphasise the importance of attachment in the IT environment, thus encouraging future work regarding affective OC in the IT context. In this regard, we want to draw attention to our limitations to correctly classify the interpretation of the results and simultaneously create space for future research. First, we point out the importance of an enriched replication of this study. Hypothesis 1 is based on the argument that the introduction of agile values leads to an increase in person-organisation fit, which consequently leads to a rise in organisational commitment. This reasoning was derived from research by [7] and [28]. Unfortunately, we were not able to measure the person-organisation fit aspect in our study. Furthermore, we would like to point out that the scales used only allow a measurement of the application of agile practices, but at the same time do not indicate that agile values are actually adapted in the company. We consider the investigation of the influence of agile practices on person-organisation fit as an important field of research, which is why we recommend to inspect this in future research. Second, our study was explorative in character, and therefore, it includes modest R^2 values. Because of the explorative character of this study, these results are comprehensible. We compared the variance with other explorative research in the area of affective OC and found similar results [e.g. 33, 56] because of which we think that our study brings essential contribution to the current agility research. In future, a replication of the study with a bigger sample size could lead to results with higher variance. Finally, we would also like to point out the possibility of reverse effects in the model. As OC leads to positive behavior [57], we recognize that the extent of agile practices may also be affected by the appearance of affective OC. For future research we therefore also recommend an investigation of the interaction of the presented independent and dependent variables.

7 Conclusion

Our paper provides insights into the influence of APM practices on affective OC. Based on structural equation modelling, our results demonstrate (1) the direct impact of agile ISD on affective OC via affecting values within the organisation and (2) the indirect impact of agile ISD on affective OC via following the agile principle of self-organisation and the consequent fostering of JA and SS. Our study, therefore, sheds light on the effects of agile practices on affective OC, while emphasising the importance of empowered teams and their relationship with leadership in the IT context.

The Complexity Trap – Limits of IT Flexibility for Supporting Organizational Agility in Decentralized Organizations

Tobias Segert[1], Friedrich Holotiuk[1], and Daniel Beimborn[2]

Abstract. In times of digitalization, organizations are transforming to become more agile. Decentralizing decision-making to lower levels of the organization allows firms to better detect changes in their environment and to sense new opportunities. Simultaneously, the digital transformation of a firm is increasingly relying on a flexible IT function. This study explores how decentralization of decision-making power increases organizational agility and to what extent this relationship is dependent on IT flexibility. We conducted a quantitative study using two rounds of surveys with 123 respondents from the consulting industry. Based on covariance-based SEM, we find that too much flexibility of the IT function in combination with decentralized decision-rights creates a complexity trap and, thus, decreases organizational agility. These findings carry several theoretical contributions for organizational agility research and shed new light on the role of IT flexibility for digital transformation.

Keywords: Organizational Agility, Decentralization, IT Flexibility, Detecting Capability, Digitalization

1 Introduction

The concept of organizational agility has been discussed as a solution for organizations to prosper in volatile environments. The term *agility* was coined in the Manufacturing and Information Systems (IS) literature to define a firm's ability to seize opportunities due to changes in the environment [1]. Today, this concept is more relevant than ever: digitalization is creating an increasingly complex and unpredictable environment [2]. Digitalization is "a sociotechnical process of applying digitizing techniques to broader social and institutional contexts that render digital technologies infrastructural" [4 p. 2]. Among others, it changes market boundaries, substitutes physical labor with new technology, eliminates cognitive labor by increased application of software algorithms, and replaces physical products and services with new digital offerings [2].

Trying to compete in such a fast-changing environment is a complex task and organizations struggle to find an efficient organizational design that promotes their

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

adaptability to those unforeseeable changes [4]. One solution to transform the organization is to delegate responsibilities to lower levels of the organization to increase the employees' ability to respond to changes. Research has shown that increased decentralization has been beneficial towards organizations' ability to respond to change. However, extant theory is scarce in explaining why this relationship exists [5].

Today, firms' operations are highly dependent on IT [3]. In times of digitalization, the importance of digital options has been stressed as an enabler of organizational agility [6], [7]. In this context, Byrd and Turner [8] emphasize the supporting role of the IT function for organizations. Even though the enabling roles of both IT flexibility and decentralization are separately well recognized in the literature, the question remains how they are interrelated with regard to organizational agility. Hence, we derive the following research question: *How does the decentralization of decision-making rights complement with IT flexibility in enabling organizational agility?*

To answer this question, our research uses a structured survey, collecting data at two points in time. We develop a conceptual model based on constructs from extant research. We draw on a sample from the professional service industry and analyze our hypotheses using covariance-based SEM. Our findings uncover the limits of IT flexibility as firms are experiencing a *complexitiy trap* when high decentralization and high IT flexibility interfere. The remainder is structured as follows: section 2 introduces the conceptual model and hypotheses. Afterwards, the sample and measurement development are explained in section 3. Section 4 presents the findings based on the tests of the hypotheses. Finally, we discuss the main implications and conclude the paper.

2 Model Development

Our theoretical model (Figure 1) is derived from extant literature.

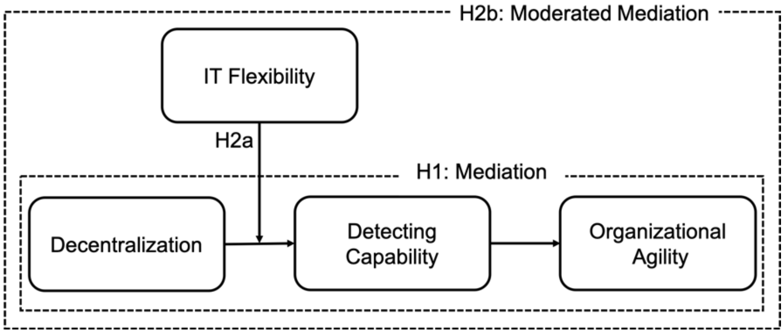

Figure 1. Conceptual Model

First, we conceptualize how decentralization of decision rights enhances agility by proposing detecting capability as a mediator. Second, we examine to what extent this relationship is conditional on IT flexibility. Understanding these mechanisms can help designing organizations that rely on the flexibility of IT to face the challenges of digitalization. A summary of all constructs with definitions can be found in Table 1.

Within the IS literature, agility had first been used in the software development domain. Later, scholars also applied the concept of agility to the entire organization. They offer new theoretical arguments for how the organizations' ability to thrive in a digitalized world is dependent on IT capabilities. Scholars point out the difference between agility and flexibility [9], responsiveness [10], dynamic capabilities [9] and strategic flexibility [11]. Zhang and Sharifi [12] define the concept of agility as the ability to adequately respond to anticipated or unexpected changes in the environment (like the advent of new market players or digital technologies) and to see change as an opportunity. Additionally, scholars have noted the importance of sensing change for the concept of organizational agility [6], [13].

Table 1. Summary of key constructs

Construct	Definition	Reference
Decentralization	"The extent to which power over decision making in the organization is dispersed among its members" with a focus on vertical decentralization which "refers to the extent to which formal decision-making power is "delegated" down to the chain of line authority."	[15 p. 326]
IT Flexibility	Ability of the IT function to provide and support the business unit with ex-post adjustments to IT applications.	[15]
Detecting Capability	Firm-wide capability to proactively detect sudden changes in the business environment.	[6]
Organizational Agility	"Firm-wide capability to deal with changes that often arise unexpectedly in business environments via rapid and innovative responses that exploit changes as opportunities to grow and prosper"	[8 p. 933]

2.1 Detecting Capability as a Mediator of the Relationship between Decentralization and Organizational Agility

Based on existing research on agility, we have identified two established research streams as foundation for our model: one stream focuses on the importance of detecting capabilities for organizational agility, and the other, stemming from organizational design, looks at the role of decentralized decision making for detecting capabilities.

Detecting Capability and Organizational Agility

First, we follow the initial definition of organizational agility, defined as a "firm-wide capability to deal with changes that often arise unexpectedly in business environments via rapid and innovative responses that exploit changes as opportunities to grow and prosper" [8 p. 933]. The detecting capability, however, is defined as the firm-wide capability to proactively detect sudden changes in the business environment [6].

We argue that the concept of detecting environmental change and the concept of responding to these changes are discriminant in how they are facilitated in organizations. The ability to detect change is formed, e.g., by the capability to track competitors' actions, to identify changes in the customer's demand, or to recognize shifts in the economy [11]. By contrast, the capability to react to change encompasses the ability to make rapid changes to organizations' products, IT applications, supply chains, resource allocation, or operations [7], [11]. The rationale is that the constant screening of the environment and the detection of possible changes enables organizations to quickly act and capitalize on this change. We conclude that organizations which are aware of threats and opportunities posed in its environment are better able to react to those changes. Consequently, organizations with superior detecting capability are better prepared to react quickly to changes.

Decentralization and Detecting Capability

According to Winkler and Wessel [16], decision rights are concerning different research themes like IT governance and firm structure. We concentrate on the latter theme, which emphasizes the influence of information systems on firm structures [16]. Following Mintzberg [14], there are two distinct types of decentralization on the organizational level: horizontal and vertical decentralization. We focus on vertical decentralization, which describes "the extent to which formal decision making power is 'delegated' down to the chain of line authority" [15 p. 326]. The delegation of decision rights to lower levels of the hierarchy encourages lateral and vertical communication across employees [5] and increases employees' satisfaction and motivation [17]. As Hage and Dewar [18] point out, centralized decision-making power in the hands of a few impedes the flow of creative thoughts across various members within the organizations and blocks innovative ideas. The rationale is that innovative ideas pose threats to the existing distribution of power in organizations. In centralized organizations, innovative ideas must pass several managers along the chain of command before receiving approval or resource support and are, therefore, more likely to be rejected [19].

Therefore, organizations with a decentralized structure, having many empowered employees on lower levels of their hierarchy, show a better flow of ideas concerning the opportunities and threats they are facing. Employees in decentralized structures are also more motivated [17] to screen and understand the complex changes of the now digitalized environment that influence their work. We conclude, organizations with a high level of decentralization can better detect and understand changes in their environment, e.g., in the form of new IT innovation, or changing customer demands.

Decentralization on Organizational Agility *via* Detecting Capability

Following the extant literature, the positive relationships of decentralization on detecting capability and of detecting capability on organizational agility are well-established. Still, there are different findings regarding the relationship between decentralization and organizational agility. On the one hand, literature suggests that a high decentralization of decision-making power is associated with high organizational agility [20]. Delegating decision-making rights down the chain of command is believed to increase the speed in decision making allowing for faster reaction to changes. On the other hand, scholars point out that decentralized decision-making limits organizations' ability to respond to immediate threats [21]. If every subunit in the organization has the authority to react independently to external changes, the organization might act in many different and possibly even contrary ways. Hence, decentralization requires additional coordination efforts to manage the independent subunits or employees to overcome increased complexity [22].

Based on the mixed findings regarding the association between decentralization and organizational agility [21], and based on the fact that the relationships between detecting capability and organizational agility [11] and between decentralization and detecting capability [18] are well established, we propose that detecting capability acts as a mediating variable. Thus, detecting capability explains the effect of decentralization on organizational agility. This means that the effect of decentralization on organizational agility is due to the detecting capability. The vertical decentralization of decision rights enhances organizations' ability to detect changes posed in the environment, which increases organizational agility. Accordingly, we suggest that decentralization is not directly increasing organizational agility. In fact, decentralization only indirectly enhances organizational agility by increasing organizations' capability to detect change. We hypothesize a mediating effect:

The effect of decentralization on organizational agility is mediated by detecting capability. (H1)

2.2 The Moderating Effect of IT Flexibility

In times of digitalization, the role of IT units is heavily discussed. We regard IT flexibility as the ability of an IT unit to provide and support the business side with ex-post adjustments to IT applications [15]. This focuses less on a technical understanding (such as: modular, state-of-the-art IT infrastructures), but rather on an organizational understanding (such as: defined responsibilities, IT service processes, and sufficient resources) of IT flexibility and matches the business side's perception of IT flexibility.

The literature holds different perspectives which offer opposite indications on the effect of IT flexibility. Whereas positive effects of IT flexibility are reasoned with more tailored IT applications supporting diverse business units, negative effects of IT flexibility are reasoned with increased complexity caused by too many and unstandardized IT applications which cripple the IT function [23]. While Overby et al. [11] and Sambamurthy et al. [6] propose a direct effect of digital options on organizational agility, we follow the argumentation of Tallon and Pinsonneault [13] that IT flexibility can also act as a moderator variable in agility research. In the context of our study, using IT flexibility as a moderator allows us to conceptualize that organizations with similar degrees of decentralization could have different levels of detecting capability depending on the flexibility of their IT function. This yields new insights into whether the effect of decentralized decision-making on the organizations' detecting capability might be stronger in combination with a flexible or inflexible IT.

Currently, we find two opposite perspectives in the literature about how decentralization and IT flexibility complement each other. Some scholars argue for a positive interaction effect between IT governance decentralization and the degree of IT architecture modularity when it comes to IT agility [24]. The rationale is, that a highly modular IT architecture in combination with a high IT governance decentralization reduces the coordination efforts between different departments and enhances the speed when it comes to decisions regarding the adaptation of new IT applications. However, the idea of decentralizing decision rights in IT governance is distinct to the idea of decentralizing decision rights in the overall firm structure [16]. In addition, our conceptualization of IT flexibility as the ability of the IT function to support the business side with ex-post adjustments to IT applications is different to the conceptualization of IT architecture modularity, which is defined by loosely coupled subsystems that communicate through standardized interfaces [24]. Another argumentation for a positive interaction effect of IT flexibility and decentralized decision-rights is provided by the increased availability of digital options [13], which allows decentralized business units to reap the benefits of tailored IT applications to improve their process of detecting changes.

Contrary to the positive interaction effect between decentralization and IT flexibility, literature suggests a negative interaction effect based on findings about IT silos and shadow IT. In decentralized organizations, employees are empowered to make own decisions. While this is generally associated with positive effects (e.g., satisfaction and motivation), it can be unfavorable when employees are allowed to order many tailored IT solutions through a flexible IT function, because the diversity and number of IT applications in the organization increases complexity [23]. As Tiwana and Konsynski [24] point out, interdependencies of IT applications spanning across the organization pose several threats to IT agility when changes in the existing IT application portfolio are made. Since not all members of the organization have a holistic understanding of the interplay of the organization’s IT applications, they cannot recognize the problems that surface when integrating or adapting new IT applications. Thus, negative effects of IT flexibility could kick in and cause organizations to end up in a *complexity trap,* which reduces the alertness for change like new IT opportunities [24]. For example, when employees on the lower level of the organization are delegated to assess the challenges and opportunities of a new product, highly flexible internal IT offerings will likely lead to employees working with different methods based on different IT applications they deem appropriate (they are authorized to decide what is appropriate). Thus, comparing results of the assessment becomes more complex and causes uncertainty in the organizations’ detecting process [23].

In summary, there are two opposite predictions about how decentralization and IT flexibility complement each other with regard to the detecting capability of an organization. Hence, we derive the following hypothesis with an unknown direction of the moderating effect of IT flexibility:

The relationship between decentralization and detecting capability is moderated by IT flexibility. (H2a)

The argumentation for a moderation effect of IT flexibility on the relationship between decentralization and detecting capability also suggests moderated mediation. Since we argue, that detecting capability mediates the relationship between decentralization and organizational agility (H1), and the direct relationship between decentralization and detecting capability is moderated by IT flexibility (H2a), we also hypothesize that the mediating effect is moderated by IT flexibility. This means that organizations with the same level of decentralized decision-making end up with different levels of organizational agility dependent on the degree of the flexibility of their IT function. This is, as argued above, because the effect of decentralization on detecting capability is not stable, but changes depending on different levels of IT flexibility:

The indirect relationship between decentralization and organizational agility via detecting capability is moderated by IT flexibility. (H2b)

3 Method

To test our hypotheses, we conducted an empirical study. We developed two structured questionnaires. The first survey contained multiple-item scales for the measurement of three constructs (decentralization, IT flexibility, and detecting capability), the second survey measured organizational agility.

3.1 Sample

Data was collected from the consulting industry. The market for standard consulting services has become increasingly competitive, leading to eroding margins [25]. New technology-based services such as data analytics and artificial intelligence applications are becoming increasingly important and change clients' demand. This forces consultancies to compete in markets that were once solely occupied by technology companies [25]. Compared to other industries, the need to stick to certain IT applications is less rigid in the consulting industry. In the manufacturing industry, for example, applications are interfacing with adjacent firms to a much higher degree. Besides the quick change of clients' demand, Software-as-a-Service offerings by large business providers, such as SAP with S/4Hana Cloud, increase technology companies' grip on IT related services [25]. Since agility allows organizations to stay competitive, it is highly important in the professional service industry. We targeted consultants in both higher and lower hierarchical positions in their respective company to answer our survey. Therefore, all hierarchical levels of the organizations are represented: 50% of the respondents are consultants, 30% are managers, and 15% belong to the top management of their consultancy. About one third of the consultancies have an IT focus, whereas one quarter focuses on auditing and another quarter on strategy and process consulting. Therefore, our dataset encompasses a good mix of the different specializations within the consulting industry. About 40% of the consultants that answered the survey have been working in their consultancy for more than four years, so we assume that consultants in our sample have sufficient knowledge to give reasonable answers to our survey.

3.2 Data collection procedure

An invitation to participate in the first online survey round was distributed through various channels. The first survey round was open for completion from June to August in 2017. Only consultants were allowed to answer the survey. The survey was mainly sent out to consultants in Germany. Consultants were assured that all answers would be kept anonymous. The survey was distributed via the authors' personal networks, the university's network, and professional social networks Xing and LinkedIn. Since consultants were also asked to forward the invitation to their colleagues, we cannot report the final number of contacted consultants. For the second survey round, personal links were sent out to those 181 consultants that answered the first survey *and* left their email address for a second survey. In this second survey, we collected data about the dependent variable organizational agility. The survey was open for completion from May to June in 2018. Ultimately, 123 consultants participated in both of our survey rounds.

3.3 Measures

The survey contained multiple-item scales for the measurement of decentralization, IT flexibility, detecting capability and organizational agility. Adaptations to the original questions were made to reflect the consulting industry's specialties and to improve the consultants' understanding of the questions [26]. An overview of the constructs and items can be found in the appendix. The items were developed in English; we followed the standard translation and back-translation procedure to create German equivalent versions of the measures. All items were pre-tested in both languages with potential participants and fellow researchers to ensure content validity. Means, standard deviations, and correlations among the latent variables are presented in Table 2.

Table 2. Constructs measures and quality criteria

	Variable	1	2	3	4	CA	CR	AVE
1	Decentralization	*.684* [a]				.719	.724	.468
2	IT Flexibility	.285*	*.768*			.803	.810	.590
3	Detecting Capability	.623**	.459**	*.771*		.710	.814	.594
4	Organizational Agility	.296*	.376**	.636**	*.737*	.779	.780	.543

[a] Square roots of the AVE reported on the diagonal in italic, N = 123, * $p < .05$ / ** $p < .001$
CA = Cronbach's Alpha, AVE = Average Variance Extracted

Measures for the independent and dependent variables were collected at two different points in time: First, the perceived horizontal decentralization of consultancy was measured with a five-point Likert scale, using a three-item measure from Claver-Cortés et al. [27]. Decentralization in this research is the extent to which a consultant experiences decision rights being distributed to lower levels of the chain-of-command. Consultants rated the perceived flexibility of their IT on a five-point Likert scale, using a three-item measure from Martin et al. [15]. IT flexibility in this research is the extent to which the IT function is able to provide and support ex-post adjustments to IT applications. The detecting capability of organizations was measured with a seven-point Likert scale as this construct is a dependent variable. Based on Ahsan and Ngo-ye [28] and Sambamurthy et al. [6] we derived three items. Detecting capability comprises proactively detecting changes in the business environment. Lastly, organizational agility is defined by Lu and Ramamurthy [7] with two dimensions: market capitalization agility and operational adjustment agility. To maintain a clear conceptual separation between the idea of detecting and reacting to change, we focus on operational adjustment agility. This dimension emphasizes the reactivity of operational activities as an enabler of innovative initiatives in times of change [7] and, thus, represents the original idea of organizational agility by focusing on the organizations' ability to react to changes [12], [13]. Additionally, the measurement model would not structurally change when using a first-order construct for organizational agility with two dimensions (market capitalization agility and operational adjustment agility). We measure organizational agility using the three items of the operational adjustment dimension by Lu and Ramamurthy [7].

3.4 Testing for Biases

Although a time-lag design (surveys at two points in time) mitigates the concern of common method variance, several additional procedural and statistical remedies as suggested by Podsakoff et al. [26] were taken into consideration. Participants were assured anonymity and confidentiality of their responses to limit concerns about evaluation apprehension and social desirability. Buffer items, not relevant for this research model, were included in the survey. We also checked for nonresponse bias. The first 30% of the responses were compared with the last 30% of the responses for both survey rounds. The independent sample t-test found no statistically significant difference ($p < .05$), indicating that nonresponse bias is not an issue in our study. Finally, comparing the responses for the German and English version of the survey did not result in any statistically significant difference ($p < .05$).

4 Results

4.1 Validation of Measurement Model

We run a confirmatory factor analysis with Mplus (Version 8.1) to test whether the collected data reflects the hypothesized measurement model [30] and to establish convergent and discriminant validity of our measures. Following Hu and Bentler [31], the overall model fit was very good (χ^2 (48) = 49.34, CFI = .997, TLI = .996, SRMR = .038, RMSEA = .015). All of our fit indicators are above the threshold of .95 for the CFI and TLI value and below the thresholds of .08 and .06 for the SRMR and RMSEA value, suggesting a good model fit [31]. Each item loaded on its appropriate factor, all standardized factor loadings were significant ($p < .000$) and larger than .59. The correlation among all latent constructs were all substantially smaller than 1, and the square root of the AVE for each construct was larger than its highest correlation with any other construct (see Table 2), indicating that our constructs are sufficiently discriminant.

4.2 The Mediating Role of Detecting Capability

We applied covariance-based structural equations modeling (CBSEM) to examine the relationships among the latent variables. Following Cheung and Lau [32], we used a three-step approach for testing moderated mediation with latent moderated structural equations (LMS). This procedure produces more accurate parameter estimates and confidence intervals than commonly used regression-based approaches, which rely on observed variables and do not correct for measurement errors [32]. We used Mplus with maximum likelihood estimation to examine the moderated mediation model.

First, because the LMS approach does not provide the usual fit indices, we assessed the overall model fit without the interaction (moderation) term following Cheung and Lau [32]. The fit indices indicate that the suggested model fits the data very well (χ^2(49) = 50.19, CFI = .998, TLI = .997, SRMR = .039, RMSEA = .014).

In a second step, we evaluated the whole model (Figure 2) including the interaction between decentralization and IT flexibility. 2,000 bootstrap samples were generated to examine the model. Standardized path coefficients (β) are reported in Figure 2. Our model explains 44 percent of the variance in detecting capability ($R^2 = .435$) and 49 percent of the variance in reacting agility ($R^2 = .489$).

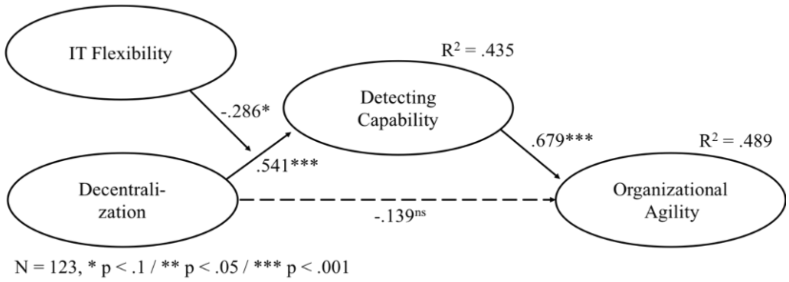

Figure 2. Estimation of the measurement model

To test the mediating effect of detecting capability on the relationship between decentralization and organizational agility (H1) we test the two direct effects between decentralization and detecting capability as well as between detecting capability and organizational agility. Decentralization has a statistically significant, positive relationship with detecting capability (β = .541, p = .000), and detecting capability has a statistically significant, positive relationship with organizational agility (β = .679, p = .000). Subsequently, we test the direct effect between decentralization and organizational agility, and the indirect effect of decentralization on organizational agility via detecting capability. The direct relationship between decentralization and organizational agility is positive and significant (β = .300, p = .008). However, the inclusion of the mediator variable detecting capability leads to a statistically non-significant relationship between decentralization and organizational agility (β = -.139, p = .485). We conclude that the relationship between decentralization and organizational agility is fully mediated by detecting capability (confirming H1).

4.3 The Boundaries of IT Flexibility

Hypothesis 2 proposes a moderating effect of IT flexibility on the positive relationship between decentralization and detecting capability (H2a) and an indirect effect of decentralization on organizational agility through detecting capability conditional on IT flexibility (H2b). Thus, we report the p-value of the moderation and the mediation effect. Moreover, we follow the widely acknowledged argumentation, that since the sampling distribution of the product of two path coefficients is not normal, the sampling distribution of moderation and mediation effects is not normal either [33]. Therefore, using a t-test or a Sobel test would not be appropriate to evaluate the estimates' significance, because it requires a normal distribution. Consequently, we additionally use a non-parametric procedure to interpret the statistical significance of the moderation and mediation effects. The bias-corrected bootstrap confidence interval (CI) produces more accurate results than parametric tests (e.g., t-test) since it allows the interaction term and the indirect effect to be non-normally distributed. A particular effect is deemed statistically significant if the bias-corrected bootstrap confidence interval does not contain zero [33]. Based on these quality criteria, we find in our analysis:

First, the interaction effect between decentralization and IT flexibility on detecting capability is statistically significant, since the bootstrap confidence interval does not contain zero, and negative (H2a: $\beta = -.286$, 95% CI [-.648, -.022], $p = .057$). We find that IT flexibility acts as a moderator on the relationship between decentralization and detecting capability (confirming H2a).

Second, supporting the idea of a moderated mediation effect, the analysis is based on the index of moderated mediation [34]. We find the interaction effect between decentralization and IT flexibility on the mediated relationship (decentralization on organizational agility through detecting capability) to be also statistically significant and negative (H2b: $\beta = -.194$, 95% CI [-.454, -.009], $p = .075$). We find that IT flexibility acts as a moderator on the mediation effect of decentralization on organizational agility via detecting capability (confirming H2b).

Additionally, to provide a more nuanced analysis of H2b, we inspect the moderated mediation effect at various levels of IT flexibility. This procedure allows us to understand the nature of the moderated mediation effect in more detail [35]. For low levels of IT flexibility (one standard deviation below the mean) the effect of decentralization on organizational agility is high and significant (estimate = .534, 95% CI [.211, .968]). For levels of IT flexibility around the mean, the effect of decentralization on organizational agility through detecting capability is considerably lower and significant (estimate = .368, 95% CI [.150, .788]). Finally, for high levels of IT flexibility (one standard deviation above the mean) the effect of decentralization on organizational agility through detecting capability is considerably lower, but not significant (estimate = .201, 95% CI [-.024, .673]). To gain a deeper understanding of the magnitude and significance of the mediation effect at different levels of IT flexibility, we visualize the conditional indirect effect in Figure 3.

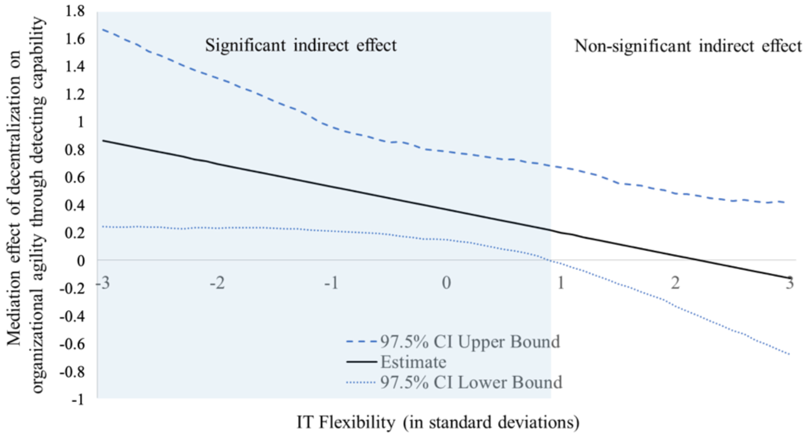

Figure 3. Mediation effect conditional on IT flexibility

A lower IT flexibility resulted in a higher mediation effect of decentralization on organizational agility through detecting capability. However, the mediation effect was only significant when IT flexibility was lower than +.8 standard deviation from the mean (shaded area in Figure 3). To safeguard the moderated mediation, we can report that the path coefficient between IT flexibility and detecting capability is positive and significant ($\beta = .361$, $p = .001$), and that the path coefficient between IT flexibility and organizational agility is statistically not significant ($\beta = .114$, $p = .325$).

5 Discussion

Our study supports earlier studies that show organizations with decentralized decision-making rights are better able to detect changes in their environment as the natural flow of innovative ideas is encouraged [18] and more employees are involved in the process of screening future changes [17]. Using this as a foundation, we provide two main contributions to the discussion from our analysis:

First, we uncover detecting capability as a mediator between decentralization and organizational agility. We show that the effect of decentralization on organizational agility is not only due to the fact that more employees can react to experienced changes by altering internal routines and processes independently. Instead, we find that the effect of decentralization on organizational agility is due to the increased capability to detect change. The decentralization of the organizational structure increases organizations' accumulated and shared knowledge about possible changes, which increases the organizations' ability to respond to these changes by appropriate actions. This provides a better understanding of how decentralization affects organizational agility.

Second, we explain the impact of IT flexibility on the relationship between decentralization and organizational agility via detecting capability. For organizations trying to improve their detecting capabilities by decentralizing decision-rights, high IT flexibility comes at a cost. Interestingly, too much flexibility of the IT function in combination with vertically distributed decision-rights decreases organizational agility. We attribute this to the fact that, if organizations have many employees at lower levels of the hierarchy allowed to make individual decisions, and at the same time an IT department flexible enough to satisfy the individual demands of those employees, organizations end up in a *complexity trap*. We find that decentralized decision-making combined with too many individual IT applications or components (provided through the flexible IT function) makes information and new solutions throughout the organizations less comparable. The *complexity trap* hinders the development of a shared understanding of future changes in the market and, hence, weakens organizations' agility. Nonetheless, we do not dismiss the widely acknowledged argumentation that IT capabilities have a positive effect on organizational agility [6], [11]. For example, Tiwana and Konsynski [24] found a positive interaction effect between IT governance decentralization and IT architecture modularity with regard to IT agility. Still, we provide theoretical and empirical evidence to the limits of IT flexibility. A highly flexible IT function in combination with highly decentralized decision rights decreases the capability to detect change, and, in turn, decreases also the ability to react to change. The *complexity trap* illustrates that providing many different IT applications in an organization with spread-out decision making, eliminates the potentially positive effects of the two measures due to complexity. Hence, we urge that potential harmful effects of (too extensive) IT flexibility and the complexity coming along with it should play a more prominent role in further organizational agility research. Additionally, further research should explore how decentralization and IT flexibility can be enhanced without increasing harmful complexity. We encourage research to analyze if a "fit" makes sense: the degree of decentralization must match the degree of IT flexibility.

As our study carries some substantial contributions, it also has some limitations that bear mentioning as well. First, our sample size is relatively small due to the fact that our study design required respondents to answer two surveys at different points in time. Second, our results indicate that a lower IT flexibility reduces the effect of decentralization on organizational agility through detecting capability. However, there is no statistically significant mediation effect when IT flexibility is very high (+.8 standard deviation from the mean). Strictly speaking, our results do not support the idea that a very high IT flexibility leads to a very low mediation effect. However, Figure 3 shows that the mediation effect conditional on the moderator is stable. Therefore, we are confident that our results are also valid for high levels of IT flexibility, and that the insignificance for very high levels of the moderator is rather due to the relatively small sample size and thereby a lack of statistical power. Third, our study relies only on data from the consulting service industry. Future research needs to extend our findings to different industries to validate our findings, to allow for generalization, and to find more explanations of the possible adverse effects IT flexibility.

6 Conclusion

In this study, we provide a theoretical explanation as well as empirical evidence for both how and why decentralization relates to organizational agility and to which degree this relationship depends on the IT flexibility. Based on our findings, we recommend managers undergoing a digital transformation to provide decentralized structures that empower employees to increase their understanding of possible changes that are likely going to affect the firm. This will increase organizations' ability to react to those changes, e.g., through improvements and additions to their internal processes.

However, we have to stress that decentralization in combination with a highly flexible IT should be treated with caution. We find that the effect of decentralization on the capability to detect changes is significantly reduced in organizations with a highly flexible IT function. We do not claim that IT flexibility is generally harmful to the detecting capability of organizations and thus agile organizations. However, managing the digital transformation of organizations requires to carefully consider the level of IT flexibility and decentralization to avoid the *complexity trap*. Furthermore, our analysis indicates that further research is necessary to investigate what causes possible drawbacks, and how IT flexibility and decentralization can be reconciled to support agility.

Appendix

Table 3. Overview Items and Loadings

Name	Item Label	Loading	Reference
DEC1	In your consultancy, managers and consultants can independently from top management decide about priority of projects and clients.	.718	[27]
DEC2	In your consultancy, managers and consultants can independently from top management decide about working overtime.	.594	
DEC3	In your consultancy, managers and consultants can independently from top management decide about employee recruitment and layoff	.732	
ITF1	Our IT unit/provider reacts flexibly to change requests from the consulting team.	.878	[15]
ITF2	The IT unit/provider realizes change requests from the consulting team in appropriate time.	.745	
ITF3	If there are critical bugs in our IT applications, they get fixed in a timely manner.	.667	
DET1	We seek novel approaches to satisfy future clients' needs.	.735	[28] [6]
DET2	The screening for unforeseeable changes is implemented in all our business activities.	.732	
DET3	We are constantly looking for opportunities to add new value to our clients.	.841	
OA1	We quickly capitalize changes and apparent chaos as new opportunities for services.	.686	[7]
OA2	We are quick to make and implement appropriate decisions in the face of client changes.	.715	
OA3	We are quick to react to new services launches by competitors with appropriate changes.	.804

Platform Openness: A Systematic Literature Review and Avenues for Future Research

David Soto Setzke[1], Markus Böhm[1], and Helmut Krcmar[1]

[1] Technical University of Munich, Chair for Information Systems, Munich, Germany
{setzke,markus.boehm,krcmar}@in.tum.de

Abstract. Open platforms such as Facebook or Android have stimulated innovation and competition across industries. Information systems literature has analyzed platforms from a variety of perspectives. The aim of this paper is to synthesize and integrate extant interdisciplinary research on the concept of platform openness. Towards this end, we conducted a literature review and analyzed the results with deductive and inductive coding approaches. We identified five distinct themes: measurement frameworks, implementation mechanisms, drivers for opening and closing platforms, trade-offs in designing openness, and the impact of changing openness on ecosystems. We propose three avenues for future research: finding the optimal degree of platform openness, integrating perspectives on accessibility and transparency, and analyzing the influence of openness and other factors with configurational theories. This paper contributes to research on platforms by laying out the main themes and perspectives in the research stream of platform openness and by identifying areas for future research.

Keywords: Platform Openness, Digital Platforms, Platform Ecosystems

1 Introduction

Digital platforms have transformed entire industries by leveraging the concept of open innovation [1] and have stimulated generativity[1] and competition [2, 3]. The cases of the social network platforms MySpace and Facebook are prototypical examples for the competitive advantages of open platform strategies. While MySpace kept their system closed, trying "to create every feature in the world" [4] on their own, Facebook decided in 2007 to open themselves to a worldwide pool of third-party developers, allowing them to build applications on top of the social networking platform [5]. Six months later, 8.000 third-party applications had been added and one year later, Facebook surpassed MySpace in terms of unique monthly visitors [6, 7]. When Apple initially released the iPhone with its iOS[2] operating system in 2007, it was closed to external developers but soon after, Apple released an official Software Development Kit (SDK)

[1] We refer to generativity as "a technology's overall capacity to produce unprompted change driven by large, varied, and uncoordinated audiences" [2].
[2] Until 2010: iPhone OS

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

and set up a distribution channel for third-party applications, the Apple AppStore [8]. Google's Android operating system entered the market of mobile platforms later but was released under an open source license and came with a less restrictive application marketplace. [9]. In 2010, Android first surpassed iOS in terms of worldwide smartphone sales and has remained the dominating mobile platform since then (with a market share of 87.8 % as of 2017) [10].

These real-world examples show the strategic role played by platform openness. Information Systems (IS) literature has analyzed the phenomenon of platforms from a variety of perspectives [3]. The concept of platform openness is commonly referred to as placing restrictions on the development, commercialization, or use of a platform [11]. More specifically, platform openness is controlled by platform owners through the use of platform governance mechanisms, such as "deliberate regulations and rules about access and boundary control" [12]. In IS literature, platform openness has started to gain traction in the last years but each study focuses on different aspects [11-17]. This is aggravated by the fact that relevant insights are also to be found in the neighboring literature streams of management [18-22] and computer science [23-25]. Hence, IS research lacks an integrated view of different, inter-disciplinary perspectives on platform openness. Due to the fragmentation of knowledge on platforms, scholars have called for consolidating extant research perspectives (see, e.g., de Reuver, Sørensen and Basole [3]).

The purpose of this paper is to synthesize the current state of research and to integrate different perspectives on platform openness in IS literature and neighboring literature streams. To this end, we conducted a systematic literature review and analyzed the resulting publications with deductive and inductive coding approaches. We find that literature focuses on technological accessibility but neglects the perspective of transparency. Furthermore, we identify five distinct themes: measuring platform openness, mechanisms for implementing openness, drivers for opening up or closing down, trade-offs in designing the degree of openness, and the impact of changing degrees of openness on platform-centric ecosystems.

The remainder of this paper is structured as follows. The first section describes the design of the literature review and the employed coding approach. The second section structures the analyzed publications with a deductive coding scheme based on different research perspectives. Subsequently, we present and discuss the identified research themes. Finally, we present and discuss areas for future research and conclude the review.

2 Design of the literature review

For conducting our literature review, we followed the guidelines of Webster and Watson [26]. Drawing on the typology of literature reviews developed by Paré, Trudel, Jaana and Kitsiou [27], our review constitutes a descriptive review since our goal was to synthesize and represent the current state of the art of research on platform openness. We restricted our review to the openness of digital platforms following the conceptualization of de Reuver, Sørensen and Basole [3] as "purely technical artefacts where the platform is an extensible codebase, and the ecosystem comprises third-party modules complementing this codebase". We focused on the journals included in the *AIS Senior Scholars' Basket of Journals*. To include the perspective of management, we also selected the journals *Management Science* (MS) and *Organization Science* (OS). We conducted a search with the term "platform AND open*" on titles, abstracts, and keywords and screened the abstract of 53 publications, resulting in eleven selected articles. If the relevance for our review was unclear after reading the abstract, we read the full article. In a second step, we extended our search to highly ranked IS conferences and the IEEE Explore Digital Library to include the perspective of computer science. We restricted our search to the more specific term "platform AND openness" in order to get a manageable set of publications, resulting in 685 potentially relevant articles. Again, we screened the abstracts in order to decide whether to include the article, resulting in 14 selected publications. Afterwards, we performed a forward and backward search on the articles that were selected so far, leading to the inclusion of another 48 articles. Finally, our sample comprised 73 relevant articles (see **Table 1**).

Table 1. Summary of the literature search process

Outlet		*Search*	*Hits*	*Selected*
Top journals	AIS Basket of Eight	*"platform AND open*"* in Title | Abstract | Keywords	34	8

	Conferences		-	18
	Dissertations		-	2
	Books		-	4
	Other		-	4
Total			738	73

In a next step, we iteratively coded the articles, using both a deductive and inductive approach [28]. Our deductive scheme was adapted from the guidelines of Bandara, Furtmueller, Gorbacheva, Miskon and Beekhuyzen [29] and comprised definition and measurement frameworks of platform openness, employed research methodologies, future work, and distinct levels of openness. Regarding our inductive approach, we engaged in open coding, axial coding, and selective coding to capture and distill concepts emerging from our sample of publications [28]. Based on 50 definitions of platform openness from our article sample, we clustered recurrent themes and extracted three distinct levels and two dimensions in order to classify extant research perspectives. Furthermore, five distinct research themes emerged throughout our open coding process[3]. Based on our classification and the identified themes, we derived promising avenues for future research. **Table 2** gives an overview of the results of our literature review, our approach to generate these results, and the respective section of this paper.

Table 2. Overview of the results of this literature review

Section	*Results*	*Approach*
3	Classification of extant research	Inductive and deductive coding of identified literature
4	Central themes in extant research	Inductive and deductive coding of identified literature
5	Avenues for future research	Analysis of classification table from section 3 and identification of unanswered questions in central themes from section 4

3 Research perspectives on platform openness

Of our analyzed articles, 68 % employ an explicit definition of platform openness (see, e.g., Eisenmann, Parker and Van Alstyne [11], Boudreau [18], Anvaari and Jansen [23], Arakji and Lang [31]) while only 30 % use or introduce a qualitative or quantitative framework for measuring openness (see, for example, Benlian, Hilkert and Hess [13], Ondrus, Gannamaneni and Lyytinen [17], Anvaari and Jansen [23]). In terms of research methodologies, we distinguish between qualitative, quantitative, mixed, design science, and conceptual research approaches [29]. A 33 % of the papers are based on qualitative research methods, such as single or multiple case studies conducted with, for example, app stores [14, 32] or mobile payment platforms [33, 34]. Quantitative research methods are employed in 31 % of the papers, comprising mostly econometric analyses [7, 15], surveys [35], and simulations [31, 36]. Conceptual and mixed approaches are represented with 19 % [37] and 13 % [38], while design science strategies are only used in 4 % of the analyzed publications [16].

Based on different definitions of platform openness, we identified three distinct levels and two dimensions. Openness can be implemented on three levels: organization, technology, and users. The organizational level "relates to the strategic involvement of key stakeholders who control the platform and provide the platform services to different user groups" [17]. The technology level refers to the provisioning of "technical means

[3] For instance, the theme "trade-offs in designing the degree of openness" was derived from codes such as "Decisions to open a platform entail tradeoffs between adoption and appropriability" [11] or "[..] it may be a trade-off between attracting a developer community […] and ensuring high standards" [30].

for complementary providers (i.e. companies that provide alternative technology, products or services for the platform) to access the core functions of the platform" [39].

On the user level, openness "is defined by the level of discrimination that the platform exercises against different segments of the potential customer base" [17]. Furthermore, openness can be categorized as either providing accessibility or transparency [23, 44, 51]. Accessibility focuses on the degree of discrimination against different roles and determines whether providers, third-party developers, or end users are allowed to join and access the platform [23, 51, 52]. Transparency, on the other hand, relates to the "understanding of what is happening and why" and thus determines whether platform-related governance decisions are comprehensible [23, 51]. On each of these levels, a platform can be open or closed. Furthermore, for each of these levels, the platforms' degrees of accessibility and transparency can be determined. On the technology level, for example, accessibility refers to the degree to which third-party developers are allowed to contribute to the platform by building new applications. Transparency, on the other hand, refers to the degree to which it is made understandable to these developers how and under what conditions third-party applications can be created and distributed through channels like the platform's application marketplace. Similarly, on the user level, accessibility reflects the possibility for users to participate on a platform (such as Uber), while transparency refers to how and to what extent the rules for participating are made comprehensible. The resulting coding matrix of our publication sample shows that most papers focus on accessibility on the technology and user level, while the dimension of transparency on all the levels is mostly neglected, especially on the user and organization level (see **Table 3**).

4 Central themes in research on platform openness

4.1 Measuring platform openness

Platform openness should not be measured as a binary variable, but rather depicted as a continuum [50]. As already introduced earlier, Eisenmann, Parker and Van Alstyne [11] distinguish between four distinct roles in ecosystems (sponsors, providers, complementors, and end users) towards which platforms can be open or closed. Still, even in platforms that are seemingly open towards a specific role, openness may still be restricted to a certain degree. The source code of the operating system Linux, for example, is accessible to everyone, but contributors need to adhere to strict governance processes comprising code review and quality appraisal [18, 24]. The framework of architectural openness developed by Anvaari and Jansen [23] considers this distinction. The architecture of a platform is divided into four layers: kernel, middleware, native applications, and extended applications. The framework shows whether it is possible to modify, extend, or integrate each layer and whether permission by the platform owner is needed for these activities.

Other frameworks focus on specific architectural aspects. Schlagwein, Schoder and Fischbach [16] propose a matrix-based framework for measuring the openness of platform resources along the dimensions of access and control. Access to resources can be exclusive, on a group-basis, or open. Control of resources can be exercised by the platform owner, by a group, or by an external actor. Ghazawneh and Henfridsson [14] focus on distribution channels and present a typology for digital application marketplaces. They distinguish between closed, censored, focused, and open marketplaces with different regulatory designs. Taking the perspective of complementors, Benlian, Hilkert and Hess [13] develop an instrument for measuring complementors' perceived platform openness along the dimensions of technical platform, distribution channel, accessibility, and transparency.

4.2 Mechanisms for implementing openness

For structuring mechanisms for implementing openness, we draw on the notion of horizontal and vertical openness by Eisenmann, Parker and Van Alstyne [11]. Horizontal openness refers to allowing rival platform's users to interact with the own platform or allowing additional parties to participate in the platform's commercialization or technical development. Vertical openness refers to granting third-party developers access to resources for developing complementary applications.

For implementing horizontal openness, platform owners choose to establish interoperability with other platforms in order to increase their market potential, either as part of a competitive or collaborative strategy (see, for example, the interoperability agreement between the instant messaging services of Yahoo and Microsoft) [11, 17]. Another strategy, that is especially attractive for mature platforms, consists of licensing the own platform to additional providers while retaining control over the platform's technology (see, e.g. Microsoft Windows) [11]. Going even further, platform sponsors may also give up ownership over technology and invite partners for joint sponsorship and development (see, for example, the Linux operating system or other open source software projects) [11, 18, 50].

Vertical openness is implemented through boundary resources [49, 53], i.e. the "software tools and regulations that serve as the interface for the arm's length relationship between the platform owner and the application developer" [8]. In practice, this includes technical boundary resources such as Application Programming Interfaces (APIs), SDKs and non-technical boundary resources such as technical documentation and support or the provided community [54-56]. Furthermore, distribution channels such as app stores are offered to facilitate the diffusion of third-party complements [14]. From a policy perspective, platform owners can restrict access to resources, e.g., by charging usage fees or by reserving access to selected groups of developers [18, 57]. In addition, they can exercise content control on distribution channels through prescreening, review, and approval processes [14, 58, 59].

4.3 Drivers for opening up or closing down

Platform owners decide to open up platform boundaries when seeking to stimulate growth by increasing their user base [17]. A larger end user base leads to higher market shares while a higher developer base allows the platform owner to access external resources and stimulate innovation even or especially when lacking own competencies to innovate [60, 61]. In the case where changing the level of openness is complicated through technological or cultural constraints owners tend to more liberally open the platform when expecting an increasing developer base [15, 17]. The need to comply with or the uncertainty about legal regulations may also be factors to open or close a platform (see, e.g., the lawsuit provoked by Microsoft's decision to bundle Windows with Internet Explorer) [41, 53, 60].

The degree of openness is not a fixed, static choice, but may vary over time, shifting from closed to open or vice-versa [30, 62]. Platform-to-platform competition, for example, where each platform intends to attract more developers may incentivize platform owners to increase openness [7, 22]. On the other hand, certain features of a platform may become so valuable over time that the platform owner does not gain any more benefits by keeping these parts fully open [15]. This can be observed at the practical examples of platforms such as LinkedIn, Twitter, or Instagram. In 2015, all three of these platforms announced the discontinuation of a large portion of their formerly open APIs, mentioning, among others, competitive threads to their businesses [63-65]. This led to the shutdown of several third-party application who could not afford the transition to the companies' partner programs or whose application use cases did not meet new terms of service [66].

4.4 Trade-offs in designing the degree of openness

Two central trade-offs need to be balanced by platform owners: adoption vs. appropriability[4] [15, 50] and diversity vs. control [18, 30, 68]. First, as already shown, higher openness leads to adoption by complementary developers. Higher openness however also reduces switching costs and increases inter-platform competition, thus making it more difficult to appropriate profits [50]. Second, higher openness leads to more diversity of complementary applications through open innovation. On the other hand, the platform owner may lose control over the quality of applications and be faced with complex coordination of resources and strategic interests [18, 20]. During the so-called "Atari shock", for example, a high number of low-quality games for the video gaming platform Atari that exercised no content control at all led to its eventual demise [69].

4.5 Impact of changing degrees of openness on platform-centric ecosystems

On the sponsor level, higher platform openness leads to the necessity of increasing modularity and more complex system architectures on the technology level [70]. In collectively sponsored platforms, increased openness on the sponsor layer may be a source of conflict resulting from deciding on the inclusion of new sponsors [33]. Sponsors and providers may also benefit from lower development costs through effectively outsourcing innovation [15, 71].

Several qualitative and quantitative studies show that higher openness leads to increasing adoption among complementors and a high quantity and variety of complementary applications [7, 17, 19, 44, 59, 72-75]. Puvvala, Dutta, Roy and Seetharaman [54] support these results and show the importance of provisioning tooling and reasonable license costs. A case study on the crowdfunding platform Kickstarter

[4] We refer to appropriability as "the ability of different stakeholders to retain for themselves the financial benefits that arise through the exploitation of an innovation" [67].

shows that increased openness on the complementor side may lead to a destabilized ecosystem [12]. After relaxing the screening processes for new campaigns on their platform, campaign success rates decreased and competition between project creators increased because of an altered ratio of campaigns to backers. A particular challenge lies in determining the right degree of openness. While granting access to complementary developers is associated with a rising innovation rate, after a certain threshold the rate decreases again in a curvilinear manner due to excessive competition between developers [18, 20].

On the user level, Müller, Kijl and Martens [32] argue that stricter content control leads to higher quality of third-party applications but on the other hand, higher competition induced by low control also leads to lower prices for end users. In terms of end user adoption, Hagiu [76] and Moon and Choi [9] suggest that lower openness may induce higher use adoption due to increasing competition. Finally, the openness towards third-party developers does not influence adoption among end consumers, as shown by Nikou, Bouwman and de Reuver [46].

5 Avenues for future research on platform openness

In this section, we point out and discuss central avenues for future research that appear promising based on our literature review. First, we call for further research on finding the optimal degree of platform openness. Second, we suggest integrating perspectives on accessibility and transparency. Third, we discuss the adoption of novel research methodologies in the context of organizational and technical configurations and the role of platform openness.

The findings of Boudreau [18] and Parker, Van Alstyne and Jiang [15] characterize the relationship between innovation and openness as curvilinear, suggesting that platform openness can be optimized [13]. However, little is known about the factors that influence the threshold at which innovation decreases again. The evidence presented by Boudreau [18] is based only on data on handheld computing systems from 1990-2004 and has since then not been verified nor replicated using data on more recent platforms. As of today, recent examples of platforms with varying degrees of openness (see, as already discussed: Hofer-Shall [63], Instagram [64], Trachtenberg [65]) provide data that allow for reexamining the question of optimal openness and its accompanying conditions. The results could be valuable for theoretical advances on platform research as well as for practical guidelines on effective platform governance.

As our coding has shown, few articles consider the transparency dimension on openness, such as technical documentation, communication with end users, or transparency of market mechanisms. Yet research has demonstrated that aspects of transparency considerably influence platform adoption among complementors [54, 77, 78]. Hence, integrating perspectives on accessibility and transparency regarding platform openness promises to be a fruitful research area. For example, different best practices regarding the implementation and promotion of transparency could be identified through a multiple-case analysis of successful platforms. This could yield insights on the design of successful platform ecosystems for end users and complementors, ultimately resulting in higher platform adoption.

Several studies have identified and discussed drivers and impacts of changing degrees of openness. However, we argue that the complex causal interplay of these drivers and organizational and technical preconditions in the firms and platforms influence the degree of openness, rather than stern linear relationships (see Vis [79] for a detailed discussion). For this reason, we call for the use of research methods that take into account equifinality and complex non-linear relationships, such as fuzzy-set Qualitative Comparative Analysis (fsQCA) [80]. FsQCA with platforms as unit of analysis has been employed by, for example, Dellermann and Reck [81], Dellermann and Reck [82] and Dellermann, Jud and Reck [83] for analyzing user loyalty, platform governance, and perceived risk. Future research could examine the effect of the interplay of openness and other factors such as the number of sides or the amount of partners on successful or unsuccessful platform launches [84], deriving relevant insights for practitioners.

6 Conclusion

The goal of this paper was to synthesize the current state of research on platform openness and to identify avenues for future research. Literature analyzes platform openness on different levels and dimensions, but neglects aspects of transparency. The main themes comprise measurement frameworks, implementation mechanisms, drivers for opening and closing platforms, trade-offs in designing openness, and the impact of changing openness on ecosystems. Based on our results, we propose three distinct issues for future research: finding the optimal degree of platform openness, integrating perspectives on accessibility and transparency, and analyzing the interplay of openness and other factors with novel research methods.

Abstract. Technological innovations that are currently 'in fashion'—such as the blockchain—are subject to inflated expectations regarding their potential. Such fashion phenomena get reinforced by knowledge entrepreneurs, whose discourse highlights organizational problems and offer such innovations as solutions. Managers observing this discourse will either follow a fashion or skeptically await its outcomes. In this research project, we aim to analyze whether managers' IT competence helps them to form realistic expectations about the blockchain technology's potential and subsequently to make thoughtful technology decisions. In our model, we operationalize IT fashion as the extent to which firms' decision makers are exposed to discourse with knowledge entrepreneurs. We hypothesize this construct to have a positive effect on these managers' support for the blockchain technology. We then aim at evaluating how managers' IT competence moderates this effect —which has not been studied before.

Abstract. We analyze the growth, complexity, and generativity of the digital platform Otto.de, a revelatory case of a large German company that has opened up its internal IT platform to outside developers. We find indication for a superlinear growth pattern fueled by external developers and the introduction of microservices as well as the emergence of a structural separation within the platform. Furthermore, our research shows ways to explain the generativity of a digital platform based on the attention and activity received.

Keywords: Digital platform, generativity, complexity, platform evolution

1 Introduction, Related Work, and Purpose

The literature on digital platforms has noted important issues of architectural design determining their long-term "evolvability" and success [1–3]. In this paper, we draw on important contributions which highlight the *modularity* and *generativity* of digital platforms. Modularity conceptualizes digital platforms as being composed of a set of more or less independent modules, which are connected via well-defined interfaces to ensure the platform's core functionalities [1]. This gives rise to combinatorial innovation since peripheral modules can be changed without altering the platform's core [4]. *Generativity* in turn allows for new functions and services to be created on top of the platform. It describes a platform's ability to generate new outputs, structures, or behaviors beyond the creators' original intentions [3, 5, 6] and as such is an important impetus and mechanism of innovation. Together, modularity and generativity facilitate further development opportunities and platform evolution.

However, while previous contributions (such as [1–3, 6]) have expanded our understanding on platform evolution, we currently lack a detailed understanding of platform evolution and generativity especially in the context of companies which transform their internal operations and IT platforms into a platform model.

The purpose of this paper is to give insight into the *growth, complexity, and generativity of the digital platform Otto.de*. In doing so, we give a detailed architectural overview of the platform's main characteristics and development since its inception in 2012. This is interesting since in the course of digital transformation many companies

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

embark on a journey of opening up their internal IT platforms to outside contributors, but there are few examples of companies that have successfully transformed a legacy business model into a fully digitally one, as from catalogue shipping to e-commerce. For Otto, the platform today handles more than 90% of the company's order volume (€2.7 billion; 2 million site visits per day; up to ten orders per second) and is vital for its transformation. Moreover, the platform is interesting because it evolved fully from a single business unit's initiative toward the company's main revenue/value creator. Furthermore, it is one of Germany's largest agile development projects in a traditional enterprise—allowing insight into scaling agile in the large. The initiative started with a team of 100 staff members and has, since then, grown to its current size of 250 employees. These are organized in interdisciplinary development teams across functional areas (search, navigation, product presentation, etc.), as detailed in [7]. Finally, it is noteworthy from an architectural point of view since the platform was restructured using a microservice approach over the past years.

2 Methodological Approach and Conceptual Framework

We employ a case study approach [8]. Our data is the GitHub repository of the platform Otto.de[1]. In this paper, we do not focus on the "multi-sidedness" of the platform towards professional sellers, which had just begun in 2017. Yet, the interesting aspect here is that the platform had been "opened up" to external developers, which moves it away from an internal IT platform to a model where combinatorial innovation becomes possible through the contributions of external developers writing code which is integrated into the platform on the level of particular modules (i.e., repositories). We extracted the entire public repository via a Python script; this covers panel data tracing back from the platform's external opening in 2012 until June 2018 (6.5 years). This "digital trace data" [9] was preprocessed and resulted in a detailed overview of the platform's 59 repositories, 351 Contributors, and 8,733 Commits. Several conversations with leading managers and developers of the platform business unit confirmed the representativeness of the data for the project's development in general. For analyzing platform growth, we used the *cumulated sum of the size* (in KB) as a function of *time* (in month), as well as time series analysis drawing on phase average and linear regression methods. For analyzing complexity, we firstly extracted the bipartite relations between repositories and developers and secondly collapsed this into a one-mode network of inter-repository relations via joint developers. Gephi, an open source network analysis tool, was used for visual analysis and metrics calculation. To analyze generativity, we conceptualized *generativity* in terms of the *number of forks* of a repository. The number of forks captures the number of times external projects / developers re-use a repository for their own project or purpose. It thus illustrates the ability to generate new "output" [5] from a particular input (repository) beyond the intention of the original creators. Correlation analysis was used where we posit that *attention on* the repository (measured in terms of the *number of watchers*) and *activity* on the repository (measured in terms of number of open issues) are associated with generativity. Furthermore, we posit that *generativity* is associated with *popularity* of a

[1] https://github.com/otto-de

repository (measured in terms of number of stars). If a repository perceives a high level of attention and activity this may act as a signal for developers to further increase their own activity here, thereby contributing to its overall generativity and popularity [10].

3 Findings

Results of the growth analysis in Fig. 1A point to a stepwise growth; the sharp increase since 2015 indicates a superlinear pattern. This would correspond to the examples of open source software development presented in the work of Scacchi [11]. A conclusion can be drawn from the shape of the growth curve and the trend figure: the activity of the actors is linked to the creation of new repositories. No repositories were created in 2014 and commits stagnated. In 2015, however, 28 repositories were newly created and the activity increased. The pause in 2014 can be explained by the planning and development of concepts for future development. Regression and phase average analysis pointed to further seasonality effects reaching their lowest point in the summer months.

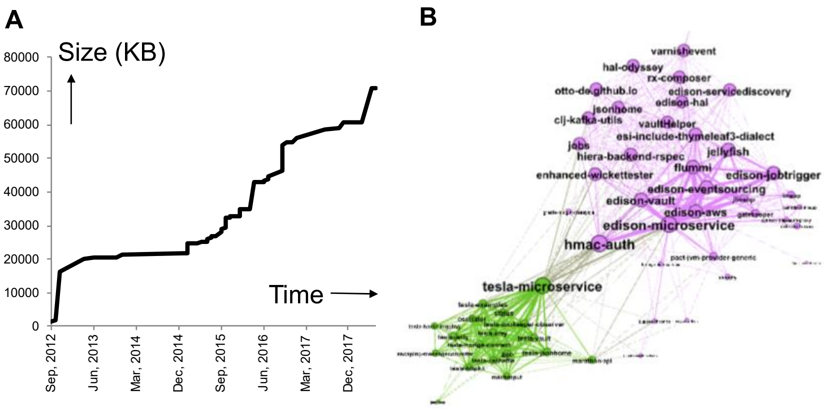

Figure 1. Growth of size in time (a) and network (b) of Otto.de repositories

Complexity analysis pointed to the emergence of two different clusters (see Fig. 1B), which were demarcated by two main hubs (i.e., Tesla and Edison Microservice). This is in consonance with the findings of Singh et al. [12] and Um et al. [13] that the development of a network has a basic structural pattern. The distributed architecture of the digital platform allows the individual "building blocks" to be developed separately. Platform microservices (e.g., Tesla and Edison) are written in different programming languages and controlled by different teams, but adhere to standards on RESTful APIs in order to ease the process of transferring data. The relationship mapping also allows conclusions about the generativity and the knowledge exchange in such externally-infused projects, suggesting that more than 100 third-party developers participated.

Further analyses regarding *generativity* using Spearman's Correlation Coefficient suggested robust to strong associations between *attention* (watchers) and *generativity* ($r(57)=.29$, $p<0.05$), *activity* (open issues) and *generativity* ($r(57)=.35$, $p<0.01$), as well as *generativity* and *popularity* (stars) ($r(57)= .68$, $p<0.001$). Further research aims at developing a multivariate model for *explaining* generativity including controls such as age or quality of a repository. Moreover, it would be interesting to link generativity to user base-related popularity measures such as platform usage or user satisfaction.

4 Concluding Remarks

The study has preliminary implications for academics interested in platform evolution and companies wishing to open their internal IT platforms. First, modularitization of the platform enables superlinear growth, but also creates the possibility that structural patterns and separations emerge which are reinforced over time. Second, retaining outside contributions from external developers over longer time periods seems possible, but we need a greater understanding of the mechanisms of disembedding platforms from local contexts and developer participation in mixed corporate-volunteer contexts. Further research should thus investigate in more detail how the e-commerce company and others collaborate online and offline with different developer and stakeholder groups working on different components of a digital platform.

Security and Privacy of Personal Health Records in Cloud Computing Environments – An Experimental Exploration of the Impact of Storage Solutions and Data Breaches

Michael Adelmeyer[1], Pascal Meier[1], and Frank Teuteberg[1]

[1] University of Osnabrück, Institute of Accounting and Information Systems, Germany
{michael.adelmeyer,pascal.meier,frank.teuteberg}@uos.de

Abstract. In the course of the digitization in healthcare, the collection and central storage of large health-related datasets in clouds in the form of personal health records is growing. However, the use of cloud services for sensitive data is associated with security and privacy risks. Further, the delegation of control over security and privacy measures to the cloud provider requires trust on the users' side. In order to investigate the role of security and privacy when storing and processing patient data, we conducted an online experiment, in which third-party cloud services are compared to private on-premise data centers. Additionally, we examine the impact of data breaches on the perceived security, privacy, control and trust in both storage scenarios. Our results indicate that cloud-based personal health records still face concerns regarding perceived security, privacy, control and trust amongst end-users. Nevertheless, after a data breach, no significant differences between both solutions exist.

Keywords: Cloud Computing, Personal Health Records, Security, Privacy.

1 Introduction

Personal health records (PHRs) can improve the collaboration between different healthcare actors and patients and ease the sharing of data [1] by providing central repositories of the users' state of health [2]. When providing PHRs for patients, cloud computing (CC) offers numerous benefits, such as scalable computing resources at minimal costs [3]. Yet, adopting CC services for sensitive health data introduces risks associated to security and privacy, as the data are stored externally or even in public environments, which entails additional challenges, such as access control or privacy protection [4], [5]. Compared to private on-premise data storage, the control over the data and corresponding security and privacy measures is delegated to the cloud provider, which requires trust in the capabilities of the provider on the users' side [4]. Since data security and privacy are crucial determinants for the adoption of PHRs [6], [7], it is necessary to evaluate whether patients' data should be stored and processed on-premise or externally, via scalable CC services. For PHR providers, the users'

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

acceptance, which is prerequisite for a sustainable adoption of the provided service, heavily depends on the selection of a secure and trustworthy storage solution [8].

Generally, data security and privacy issues are regarded as a central inhibitor for the adoption of cloud-based PHRs [5], [8]. For example, the cloud-based PHR app *vivy*, which was recently launched by several major German health insurances, faces massive criticism for data security and privacy issues, e.g., related to data hosting and processing at the underlying Amazon cloud platform [9]. Due to the high value and sensitivity of the data stored in PHRs, cloud environments are an attractive target of malicious attacks [5]. In case of a data breach, the security or privacy of the protected health data are compromised due to an impermissible use or disclosure [10]. The delegation of control in cloud environments [5], [11] and the corresponding need for trust [4] are connected to the perceived security and privacy of PHR users and in view of the theory of reasoned action [12], ultimately influencing the intention to use or adopt cloud-based PHRs [6]. Since CC faces skepticism [11], it is necessary to determine the importance of the factors that influence the intention to use cloud-based PHRs services to ensure their sustainable adoption. However, previous research either focuses on security or privacy related aspects [1], [5], [11], [13–15] or lacks a focus on either PHRs [11], [16] or CC [6], [7], [17]. Although data breaches continually impact the healthcare sector [5], [10], little research has been conducted on their outcome on users of cloud-based PHRs. Therefore, we adopt an experimental approach to investigate the participants' perceived security, perceived privacy, trust, perceived control and intention to use when using a PHR of a provider who stores and processes personal health data (a) at a cloud provider or (b) an on-premise data center. Additionally, the impact of data breaches on the targeted constructs is investigated. We examine the following research questions (RQ):

RQ1: Do patients' perceived security, perceived privacy, trust and perceived control differ between cloud environments and private on-premise data centers when storing personal health data in PHRs?

RQ2: In case of a data breach, to which extent do patients' perceived security, perceived privacy, trust and perceived control differ when using cloud environments compared to private on-premise data centers?

Based on the RQs, the study is structured as follows: First, hypotheses (H) targeting the above-mentioned constructs are derived from the literature. Second, the experimental approach and design are described. Afterwards, we analyze the collected data. In the conclusion, the findings are discussed.

2 Theoretical Background and Hypotheses Development

2.1 Data Security and Privacy

Although CC plays a significant role in healthcare, the technology still faces data security and privacy concerns, especially in PHR provisioning [8], [14], [15], [17], [18]. As the two concepts are strongly connected, individuals often may not fully understand the difference between security of systems and privacy of their data [19],

[20]. Individuals choose to disclose information, although this might impact their privacy [21], which is decisively based on trust and the perception of risks related to data security and privacy. Yet, individuals may decide to refrain from disclosures that would affect the security of their data [19]. Therefore, it is necessary to examine both concepts individually [19], which is not always the case in existing literature on cloud-based PHRs [13], [14]. Although multiple definitions exist, we adapt the most common-sense understanding of privacy [22] as an individual's ability to control the use of his or her own data [13], [20]. Besides perceived control [11], trust is a central determinant of users' intention to disclose information [21]. Whereas privacy focuses on individuals' control over their data, security is an overarching principle with focus on data confidentiality, integrity and availability [17]. Hence, in order to comply with privacy requirements, data security provides the technical foundations [18], [20].

Since certain information stored in PHRs is shared with multiple actors, risks for data security and privacy arise [15], [17]. Consequently, the infrastructure via which PHRs are provided should be rigorously secured [8], [17]. However, this is a central challenge for cloud environments, especially for public clouds [4], [14], [18], where the probability of unauthorized access to data is significantly higher compared to traditional systems [23]. Therefore, data security is of great importance for the provision of PHRs via cloud environments [1]. Hence, on the side of PHR and cloud service providers, extensive data security and privacy requirements must be considered to guarantee an equal level of data security compared to on-premise data centers [8]. Thus, we hypothesize that users' perceptions of security (SEC) and privacy (PRI) are more positive when PHRs are stored and processed on-premise, as using cloud services introduces additional risks and uncertainties [1], [4], [13], [24]:

H1a/H2a: The users' SEC/PRI is higher when their data are stored in on-premise data centers compared to cloud environments.

Despite the sensitivity of PHR data, the risks associated to CC and the higher probability of data disclosures in cloud environments [23], the impact of actual data breaches on users' SEC and PRI is only scarcely explored. If the security and privacy of users' personal health data were compromised in a data breach, this will likely lead to increased perceived risks and an increased motivation for protection [19]. Due to the value and sensitivity of health data stored in PHRs, data breaches occur frequently [10] and potential consequences are severe [13], regardless of the underlying storage solution. From the service users' perspective, the impact of and dealing with potential consequences are the same irrespective of whether a data breach occurred within a cloud or a conventional IT environment [23]. Thus, we hypothesize that the individuals' levels of SEC and PRI do not differ after a data breach:

H1b/H2b: After a data breach, the users' SEC/PRI is equal regardless of whether the data are stored in on-premise data centers or cloud environments.

2.2 Trust

Trust (TR) is defined as the willingness of a trustor to be vulnerable to the actions of a trustee, based on the expectation that the trustee will perform a particular action relevant to the trustor, irrespective of the ability to monitor or control the trustee [25]. In the context of the acceptance of information systems, different trust targets exist, such as trust in a technology or a provider [26]. With regard to PHRs, the user takes the role of the trustor and the PHR provider the role of the trustee, who may utilize CC as underlying technology [24]. For the general adoption and use of cloud services, trust has been identified as a key factor [24], [27], as users delegate their control over data security and privacy to the provider, whose actions, in turn, are difficult to monitor [4]. In healthcare, users' trust in security and privacy mechanisms of cloud providers is seen as a core determinant [8], [13]. The trustor must be confident that the cloud technology adopted in a certain healthcare data sharing scenario complies with security and privacy requirements [18]. Hence, when storing and processing personal health data in a PHR, we conclude that users' trust in the PHR provider is lower when the data are stored in a cloud environment compared to on-premise data centers directly operated by the provider, since users perceive more risks associated to CC [11], [13], [16]. However, there should be no difference in the users' trust after a data breach, as the perceived risks and the corresponding lower trust levels towards the technology are superposed by the decrease of trust in the PHR provider [26]:

H3a: The users' TR is higher when their data are stored in on-premise data centers compared to cloud environments.
H3b: After a data breach, the users' TR is equal regardless of whether the data are stored in on-premise data centers or cloud environments.

Although most studies investigate the influence of perceived risks on trust [20], Mitchell (1999) identified that there is a bi-directional relationship between TR and perceived risks [28] that include SEC and PRI. This has, among others, been empirically proven by Hsin Chang and Wen Chen (2008) [29]. Regarding the acceptance of health clouds, trust in healthcare cloud providers and in privacy-preserving mechanisms influence the patients' information privacy concerns [13]. Thus, focusing on the role of security and privacy when storing personal health data in PHRs, we analyze the influence of TR on SEC and PRI:

H4/H5: The higher the users' TR, the higher the SEC/PRI.

2.3 Control

Another important aspect of privacy is the perceived control (CO) over a system or technology [30], which is largely determined by the extent to which a user is able to employ a system in order to achieve an intended goal [31]. In cloud environments, the users' control over data and privacy or security measures is largely delegated to the cloud provider [11], [24]. In consequence, users perceive lower control over their data, which is why they connect CC with insecurities [11]. Thus, CO additionally refers to the extent to which users perceive that they have an impact on the control over their activities and data in the cloud service used [32]. Due to the sensitivity of data stored in a PHR, it is necessary that the users perceive to be in control and to be able to decide over the access to and the usage of their data. In this context, CO aims at both internal and external control. This means that the user feels capable of using the system and further, that the situation allows this [33]. Compared to on-premise data centers, the provision of PHRs via cloud environments mainly differs in terms of external control, since CC is afflicted with uncertainties regarding the security and privacy of data [4], [24]. However, in case of a data breach occurring at either storage solution, we hypothesize that the awareness of uncertainties and risks connected to CC services only plays a minor role, as a loss of control over information is regarded as material for the perception of a privacy invasion [11]. Consequently, the CO for both PHR data storing and processing solutions adjusts to a comparably low level:

H6a: The users' CO is higher when their data are stored in on-premise data centers compared to cloud environments.

H6b: After a data breach, the users' CO is equal regardless of whether the data are stored in on-premise data centers or cloud environments.

As trust is defined irrespectively of the ability to monitor or control the trustee [25], we do not assume a connection between CO and TR. Yet, SEC and PRI of PHRs are often linked to users' CO, for example, by implementing access controls for PHRs [17] or health data in clouds in order to increase data security and privacy [15]. In cloud environments, recent studies suggest that cloud users' CO majorly determines their PRI [11]. Hence, fostering users' CO by means of security and privacy measures enhances the users' SEC and PRI when storing and processing health data in PHRs:

H7/H8: The higher the users' CO, the higher the SEC/PRI.

2.4 Intention to Use

Following the theory of reasoned action, individuals' intentional behaviors to adopt or use a system are ultimately determined by their attitudes [12], [34]. The intention to use (ITU) can be defined as the intention of a customer or service user to (continually) use a provider and his service (also after an incident) [24], [32]. Besides a general attitude towards a service, the ITU of a person is measured based on risks and benefits regarding a scenario or technology [13], [24]. Due to the steadily increasing complexity of technology, trust plays a crucial role in the acceptance of and the ITU information systems [26], such as cloud environments. In view of the impact of users' security and privacy concerns towards CC, higher levels of security and privacy perceptions positively affect the ITU cloud services [16]. In this context, PRI and SEC are majorly determined by the delegation and the corresponding loss of control in cloud environments [11], [18], which ultimately affect the ITU cloud services [11]. In healthcare, control, trust, security and privacy are proven to influence the ITU cloud services, as end-users are not able to fully control the storage and processing of their data due to the control delegation and the opaque nature of cloud services [18], [24] as well as due to the sensitivity of data [13], [18]. Especially security and privacy are regarded as important requirements for the adoption of cloud-based PHRs [6], [8]. Further, trust is an antecedent of individuals' disclosure behavior [21]. Thus, it is assumed that SEC, TR, CO and PRI have a positive impact on the ITU in PHR data sharing scenarios:

H9/H10/H11/H12: The higher the users' SEC/TR/CO/PRI, the higher the ITU.

2.5 Research Model

The constructs and hypotheses are summarized in a research model (see Figure 1).

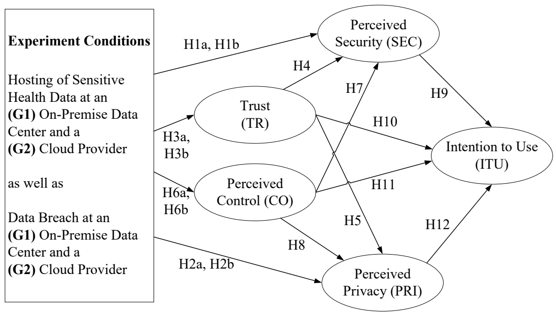

Figure 1. Research Model

3 Research Approach

3.1 Experimental Design and Procedure

In order to test the previously developed hypotheses, we conducted a web-based experiment using vignettes [35]. Overall, we applied a two-group posttest-only design [36], which was extended by an additional stimulus (X_2) and a second posttest (P_2) in both groups to determine the impact of a data breach on the outlined constructs. The overall procedure of the experiment is visualized in Figure 2.

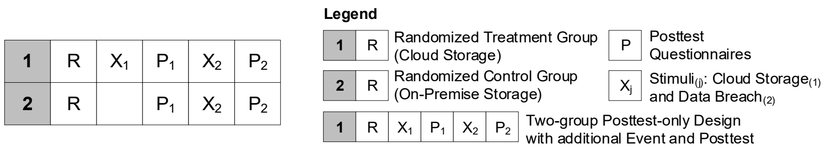

Figure 2. Experimental Setup

The random allocation (R) of the participants to the two experiment groups G1 and G2 took place in an unnoticeable first step of the experiment. Afterwards, a vignette was displayed, which can be described as a focused description of a hypothetical scenario that puts the subjects in a fictitious role in which they are asked to respond in certain ways [35]. Our vignette[1] introduced the participants to the German healthcare system, in which health-related data are stored decentrally. As a result, a medical treatment based on all existing health data is difficult, because stakeholders often cannot access all patient data. The participants are asked to act as longtime users of a service called *Vitalife*, which offers a PHR web service. The service provides a central storage and management of users' relevant personal health and related data. The first

[1] The full scenarios can be retrieved under the following link: http://bit.ly/WI-19

manipulation between group 1 (G1, treatment) and group 2 (G2, control) was conducted by using two data storage solutions of the PHR service provider *Vitalife*, i.e., a third-party cloud service (G1) (X_1) and a private on-premise data center directly operated by *Vitalife* (G2). The participants of both groups were identically informed about data security and privacy measures of the respective systems in use. Both storage solutions comply with common information security standards, such as ISO 27001, which require the development and implementation of a strict security program. Further, the third-party cloud service used by *Vitalife* complies with the cloud-related ISO 27017/27018 standards for IT security controls and the processing of personal data in cloud services. Both solutions offer an availability of 99.9 percent.

After the vignette, the first posttest (P_1) is conducted to measure the participants' attitudes towards the different storage solutions prior to a data breach. In the subsequent textual description of the event [24], [27] (X_2), the subjects are informed by *Vitalife's* customer service about a data breach at the employed cloud service provider (G1) or the on-premise data center (G2), in the course of which the PHR data of the participants were stolen. In both groups, an employee of *Vitalife* has been made responsible for the data breach, as he inadvertently opened a link in a phishing e-mail and thus enabled hackers to access the system. In order to allow for a comparison of the users' SEC, PRI, CO and TR before and after the data breach, a second identical posttest (P_2) was conducted directly after the event in both groups. In both tests, the participants were ultimately asked for their ITU the service based on their experience.

3.2 Operationalization of the Constructs

In the questionnaires, the subjects were surveyed regarding the outlined hypothetical constructs using several items derived from the literature (see Table 1).

Table 1. Constructs and Item Sources

Construct	*Adapted Definition*	*Source*
SEC	The perception of PHR service users regarding the capabilities of a provider to protect their data, which include safe transmission, prevention of unauthorized modification, access or interference.	[20]
PRI	The PHR service users' perceived ability to control the acquisition and use of their personal information [20], which includes the general concern of the provider, the adherence to privacy laws or the prevention of unauthorized information disclosure.	[20]
TR	The willingness of a PHR service user to be vulnerable to the actions of a PHR service provider, based on the expectation that the provider safely stores and provides patients' health data [25].	[37]
CO	The extent to which PHR service users perceive that they can impact the storing and processing of their health data as well as the access rights of other stakeholders to their data.	[31]
ITU	The intention to voluntarily use the provided PHR service, which stores health data in the cloud or in an on-premise data center.	[13], [32]

All items were measured by means of a seven-point Likert scale ranging from 1 ("strongly agree") to 7 ("strongly disagree"). For SEC and PRI, 6 items each from Flavián and Guinalíu (2006) [20] were used. TR was measured based on 11 items from McKnight et al. (2002) [37], with 4 items targeting the integrity (TRI) and ability (TRA) each as well as 3 items measuring the benevolence (TRB) of *Vitalife*. For CO, 4 items of Lee and Benbasat (2011) [31] were used. ITU was measured with 3 items adapted from Ermakova (2014) [13] and one from Walter et. al (2014) [32].

3.3 Participants and Data Collection

To test our proposed hypotheses, the previously described experimental concept was carried out as a web-based survey in February 2018. In total, 238 undergraduate economics and information systems students participated in the voluntary experiment, which was rewarded with minor raffled incentives. Out of the 238 answers, we only considered complete datasets for the analysis and eliminated answers with response patterns or significantly faster overall response times. Among the remaining 217 datasets, 104 participants belong to group 1 and 113 to group 2, with an overall of 35 % female and 65 % male participants and an average age of 20.6 years.

4 Data Analysis and Results

4.1 Construct Validity and Reliability

In order to ensure the validity and reliability of the collected data, several tests were conducted. The analysis of variances tests (ANOVA), Levene tests of variance equality and t-tests for the control variables gender, age, health condition and CC experience did not indicate significant differences between the groups (N = 217). Therefore, a homogeneous distribution of the participants can be assumed. Given a mean self-estimation of 3.37, it can be concluded that the participants are fairly knowledgeable in CC. Since most of the hypotheses and the research model are based on the first posttest, the validity and reliability are assessed based on the corresponding data and are thus concluded for the second posttest. The data were examined in order to preclude a common method bias (CMB) using Harman's one-factor test [38]. The 30 indicators used were examined in a factor analysis. Since the resulting extraction of one factor explaining 45.783% of the variance is below the threshold of 50%, we do not assume a CMB [38]. Subsequently, we assessed the one-dimensionality of the constructs in an exploratory factor analysis. All indicators meet the respective thresholds for Measure of Sampling Adequacy (MSA) (> .5), the Kaiser-Meyer-Olkin-criterion (KMO) (> .5), communalities (> .5) and the Bartlett-test (< .05) [39], except from the items TRB2 and TRB3 with communalities < .5 (.450 and .498). Hence, both items were dropped from further analyses, which, using reflective measurement, does not affect the meaning of a construct [39], [40]. Further, according to Kaiser's rule, five common factors with an eigenvalue of > 1, which explain 66.915% of the variance, could be extracted. This confirms our predetermined five constructs SEC, PRI, CO, TR and ITU [39]. Although items with loadings > .6 are considered as reliable [41], we dropped all items with loadings < .7 in order to achieve better construct validity, as suggested by Nunnally and Bernstein (1994) [42]. This concerns our items TRA1 (.699), TRA4 (.576), PRI4 (.698) and SEC2 (.680). Further, since the cross loadings of the items PRI5 (.697 to TR), TRI1, TRI3 and TRI4 (.643, .657 and .692 to PRI) are relatively high, the respective items were dropped in order to strengthen discriminant validity, which did not adversely affect our previously conducted analyses.

The construct's internal consistency reliability was assessed calculating the Cronbach's Alpha (CA), the inter-item correlation (IIC) and the corrected inter-scale correlation (CISC). For CA, IIC and CISC, the recommended threshold values (CA ≥ .7; IIC ≥ .3; CISC ≥ .5) are met for all constructs (see Table 2). The reliability of the constructs in terms of quality criteria of second order was assessed examining the composite reliability (CR) and the average variances extracted (AVE) (see Table 2). For both measures, the thresholds are met (CR ≥ .6; AVE ≥ .5). Regarding the indicator reliability (IR) (not listed in Table 2), the required threshold of ≥ .4 is met by all indicators (lowest IR = .545). Therefore, we assume convergent validity in the context of construct validity. Next, we evaluated the discriminant validity by checking for the Fornell-Larcker criterion, which states that the square roots of the AVE (dark cells) need to be higher than the corresponding correlations between the constructs [43]. Since this is the case for all our constructs, discriminant validity for all factors can be assumed. Thus, our constructs serve for further hypotheses testing.

Table 2. Discriminant Validity

Factor	*# Items*	*CISC*	*IIC*	*CA*	*CR*	*AVE*	*CO*	*ITU*	*PRI*	*SEC*	*TR*
CO	3	.754-.829	.752	.901	.938	.835	.914				
ITU	4	.701-.856	.708	.906	.934	.781	.578	.884			
PRI	4	.623-.683	.539	.824	.883	.653	.629	.629	.808		
SEC	5	.682-.830	.680	.914	.936	.746	.592	.607	.640	.863	
TR	4	.527-.654	.486	.791	.865	.616	.555	.580	.681	.577	.785

4.2 Hypotheses Testing

To examine the influence of the experiment conditions on the latent variables TR, CO as well as on SEC and PRI, we conducted analyses of means (two-sample t-test). To evaluate the differences between the constructs regarding cloud service (G1) and on-premise data storage (G2) before ("a" hypotheses, G1 and G2) and after a data breach ("b" hypotheses, G1E and G2E), the results of the first and the second posttest were compared between G1 and G2 (see Table 3). As the Levene tests are not significant, we assume variance homogeneity for all constructs. Since significant differences for all constructs between G1 and G2 ($p < .05$) were identified, H1a, H2a, H3a and H6a are supported. Regarding the outcome of the event on the hypotheses, no significant differences can be identified for SEC, PRI and TR except for CO ($p = .026$). Hence, except from H6b, we find support for H1b, H2b and H3b.

Table 3. Significance Levels and Mean Values

Construct	*Result*	*G1 and G2*	*G1E and G2E*
SEC	Mean Value G1; G2	3.217; .2.890	4.931; 4.850
	Sig. t-Test (Levene)	.038 (.116)	.617 (.206)
PRI	Mean Value G1; G2	2.623; 2.352	3.421; 3.188
	Sig. t-Test (Levene)	.033 (.735)	.091 (.055)
TR	Mean Value G1; G2	2.618; 2.316	3.447; 3.232
	Sig. t-Test (Levene)	.003 (.958)	.114 (.108)
CO	Mean Value G1; G2	2.798; 2.443	3.683; 3.295
	Sig. t-Test (Levene)	.029 (.506)	.026 (.388)

The relationships between the constructs and their impact on the dependent variables were evaluated using partial least squares (PLS) structural equation modeling (SEM) with SmartPLS 3.0 [44]. In order to evaluate the model fit, we checked for the CMIN/DF as well as the SRMR of the model (2.661, .073), which meet the required thresholds (CMIN/DF $\leq$ 3.0, SRMR $\leq$ .08) [45], [46]. Since further fitness criteria range slightly above or below the recommended thresholds (in brackets), i.e., CFI = .909 ($\geq$ .9), RMSEA = .088 ($\leq$ .08, should not exceed $\geq$ .1) and GFI = .837 ($\geq$ .9), we assume a good model fit. Especially RMSEA values are debatable and thus drawing absolute cutoffs is inadvisable [41], particularly when considering smaller sample sizes with $n \leq 250$ [46]. Afterwards, the path correlations of our SEM were evaluated in order to identify significant correlations between the constructs (see Figure 3).

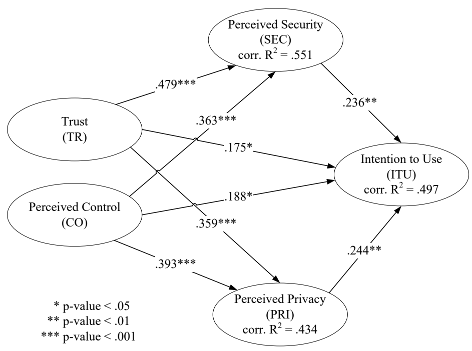

Figure 3. PLS Model

Strong statistically significant relationships between TR and SEC and PRI as well as between CO and SEC and PRI can be confirmed. Hence, we find support for H4, H5, H7 and H8 in our model. Further, path coefficients of $\geq$ .236 between SEC as well as PRI and ITU point to a moderate influence of both constructs on ITU. Therefore, H9 and H10 can be confirmed. Since CO and TR largely determine SEC and PRI (R^2 = .551 and .434), which again have a strong effect on the ITU and despite the relatively low but still significant ($p < .05$) path correlations (.175 and .188), we assume a low but significant impact of TR and CO on ITU. Thus, H10 and H11 can be confirmed. Based on the analyses, the statuses of our hypotheses are shown in Table 4.

Table 4. Statuses of the Hypotheses

H	*Relation*	*Status*	*H*	*Relation*	*Status*
1a	SEC(G2) > SEC(G1)	Supported	6a	CO(G2) > CO(G1)	Supported
1b	SEC(G2E) = SEC(G1E)	Supported	6b	CO(G2E) = CO(G1E)	Not Supported
2a	PRI(G2) > PRI(G1)	Supported	7	CO ↑ ⇒ SEC ↑	Supported
2b	PRI(G2E) = PRI(G1E)	Supported	8	CO ↑ ⇒ PRI ↑	Supported
3a	TR(G2) > TR(G1)	Supported	9	SEC ↑ ⇒ ITU ↑	Supported
3b	TR(G2E) = TR(G1E)	Supported	10	TR ↑ ⇒ ITU ↑	Supported
4	TR ↑ ⇒ SEC ↑	Supported	11	CO ↑ ⇒ ITU ↑	Supported
5	TR ↑ ⇒ PRI ↑	Supported	12	PRI ↑ ⇒ ITU ↑	Supported

5 Conclusion

5.1 Discussion and Implications

The results of the structural equation model indicate that TR, CO, SEC and PRI are key determinants of the intention to use PHR services. In addition, TR and CO both significantly determine SEC and PRI (H4, H5, H7, H8), which ultimately determine the ITU the provided service, independently of the underlying storage solution (cloud vs. on-premise) (H9, H10, H11, H12). Given the similar outcome of both - the storage solution and the data breach - on SEC and PRI, it is possible that the participants did not significantly differentiate between the constructs [19]. Thus, apart from the necessity to comply with strict healthcare regulations, PHR providers need to consider measures that strengthen the TR, CO and especially the SEC and PRI of potential users, e.g., by providing transparency over control, security and privacy measures. Although previous research found that the positive aspects of health clouds outweigh patients' privacy concerns [13], the results of the experiment reveal that the subjects' SEC, PRI, CO and TR are significantly higher when personal data in the form of PHRs are stored on-premise compared to cloud environments (H1a, H2a, H3a, H6a) (RQ1). Thus, despite the relatively high maturity of the technology and the efforts undertaken by theory and practice, CC still faces skepticism regarding the provisioning of PHRs. Providers of PHR solutions need to be aware of this perception and have to decide whether to offer their services via cloud environments or on-premise solutions. When offering cloud-based PHR services, providers might rely on private clouds in order to minimize concerns on the users' side. Further, hybrid cloud infrastructures can be used for encrypted or non-sensitive data in order to realize cloud-related benefits. However, in case of a data breach, no significant differences regarding SEC, PRI and TR between the two solutions could be determined (H1b, H2b, H3b), except for CO (H6b) (RQ2). In cloud environments, data breaches might entail a considerably larger impact on the side of the provider compared to on-premise environments [23]. Hence, cloud services need to emphasize their measures regarding security and privacy and foster the trust of (potential) end-users, e.g., by providing certifications [8], as cloud users seek for external control agents [11]. In order to avoid severe consequences for PHR service users in case of a data breach, strong encryption mechanisms should be implemented [1], [15]. Although both storage solutions were compliant to ISO27001, the SEC, PRI and TR in the cloud scenario were found to be lower. Thus, besides providing certifications, further measures are necessary in order to foster users' perceptions of the constructs. In addition, the experiment revealed that the participants' CO regarding the on-premise solution is still significantly higher after a data breach, even though the participants' abilities regarding control did not vary between the experiment groups. This is presumed to be ascribed to the control delegation and the associated reservations towards cloud environments, which draws the attention of cloud-based PHR providers on establishing measures to particularly foster their users' CO.

5.2 Limitations and Future Research

Since the applied vignette technique puts the participants in a fictitious scenario, the behavior of the subjects might be different compared to a real-world scenario [35]. In addition, using students as experiment participants is not without controversy in the field of information systems and partially limits the generalizability of the results. However, since students reflect the future target group and are early adopters of innovative technologies, such as CC and PHRs, we argue that students are an adequate sample group for the experiment conducted [24], [32]. In this context, it is necessary to note that the experiment was conducted based on a relatively homogeneous sample group, which might influence the overall results. Concerning the evaluation of the model fit, our research model revealed slight weaknesses in terms of some fit indices. Nevertheless, since the deviations from the recommended thresholds are relatively small and cutoff thresholds are discussed controversially [41], we argue that the overall model is not endangered. Further, although established items for measuring trust were derived from the literature [37], several items had to be dropped. Yet, since we used reflective measurement, the meaning of the constructs TR, PRI and SEC was not affected [39], [40]. However, using constructs which strongly differ in the number of items (e.g., TR and ITU) might lead to distorted results. In addition, due to the temporal proximity of the two posttests conducted, an impact of the first on the second survey resulting in a certain bias is possible.

Regarding the data breach, the manipulation of the subjects can possibly be ascribed to multiple factors. In G1, the data are stored externally at a cloud provider, whereas in G2, the data are stored on-premise, which might lead to different accusations towards the actors. However, the examined scenarios reflect the practical problem of companies whether to provide their services via external cloud solutions or on-premise data centers [8], [17]. In this context, it needs to be noted that the use of certain PHR systems might not be purely voluntarily, but instead stipulated by politics or certain healthcare actors. Although control is seen as a core principle of privacy [30], the adoption of privacy as control in the course of this study can be regarded as simplification of the complex nature of the construct [22], [30]. As we concentrated on trust and control as influencing factors of SEC and PRI, the examination of further constructs or the application of behavioral explanation models is possible.

Our study provides multiple starting points for future work. For example, besides investigating TR and CO as influencing factors of PRI and SEC, further constructs (e.g., benefits) can be examined regarding their influence on the two constructs. Additionally, the cause for the higher perceived control in the on-premise solution after a data breach and the correspondingly adjusted levels of SEC, PRI and TR allow for further investigation. A practical validation of the results by means of an examination of a commercial PHR provider, e.g., in the form of a case study, is desirable. In this context, the implications and results from the present study may serve as a foundation for additional qualitative studies or the examination of actual privacy behaviors. Moreover, our experimental setup even allows for richer insights and analyses, e.g., a cross-comparison between the groups before and after the breach.

6 Acknowledgements

The authors would like to thank the experiment participants, the other project members, specifically Ms. Miftari and Ms. Imhorst, for their valuable and substantive help, as well as the reviewers for their constructive feedback. This contribution was prepared within the research project “Dorfgemeinschaft 2.0”. The project is funded by the Federal Ministry for Education and Research (BMBF) (funding code 16SV7453).

Abstract. Die aktive Integration eines Patienten in seinen Behandlungsverlauf besitzt große Potentiale zur Verbesserung der Behandlungsqualität. Als Ansatz zur besseren Patientenintegration werden häufig Patientenportale genannt. Die bestehenden Lösungen fokussieren jedoch vornehmlich auf die Zugänglichkeit elektronischer Patientenakten aber nicht auf die Integration von einrichtungsübergreifenden Informationen zum Behandlungsverlauf, auch Patientenpfad genannt. Der Beitrag schlägt daher eine Referenzarchitektur zur Integration von Pfadsystemen in Patientenportale vor. Ihre Anwendbarkeit wird anhand der Gestaltung eines Patientenportals für die Multiple Sklerose Behandlung demonstriert.

Keywords: Patientenpfade, Patientenportale, Referenzarchitektur, Integration

1 Einleitung

In der aktuellen Diskussion um die Verbesserung der Kontinuität der medizinischen Versorgung nehmen die personalisierte Medizin und die Förderung der Selbstbestimmung des Patienten (Patient Engagement) einen festen Platz ein. Dabei spielt auch die informatorische Integration des Patienten in den Behandlungsprozess eine zentrale Rolle. Über diese Form der Integration werden die Optimierung der Therapieadhärenz, positive Verhaltensänderungen beim Patienten sowie die Verbesserung von Prozess- und Ergebnisqualität erwartet. Sie bildet die Grundlage für die Einflussnahme des Patienten auf seinen Behandlungsprozess. In der Konsequenz soll der patientenindividuelle Outcome verbessert werden [1, 2]. Dies setzt jedoch voraus, dass der Patient seine Behandlung adäquat verfolgen kann, intendierte Behandlungspläne inklusive Falldokumentation zur Verfügung stehen und der Patient in der Lage ist, seinen Gesundheitsstatus nachzuvollziehen. Personal Health Records, Gesundheitsapps und Patientenportale [3, 4] ermöglichen grundsätzlich die informatorische Integration [5]. Dahingegen steht die Integration des Patienten in den Behandlungsprozess, d. h. die Bereitstellung und Mitwirkung des Patienten an einrichtungsübergreifenden Patientenpfaden und somit die Förderung des Selbstmanagements, noch am Anfang [6].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Der vorliegende Beitrag geht der Frage nach, wie einrichtungsübergreifende Patientenpfade im Kontext von Patientenportalen implementiert werden können. Dabei werden Patientenportale als Anwendungssysteme betrachtet, die die Integration des Patienten in die Informationssystemlandschaft mehrerer Leistungserbringer zulassen. Patientenportale können in verschiedenen Realisierungsformen auftreten (z. B. Web-Präsenz oder Apps). Die Schwerpunkte der Untersuchung sind die Erarbeitung eines Anforderungskatalogs und die Ableitung eines Referenzarchitekturvorschlags zur standardbasierten Implementierung einer pfadunterstützenden Anwendungssystemlandschaft (PAS). Im Zuge des Beitrags wird die Anwendung des Referenzarchitekturvorschlags anhand eines Patientenportals für die Versorgung von Multiple Sklerose (MS) Patienten demonstriert. Forschungsmethodisch ordnet sich die Arbeit in die gestaltungsorientierte Forschung ein [7] und zielt auf die Erarbeitung eines technischen Artefakts ab. Um dem Forschungsanspruch einer gestaltungsorientierten Theoriebildung [8] gerecht zu werden, wird die Referenzarchitektur als gestaltungsleitendes Artefakt betrachtet, das in verschiedenen Anwendungssystemlandschaften instanziiert werden kann. Etablierte Standards sowie eine rollenorientierte Beschreibung der Anwendungskomponenten ohne Konkretisierung der Systeminstanzen bilden dabei die Grundlage. Durch die rollenorientierte Beschreibung wird sowohl ein Abgleich mit existierenden Systeminstanzen (z. B. bestehende Anwendungssysteme) als auch die Entwicklung neuer Komponenten ermöglicht.

Die Struktur der Arbeit folgt dem von Peffers et al. postulierten Vorgehen für die Design Science Forschung [9]. Abschnitt 1 motiviert das Problemfeld und stellt die Problemklasse dar. In Kapitel 2 wird auf die Rolle von Patientenpfaden im Zusammenhang mit Patient Engagement und Patient Empowerment eingegangen (theoretische Basis). Aufbauend auf dem Gestaltungsziel werden in Abschnitt 3 die zentralen Anforderungen erarbeitet (Ziele der Lösung) und diese in Abschnitt 4 in einen Referenzarchitekturvorschlag als Design-Artefakt überführt. In Abschnitt 5 wird die vorgeschlagene Referenzarchitektur für einen Anwendungsfall instanziiert (Demonstration) [9].

2 Grundlagen

In den letzten Jahren findet ein verstärkter Diskurs zu den Konzepten, Maßnahmen und Auswirkungen einer stärkeren Einbindung des Patienten in die eigene Gesundheitsversorgung statt [10]. Zwei dabei adressierte Konzepte sind Patient Empowerment und Patient Engagement. Ersteres beschreibt die Ermächtigung des Patienten, mehr Verantwortung für seine gesundheitsrelevanten Entscheidungen zu übernehmen [11, 12]. Hingegen zielt Patient Engagement auf das Verhalten eines Patienten ab [1, 13]. Obgleich diskutabler Evidenz herrscht Einigkeit über die Vorteilhaftigkeit des Patient Engagement für die Verbesserung der Versorgungsqualität und -organisation [14], insbesondere in der Versorgung chronischer Erkrankungen [15]. Die Information, Edukation und Partizipation des Patienten werden dabei als essentielle Bestandteile hervorgehoben [11, 16]. Das aktive Gesundheitsverhalten eines Patienten im Sinne des Patient Engagement äußert sich somit in seiner informatorischen Teilhabe, welche wiederum eine optimale Kommunikation zwischen Versorgungsteam und Patient voraussetzt [13].

Patientenpfade stellen ein wesentliches Instrumentarium zur Verbesserung sowohl des Patient Empowerment als auch des Patient Engagement dar. Sie gehen auf das Konzept des Behandlungspfads (kurz: Pfad) zurück. Ein Pfad wird als standardbasierter Soll-Behandlungsablauf verstanden, der das multidisziplinäre Setting, die lokalen Gegebenheiten und den aktuellen Stand der Evidenzforschung vereint. Im Vordergrund steht die Vorausplanung konkreter Handlungsschritte, die an zeitliche bzw. definierte Zustandsänderungen geknüpft sind [17, 18]. Patientenpfade heben darüber hinaus den Patientenbezug hervor. Sie dienen insbesondere der nahtlosen Versorgung chronisch kranker Patienten über verschiedene Gesundheitssektoren hinweg, der Patienteninformation und -aufklärung sowie der Planung des patientenindividuellen Behandlungsprozesses unter Einbeziehung individueller Patientenbedürfnisse [19, 20].

Die Realisierung von Patienten Engagement wird mit Blick auf europäische Vorreiternationen und ihren Patientenportalen wie z. B. Dänemarks sundhed.dk oder Estlands e-tervis.ee deutlich. Im Mittelpunkt stehen hierbei die digitale Bereitstellung von medizinischen Dokumenten, Informationen über empfangene Behandlungen sowie deren Freigabe an Bevollmächtigte und weitere Dienste, wie Terminvereinbarungen, Medikamentenverschreibungen oder Kommunikationsangebote. Für Deutschland wird aktuell neben regionalen Initiativen das von vielen Krankenkassen unterstützte Patientenportal „Vivy“[1] diskutiert. Die Integration des Betroffenen als Mitgestalter seines individuellen Patientenpfades ist dabei jedoch bislang kaum berücksichtigt.

3 Anforderungsanalyse

Gleichwohl die Studienlage [18] und das politische Einfordern von Pfadsystemen (z. B. [21]) grundsätzlich für die Anwendung, und damit für die technische Unterstützung sprechen [22, 23], sind die Akzeptanz und Durchsetzung in der Praxis mangelhaft, woraus sich die folgenden Anforderungsbereiche ergeben.

3.1 Nutzeranforderungen für Pfadsysteme

Zur angemessenen Abbildung der Komplexität von Behandlungsprozessen sollten sich Werkzeuge zur Pfaderstellung und -pflege am fachlichen Kontext orientieren [24, 25] und alle Lebensphasen von Patientenpfaden unterstützen [26] (s. Tab. 1).

Tabelle 1. Behandlungsplanung

Nr.	*Beschreibung*
A1	**Leistungserbringer:** Zur Behandlungsplanung sollten typische Pfadvarianten und zugehörige Entscheidungsgrundlagen festgelegt werden können. Vorzugsweise sollte die Gestaltung und Editierung modellbasiert in einem integrierten Tooling erfolgen. **Patient:** Therapiemöglichkeiten und korrespondierende Pfadvarianten sollten für den Patienten erkennbar sein. Die möglichen Pfade sollten für den Patienten kognitiv erfassbar sein.

[1] https://www.vivy.com/

Nr.	Beschreibung
A2	**Leistungserbringer:** Für die Instanziierung eines Pfades sollten Ein- und Ausschlusskriterien hinterlegt werden. Der Patientenpfad sollte durch den Leistungserbringer individuell konfiguriert werden können. **Patient:** Der Patient sollte bei der Instanziierung des Pfades erkennen können, warum eine konkrete Pfadkonfiguration festgelegt wurde und hinsichtlich welcher Kriterien die Behandlung gestaltet wird.

Im ärztlichen Alltag ist es häufig notwendig, auf den Fallkontext und den Patientenwunsch zur Laufzeit eingehen zu können [27] (s. Tab. 2). Dadurch wird die Akzeptanz der Pfadnutzung gefördert.

Tabelle 2. Behandlungsorganisation

Nr.	Beschreibung
A3	**Leistungserbringer:** Durch den Leistungserbringer sollte jederzeit im Behandlungsverlauf eine ad-hoc Modifikation des Pfades möglich sein. Jede Modifikation sollte begründet werden, sodass es für den Fallkontext dokumentiert bleibt. **Patient:** Änderungen im Behandlungsverlauf sollten dem Patienten kommuniziert und die Gründe in nachvollziehbarer Weise dargestellt werden. Der Patient sollte in der Lage sein, Modifikationswünsche zu kommunizieren.
A4	**Leistungserbringer:** Die Nutzung von Pfaden sollte sich in ein dauerhaftes Prozessmanagement einbetten. D. h., die beteiligten Akteure begutachten und diskutieren in regelmäßigen Zyklen, inwieweit die Pfadvorlagen überarbeitet werden müssen. **Patient:** Änderungen von Pfadvorlagen sollten für den Patienten vor dem Hintergrund der eigenen Pfadinstanz transparent gemacht werden. Unterschiede zu Standardpfaden und nachträgliche Anpassungen sollten kommuniziert werden.

Mit der Nutzung von Behandlungspfaden gehen meist auch Wirtschaftlichkeitsüberlegungen einher [28]. Zudem wird sich eine höhere Sicherheit der Einhaltung von Prozessplänen erhofft. Diese Standardisierung in Form von Behandlungspfaden zieht jedoch gleichzeitig die Kritik des mangelnden Patientenbezugs (hinsichtlich Adäquanz und Zugänglichkeit) nach sich (s. Tab. 3) [29].

Tabelle 3. Behandlungsmonitoring

Nr.	Beschreibung
A5	**Leistungserbringer:** Der Leistungserbringer sollte patientenverständliche Informationen im Pfad hinterlegen können, welche der Edukation konkreter Patientenkohorten dienen. **Patient:** Der Patient sollte Zugang zu seinem Pfad haben und sich mittels verständlichen Statusinformationen und Zusatzmaterialien über den Fortgang seiner Behandlung informieren können.
A6	**Leistungserbringer:** Pfade sollten individualisiert und bei Bedarf um patientenindividuelle Informationen und Funktionen erweitert werden können. **Patient:** Pfadinformationen sollten mit korrespondierenden Assistenzfunktionen verknüpft sein und dem Patienten bedarfsgerecht und personalisiert zur Verfügung gestellt werden.

Nr.	Beschreibung
A7	**Leistungserbringer:** Informationen über den Ist-Zustand der Behandlung sollten durch den Leistungserbringer im Pfad hinterlegt und im Zuge eines prozessorientierten Qualitätsmanagements überprüft werden können. **Patient:** Der Patient sollte den aktuellen Zustand seiner eigenen Pfadinstanz vor dem Hintergrund der ursprünglich intendierten Behandlungsplanung analysieren und Abweichungen nachvollziehen können.

3.2 Systemanforderungen für Pfadsysteme

Auf Grundlage der Nutzeranforderungen A1-A7 sind in Tabelle 4 funktionale Anforderungen herausgearbeitet. Die funktionalen Anforderungen repräsentierten einen Basissatz, der in Abhängigkeit vom spezifischen medizinischen Einsatzszenario hinsichtlich Funktionsumfang und Integrationstiefe der Pfadanwendung variieren kann. Dieser Basissatz bestimmt den Rahmen für die zu gestaltende PAS. Die PAS ist dabei nicht als einzelnes Softwareprodukt zu verstehen, sondern als System von Anwendungssystemen, welches sich im Kern aus dem beteiligten klinischen Anwendungssystem (KAS) [30], dem Patientenportal mit seinen Modulen sowie externen Infrastrukturen, Systemen und Diensten konstituiert [31].

Tabelle 4. Funktionale (F) Anforderungen zur Umsetzung des Pfadsystems

Nr.	Beschreibung
F1	Die Aufgaben- und Terminsteuerung sollte in der PAS aktiv erfolgen. Termine sowie Aufgaben sollten aktiv in die beteiligten Systeme (KAS, Patientenportal etc.) kommuniziert werden können.
F2	Die PAS sollte in der Lage sein, beteiligte Anwendungen darüber zu informieren, wenn sich der Status eines Patienten, eines Fallverlaufs, einer Behandlung oder konkreter Werte ändert.
F3	Pfadvorlagen sollten mittels eines geeigneten Toolings (z. B. Modellierungswerkzeug) komfortabel erstellt und verwaltet werden können sowie den beteiligten Systemen zur Verfügung stehen.
F4	Die Pfadvorlagen sollten in die Falldokumentation der PAS integriert sein und patientenspezifisch instanziiert werden können.
F5	Patientenpfade sollten für berechtigte Akteure im Fallkontext des Patienten einsehbar und editierbar sein. Die Modifikation des geplanten patientenindividuellen Pfades sollte jederzeit möglich sein, aber auch die Möglichkeit zur Begründung von Modifikationen ist unerlässlich.
F6	Auswertungs- und Monitoring-Funktionalitäten sollten zentralisiert für jeden Stakeholder erfolgen können (Management-Cockpit). Alternativ sollten bestehende Process Mining Tools (z. B. ProM, RapideMiner, BAB) integrierbar sein.
F7	Pfadinstanzen sollten sich kontinuierlich der Dokumentationslage der beteiligten KAS und anderer Dokumentationssysteme anpassen.

4 Referenzarchitektur

Auf Basis der erhobenen Nutzer- und Systemanforderungen werden im Folgenden die Komponenten und Module im Sinne von Architekturbausteinen erarbeitet (Abs. 4.1) und eine Referenzarchitektur entwickelt (Abs. 4.2), die am Beispiel der Implementierung eines Patientenportals für die MS-Versorgung (Abs. 5) illustriert wird.

4.1 Module mit Pfadbezug in Patientenportalen

Der Funktionsumfang von Patientenportalen spiegelt die krankheitsspezifischen informatorischen Bedürfnisse eines Patienten wider [3]. Die Konfiguration bzw. Instanziierung eines Patientenportals können somit auch hinsichtlich Auswahl und Umsetzung der Funktionsumfänge variieren. Die in Tabelle 5 vorgeschlagenen Module beschreiben die Funktionalitäten, die für die Umsetzung von Patientenpfaden in Patientenportalen notwendig sind. Die Menge ist jedoch nicht als abgeschlossene Menge zu betrachten, da der Versorgungskontext weitere Module erforderlich machen kann.

Tabelle 5. Beschreibung der Patientenportalmodule

Modul	*Beschreibung*	*Referenz*
	Infrastruktur-/Kernelmodule	
Kernel	Dieses Modul implementiert die grundsätzlichen Funktionalitäten und Konfigurationen (Authentifizierung, Identitäts-, Demografisches Daten- und Softwareschnittstellen-Management sowie Metadaten-Konfiguration).	[32]
	Spezifische Pfadmodule	
Care Plan Module	Dieses Modul implementiert solche Pfadfunktionalitäten, die durch Patient Engagement beeinflussbar sind.	F1-F7
Self-Tracking Module	Dieses Modul implementiert das Monitoring des Gesundheitsstatus.	F6
	Pfadassoziierte Module (siehe Funktionsdomänen in [3])	
Encounter Module	Dieses Modul implementiert Funktionalitäten zum Management von Terminen und anderen ärztlichen sowie pflegerischen Interventionen.	F1, F2
Documentation Module	Dieses Modul implementiert die Zugriffsfunktionalitäten auf die medizinische Akte und andere medizinische Dokumentation sowie die Bereitstellung von Dokumentation durch den Patienten.	F2, F4
Assessment Module	Dieses Modul implementiert die Screening- und Fragebogen-Funktionalitäten.	F1, F7
Education Module	Dieses Modul implementiert die Funktionalitäten zur patientenindividuellen Therapieunterstützung (Übungsanleitungen, Erklärungsmaterialen etc.).	F5
Medication Module	Dieses Modul implementiert die medikationsbezogenen Verwaltungs- und Monitoring-Funktionalitäten.	F7

Grundlegend wird eine Unterteilung in Kernelmodule, spezifische Pfadmodule und pfadassoziierte Module[2] vorgenommen. Die *Kernelmodule*, auch Kernel genannt [32], beinhalten die Basiskonfiguration sowie die zentralen Funktionalitäten und Schnittstellen, von denen die Funktionalitäten der spezifischen Pfad- und pfadassoziierten Module abhängig sind (z. B. Rechteverwaltung). Die *spezifischen Pfadmodule* verantworten

[2] **Komponenten:** eigenständige Einheiten in einer Architektur,
Module: logische Teileinheiten von Komponenten

Funktionalitäten zur Abbildung und Ausführung konkreter Pfadinstanzen. *Pfadassoziierte Module* hingegen bilden fachliche Funktionalitäten mit Bezug zum Pfad ab. So kann sich bspw. ein Patient im pfadassoziierten Modul „Documentation“ alle Dokumente anzeigen lassen, welche mit dem Pfadschritt einer Anamnese verknüpft sind. Ebenso sind Termine oder verknüpfte Medikationen mit den Modulen „Encounter“ bzw. „Medication“ abrufbar.

Die Module können Schnittstellen zu externen Geräten (z. B. Blutdruckmessgeräte) und Anwendungen (z. B. Gesundheits-Apps) vorsehen. Da externe Systeme in verschiedenen Kontexten zum Einsatz kommen können, dienen sie als fallabhängige Integrationspunkte. Die Referenzarchitektur verweist für die Schnittstellen des Patientenportals explizit auf die Ressourcen des Fast Healthcare Interoperability Resources-(FHIR)-Standards[3], um Orientierung zu geben, welche Informationstypen das jeweilige Modul bereitstellen sollte. Grundsätzlich müssen Schnittstellen zu externen Anwendungen an das jeweilige Krankheitsbild und den Einsatzkontext angepasst werden, sodass auch andere Standards oder Formate zum Einsatz kommen können.

4.2 Referenzarchitektur zur Integration von Patientenportalen in PAS

Abbildung 1 stellt die Referenzarchitektur dar, in der die Rollen[4] einzelner Komponenten sowie die Schnittstellen zwischen diesen zusammengefasst werden. Dabei wird der Architekturvorschlag von Schlieter et al. [31] aufgegriffen und um die Kommunikationsbeziehungen zwischen Back-End-Diensten und Patientenportal erweitert. Zudem werden die Ausgestaltung der dort benannten Patient-Frontends konkretisiert und die Integration mit den vorgeschlagenen Pfadsystemen aufgezeigt. Die dargestellte Referenzarchitektur geht von einer einrichtungsübergreifenden Realisierung von Patientenpfaden und Falldokumentation aus. Dieses Implementierungsparadigma findet sich häufig bei der Umsetzung einrichtungsübergreifender Informationssysteme zum Patientendatenaustausch (z. B. [5]).

Entsprechend Abbildung 1 verantwortet das *„Patient-oriented Pathway Repository“ (PPR)* die Persistierung der Pfadinstanzen. Die Pfadvorlagen werden im *Template Repository (TR)* hinterlegt. Die professionelle Steuerung, d. h. die Verwendung der Pfade durch den Leistungserbringer, erfolgt durch den *Professional Pathway-Service (PrPS)*. Diese Komponente fasst dabei die in [31] erwähnten Komponenten zur Pfadinstanzierung, -modifikation sowie die Komponenten zur Datenaggregation und Pfadanalyse zusammen. Zudem setzt sie aktive Pfadveränderungen und Automatismen bei der Pfadausführung um und ermöglicht dem Leistungserbringer die Beeinflussung der Pfadausführung.

Die Komponente *Patient Pathway Service (PaPS)* dient der Ausführung von Pfaden aus der Sicht des Patienten. Diese Komponente setzt die pfadbezogenen Funktionen für

[3] http://hl7.org/fhir/

[4] Die in der Referenzarchitektur benannten Komponenten werden als Rollen betrachtet, die ein Anwendungssystem einnehmen kann. Beispielsweise, können die klinischen und professionellen Anwendungssysteme gleichzeitig als Komponenten in anderen Informationsinfrastrukturen, zum Beispiel einer elektronischen Akteninfrastruktur, enthalten sein.

den Patienten um. Sie ermöglicht bspw. den lesenden Zugang von Pfadinformationen. Gleichsam stellt sie Funktionalitäten zur Verfügung, die eine direkte Beteiligung des Patienten am Behandlungsprozess durch Modifikation von Pfadinstanzen ermöglichen. So können Fragebögen im Pfad hinterlegt werden, die in Abhängigkeit vom Behandlungsfortschritt durch den Patienten ausgefüllt werden müssen.

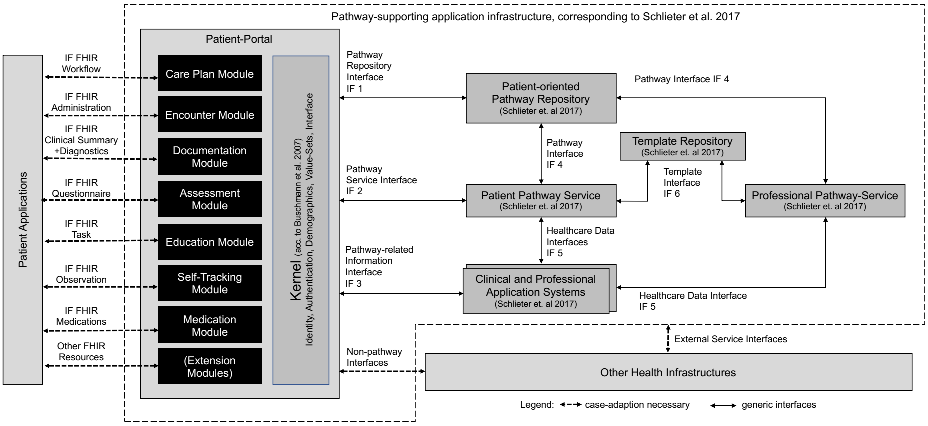

Abbildung 1. Referenzarchitektur zur Einbindung von Patientenportalen in PAS

Die Komponente *Clincial and Professional Application Systems (CAS)* repräsentiert die bestehenden klinischen Dokumentations- und Managementsysteme (KAS, Laborinformationssysteme, Arztpraxisinformationssysteme etc.). Diese Systeme sind Bestandteil der PAS, wenn sie Informationen und Funktionen bereitstellen, die für die Planung, Ausführung oder das Monitoring des Pfades Relevanz haben.

Zwischen den dargestellten Komponenten sind verschiedene bidirektionale Schnittstellentypen (siehe Abb. 1) definiert. Tabelle 6 stellt diese, die Informationen, sowie die Zugriffsarten dar. Die Zugriffsart „aktiv“ repräsentiert die Bereitstellung auf Anfrage. "Reaktiv" repräsentiert die unaufgeforderte Bereitstellung und automatisierte Verarbeitung als Reaktion auf ein auslösendes Ereignis.

Tabelle 6. Schnittstellentypen (SST) der Referenzarchitektur

SST	*Beschreibung*	*Information und Zugriff*
IF1 – Pathway Repository Interface	Die Schnittstelle dient dem direkten Zugriff auf die Rohdaten der Pfadinstanzen. Es handelt sich hierbei um den in [31] genannten Zugriff auf das Repository auf Basis des IHE XDS.b-Standards.	Vollständige Pfadinstanzen, aktiver Zugriff
IF2 – Pathway Service Interface	Die Schnittstelle setzt den Austausch von Pfadeinzelinformationen um. Das umfasst Schnittstellen zur Anpassung und Konsumierung von Pfadinformationen. Die Schnittstelle fungiert auch als Service-Schnittstelle zum Auslösen von Funktionen der Patienten-Pfadkomponente.	Statusänderungen, Pfadinformationen, aktiver und reaktiver Zugriff

SST	*Beschreibung*	*Information und Zugriff*
IF3 – Pathway-related Information Interface	Die Schnittstelle dient dem Austausch von pfadrelevanten Informationen. Das können Informationen sein, die mit der direkten Ausführung des Pfades assoziiert sind oder die Auswirkungen auf den Pfadverlauf haben.	Pfadbeeinflussende und pfadresultierende Fachinformationen, aktiver und reaktiver Zugriff
IF4 – Pathway Interface	Diese Schnittstelle repräsentiert den Zugriff der aktiven Pfad-Service-Komponenten auf die Pfadinstanzen.	Pfadinstanzen, aktiver Zugriff
IF5 – Healthcare Data Interfaces	Die Schnittstelle dient dem Austausch von Daten zur Beeinflussung von Pfadinstanzen bzw. zur Umsetzung von Pfadverläufen. Über diese Schnittstelle werden bspw. Daten kommuniziert, die Entscheidungen in einem Pfad beeinflussen.	Informationen, die den Pfadverlauf beeinflussen, aktiver und reaktiver Zugriff
IF6 – Template Interface	Das Template Interface dient der Bereitstellung und Modifikation von Pfadvorlagen.	Pfadvorlagen, Anpassung von Pfadvorlagen, aktiver Zugriff
External Service Interfaces	Die Pfad-Services können bei der Ausführung von weiteren Infrastrukturen (z. B. Anwendungssystemlandschaften für den Labordatenaustausch) abhängig sein.	Variabel, aktiver und reaktiver Zugriff
Non-pathway Interfaces	Pfade und korrespondierende Module des Patientenportals können auf konkrete Informationen und Funktionen verweisen. Diese Informationen beeinflussen jedoch den Pfadverlauf nicht oder führen nicht zu Änderungen im Pfad. Schnittstellen zur Kommunikation solcher Informationen werden daher als Non-pathway Interfaces klassifiziert.	Variabel vorrangig aktiver Zugriff in Bezug auf die Pfadausführung

5 Demonstration – Fallbeispiel Multiple Sklerose

5.1 Fallkontext – Integrierte Multiple Sklerose Versorgung

Die MS ist eine chronisch entzündliche, degenerative Erkrankung des zentralen Nervensystems [33]. Als „Krankheit der 1000 Gesichter“ ist sie gekennzeichnet durch ein heterogenes, stark beeinträchtigendes Beschwerdebild [34]. Aus dem jungen Eintrittsalter resultieren auch Eigenschaften der Patienten, welche insbesondere im Kontext moderner, partizipativer Versorgungsansätze fördernd wirken. So wird jüngeren Betroffenen eine IT-Affinität und höhere Kompetenz in der Erschließung sowie Nutzung elektronischer Gesundheitsangebote zur Förderung der eigenen Patientenkompetenz zugesprochen [35, 36].

Im Zuge des Projektes „Integriertes Betreuungsportal Multiple Sklerose“ (IBMS) wird ein Patientenportal für MS-Patienten entwickelt, das die Heterogenität und Individualität der Erkrankung berücksichtigen soll. Das Patientenportal soll sich in die bestehende Informationssystemlandschaft am Universitätsklinikum Dresden (UKD) einbetten und darüber hinaus andere Leistungserbringer der sächsische Gesundheitswirtschaft einschließen. Ein Teilziel des Projektes ist es, bei der Entwicklung des Patientenportals die bestehenden Systeme des UKD sowie der Region in Form einer Integration zu berücksichtigen. Zu den existierenden Systemen gehören das am UKD eingesetzt Fachanwendungssystem Multiple Sklerose Dokumentationssystem^{3D} (MSDS^{3D}) zur Dokumentation von MS-Behandlungen und die IHE-basierte CCS Telehealth Ostsachsen Plattform (THOS) zur Implementierung einrichtungsübergreifender Telemedizin-Lösungen. Die Patientenzugänglichkeit über ein Patientenportal ist ein Teilziel des Projektes. Ein Patient soll sowohl seinen Behandlungsverlauf, seine medizinische Dokumentation als auch seinen Erkrankungsstatus nachvollziehen können.

5.2 Applikation der Referenzarchitektur

Im Rahmen des Fallkontextes wird auf Basis der vorgestellten Referenzarchitektur ein Patientenportal für das beteiligte MS-Zentrum konzipiert und implementiert (vgl. Abb. 2). Dazu wurden die bestehenden Anwendungssysteme analysiert und mit den Rollen der Referenzarchitektur abgeglichen. Vorhandene Anwendungssysteme sind die XDS.b-basierte Fallakte und der Integrated Clinical Pathway (ICP)-Service, welche die Rollen *PPR* bzw. *PrPS, PaPS* und *TR* der Referenzarchitektur umsetzen, sowie das Klinisches Anwendungssystem MSDS^{3D} (s. Tab. 7), welches die Rolle des *CAS* realisiert. Vorgesehen ist außerdem, externe Praxisinformationssystem in der Rolle von *CAS* in die Lösung einzubinden. Der Patient Pathway-Manager wird im Zuge des Projektes entwickelt und in die Anwendungssystemlandschaft integriert.

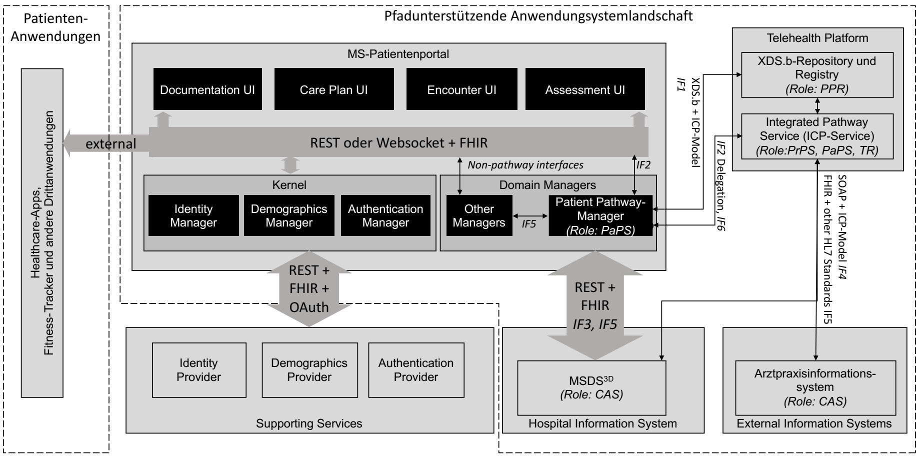

Abbildung 2. Anwendungssystemarchitektur für ein MS-Patientenportal

Die aktuelle Anwendungssystemarchitektur umfasst die Präsentationsschicht, welches dem User Interface (UI) entspricht und die fachlichen Module der Referenzarchitektur (s. Abb. 1, links) repräsentiert. Das Backend besteht aus einem erweiterbaren *Kernel*, der das Kernel-Modul der Referenzarchitektur (s. Abb. 1, links) repräsentiert, sowie aus verschiedenen *Domain-Managern*. Die Präsentationsschicht ist vom Backend über standardisierte REST-basierte FHIR- bzw. Websocket-Schnittstellen entkoppelt.

Dadurch fungiert das Backend gleichzeitig als Middleware, welche die Anbindung von Drittanwendungen (s. Abb. 2, links), z. B. das FHIR-basierte "Apple Health Records" [37], ermöglicht.

Mit Bezug zum Patienten verantwortet der *Kernel* die systemweit eindeutige Identifikation, die Akquise und Bereitstellung demografischer Daten sowie die Authentifizierung und Zugriffskontrolle am Patientenportal. Der *Kernel* ist so gestaltet, dass zur Wahrnehmung seiner Verantwortlichkeiten auf externe Dienste zurückgegriffen werden kann. Die *Domain-Manager* setzen die domänenspezifische Geschäftslogik um, wobei ein UI-Modul zumindest durch einen *Domain-Manager* verantwortet wird. Der *Patient Pathway-Manager* realisiert die Logik für das Care Plan Modul und nutzt die vorhandenen anderen *Domain-Manager*, welche den Zugang zu den jeweiligen Fachdaten aus den CAS gewährleisten.

Tabelle 7. Komponenten und deren Schnittstellen in der MS-Patientenportalarchitektur

Komponente *(Status der Verfügbarkeit) - Aufgabe;* ***Schnittstelle:*** *Typ: Datenmodell*	*Rolle*
Patient Pathway-Manager (zu implementieren) – Patientenseitige Ausführung von Pfaden **Schnittstellen:** *IF1:* Proprietäre Beschreibung (CPMod-Format) [24], FHIR Workflow-Ressourcen[5] (aktiv), *IF2:* ICP-Service im Sinne eines Business Delegates [32], SOAP-Calls proprietär (aktiv).	PaPS
XDS.b-Registry und Repository (existent) – Speicherung von Patientendaten und -pfaden **Schnittstellen:** *IF1, IF4:* CPMod für Patientenpfade, Repository-Schnittstellen (XDS.b-basierter Austausch, aktiv)	PPR
ICP-Service (existent) – Ausführung von Pfaden auf Seiten der Leistungserbringer **Schnittstellen:** *IF2:* FHIR Workflow-Ressourcen (aktiv und reaktiv), *IF4, IF6*: CPMod (aktiv) *IF5:* FHIR-Ressourcen: Observation (aktiv und reaktiv), Ereignisse (FHIR-Ressourcen: Events[6], reaktiv), Appointment und Task[7] (aktiv und reaktiv)	PrPS PaPS
MSDS^{3D} (existent) – Dokumentation von MS-Fällen **Schnittstellen:** *IF3*: FHIR-Communication-Ressourcen (reaktiv), Kommunikation von Patientendaten (Non-pathway Interfaces).	CAS
UI-Module Documentation, Care Plan, Encounter, Assessment (zu implementieren) – Umsetzung von Patientenfunktionen **Schnittstellen:** *intern und extern:* FHIR-Ressourcen gemäß Schnittstellen zu externen Anwendungen in Referenzarchitektur (siehe Abb. 1) auf Basis JSON + Websocket, alternativ REST	Module
Kernel-Module Identity Manager, Demographics Manager, Authentication Manager (zu implementieren) – Anbindung externer Dienste **Schnittstellen:** *Non-pathway Interfaces:* FHIR-Administration-Ressourcen, OAuth, Json Web Token (JWT)/JSON-Format	Kernel

Zur Komposition der einzelnen Anwendungssysteme in ihrer jeweiligen Rolle (s. Abb. 1) müssen Schnittstellen zur Anbindung an das Patientenportal im Sinne der Referenzarchitektur (s. Tab. 6) geschaffen werden. Die semantische Interoperabilität wird

[5] https://www.hl7.org/fhir/workflow.html
[6] https://www.hl7.org/fhir/event.html
[7] https://www.hl7.org/fhir/task.html, https://www.hl7.org/fhir/appointment.html

sichergestellt, indem auf die vorhandenen REST-basierten FHIR- und IHE-XDS.b-basierte Schnittstellen zurückgegriffen wird (s. Tab. 7). Die Grundlage dafür ist die Erstellung eines abgestimmten Kommunikationsdatenmodells, bei dem die kontextspezifischen Informationsbedarfe von Patienten Berücksichtigung finden. Weiterhin wird auf das Clinical-Pathway-Modeling-Format (CPmod) aus [24] zurückgegriffen.

Nach aktuellem Entwicklungsstand des Patientenportals navigiert der Patient über den Menüpunkt „Meine Behandlung“ in *Care Plan UI*, in dem er entlang eines Zeitstrahls sowohl auf historische Daten als auch auf geplante Aktivitäten zugreifen kann (s. Abb. 3). Die Informationen werden über den *Patient Pathway-Manager* bereitgestellt, der wiederum unter Nutzung des *Kernels* die Datenintegrität sowie die Authentizität des Nutzers sicherstellt. Der *Patient Pathway-Manager* kann sich die Informationen zur korrespondierenden Pfadinstanz (*IF1*) sowie zur Pfadvorlage des Patienten (*IF6*) über die THOS abrufen und so den Patienten informieren, welche Schritte im Standardpfad vorgesehen sind oder Abweichungsanalysen auslösen.

Auf die Falldokumentation im klinischen Dokumentationssystem kann ebenso mittels REST-Schnittstelle (*IF3*) zugegriffen werden. Somit lassen sich bspw. Laborergebnisse mit den Pfadschritten verknüpfen. Der Patient erhält damit die Informationen, die im aktuellen Pfadschritt relevant sind. Gleichzeitig können Anfragen, Ereignisse oder Hinweise an den Patienten gesendet werden. Für das Patientenportal wird im Projekt über diesen Mechanismus eine Fragebogenkomponente integriert, über die Informationen zum Zustand des Patienten abgefragt werden können.

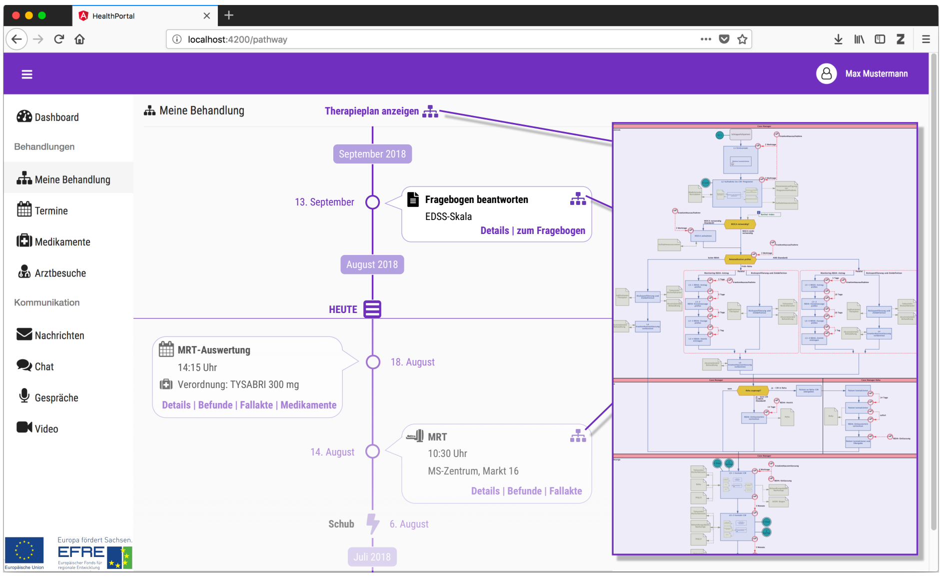

Abbildung 3. Screenshot des Patientenportals inklusive schematisch angedeutete Integration der Pfadvorlage

6 Diskussion und Fazit

Der vorliegende Beitrag widmete sich der Umsetzung von Patientenpfaden und speziell ihrer Integration in den Kontext eines Patientenportals. Dazu wurden auf Grundlage eines Anforderungskatalogs architektonische Überlegungen in eine Referenzarchitektur überführt, in welcher die typischen Systemkomponenten, deren Rollen sowie typische Kommunikationsbeziehungen spezifiziert sind. Auf Basis eines Proof-of-Concepts in der MS-Versorgung wurde sowohl die Anwendbarkeit als auch Instanziierung des generischen Architekturkonzepts aufgezeigt [38]. Bereits während der Entwicklung des Patientenportals konnten die notwendigen Funktionsbereiche eingegrenzt werden (Patientenbefragung mit n=210[8]). Die Evaluierung der Referenzarchitektur sowie der fallbezogenen Gesamtlösung aus Nutzersicht steht jedoch noch aus und wird Gegenstand der Folgearbeit sein.

Zudem muss konstatiert werden, dass der Beitrag auf die funktional-technologische Realisierung des Portals abhebt. In der Praxis zeigt sich jedoch, dass auch mit organisatorischen (Finanzierung, Einführungs-, Schulungsfragen sowie Support) und datenschutzrechtlichen Aspekten eine Vielzahl von Einführungshürden einhergehen, die im Beitrag ausgeklammert wurden. Hier kann anregt werden, den Konsens für standardisierte Verfahren zu befördern und den rechtlichen Rahmen an die digitalen Möglichkeiten anzupassen. Zentrale elektronische Akten, wie TK-safe[9] in Deutschland und die finnischen KANTA Services[10] auf europäischer Ebene, geben Einblicke wie Patientenintegration angegangen werden kann. Daraus ergeben sich Potentiale für die Umsetzung pfadgestützter Systeme, für die die aufgezeigte Referenzarchitektur als Entwurfshilfe dienen kann. Mit dem zusammengeführten Anforderungskatalog sowie den elaborierten Schnittstellentypen gibt die Arbeit eine praktische Handreiche, um den Transformationsprozess hin zu einer pfadzentrierten Patientenintegration zu gestalten.

Trotz der weitestgehend positiven Konnotation des Themas Patient Engagement existiert insbesondere um die Fragen, inwieweit bereits ohne ärztlichen Kontakt Befunde bereitgestellt oder Empfehlungen automatisiert getroffen werden können, ein ethischer Diskurs. Dieser wird in den nächsten Jahren verstärkt geführt werden müssen.

Danksagung

Das Universitätsklinikum Carl Gustav Carus Dresden, die Technische Universität Dresden und die CCS GmbH kooperieren im Rahmen des Projektes „Integriertes Betreuungsportal Multiple Sklerose". Die Durchführung des Projektes wird durch Mittel des Europäischen Fonds für Regionale Entwicklung (EFRE) und den Freistaat Sachsen ermöglicht. Der Beitrag ist dem gesamten helict-Team der TU Dresden gewidmet, welches in den vergangenen Jahren unermüdlich für die Überwindung tradierter Verhaltensreflexe und für die Entwicklung innovativer digitaler Lösungen gestritten hat.

Digitalisierung in der Stressprävention – eine qualitative Interviewstudie zu Nutzenpotenzialen

Kim Janine Blankenhagel[1], Anne-Katrin Witte[1], Rüdiger Zarnekow[1]

[1] Technische Universität Berlin, Lehrstuhl für Informations- und Kommunikationsmanagement, Berlin, Deutschland
{k.blankenhagel,a.witte,ruediger.zarnekow}@tu-berlin.de

Abstract. Stress gilt als Verursacher zahlreicher Erkrankungen, wenn er nicht mit ausreichend Entspannung und Ruhe im Gleichgewicht steht. Dauerstress und Burnout nehmen stetig zu, weshalb die Notwendigkeit für Prävention und Stressmanagement steigt. Digitale Technologien ermöglichen neue Methoden präventiven Stressmanagements, allerdings sind die Nutzenpotenziale entsprechender Systeme weitgehend unerforscht. Diese Untersuchung schließt die Forschungslücke mittels einer qualitativen Interviewstudie. Dafür wurden 15 teilstandardisierte Interviews geführt, die vier verschiedene Perspektiven (Krankenkassen, Leistungserbringer, Privatwirtschaft, Nutzer) beinhalten. Aus ihnen wurden Nutzenpotenziale digitaler Stressmanagementsysteme aggregiert, die sich in die zwei entwickelten Kategorien *Verbesserung der medizinischen Versorgung* und *Verbesserung der Inanspruchnahme* unterteilen lassen. Die Interviews ergaben, dass digitale Stressmanagementsysteme diverse Nutzenpotenziale besitzen und einen Beitrag zur Gesundheitsversorgung leisten können. Sie können niedrigschwellig in Anspruch genommen werden, stärken die Eigenständigkeit und Selbsthilfe der Nutzer und bieten innovative Ansätze, übermäßigen Stress zu erkennen und adäquat darauf zu reagieren.

Keywords: digitales Stressmanagement, Prävention, Burnout, Nutzenpotenziale

1 Einleitung

Stress ist in vielen industrialisierten Ländern weit verbreitet [1] und kann zu diversen psychischen und physischen Erkrankungen führen [2]. Hohe Arbeitsbelastungen und gestiegene Komplexität im Arbeitsalltag führen zu steigenden Anforderungen an Berufstätige, was sich häufig durch erhöhte Stresslevel äußert [3]. Diese sind Vorstufen eines Burnouts und Stressmanagement ist neben ausreichender Bewegung einer der wichtigsten Faktoren, um den Ausbruch der Erkrankung zu vermeiden [4]. Die Partizipation an herkömmlichen präventiven Angeboten zum erfolgreichen Umgang mit Stress ist allerdings gering. Gleichzeitig verbessern sich die technologischen Möglichkeiten, mittels neuartiger Sensortechnik sowie Interpretation und Analyse großer Datenmengen die medizinische Versorgung zu verbessern [5].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Die gesundheitliche Versorgungskette lässt sich in die Bereiche Prävention, Diagnose, Therapie und Rückfallprävention unterteilen, wobei sich die vorliegende Untersuchung auf die präventive Phase bezieht. Der Forschungsschwerpunkt liegt demnach bei Systemen, die für gesunde Menschen entwickelt wurden und keinen therapeutischen oder krankheitsspezifischen Bezug aufweisen. Dieser Artikel umfasst eine Erhebung und Analyse von Nutzenpotenzialen mit folgender Forschungsfrage:

„Welche Nutzenpotenziale besitzen digitale Stressmanagementsysteme?“

Unter präventiven digitalen Stressmanagementsystemen (DSMS) werden im Rahmen dieser Erhebung Bewältigungsstrategien verstanden, die dem Erhalt der Gesundheit auf seelischer, körperlicher und sozialer Ebene dienen, das Ziel haben, Stress aufgrund arbeitsbezogener Belastungen in Richtung eines gesunden Gleichgewichts zu verringern und hauptsächlich auf digitalem Wege bereitgestellt werden (angelehnt an [6]). Sie können beispielsweise mittels Websites, Gesundheits-Applikationen auf dem Smartphone oder Wearables in Anspruch genommen werden. Der Begriff Nutzenpotenzial wird als Möglichkeit für eine im Sinne des Nutzers positive Veränderung definiert, die sich auf Mortalität, Morbidität, gesundheitsbezogene Lebensqualität und Patientenzufriedenheit bezieht (angelehnt an [7]).

Bisher sind digitale Präventionsangebote überwiegend unerforscht und die Nutzenpotenziale von DSMS in der Stressprävention weitgehend unbekannt [8]. Da zum jetzigen Zeitpunkt Einschätzungen, Deutungsmuster und Handlungsorientierungen sowie die Ermittlung individueller Perspektiven fehlen, ist im Rahmen dieser Untersuchung mit Blick auf ihren explorativen Charakter die Methodik qualitativer Interviews ausgewählt worden.

2 Einbettung in die Forschungslandschaft

Die Analyse relevanter Forschungsliteratur zum Thema digitales Stressmanagement zeigt auf, dass der Bereich trotz der enormen Brisanz bisher wenig betrachtet wurde. Der Großteil aller Studien untersucht therapeutische Systeme für bereits erkrankte Personen (zum Beispiel Menschen mit stressassoziierten Erkrankungen wie Depression oder Burnout) mit zum Großteil quantitativem Studiendesign. In der Literatur lassen sich einige wenige Studien finden, die Fragen der Wirksamkeit und moderierende Faktoren digitaler Stressmanagementsysteme thematisieren (zum Beispiel [9–11]). Sie untersuchen allerdings hauptsächlich medizinische Aspekte, während der vorliegende Artikel zusätzlich den Anwender und seine Bedürfnisse sowie gesamtgesellschaftliche Aspekte adressiert, sodass eine ganzheitliche Sicht entwickelt werden kann. Des Weiteren wurden verschiedene Perspektiven und Sichtweisen der relevanten Stakeholder einbezogen und verglichen, wodurch sich diese Analyse von bereits vorliegenden Studien abhebt.

In der Literatur werden neben Stressmanagement zwei weitere Begriffe zur Vermeidung eines Burnouts benannt. Die Definition von DSMS grenzt sich von dem in der Literatur thematisierten „Job Redesign“ insofern ab, als dass DSMS von den

Nutzern selbst angewendet werden, wohingegen Maßnahmen des Job Redesigns hauptsächlich von Seiten der Arbeitgeber umgesetzt werden und eine Änderung der Rahmenbedingungen fokussieren [12]. Maßnahmen des „Job-Craftings“, bei dem wie bei DSMS die Aktivität des Nutzers im Zentrum steht, sind ähnlich zu solchen von DSMS. Beim Job-Crafting liegen die Aktionen allerdings hauptsächlich in stark arbeitsbezogenen Interventionen [13], wobei DSMS in einem allgemeineren Ansatz stressbezogene Interventionen anbieten, die sich nicht alle zwingend auf den Themenbereich Arbeit beziehen müssen.

3 Methodik

Um die Nutzenpotenziale von DSMS zu eruieren, wurden im Frühjahr 2018 fünfzehn teilstandardisierte, leitfadengestützte Interviews durchgeführt. Mit dem Ziel eines ganzheitlichen Verständnisses wurden die vier zentralen Perspektiven der Krankenkassen (n = 3), der Leistungserbringer (Psychotherapeuten, medizinisches Personal; n = 4), der Privatwirtschaft (Anbieter von DSMS auf dem freien Markt; n = 4) und der Nutzer (n = 4) einbezogen. Insgesamt wurden 25 Interviewanfragen per E-Mail und eine Anfrage in einer Quantified-Self-Gruppe versendet, aus denen zehn telefonische und fünf persönliche Gespräche in deutscher Sprache resultierten.

Die Auswahl der Interviewpartner erfolgte nach Flickl [14] gemäß der Fallauswahl mittels eines qualitativen Stichprobenplans, um eine gezielte Auswahl besonders aussagekräftiger Fälle aufzunehmen. Konkret wurden die potenziellen Interviewpartner nach der (beruflichen) Erfahrung und Auseinandersetzung im Bereich der Stressprävention und der Nutzung digitaler Technologien zum Stressmanagement (mindestens zwei Jahre) rekrutiert. Die Voraussetzung zur Teilnahme am Interview war je nach Personengruppe entweder die Nutzung (Nutzer/Leistungserbringer) oder das Angebot (Privatwirtschaft/Krankenkassen) mindestens eines DSMS. Im Durchschnitt dauerte ein Interview 53 Minuten. Zu Beginn aller Interviews stellte der Interviewer sich und das Forschungsvorhaben vor und erläuterte Absicht sowie Struktur des Interviews. Mit dem Einverständnis der Interviewpartner wurden alle Gespräche aufgezeichnet, transkribiert und gemäß der qualitativen Inhaltsanalyse nach Mayring [15] mit einer Software für qualitative Analyse (MaxQDA) ausgewertet. Die identifizierten Nutzenpotenziale wurden codiert, aggregiert und analysiert. Abbildung 1 visualisiert das methodische Vorgehen, das in den folgenden Abschnitten präziser erläutert wird.

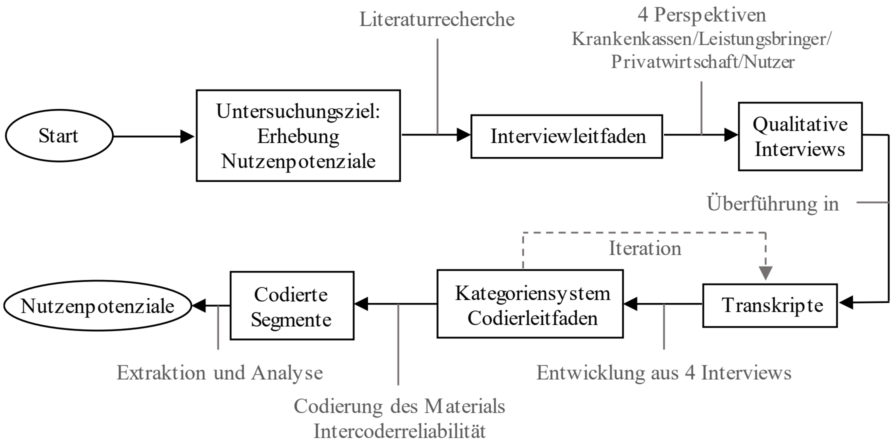

Abbildung 1. Methodisches Vorgehen

3.1 Interviewleitfaden

Der zugrundeliegende teilstandardisierte Interviewleitfaden basiert auf den etablierten Prinzipien von Döring und Bortz und beruht auf einer vorangegangenen Sichtung der Literatur [16]. Aus dieser wurden Hinweise zu Nutzenpotenzialen aus vorhandenen Konzepten und Theorien zu DSMS deduziert und daraus Interviewfragen abgeleitet. Zunächst wurden das Profil des Interviewpartners und entsprechende Erfahrungen erfragt. Im Anschluss wurden Erzählaufforderungen zum Aufbau, zur Funktionsweise und zur Interaktion mit dem vorhandenen bzw. genutzten DSMS gesetzt, um darauffolgend in die Erhebung der Nutzenpotenziale überzugehen. Neben den Nutzenpotenzialen wurden auch Nachteile und Grenzen von DSMS erfragt. Da sich der Wissensstand und die Perspektiven der befragten Akteursgruppen unterscheiden, wurden für jede der vier Personengruppen die Interviewleitfäden spezifisch angepasst. Allgemein sind die Fragen nach dem Prinzip der Offenheit formuliert [17], sodass die Interviewten ihrer Sachkenntnis und ihren Interessen entsprechend antworten konnten. Um sicherzustellen, dass der Leitfaden sowohl zeitlich als auch inhaltlich angemessen und zielführend ist, wurde er vorab einzeln in jeder Personengruppe getestet.

3.2 Kategoriensystem

Die Entwicklung eines Kategoriensystems wurde regelbasiert nach Mayring [15] durchgeführt. Zunächst wurde das gesamte Material gesichtet und einer der Autoren entwickelte induktiv in einem iterativen Prozess das Kategoriensystem. Des Weiteren wurde ein vorläufiger Codierleitfaden erarbeitet, in dem die Ausprägungen der einzelnen Kategorien definiert und um Ankerbeispiele erweitert wurden. Daneben beinhaltet der Codierleitfaden weitere Codierregeln. Demnach sind die entwickelten Kategorien disjunkt, erschöpfend und überlappungsfrei und gebildete Unterkategorien stellen Ausprägungen ihrer Oberkategorien dar. Es wurden nur zusammenhängende

Textstellen mit mindestens drei Worten und maximal fünf Sätzen codiert. Nach einer Probecodierung von vier Interviews wurde eine endgültige Fassung des Codierleitfadens festgelegt. Um die Intercoderreliabilität sicherzustellen, codierte einer der anderen Autoren einen Teil des Interviewmaterials mit einem Kohens-Cappa-Koeffizienten von 0,81. Nach gemeinsamer Diskussion der unklaren Zuordnungen wurden die restlichen Interviews codiert. Es sind zwei Hauptkategorien (*Verbesserung der medizinischen Prävention* und *Verbesserung der Inanspruchnahme*) entstanden, die Abbildung 2 entnommen werden können. Sie veranschaulicht überdies die acht entwickelten Unterkategorien.

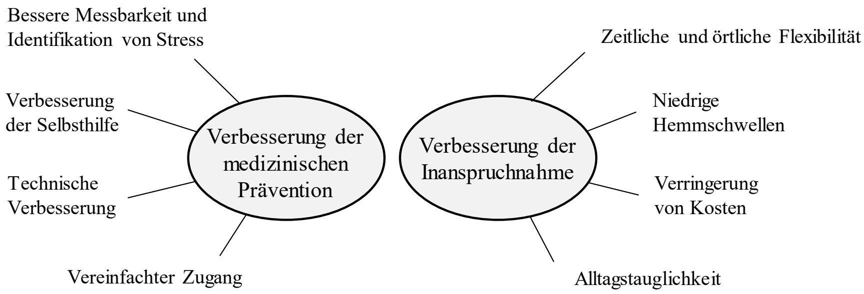

Abbildung 2. Kategoriensystem

4 Nutzenpotenziale von DSMS

Die erhobenen Interviews ergeben Nutzenpotenziale in den zwei Bereichen medizinische Prävention und Inanspruchnahme. Mit einem Anteil von 61 % und 99 Textstellen (Codes) wurde in Summe die Kategorie *Verbesserung der medizinischen Prävention* am häufigsten thematisiert. An zweiter Stelle folgen Aussagen zu besseren Bedingungen der Inanspruchnahme (63 Codes, 39 %). Betrachtet man die Verteilung in den einzelnen befragten Gruppen getrennt, so spiegelt sich die oben genannte Reihenfolge bei den Anbietern der Privatwirtschaft und bei den Leistungserbringern wieder. Hingegen nennen die Nutzer und die Krankenkassen Nutzenpotenziale im Zusammenhang mit der Verbesserung der medizinischen Prävention und bezüglich der Inanspruchnahme nahezu gleich häufig mit einem leichten Schwerpunkt auf der Verbesserung der Inanspruchnahme. An dieser Verteilung lässt sich erkennen, dass die Nutzer und die Krankenkassen den Nutzen von DSMS gleichermaßen in medizinischen wie in nicht-medizinischen Gesichtspunkten (verbesserte Bedingungen für die Inanspruchnahme) sehen. Für die Privatwirtschaft und die Leistungserbringer ist der medizinische Fokus ausgeprägter, was mit ihrer beruflichen Ausrichtung und Erfahrung einhergeht und übereinstimmt. Abbildung 3 illustriert die Verteilung der Codes.

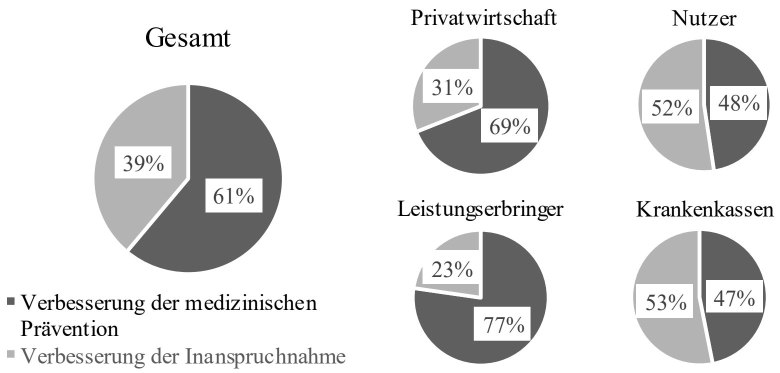

Abbildung 3. Verteilung der Codes

4.1 Verbesserung der medizinischen Prävention

Dieser Abschnitt thematisiert die von den Interviewpartnern genannten Nutzenpotenziale beim Einsatz von DSMS, die zu einer Verbesserung der medizinischen Prävention führen. Eingeschlossen wurden alle Aussagen der Interviewpartner, die sich auf den Umgang, die Messung und Bewertung von Stress beziehen, Empfehlungen, Übungen oder andere medizinische Anregungen bezüglich digitalem Stressmanagement beinhalten oder die Interaktion mit tragbaren Computer- und Internettechnologien thematisieren, die einen direkten Einfluss auf die medizinische Prävention von Stress besitzt. Zusammenfassend werden die bessere Messbarkeit und Identifikation von Stress (42 Codes, 42 %), die verbesserte Selbsthilfe (19 Codes, 19 %), technische Verbesserungen (22 Codes, 22 %) und der vereinfachte Zugang (16 Codes, 16 %) genannt.

Bessere Messbarkeit und Identifikation von Stress. Die Unterkategorie *Bessere Messbarkeit und Identifikation von Stress* ist innerhalb der Kategorie *Verbesserung der medizinischen Prävention* am stärksten thematisiert. Dies zeigt, dass die Funktionalität der Stressmessung bei DSMS weitreichende Nutzenpotenziale mit sich bringt. Bis auf die Krankenkassen diskutieren diese Thematik alle befragten Akteursgruppen ausführlich. Das zurückhaltende Verhalten der Krankenkassen könnte damit erklärt werden, dass die DSMS der Krankenkassen hauptsächlich websitebasierte Programme darstellen, die über keine Stress messenden Funktionen verfügen.

Die Leistungserbringer erklären, dass Stress ein unspezifisches und abstraktes Erscheinungsbild ist und erst dann gesundheitsschädlich oder sogar krankhaft wird, wenn er häufig und langanhaltend auftritt. Die Messung von Stress steht daher im Zentrum der Aufmerksamkeit. Da Stress zu körperlichen Reaktionen wie beispielsweise vermehrter Schweißbildung, flacher Atmung oder Verspannungen führt, können durch Messung entsprechender Parameter Hinweise auf aktuelle Stresslevel gewonnen werden. Die Leistungserbringer und Anbieter aus der Privatwirtschaft benennen die Messung der Herzratenvariabilität, des Hautleitwiderstands, der

Atemfrequenz oder muskulärer Spannungen (zum Beispiel im Nacken) als geeignete Parameter zur Bestimmung von Stressbelastungen. Dafür bieten sich insbesondere Wearables an.

Wenn die gemessenen Größen vom DSMS in ein für den Nutzer verständliches Stresslevel übersetzt werden, wird er in die Lage versetzt, eigene Stressbelastungen zu erkennen und auszuwerten. Ursache- und Wirkungsbeziehungen können klar dargestellt werden, was einen hohen motivationalen Mehrwert mit sich bringt. Die Nutzer berichten davon, dass ein Stress messendes Gerät schnell eine Ankerfunktion übernimmt und sie es nach einigen Nutzungszyklen - durch Konditionierung - bereits mit Entspannung und Stressabbau assoziieren. Zu Beginn der Stressprävention ist es besonders gewinnbringend, wenn eine Auswertung der Stresslevel detailliert im Zeitverlauf dargestellt wird, da der Nutzer seine potenziell hohen Stresswerte mit entsprechenden Situationen und Ereignissen in Verbindung setzen kann. So wird es dem Nutzer erleichtert, seine individuellen externen Stressoren zu identifizieren. An dieser Stelle erkennen insbesondere die Anbieter der Privatwirtschaft, die Nutzer und die Leistungserbringer beträchtliche Nutzenpotenziale und sehen einen klaren Mehrwert gegenüber herkömmlichen Präventionsmaßnahmen (wie beispielsweise Informationsveranstaltungen oder routinemäßige Gesundheits-Checks beim Arzt). Des Weiteren ermöglicht die selbstständige Messung des Stresslevels dem Nutzer, geeignete Übungen zur Stressreduktion abzuleiten und deren Erfolg zu bewerten. Die Interviewpartner betonen den Vorteil tragbarer Internettechnologien insofern, als mit ihnen Stressmessung auch im alltäglichen Leben unabhängig von einem Arztbesuch möglich ist.

Insgesamt bieten DSMS neuartige Möglichkeiten, unabhängig und alltagsnah Stresswerte zu messen und zu dokumentieren. Diese Funktionen haben Potenzial, die Diagnostik von Stress oder eines drohenden Burnouts zu verbessern, und stellen eine fundierte Basis dar, um Anti-Stress-Maßnahmen auszuwählen und durchzuführen.

Verbesserung der Selbsthilfe. In der Unterkategorie *Verbesserung der Selbsthilfe* finden sich Aussagen aller interviewten Akteursgruppen, wobei sich die Leistungserbringer mit ihrem medizinisch-therapeutischen Wissen besonders intensiv einbringen.

Aus Sicht der Interviewpartner können DSMS in drei Bereichen Unterstützung zur Selbsthilfe leisten. Zunächst stellen sie Material zur Wissensvermittlung zur Verfügung, in dem klassischerweise Inhalte zu Stressarten, Warnsignalen, Symptomen und der Wirksamkeit (präventiver) Maßnahmen vermittelt werden. Laut der Anbieter der Privatwirtschaft, der Leistungserbringer und der Krankenkassen lässt sich dieser Bereich sehr gut an digitale Dienste abgeben, da in der Wissensvermittlung weder individuelle Interaktionen noch persönliche Beziehungen vonnöten sind. Auf diese Weise entsteht Zeitersparnis und die Nutzer können ihren Fokus auf weitere Übungen legen. Der zweite Bereich beschreibt Interventionen reflektiver Art, die häufig achtsamkeitsbasiert sind und Körpergefühl sowie -wahrnehmung schulen. Mit dem Ziel einer verbesserten Selbstbeobachtung erlernen die Nutzer autonom, ihren Gesundheitszustand besser einzuschätzen. Durch die begleitende Messung der Stresslevel können die Nutzer außerhalb des ärztlichen Umfelds relevante Parameter aufnehmen und diese eigenständig mit den Erkenntnissen der Selbstbeobachtung abgleichen. Des Weiteren umfassen achtsamkeitsbasierte Übungen kurz- bis mittelfristige Bewältigungsstrategien (wie beispielsweise Atemübungen), die den Nutzern in stressigen Phasen unverzüglich helfen können, Stress abzubauen.

Der dritte Bereich besteht aus Interventionen, die Übungen zum Aufbau von Anti-Stress-Ressourcen zur Verfügung stellen und hauptsächlich der langfristigen Stressbewältigung dienen. Die diesbezügliche Eignung von DSMS wird von den Interviewpartnern rege diskutiert. Die Anbieter in der Privatwirtschaft und die Nutzer erkennen Nutzenpotenziale hinsichtlich der Entscheidung, welche Ressourcen für ausreichend Erholung im Alltag sorgen können. Demnach sehen sie Vorteile in allen drei genannten Bereichen, auch wenn die dritte Ebene klassischerweise im Rahmen einer Therapie thematisiert und zwischenmenschlich bearbeitet wird. Da eine Therapie erst nach Ausbruch einer Erkrankung ansetzt, bieten DSMS die Möglichkeit, schon vorher eine Präventionskultur zu etablieren und gleichzeitig langfristige, individuell passende Stressbewältigungsstrategien für den Nutzer zu eruieren.

Technische Verbesserungen. Die Unterkategorie *Technische Verbesserungen* ist stark geprägt von Aussagen der Privatwirtschaft, für die die Entwicklung und technische Umsetzung von DSMS naturgemäß im Zentrum stehen. Auch die Leistungserbringer bringen sich rege ein.

Ein Vorteil tragbarer Computer- bzw. Internettechnologien liegt unter anderem in permanent durchführbarer Stressmessung. Folglich kann sofortiges Feedback durch Hinweise und Warnungen an den Nutzer gesendet werden, sodass Maßnahmen zum kurzfristigen Stressabbau unmittelbar getroffen und die stressige Situation zeitnah gelöst werden kann. Diese dauerhafte Verfügbarkeit wird von den Interviewpartnern als Schlüsselkomponente für aktives und wirksames Stressmanagement eingestuft.

Die Stressmessung und die Erhebung weiterer Daten wie beispielsweise Selbsteinschätzungen des Nutzers bieten eine solide Datengrundlage, um fundiert Einschätzungen des Gesundheitszustands zu treffen. Daneben lassen die Daten Rückschlüsse auf die Wirksamkeit durchgeführter Interventionen und Übungen zu. Neben der Verwendung der Datenmenge für ein wirksames Stressmanagement könnte diese mit dem Einverständnis des Nutzers auch für bevölkerungsweite Analysen oder für solche von Teilpopulationen genutzt werden, um Vorhersagen und Annahmen über Krankheitsverläufe (gleichartiger Patientengruppen) zu verbessern. Dies birgt das Potenzial einer stärkeren Evidenz wissenschaftlicher Forschung.

Eine maßgeschneiderte Bereitstellung für den individuellen Nutzer stellt aus Sicht der Interviewpartner ein sehr bedeutendes Nutzenpotenzial dar. Die Leistungserbringer und die Privatwirtschaft konkretisieren, dass Individualität technisch mithilfe künstlicher Intelligenz geeignet realisiert werden kann. Es werden lernende Systeme favorisiert, die auf Basis von Algorithmen das Profil und die Merkmale eines Nutzers mit der Zeit erlernen und somit zu einem sehr individuellen DSMS führen, das Stresssituationen sowie wirksame Maßnahmen nutzerbezogen eruiert. Durch die Erstellung nutzerspezifischer Empfehlungen und Zusammenfassungen entstehen präzise und gewinnbringende Rückmeldungen und Interaktionen zwischen DSMS und Nutzer. Auch die automatische Erkennung von Stimmlagen, Gemütszustandsveränderungen sowie Abweichungen vom normalen Muster zählt zu den Funktionalitäten, die durch den Einsatz künstlicher Intelligenz vermehrt zur Verfügung gestellt werden können. Die Leistungserbringer betonen, dass hinter jeder Stressbelastung oder arbeitsbezogenen Depression ein sehr individueller Verlauf steckt, der bei nicht-individualisierten DSMS keine Berücksichtigung findet. Daher sollten die Themenbereiche Individualisierung und künstliche Intelligenz verstärkt fokussiert werden.

Vereinfachter Zugang. Digitale Technologien besitzen den Vorteil eines einfachen Zugangs für einen Großteil der Bevölkerung. Dieser Aspekt wird insbesondere von den Krankenkassen hervorgehoben. Durch einfache und schnelle Zugangsmöglichkeiten wie das Aufrufen einer Website oder das Herunterladen einer Applikation auf das Smartphone kann eine große Anzahl an Personen mit nur geringem Aufwand zeitunabhängig beginnen, mit einem DSMS zu arbeiten. Dies ist besonders für Menschen in strukturschwachen Regionen mit wenig Zugang zu medizinischer Unterstützung von Vorteil. Dank der guten Skalierbarkeit können eine große Zielgruppe und auch neue Personengruppen, die von herkömmlichen Präventionsangeboten nicht angesprochen werden, erreicht werden. Dazu zählen insbesondere junge Menschen und technikaffine Personen.

4.2 Verbesserung der Inanspruchnahme

Der Einsatz digitaler Technologien bewirkt einige Nutzenpotenziale, die sich nicht direkt auf die medizinische Versorgung beziehen. Dieser Abschnitt thematisiert die von den Interviewpartnern genannten Nutzenpotenziale im Einsatz von DSMS bezüglich der Verbesserung der Bedingungen der Inanspruchnahme. Eingeschlossen wurden alle Aussagen der Interviewpartner, die sich auf die Art und Weise der Nutzung des Systems sowie auf die Rahmenbedingungen der Nutzung und dessen (nicht-medizinische) Auswirkungen beziehen. Zusammenfassend werden zeitliche und örtliche Flexibilität (20 Codes, 32 %), eine sehr gute Alltagstauglichkeit (16 Codes, 25 %), niedrige Hemmschwellen (16 Codes, 25 %) sowie eine Verringerung von Kosten (11 Codes, 18 %) genannt.

Zeitliche und örtliche Flexibilität. Die Unterkategorie *Zeitliche und örtliche Flexibilität* ist geprägt von Äußerungen der Nutzer und der Krankenkassen. Aufgrund der Schnelllebigkeit im (beruflichen) Alltag ist Zeit bei stressgeplagten Menschen oder bei Personen mit ausgeprägter Arbeitsbelastung häufig ein sehr kritischer Faktor. Daher sind kurze Bearbeitungszeiten (die Interviewpartner empfehlen 5–15 Minuten pro Tag) und zeitliche Flexibilität Parameter, die für viele Personen (insbesondere bezüglich der genannten Zielgruppe) von besonderer Bedeutung sind. Da die Nutzung eines DSMS weder mit Fahrtzeiten noch mit festen Terminen verbunden ist, bietet sie neue Freiräume durch flexible Nutzung. Auch die Ortsunabhängigkeit ist gerade für Berufstätige von Relevanz. Die mögliche Verwendung eines DSMS am Arbeitsplatz oder in gewohnten Umgebungen, wie dem eigenen Zuhause, eröffnet diverse Vorteile.

Alltagstauglichkeit und niedrige Hemmschwellen. Alle Interviewpartner sehen in der Nutzung von DSMS Vorteile aufgrund der hohen Alltagstauglichkeit. Da DSMS häufig auf mobilen Endgeräten wie Smartphones oder Wearables verfügbar sind, lassen sie sich nach den Erfahrungen der Nutzer sehr gut mit sich führen und in den Alltag integrieren. Demnach ist es möglich, während des Tages kurzfristig auf Hinweise des DSMS zu reagieren. Außerdem führt eine intelligente Steuerung von Hinweisen und Handlungsempfehlungen (beispielsweise keine Störungen bei einem Aufenthalt in einem bestimmten Konferenzraum) dazu, dass die Interaktion mit einem DSMS an situative Gegebenheiten angepasst ist und daher die Integration in den Alltag weiter verbessert wird.

Digitale Dienste wie DSMS können anonym und mit nur geringem Aufwand in Anspruch genommen werden. Dies senkt unter den Nutzern die Hemmschwelle, entsprechende Systeme auch tatsächlich zu gebrauchen. Die Leistungserbringer berichten aus ihrer Erfahrung, dass im Bereich psychischer Erkrankungen oder eines Burnouts Anonymität und Unverbindlichkeit sehr häufig wichtige Voraussetzungen dafür darstellen, dass sich Risikopatienten oder auch Menschen mit Symptomen überhaupt dafür entscheiden, Unterstützung anzunehmen. Der geringe Aufwand, mithilfe von DSMS Maßnahmen zur Stressbewältigung zu treffen, und die damit verbundene Anonymität und Unverbindlichkeit führen aus Sicht der Interviewpartner zu klaren Vorteilen und einer allgemein höheren Beteiligung.

Verringerung von Kosten. Die Privatwirtschaft, Leistungserbringer und Krankenkassen sind der Überzeugung, dass der Einsatz von DSMS langfristig zu Kosteneinsparungen im Gesundheitssystem führt. Die Kategorie *Verringerung von Kosten* ist in starkem Maße von den Aussagen der Krankenkassen geprägt. Einsparpotenziale werden zum einen darin gesehen, dass infolge erfolgreicher Prävention die Zahl der Burnout-Erkrankungen und damit die Behandlungskosten und Krankenhausaufenthalte zurückgehen. Des Weiteren bieten DSMS die Möglichkeit, im Falle des Ausbruchs einer Burnout-Erkrankung einige geeignete Therapiebestandteile wie beispielsweise die Psychoedukation, an digitale Systeme abzugeben und damit Therapiekosten bei gleichbleibender Qualität einzusparen. Aufgrund der guten Skalierbarkeit sind DSMS ökonomisch effizient. Neben der Verringerung der Kosten für das Gesundheitssystem führt aus wirtschaftlicher Sicht die allgemeine Verringerung krankheitsbedingter Ausfälle zu einer gesteigerten Produktivität. Die Forschung könnte vom Einsatz von DSMS durch eine schnelle und kosteneffektive Sammlung von Daten profitieren, die sonst traditionell mit Fragebögen erhoben werden.

Tabelle 1 listet die genannten Nutzenpotenziale auf und gibt zusätzlich an, ob sich diese konkret auf Stress und Burnout beziehen oder auch auf andere strukturgleiche Anwendungsfälle übertragbar sein könnten. Diese Beurteilung stammt aus den Erkenntnissen des Interviewmaterials und wurde um eine gemeinsame Diskussion der Autoren ergänzt. Des Weiteren ist durch Kreise gekennzeichnet, wie häufig das jeweilige Nutzenpotenzial von den verschiedenen Akteuren genannt wurde.

Tabelle 1. Nutzenpotenziale von DSMS

Nutzenpotenziale	*PW*	*N*	*LE*	*KK*
Bessere Messbarkeit und Identifikation von Stress				
Arzt-unabhängige und alltagsnahe Messung von Stress	●	◑	●	◑
Bessere Diagnostik und Überwachung von Stress	●	◑	●	○
Auswertung individueller Stressbelastungen im Zeitverlauf zur Identifikation externer Stressoren	●	●	●	○
Verbesserung der Selbsthilfe				
Kurzweilige, digitale Wissensvermittlung	●	◑	●	●
Interventionen reflektiver Art für kurz- bis mittelfristige Stressbewältigungsstrategien	●	◑	●	◑
Interventionen zum Aufbau von Anti-Stress-Ressourcen zur langfristigen Stressbewältigung	●	●	◑	◑
Technische Verbesserung				
Sofortiges Feedback (bspw. in Stresssituationen) vom DSMS durch Hinweise und Warnungen	●	●	●	◑
Bessere Datengrundlage (Gesundheitszustand/ Wirksamkeit/ Evidenz)	●	○	●	◑
Einsatz künstlicher Intelligenz durch lernende Systeme	●	◑	●	◑
Vereinfachter Zugang				
Einfache und schnelle Zugangsmöglichkeiten; sehr gute Skalierbarkeit	◑	○	◑	●
Zeitliche und örtliche Flexibilität				
Zeitliche Flexibilität, keine festen Termine oder Fahrtzeiten; Nutzung an diversen Orten möglich	◑	●	◑	●
Alltagstauglichkeit				
Gute Integration in den Alltag; ständige Stressmessung	●	●	●	●
Niedrige Hemmschwellen				
Anonyme und unverbindliche Nutzung	◑	●	●	●
Verringerung von Kosten				
Kosteneinsparungen aufgrund geringerer Anzahl an Burnout-Erkrankungen, geringeren Behandlungskosten, höherer Produktivität	◑	○	◑	●

5 Grenzen von DSMS

Mit insgesamt 37 Textstellen adressieren die Interviewpartner neben den zahlreichen Nutzenpotenzialen ebenfalls Grenzen und Nachteile von DSMS. Alle Akteursgruppen benennen fehlende wissenschaftliche Fundierung sowie Evidenz und die damit einhergehende mangelnde Sicherstellung von Qualitätsansprüchen. Insbesondere für die Nutzer ist nicht ersichtlich, welche auf dem Markt angebotenen DSMS eine hohe Qualität aufweisen.

Auch datenschutzrechtliche Risiken werden von den Interviewpartnern häufig genannt. Mangelnde Sicherstellung von Anonymität, unsichere Datenübertragung mit möglichen Missbrauchsfolgen sowie fehlende Aufklärung und fehlende Datenhoheit werden DSMS nachteilig zugeschrieben.

Die Anbieter aus der Privatwirtschaft, die Krankenkassen und die Leistungserbringer diskutieren hohe vorherrschende Abbruchquoten bei DSMS. Insbesondere bei reinen Selbstmanagement-Programmen, die unbegleitet sind, scheinen Motivation und Durchhaltevermögen bei einigen Nutzern problematisch zu sein. Die Experten führen dies auf die naturgemäße Unverbindlichkeit von DSMS und auf das Fehlen einer menschlichen bzw. sozialen Komponente zurück. An dieser Stelle weisen die Leistungserbringer und die Krankenkassen darauf hin, dass aufgrund der individuellen Umgebung, der Berufswelt und konkreten Arbeitssituation mit ihren jeweiligen spezifischen Merkmalen und Anforderungen digitale Systeme den Bereich der langfristigen und strategischen Stressbewältigung ohne menschlichen Einbezug nicht ausreichend abbilden können. Daher sehen sie für diesen Teilbereich der Stressprävention die Integration medizinischen Fachpersonals als notwendig an und erkennen Grenzen der Internettechnologie.

Allgemein entstehen durch die Nutzung von DSMS Abhängigkeiten zu einer Internetanbindung, zu einem Stress messenden Gerät bzw. einem Smartphone. Die Leistungserbringer ergänzen, dass durch dessen ständige Verfügbarkeit eine klare Trennung zwischen Alltag und Stressreduktion bzw. Arbeit und Stressreduktion fehlt. Herkömmliche Präventionsmaßnahmen sind oft mit einer Anreise verbunden, wodurch in der Regel eine bessere Konzentration für die einzelnen Interventionen aufgebracht werden kann. Tabelle 2 listet die genannten Grenzen auf und gibt zusätzlich an, ob sich diese konkret auf Stress und Burnout beziehen oder auch auf andere strukturgleiche Anwendungsfälle übertragbar sein könnten.

Tabelle 2. Grenzen von DSMS

Grenzen	*PW*	*N*	*LE*	*KK*
Mangelnde Sicherstellung von Qualitätsansprüchen	●	●	●	●
Nichteinhaltung datenschutzrechtlicher Ansprüche	●	◑	●	◑
Hohe Abbruchquoten	◑	○	●	◑
Abhängigkeiten von Internetanbindungen oder Stress messenden Geräten	○	◑	●	○
Fehlende Abgrenzung der Stressreduktion vom Alltag	○	◑	●	○

▭ Burnoutspezifisch ● ≥ 50% ◑ < 50% ○ Keine Nennung

6 Diskussion

Die Analyse des Interviewmaterials lässt den Schluss zu, dass DSMS in der Lage sind, sowohl kognitive, emotionale als auch muskuläre Ebenen der Stressreduktion zu adressieren. Die Bereiche der Wissensvermittlung und der Unterstützung der Achtsamkeit sowie Körperwahrnehmung verfügen aus Sicht der Interviewpartner über besonders große Nutzenpotenziale, die vor allem auf die neu entstehenden Möglichkeiten der alltäglichen und dauerhaften Stressmessung zurückgeführt werden. Der Einsatz von Wearables macht Symptome auf medizinischer Grundlage erkennbar und lässt Rückschlüsse auf geeignete Stressreduktionsmaßnahmen zu. Dem stehen DSMS auf Basis selbst wahrgenommener Reaktionen gegenüber, die über keine Stress messenden Funktionalitäten verfügen. Da diese in der Regel weniger individuell sind und meist nur generelle Übungen und Hinweise vermitteln, werden sie im Vergleich als nachteilig angesehen. Der Einbezug einer Stress messenden Technologie wird von den Interviewpartnern klar gewünscht. Der Großteil der in dieser Untersuchung eruierten Nutzenpotenziale im Bereich der medizinischen Prävention entsteht erst durch das Vorhandensein alltagsnaher Stressmessung (beispielsweise bessere Diagnostik/Überwachung von Stress, sofortiges Feedback, Einsatz künstlicher Intelligenz etc.). Ob allerdings sofortiges Feedback mittels Hinweise oder Warnungen in Stresssituationen auch dazu führen könnte, dass eine Stressreaktion noch weiter verschärft wird, bleibt unklar und sollte in weiteren Forschungsvorhaben adressiert werden.

Des Weiteren ist es fragwürdig, inwiefern DSMS auch in der langfristigen Stressbewältigung und beim Aufbau von Anti-Stress-Ressourcen Nutzen bringen. Auf der einen Seite sind stressauslösende Situationen derart komplex und individuell verschieden, dass für strategische Stressbewältigungsstrategien eine rein digitale Bearbeitung ohne menschlichen Einbezug nicht ausreichend ist. Auf der anderen Seite ist denkbar, dass die Weiterentwicklung künstlicher Intelligenz derart individuelle Systeme hervorbringen kann, dass arbeitsbezogene Ausgangsbedingungen nach therapeutischen Verfahren erfolgreich analysiert und interpretiert werden können und damit das DSMS dem Nutzer maßgeschneiderte Anregungen vermitteln kann.

Im Vergleich lässt sich feststellen, dass die in dieser Untersuchung ermittelten nicht-burnoutspezifischen Vorteile digitaler Technologien wie beispielsweise vereinfachter Zugang, Anonymität oder zeitliche Flexibilität mit den in der Literatur bekannten Nutzenpotenzialen übereinstimmen. Hingegen sind Kenntnisse über die erarbeiteten burnoutspezifischen Nutzenpotenziale von DSMS in der Literatur weniger verbreitet. Dies zeigt, dass zur erfolgreichen Stressprävention und damit zur Vermeidung eines Burnouts einige Besonderheiten gelten, die in der Entwicklung entsprechender DSMS Berücksichtigung finden sollten. Da typischerweise Menschen mit einer intensiven arbeitsbezogenen Belastung und mit wenig Erholungsmöglichkeiten burnoutgefährdet sind, sollten DSMS mit möglichst kurzen Bearbeitungszeiten bedienbar sein. Sie adressieren somit Schnelllebigkeit und Zeitdruck, sodass auch stark stressgeplagte Menschen zeitliche Freiräume für die Nutzung realisieren können. Des Weiteren kann den derzeit vorliegenden hohen Abbruchquoten mittels Gamification und Motivationselementen begegnet werden.

Zukünftige Forschungsbereiche werden von den Autoren darin gesehen, die neu erhobenen Nutzenpotenziale anhand realer Anwendungsbeispiele zu untersuchen und quantitativ zu validieren. Durch den Einbezug der Perspektive von Arbeitgebern, die als ein Teil der stressauslösenden Quellen eines Burnouts angesehen werden, können eine Erweiterung der Nutzenpotenziale und ein Vergleich mit wirtschaftlichen Anforderungen erfolgen.

7 Limitationen

Die subjektive Verwendung sprachlichen Materials kann zu Interpretationsdifferenzen führen. Daher lassen sich subjektive Einflüsse aufgrund der persönlichen Erfahrung und des Wissensstands der Autoren im Rahmen der Interviewführung und bei der Auswertung der erhobenen Interviews nicht ausschließen. Durch Cross-Validierung wurde dieses Risiko minimiert.

Des Weiteren kann es aufgrund der unterschiedlichen Interviewformate (telefonisch oder persönlich) zu situativen Unterschieden gekommen sein.

Aufgrund der Voraussetzung, nur am Interview teilnehmen zu können, wenn ein DSMS bereits genutzt bzw. angeboten wird, könnten einseitig verzerrte Nutzenpotenziale erhoben worden sein. Somit ist eine Generalisierbarkeit der Aussagen auf die gesamte Bevölkerung fraglich. Dies betrifft insbesondere die Perspektive der Nutzer: die frühe Verwendung neuartiger Technologien lässt eine grundsätzliche Offenheit und Präferenz digitaler Systeme vermuten.

Alle Interviewpartner sind Teilnehmer im deutschen Gesundheitssystem, das durch deutsche und europäische Gesetze und Vorschriften wesentlich geprägt ist. Daher ist eine Übertragung auf nicht-europäische Länder zunächst nicht uneingeschränkt möglich.

8 Fazit

Zusammenfassend bestätigen die geführten Interviews, dass DSMS diverse Nutzenpotenziale besitzen und einen Beitrag zur Gesundheitsversorgung leisten können. Mittels digitaler Technologien zur Stressmessung entstehen neue Möglichkeiten, übermäßigen Stress zu erkennen und darauf zu reagieren. DSMS können niedrigschwellig in Anspruch genommen und die Eigenständigkeit und Selbsthilfe der Nutzer gestärkt werden. Die Digitalisierung der Prävention bringt allerdings auch Nachteile mit sich, unter die insbesondere datenschutzrechtliche Risiken, hohe Abbruchquoten und mangelnde Sicherstellung von Qualitätsansprüchen fallen.

User Dynamics in Mental Health Forums – A Sentiment Analysis Perspective

Elena Davcheva, Martin Adam, Alexander Benlian

Technical University Darmstadt, Information Systems & E-Services, Darmstadt, Germany
{davcheva,adam,benlian}@ise.tu-darmstadt.de

Abstract. Individuals around the world in need of mental healthcare do not find adequate treatment because of lacking resources. Since the necessary support can often not be provided directly, many turn to the Internet for assistance, whereby mental health forums have evolved into an important medium for millions of users to share experiences. Information Systems research lacks empirical evidence to analyze how health forums influence users' moods. This paper addresses the research gap by conducting sentiment analysis on a large dataset of user posts from three leading English-language forums. The goal of this study is to shed light on the mood effects of mental health forum participation, as well as to better understand user roles. The results of our exploratory study show that sentiment scores develop either positively or negatively depending on the condition. We additionally investigate and report on user forum roles.

Keywords: Mental Health, Sentiment Analysis, Big Data, Forums, Natural Language Processing

1 Introduction

Mental disorders are defined as "a combination of abnormal thoughts, perceptions, emotions, behavior and relationships with others" [1]. The term comprises depression, bipolar disorder, schizophrenia, dementia, and developmental disorders such as autism. An estimated 300 million people are affected by depression alone (worldwide) and 15% of people aged 60 and over suffer from one or more disorders [2]. What is more, the world population is aging rapidly. Between 2015 and 2050, the proportion over 60 years will nearly double, from 12% to 22% [2]. Health systems have not yet adequately answered the growing burden. Between 35% and 85% of affected individuals receive no official treatment [3]. In many countries, less than one psychiatrist per 100,000 people is available [4]. Moreover, the fear of stigma discourages people from seeking assistance [5]. Even if willing, those affected often cannot afford the medical treatment [6], since professional help involves expensive clinical procedures [7]. The medical cost of mental health exceeds $200 billion in the U.S., making it the costliest medical condition in the country [8].

The digitalization of health information has created opportunities for individuals to seek self-help and connect directly to other affected individuals [9]. Online information

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

is free, anonymous, and time- and location-independent [11]. 80% of the U.S. population with Internet access gather information from mental health discussions, and 34% of those read others' personal stories [12]. Mental health forums are particularly appealing to those individuals who are afraid that coming out of the cloak of anonymity may expose them to stigma [33]. Online information is by no means limited only to the younger generation, as the usage of social media by adults aged 60 and over nearly doubles on a yearly basis [13]. Furthermore, studies show that users are more honest and more likely to share personal stories online than in-person [14]. The chance to share experiences, connect with others with similar conditions as well as gain insights from their stories, creates a rewarding experience for the users of these forums [12].

This paper looks into online tools for mental health by longitudinally analyzing sentiment development of user posts in online mental health forums. We investigate (1) the sentiment progression in forums over time, and (2) the user role dynamics, as well as (3) the relation between user role and sentiment. We apply sentiment analysis on a dataset of 500,754 individual posts across 8 mental health conditions collected from 3 leading English-language forums. We show that the longitudinal development of user sentiment differs across conditions and types of engagement. We compare user roles and their correlation to sentiment.

This study contributes to existing research by exploring how engagement in virtual healthcare communities affects users, and the potential to empower patients to self-management. We especially address the application of behavioral analytics for mental health, which has been more widely adopted for commercial purposes [16], by illustrating how text mining can help practitioners and policy-makers in understanding the value and risks of using user-led online tools [17].

2 Conceptual Background

2.1 Online Mental Health Forums

Previous IS research has focused on trust formation in online health communities, triaging of symptoms, user roles in forums [18, 20], but not on forum influence on well-being. We address this research gap by looking into conversation dynamics and their influence on user sentiment. Prior research shows that users recognize risks of posting personal medical information online, they nevertheless share as potential rewards outweigh risks [19]. User roles have been researched in terms of superusers (frequent posters), however not in terms of sentiment and its correlation to user roles.

Prior research has found online communities to be not only helpful for mitigating various mental conditions but also dangerous, as users can be influenced to commit potentially life-threatening actions, as in pro-suicide or pro-anorexia groups [21]. Many of these studies have applied manual analysis, such as user surveys or discourse analysis based on a small sample of posts. Johnsen, Rosenvinge and Gammon [22] used human readers to classify interactions in mental health forums as helpful or unhelpful based on only 102 posts. By manual assessment, Spijkerman, Pots and Bohlmeijer [23] investigated advantages of online mindfulness and meditation practice for depression and anxiety. In a comparable paper, Mitchell et. al. [24] used human coders to analyze

401 posts from 55 forum threads and found that 25% of users with ADD reported positive effects of self-medicated cannabis on their illness. Although human readers provide reliable analysis, the amount of processed posts is very limited. In this study, we analyze 500,754 forum user posts. Such a vast dataset, to the best of our knowledge, has not been analyzed yet in this context, thus allowing us to explore the shared stories and experiences of tens of thousands of individuals.

2.2 Sentiment Analysis

Recently, natural language processing (NLP) techniques such as sentiment analysis (SA), emotion classification, and stigma measurements have been increasingly applied in research on various data sources such as Twitter, Facebook, and online forums [41]. SA can determine sentiment polarity in written text [25], using a classifier such as Naive Bayes to train with a pre-annotated dataset of sentences, and then apply to new data. Sentiment in psychological literature is referred to as mood or affect. There is a long-standing position in psychological research that a well-adjusted mood is crucial for good mental health [26, 27]. A person in good mental health would express about "three times more positive than negative affect" [28]. Diehl et. al. formally showed that the absence or presence of positivity or negativity can be used to distinguish an individual's mental health status (waning vs. healthy). Therefore, while sentiment is not a tell-all signal of mental well-being, it is a fundamental indicator of the progression of a mental state.

Only few papers use SA in the context of online mental health forums. Nguyen et. al. [29] conducted a fundamental effort by comparing the sentiment expressed on depression forums with sentiment in non-depression forums, demonstrating that individuals without depression express themselves more positively. The study directly backs the application of SA as an appropriate method to analyze data from mental health forums. SA has also been applied to pharmacovigilance in social media (Twitter) – the identification of adverse drug effects – by detecting posts with negative sentiment towards specific medications [30], allowing researchers to explore drug effects across a large and diverse population. The study presents an important example in using text mining to identify potentially negative effects of treatments that might have been otherwise considered safe. Twitter alone has been used in a dozen studies where healthcare issues in general have been explored using sentiment analysis [43]. Furthermore, Cobb, Mays and Graham [31] demonstrated by using SA that talking positively about quitting smoking influences social media users to quit in real life. Via SA, the study shows that user-to-user communication can affect life choices. Aspect-based sentiment analysis has also been applied in order to examine how forum users express themselves on specific concepts such as family or therapy [42]. Finally, Wang et. al. [32] applied SA to classify a user's condition. These ways of using SA have had great success and will be even more useful in the future, considering the development of automated online diagnostic tools [6]. What has not been addressed is the effect of participating in mental health forum conversations, and if and how this depends on the way a user engages with the forum and the role they assume.

3 Research Propositions

Many studies have provided evidence that exchanging support and talking to peers can improve well-being [34]. In fact, even if people seek treatment from professionals, they often still participate in online discussions [33]. Participants also enhance their psychological well-being by providing support [35]. As a result, they feel "better informed, confident with the physician, treatment and social environment, improved acceptance of the illness, increased optimism and control, enhanced self-esteem" [34]. Disadvantageous posts may also occur due to the lack of control of quality of information, potentially destructive content that reinforces negative emotions [10, 22]. Some evidence of the possible benefits from participation exists specifically for mental health forums, although findings are mixed mainly due inconclusive studies and a lack of quantitative research [15].

Owing to the exploratory nature of the study, we use propositions to frame our central premises. In our study we look explicitly at forum users who post, therefore in this context users (or participants) are those who post on the forums, whether to ask a question, to share an experience, to provide answers or comment. By applying sentiment analysis, we test if through participation in forum conversations the affect of a participant is improved. Since threads in mental help forums are started with the purpose to solve or at least mitigate the problem of the original poster [15, 34], the sentiment is expected to improve throughout the thread if the conversation is to be proven as helpful.

P1a: The sentiment score of posts within a thread in mental health forums increases throughout the thread with each subsequent post.

Moreover, we expect that after receiving advice and support, the original poster (OP) will improve their mood, e.g. with regards to confidence, optimism, or ability to cope with their mental condition [15, 34, 36] .

P1b: The sentiment score of posts by the original poster within a thread in mental health forums increases throughout the thread with each subsequent post.

Second, we investigate whether the proposed positive sentiment progression is true outside of single threads, i.e. throughout a user's general forum participation. Studies [36] found that "helping others" was one of the empowering processes that occurred the least frequently in social support groups, since users have to actively post to assist others. High-frequency posters were found to provide more advice than asking for help [36]. Therefore, if a user is commenting on threads by other users, they will improve sentiment and keep the solution-oriented perspective.

P2: The sentiment score of user posts in mental health forums increases throughout the general participation in the forum with each subsequent post.

Third, we look into the roles that users assume in mental health forums, and the relation between roles and sentiment. Initially, users participate by passively reading [37]. In urgent cases, they will post their problem fast and receive encouragement or advice. However, users also increase their psychological well-being by commenting on and engaging with issues posted by others [35], and providing help to others will indirectly assist in coping with their initial problem. Therefore, we propose that users of mental health forums normally fall into one of two roles, either original posters or commenters. The interaction between these two user groups is what drives and defines mental health forum dynamics [38]. Proposition P3 is sentiment-independent and helps establish the dynamics of a user's forum lifetime. The analysis procedure for P3 is to look at the timeline and type of user comments - specifically original poster versus commenter.

P3: Users start their forum participation as original posters, then go on to participate and reply to threads opened by other users.

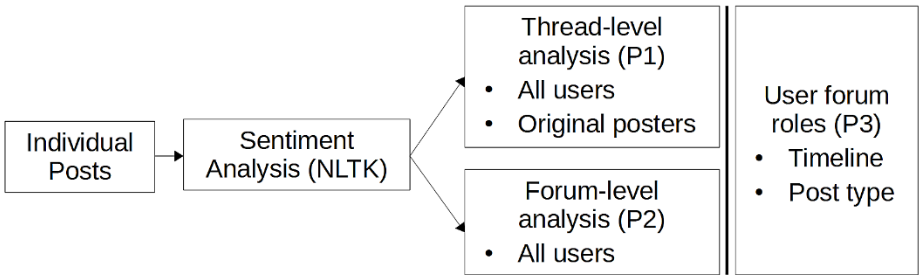

Figure 1. Research Process and Propositions

4 Methodology

To test our propositions, we apply sentiment analysis on peer-to-peer mental health forum posts. Three of the leading English-language mental health forums were scraped to create a combined set of 49,113 threads containing 500,754 individual posts from about 75,000 users across 8 conditions (i.e., depression, bipolar disorder (BD), anxiety and panic attacks, attention deficit hyperactivity disorder (ADHD), Borderline personality disorder (BPD), obsessive-compulsive disorder (OCD), post-traumatic stress disorder (PTSD)). After removing outlying users who have posted more than 30 times, each user posted on average 6,7 posts throughout a forum. The data were extracted in August 2017 and encompass all publicly available posts on the respective websites. For each post, the dataset contains information on forum username, date posted, thread name, and post content. The forums have moderators whose task is to make sure conversations do not go off-topic; thus, we can be sure that in our research we are considering discussions relevant to each condition. Additionally, moderators remove offensive or damaging material (e.g. posts that encourage self-abusive behavior). However, they do not provide advice, as the forum is a place of discussion among the users, i.e. a forum is not meant or seen as a tool to replace established practices such as therapy.

The sentiment score of a post is scored between -1 (negative) and +1 (positive). We use the Python Natural Language Toolkit (NLTK) sentiment analysis implementation with a lexicon-based classifier. Each forum post is given a score. In order to trace the sentiment progression of user posts throughout forums and threads, we map the average sentiment score of individual users' posts based on the post order within threads (P1) and forums (P2); for proposition P1b we look exclusively at posts made by the original poster within the threads the OP started.

The sentiment is calculated using the Valence-Aware Dictionary for Sentiment Reasoning (Vader) (Gilbert & Hutto, 2014), which offers several unique advantages to other models. The sentiment of a post equals the sentiment valence (or score) of each word recognized by the lexicon. If a word is part of a negation structure (e.g. neither…nor), it's valence will be reversed. If a word is used in combination with a booster word (e.g. "amazingly", "awfully"), its valence will be intensified. The Vader lexicon was built on social media data, namely Twitter tweets, New York Time (NYT) articles, and online movie and product reviews. The sources capture a variety of aspects of social media writing, as well as more analytical texts, thus generalizing well to mental health forum data as it captures features from informal online discussions, e.g. conventional use of punctuation ("good" vs. "good!!!"), capitalization, emoticons, degree modifiers ("good" vs. "very good"), as well as common slang and abbreviations ("this sux", "lol") to signal sentiment intensification. Since its creation in 2014, Vader has been iteratively empirically validated by human judges.

In order to determine the extent of improvement resulting from a prolonged forum posting, we test sentiment score trends by applying regression analysis. For P3, we test the association between user roles and conditions by applying chi-square analysis.

5 Results

Using linear regression, we analyze the sentiment score of a sequence of posts made over a period of time, either within threads or on a per-user basis. Equation (1) models the forum-wide sentiment of depression.

$$y = 0.0011 * x + 0.09 \tag{1}$$

Table 1 presents the regression results and significance for degree of improvement for sentiment trends from three points of view: (1) thread sentiment progression for OP posts only, (2) thread sentiment progression for all thread participants, and (3) sentiment progression per user throughout a forum. Table 1 shows a mild improvement in affect as users keep posting for some conditions, and deterioration in other conditions. The posts of original posters show the highest improvement. The pace of change in sentiment on forums (whether positive or negative) is slightly slower compared to patient improvement observed in therapy. For comparison, a moderate therapy treatment would last 3-4 months and would include 15-20 sessions for 50% of patients to report significant symptom improvement (Leichsenring et. al., 2004). According to our analysis, anxiety, bipolar, and depression forum users must post 100 posts in order to improve their expressed sentiment by 15%. For example, if a depression forum user posts as an OP in threads, the average sentiment improvement per post is 0,003, thus adding +0,3 to positive sentiment after 100 posts. The low R2 values point to high variability in individual user post sentiments. This is consistent with observations from previous studies with a psychological or sociological aspect, as individuals are relatively meandering in their responses [40]. Testing for weekday effects on sentiment change did not prove to be significant.

Table 1. Regression Results and P-Values for Analyzed Mental Conditions

	OP Thread Posts		*All Thread Posts*		*All Forum Posts*	
	Coeff.	**R^2**	**Coeff.**	**R^2**	**Coeff.**	**R^2**
ADHD	0.007	0.2	0.0001	0.2	0	0.2
Anxiety	0.003*	0.3	0.001*	0.4	0.001*	0.3
Autism	0.002*	0.3	-0.006**	0.3	0.002	0.3
Bipolar	0.003**	0.4	0.001	0.2	0.001**	0.2
Borderline	0.001*	0.4	0.0001	0.2	0.0001	0.2
Depression	0.003**	0.8	0.001*	0.4	0.001**	0.4
OCD	0.0001*	0.2	-0.001*	0.2	-0.001	0.1
PTSD	0.0001	0.4	0.003**	0.5	0.001**	0.4

Note: N = 500,754; * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$;, Coeff = Coefficient

5.1 Thread Sentiment Progression of Posts by all Users

Overall, 5 out of 8 tested conditions (i.e., depression, anxiety, autism, PTSD, OCD) show statistically significant sentiment trend. For depression, anxiety, and PTSD, as the conversation thread progresses, post sentiment improves marginally for every subsequent post. PTSD threads have the steepest improvement per post. On the other hand, autism and OCD mark a downward trend, with autism sentiment deteriorating the fastest per post.

Also, OCD and autism threads show significantly more fluctuation within thread posts, whereas conversations in depression, autism, and PTSD have relatively stable trend progressions.

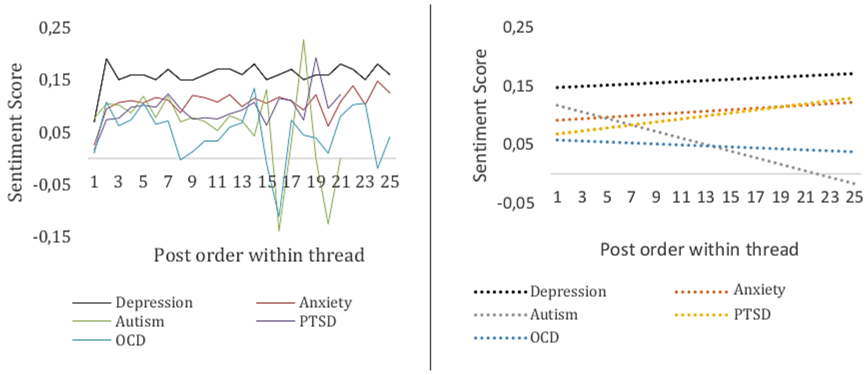

Figure 2. Average Post Sentiment Score Progression within Threads

Based on these findings, Proposition P1a can be confirmed only for depression, anxiety, and PTSD. Thus, mental health forums for these three conditions increase the expressed sentiment in threads that originally started with a lower sentiment score.

5.2 Sentiment Progression of Posts by Original Posters

Across all conditions, OP posts within threads have a positive sentiment score development for every subsequent OP post made (see Fig. 3). However, only 5 out of 8 conditions show significant trends (depression, anxiety, borderline, autism, bipolar). Autism, anxiety, and depression sentiment improve the fastest, whereas depression and borderline forum sentiment improves still, however at a slower pace.

For the most part, the depresson posts by OPs have the highest average score per post order. The anxiety forum exhibits the highest sentiment fluctuation per OP post; interestingly, if an OP opens a thread about anxiety and then immediately follows their own opening post by a second post (usually to provide more detail to their situation), the second post normally has a much lower sentiment score. Thus, those anxiety forum users may be feeling particularly negative when opening a thread, making the subsequent sentiment improvement within their own thread posts that much more substantial.

Based on these results, proposition P1b is supported for 5 out of the 8 conditions tested, showing that, as OPs or advice seekers become more engaged with the thread conversations they start, their expressed sentiment increases.

In terms of improvement per OP post, in all statistically significant conditions, autism forums show the fastest positive sentiment development. This is starkly opposed to general autism posts in a thread, where autism had the worst performance. It is important to note that OCD forums exhibit the same pattern, but without as drastic a change as in the case of autism.

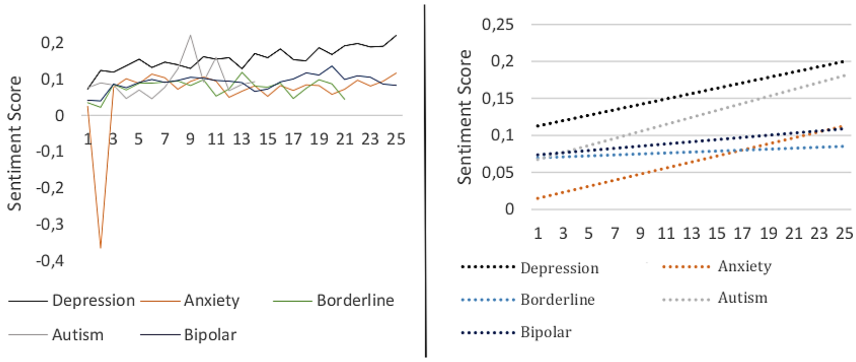

Figure 3. Average Sentiment of OP Post within Threads

Compared to OP-only thread posts, overall thread posts still do improve sentiment score with each subsequent post, however at a slower pace. The coefficients suggest that a forum participant benefits much more from OP posts. Therefore, the forum platforms could encourage users to open their own posts as a way to accelerate and strengthen the increased positivity that results from this interaction.

Additionally, many OPs (50% across all conditions) post only once within the threads they open. However, analysis results indicate that a prolonged participation in the thread which an OP starts actually improves the sentiment within OP posts. Therefore, assuming that the personality of forum members does not play a confounding role, our results suggest that users should be incentivized or encouraged to remain active posters in the threads they create, to draw maximum benefit from their participation.

5.3 Sentiment Progression of Forum-wide Posts by all Users

The 4 out of 8 tested conditions with statistically significant trends are depression, anxiety, PTSD and bipolar disorder, where all show a positive change in sentiment score as a user writes more posts. PTSD marks the highest improvement rates per comment. Of all conditions, only OCD forum users show a negative sentiment score trend with subsequent posts, however the trend is statistically insignificant.

With regards to depression forums, those users with 10 or more posts express a consistently positive sentiment score. Furthermore, the sentiment improves continuously as users post more frequently (regardless of whether as OP or commenter). In the anxiety forum, those users with 42 or more posts express a consistently positive sentiment score. The results point that depression users on average achieve consistently more positive sentiment much faster than anxiety users. PTSD and OCD forum posts show much more variability and fluctuation between positive/negative sentiment. When discussing OP posts vs. thread posts vs. Forum posts (OP and commenter) – the forum-wide posts for the 4 conditions above, even though in general showing positive trend development, mark much more fluctuation in sentiment than the other two post types.

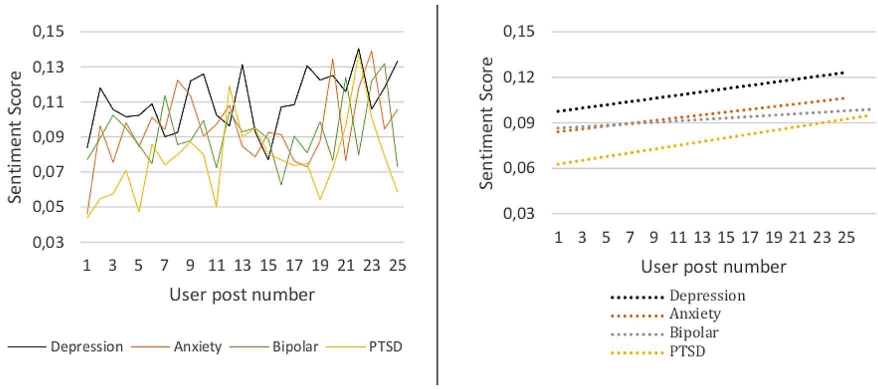

Figure 4. Average Post Sentiment Score per User Post Order within Forums

Based on the results presented, proposition P2 is supported for depression, anxiety, PTSD and bipolar forums, where exposure to mental health forums is shown to be beneficial in terms of improving a user's post sentiment per each subsequent post. For propositions P1 and P2, we can rule out familiarity as a reason for increased sentiment, as the sentiment does not appear to increase or decrease significantly faster depending on how long a user has used a forum.

5.4 User Roles Within Forums

Figure 5 shows the partition of users according to roles for each of the eight conditions examined (chi-square test significance < 0.01). We recognize three user roles: users who exclusively use forums as original posters (OP), users who exclusively act as commenters, and users who take on both roles. A very low percentage of users (15%) take on both roles, which suggests that a transition from OP to commenter or vice versa does not happen for most forum users. PTSD forums have the highest percentage of users who only post as OP (39%), as opposed to bipolar forums, where only 20% of all users are only OP.

Overall, around half of participants across forums use the forums only in a capacity of commenters, with bipolar forums having the highest percentage (64%) of users in that category. The results are concurrent with the reader-to-leader framework [39] in that only few individuals make the transfer from one group to another. Looking into the connection between user roles and sentiment scores, the average OP post sentiment across conditions is always lower than the average sentiment for commenters (see Table 2).

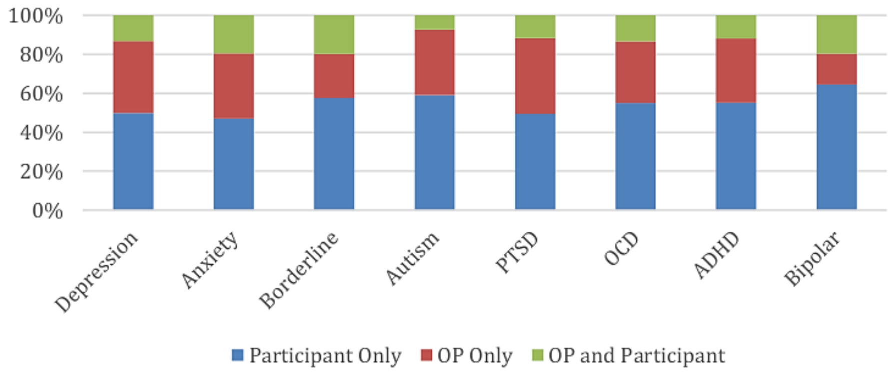

Figure 5. Distribution of User Roles across Conditions

According to the analysis results, there is a correlation between user role and sentiment score. Psychological literature supports the fact that commenters gain benefits by helping other users [36], which is also supported by our analysis. Therefore, forums may be able to further help users in best utilizing forum resources by encouraging participation into the questions and concerns posed by other users.

Table 2. Average Sentiment per User Role across Conditions

	Depres-sion	*Anxie-ty*	*Border-line*	*Autism*	*PTSD*	*OCD*	*ADHD*	*Bipolar*
OP	0.13	0.07	0.07	0.08	0.04	0.03	0.06	0.08
Com-menter	0.16	0.11	0.08	0.10	0.10	0.08	0.09	0.10

6 Discussion and Contributions

Based on our results, in their current form, mental health forums are most beneficial for depression and anxiety sufferers for all roles examined: original poster, commenter, and general forum participant. Some, yet limited benefit was observed for bipolar, borderline, PTSD, OCD, and autism forums, and no benefit for ADHD forums. Borderline forum users benefit only by posting as OP, as opposed to OCD users who only significantly benefit from general thread participation. OCD and autism forum users are the only ones to mark a worsening when participating in threads, specifically in the role of posters (not OP). Research into the content and discourse of the threads and a comparison with contents of other forums can uncover potential conversational and topical differences which might be the reason for opposing sentiment trends. Autism forum users only mark sentiment increase from OP threads. Consequently, autism forum users may benefit from having more options to share their personal stories. These differences in results are important to understand how current forum formats and specific features affect help seekers, and what new features may be beneficial to introduce in order to facilitate forum usage and maximize benefit for all users. The observations made in this study point to a need to provide more customized options for forum participation based on a user's condition – not every type of participation is equally beneficial for all types of conditions and such customizations could optimize a user's forum experience.

In this exploratory study, we apply automated text mining techniques (sentiment analysis) to provide evidence of the benefit of mental health forums. Specifically, we expand the practical application of text mining to mental health behaviors online, thus showing the potential of this technique to not only describe the behavior of thousands of users online, but also to shed light on the environment in which specific users benefit from forums the most. We show that not all users benefit the same, i.e. that mental health conditions as well as user roles are factors related to expressed sentiment. So far, mental health forums have not in any way been optimized or open to customization and personalization, and this paper shows that the individual users stand to gain from such a thing.

We contribute to research by exploring how engagement in virtual user-driven healthcare communities affects users who suffer from mental health conditions, and the potential to empower patients to self-management. Forum creators and administrators can learn from forum content with behavioral analytics in order to adjust forum mechanisms so that they register positive effects across all conditions, and not just a few. At the example of three of the leading English-language mental health forums, we show which forums are beneficial for specific conditions, so that forum creators can guide the future development of these platforms accordingly. We contribute to healthcare analytics research by demonstrating that machine learning and text analytics can uncover new information on user behavior to be used by practitioners and policy-makers in order to advance forum design. We specifically show that forums can in fact have a negative effect on user sentiment for conditions such as autism or OCD, with a further important observation that a change in user roles (e.g. from commenter to original poster) can play a significant role in sentiment development over time.

7 Limitations and Directions for Future Research

The conducted study presents an initial investigation and, thus, needs to be understood with respect to limitations. These limitations simultaneously represent opportunities for future research.

Our study does not control for all factors internal and external to mental health forums, e.g. moderation and feature effects. Also, we did not control whether users received therapy during participation in the forums, which may have affected forum sentiment. Furthermore, using different measures can help form a more detailed picture of forum effects across conditions. Given the difference in positive vs. negative sentiment development in different conditions and for different user roles, future studies can look into the specific forum mood drivers and mechanisms on a per-condition basis. Each of the investigated illnesses are independently unique, with nuances that cannot be fully captured by sentiment analysis alone; the application of various measures and an inquiry specifically regarding forum design and moderation may help to provide more detailed answers to this question. Adopting a user perspective, future studies can also address sentiment as a function of user forum life. Finally, this study presents an application of sentiment analysis on a large dataset with sensitive personal data. This raises privacy concerns which require a detailed separate study.

The digitization of health information has created opportunities for individuals to take control of their health, highlighting the evolving socio-technical change that occurs within healthcare [9]. Although our findings highlight the potential applicability of machine learning within mental healthcare practice and research, our analyses are still an initial endeavor in form of an exploratory approach. Further investigation is needed to understand how and why sentiment develop the way they do, and might be a helpful undertaking to comprehend why health forums are visited so often for advice.

Abstract. Due to reasons like demographic changes and variations in the spectrum of illness, worldwide expenditures in the health market have exploded. Contemporary information systems are evolving rapidly in the field of ubiquitous computing and nowadays support health in various fields. Wearables and tracking technologies have emerged in private life for health and fitness support. This adoption reveals future possibilities for innovating the health-supporting systems in the workplace. The crucial point of introducing wearables in the occupational health management system is the acceptance of employees. This paper provides a literature-driven measurement model to explain the behavioral intention to use wearables in the occupational health management system. The model provided is supported by 17 hypothesized relationships between relevant constructs and validated by card-sorting.

Keywords: Wearables Devices, Occupational Health Management, Technology Acceptance

1 Introduction and Motivation

Demographic developments are changing the labor market and employee demands on the working world. The world population is ageing, and the proportion of young skilled workers in developed countries is shrinking [1]. As a result of demographic change and changes in the spectrum of illnesses towards chronic degenerative diseases such as diabetes, degenerative musculoskeletal disorders, psychologically manifested diseases and addictions [2], health expenditure is at a record level [3]. In addition, a change in the value system of young employees toward more individuality and work-life balance can be observed [1]. The progressive digitalization requires an increased work speed, greater flexibility, and above all permanent willingness to learn and perform on the part of employees [1]. Not only since increases in digitalization has the workplace has been identified as the leading cause of many mental or psychological illnesses, as well as the primary cause of stress [4]. Various burdens on employees, as well as the developments mentioned above, entail an increased risk of long absences of employees in companies [5]. Workers with poor physical or mental health are often less productive, make worse

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

decisions, and have more absenteeism overall [6]. The employee absenteeism development in Germany illustrates this problem, which is of great economic relevance.

One way of reducing sick leave and creating additional incentives for employees in times of skilled-worker shortage is the introduction of an innovative occupational health management system (OHM). Both science and practice have recognized the significant positive influence of OHM on employees and organizations [7, 8].

At the same time, wearables are becoming increasingly popular with the majority of employees [9]. Research on intelligent portable systems has therefore increased in the health sector under the headings electronic health (eHealth) and mobile health (mHealth), as well as in industry [10]. This trend towards wearables can be seen in the high number of wearable manufacturers and strong industry growth.

Meanwhile, some companies are offering their employees the opportunity to participate in digital health programs in the workplace while following their health and fitness activities through wearables [11]. Studies have already shown that wearables can improve the health and well-being of individuals: Participants in health programs are happy to monitor, track and review their health data and the control of personal health data also encourages participants to behave healthier [12]. Similarly, it was found that the tracking and observing of one's physical activity, for example, leads to an increase in steps taken [13]. Furthermore, health programs which use portable devices increase the average employee participation from 20% to 60-70% [14].

Mainly due to their unique characteristics, wearables are very suitable for supporting the OHM of the future. Wearables can be worn on the body and can be used freely at work. In addition, the devices are mobile, always active and often context-sensitive. Furthermore, employees can use wearables in all areas of the company so that an organization-wide OHM is possible. Also, the possible use of gamification strategies [15] to increase employee motivation and the possibilities for personalizing health care through wearables are also promising.

However, from the employees' perspective, there are serious barriers which prevent participation in company health promotion measures. Many employees do not recognize the benefits of the measures or perceive OHM as paternalism and are afraid to embarrass themselves. Notably, the use of wearables which collect health data could be perceived as a high risk by employees. The fear of health data being misused (e.g., due to inadmissible performance monitoring of employees, as justification of salary increases, promotions or dismissals) based on the data collected is high and requires trust in the employer.

Against this background, the relevance of employee acceptance for new technologies at OHM becomes clear. Technologies and wearables cannot help to improve individual health if employees do not accept and use the technology provided. Some studies are already investigating the acceptance of wearables [3, 16, 17] and other portable technologies in healthcare [4, 18, 19]. Whereas the previous studies serve as valuable starting points, some specific aspects in the use of wearables in the working environment are missing or measure individual consumer's acceptance. Knowing the employee's level of acceptance for specific measures is necessary to increase the success of OHM. Companies must be able to predict employees' acceptance of wearables. However, as far as we know, there has been no empirical research on the acceptance of using wearables for health promotion in the workplace.

Based on a systematic literature review, we set out to deductively develop a research model that will help us to gain a better understanding of wearable acceptance in the workplace. The remainder of this paper is structured as follows: The next section describes the underlying theoretical foundations based on previous literature. The succeeding section introduces the research process, which is followed by the structural model development section. Subsequently, we provide insights into the measurement model development before we conclude with our discussion and outlook.

2 Relevant Work

2.1 Wearable Technologies in Healthcare

Wearables are specific technologies of the Internet of Things (IoT) and a concretization of ubiquitous computing aimed at improving our environment through visible or invisible, networked and intelligent electronic devices which enable a new form of human-computer interaction [20]. There are several different kinds of wearable definitions. However, for our purpose, we define wearable devices as electronic devices that can be worn on the body and measure via one or more sensors physical activities or health conditions and are (wirelessly) connected to other computers or smart devices [21]. The sensors collect a broad range of different data, such as various vital signs, physiological parameters, and environmental conditions [22, 23].

In addition to the use of wearables in health science, there are also many other fields of application, e.g., consumer goods [24], in the fields of professional and recreational sports [25], and for authorities with security tasks [26]. Within the application of wearables in the health context, a large number of overlapping terms are used. The most common definition defines eHealth as "an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve healthcare locally, regionally, and worldwide by using information and communication technology" [27, p.1]. Although there are differences between the terms, it is accepted in research to refer to eHealth as an all-encompassing term for telemedicine and mHealth and includes various forms of HIT [10].

The concepts of workplace health prevention and health promotion are complementary and overlap in many respects and therefore are partly used synonymously in practice. We refer to OHM which includes both concepts. A trend towards digitalization is discernible, not only in the health sector, but also in the area of OHM [28]. This digitalized health promotion is a possible field of application for digital health technologies. Modern technologies open up new opportunities for OHM in the areas of requirement analysis and employee awareness.

While OHM causes an increase in the health affinity of employees, promotes high participation rates, and can reach all employee target groups, criticism exists with regard to data privacy [4, 29]. One of the biggest challenges in OHM in connection with wearables relates to the solution of IT security issues, data protection concerns, and legal and ethical difficulties in handling the data. In most cases, wearables forward data to the manufacturer, third-party providers and intermediaries (e.g., insurance companies, scientists, advertising companies, and, in the case of the present work, the employer). The gathered data is often stored decentrally in a cloud. Hence, employers need to guarantee system security and assure data privacy.

In summary, the voluntary and private use of wearables for individuals who are interested in improving their health and fitness is not new. However, the wearables' usage during work and the integration in an OHM become more and more important [30]. The employees' acceptance is essential for an effective wearable usage in OHM. Empirical studies which examine the employee acceptance of OHM with wearables are surprisingly scarce, which is why we set out to deductively develop a concise structural equation model in the following sections.

2.2 Health Behavior

Regarding the field of health behavior, four main theories are used: (1) the Health Belief Model, (2) the Protection Motivation Theory, (3) Subjective Expected Utility Theory and Theory of Reasoned Action [31]. Each of the four theories assumes that an expected negative health event and the desire to avoid or reduce this occurrence will motivate self-protection. Furthermore, they explain health-related behavior on the basis of the expected value theory and the cost-benefit analysis. The Health Belief Model assumes that a person who decides to perform a health-related action takes the action from a consideration of the perceived health threat that occurs when the action is omitted and the belief in the effectiveness of the proposed measure, minus perceived barriers [32].

Moreover, the Health Belief Model is used to develop health promotion measures [33]. It incorporates four basic constructs: perceived susceptibility, perceived severity, perceived benefits and costs, and perceived barriers. The Protection Motivation Theory uses similar factors to explain health behavior (perceived vulnerability, perceived severity, response efficiency, response costs) [34] and in addition, the determinant self-efficacy is integrated into the Protection Motivation Theory. The Health Belief Model's perceived benefits and Protection Motivation Theory's response efficacy measure the same underlying construct and can be equated with the performance expectancy construct of Unified Theory of Acceptance and Use of Technology (UTAUT) [35]. It is argued that the Health Belief Model's perceived benefits are equivalent to the two determinants intrinsic and extrinsic motivation of UTAUT2 [4]. Further determinants also determine preventive health behavior. The Health Belief Model's supplementary determinants include, as preceding factors, e.g. the demographics of the individual, psychological factors, the mediator variable cues to action, advice on health, a letter from the doctor, or an emerging illness within the family or circle of friends, as well as the mediator variables self-efficacy, response efficacy and the value of action [36].

Furthermore, preventive health behavior is influenced by response efficacy and self-efficacy, as well as health motivation and health consciousness [36]. Health motivation "refers to consumers' goal-directed arousal to engage in preventive health behaviors"

[36, p.9], while health consciousness "refers to the degree to which health concerns are integrated into a person's daily activities" [36, p.10].

2.3 Technology Acceptance

Many research disciplines are investigating the adoption or acceptance of innovations. Studies on the acceptance of technologies are regarded as the most important research field in information systems (IS).

In the field of economics, particularly in connection with innovation management, adoption is understood as the acceptance of an innovation by an individual customer. A positive decision to accept an innovation by users is therefore acceptance. There are different views in literature as to whether the attitude towards innovations, the intention of behavior or benefit, the behavior, or a combination of these factors should be regarded as acceptance. In economic acceptance research, the distinction between acceptance of attitudes and acceptance of behavior has, therefore, become established. The intention to use a technology is equated with attitudinal acceptance. Therefore, this type of acceptance is not directly observable by users and is, therefore, operationalized by the behavioral intention. In contrast, when adopting innovations in the form of observable behavior (e.g., the use of a wearable for OHM), acceptance of behavior is discussed. Acceptance is then determined by usage behavior. The wearable technology in the OHM context can be seen as (technical) innovations and can either be accepted or rejected by users, in our case employees. The acceptance of attitudes is operationalized as an intention to use or behave (behavioral intention). The role of behavioral intention as a predictor of behavior has been extensively researched in IS literature and related research fields [37–39]. Behavioral intention is defined as a measure of the strength of an individual's intention to conduct a certain behavior [40].

The rich literature on adoption of technologies, and in particular the proposed Technology Acceptance Model (TAM) of Davis [41], is being studied in detail by IS researchers. However, TAM is also criticized for being too parsimonious to reliably explain complex psychological processes such as behavior and human’s technology acceptance, and it does not take influences of social and personal control factors into account [38, 42]. The results of our literature review indicate that within the plethora of acceptance models there is only one study which provides a model for measuring acceptance of mHealth applications in the OHM context [43]. The study discusses the suitability of mHealth apps for the use in the OHM context and the underlying determinants that motivate employees to use health apps at the workplace. Based on TAM, the Health Belief Model, and the Theory of Planned Behavior, the authors propose a model to explain adoption behavior. However, it does not regard aspects of motivational theory and is quite complex, due to the inclusion of fifteen explanatory constructs. Furthermore, there is no empirical validation of the proposed model. Based on these findings, we take both the specific characteristics and the use of wearables in the context of OHM into account when designing our examination model. Therefore, we transfer existing studies of relevant other contexts and present an overview of acceptance research studies which are germane for our model development.

Since wearables are small body-worn computers and part of the IoT, studies on acceptance research in both areas, as well as studies on different types of wearables, are relevant for our model development. Many researchers have demonstrated the influence of intrinsic and extrinsic motivation, which are often operationalized as perceived enjoyment and perceived usefulness [44, 45].

In addition, a relevant study on the acceptance of IoT [29] and a study on ubiquitous, pervasive technologies [46] were identified. The acceptance of IoT measures the influence of perceived usefulness, perceived ease of use, social influence, and perceived behavioral control, which are equated in the study with the constructs of UTAUT, on behavioral intention. The authors supplement their model with the constructs trust and perceived enjoyment. The results confirm a strong influence of the UTAUT determinants, but a non-significant influence of trust on behavioral intention [29]. The study of ubiquitous technologies also confirm the strong influence of perceived usefulness and perceived ease of use on the behavioral intention of pervasive computers, but cannot confirm a significant influence of compatibility, perceived overall risk, and attractiveness of alternatives [46].

We also identified some studies on wearables. It is striking that most of the studies use different combinations of the UTAUT's main determinants. In addition, the perceived enjoyment construct and intrinsic motivation are often included in the models [3, 17, 47]. The determinants trust toward the employer [17] and other forms of trust [3], as well as different forms of risk [47], are also included in the models for predicting the behavioral intention of wearables. Summarizing, we observe a significant influence of the UTAUT determinants perceived usefulness, social influence, and perceived enjoyment. Within the acceptance research of eHealth technologies, there are also studies on the acceptance of wearable-related technologies [5, 48], such as mHealth technologies [35, 49, 50], Health Information Technology [18, 51], and Wearable Health Monitoring Systems [4]. In contrast, studies on the adoption behavior of health technologies for patients or consumers, which are essential to the requirements for an acceptance study of employees, are relatively rare [4, 50, 52]. Among these empirical studies on users' eHealth adoption behavior, most studies explain the usage behavior based on TAM [18, 50] and its extension UTAUT [4, 35]. The direct and indirect influence of perceived usefulness and perceived ease of use is confirmed in all empirically tested studies. Similar to the acceptance studies for wearables, perceived enjoyment and hedonic motivation were additionally included as determinants [4].

Whereas the identified studies and models serve as a valuable starting point, none of the presented studies focus explicitly on wearables in the OHM context and therefore take the specific requirements of the acceptance of wearables in the OHM into account.

3 Structural Model Development

Based on the scientific literature presented above, we derived our hypotheses and built our structural model. We combined the Health Belief Model, and the Motivation Model, and incorporated factors from UTAUT. We present our developed structural model in Figure 1.

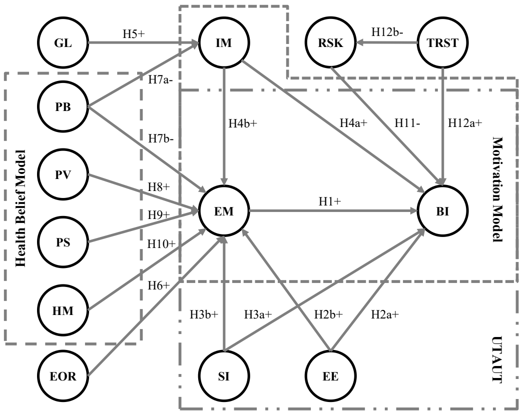

Figure 1. Structural model explaining the behavioral intention

With our model, we set out to explain our dependent variable *behavioral intention to use wearables in OHM* which can be seen as a predictor for acceptance. UTAUT takes the determinant extrinsic motivation of the motivation model as performance expectancy into account [39]. Extrinsic motivation is defined as "a construct that pertains whenever an activity is done in order to attain some separable results" [53, p.60]. Concerning wearables in OHM, extrinsic motivation is defined as the perceived probability that a wearable supports the employee in achieving its goals. Thus, we assume that the prospect of achieving these goals has a positive influence on the behavioral intention which is why we propose:

H1: Extrinsic motivation (EM) has a positive impact on the behavioral intention to use a wearable in OHM (BI).

The determinant effort expectancy [4] or the closely related construct perceived ease of use [29] was also identified as an essential factor for measuring acceptance. Effort expectancy is defined as “the degree of ease associated with the use of the system” [39, p.450]. In addition to the effort expectancy, social influence is also included in suitable acceptance models. The social influence is defined as the "extent to which consumers perceive that important others (e.g., family and friends) believe they should use a particular technology" [54, p.159] and hence, has an impact on behavioral intention and extrinsic motivation. We state that a wearable in OHM is a portable device for increasing and promoting health. We argue that friends and family have a particular interest in the individual employee's health. Thus, the close social environment motivates the individual to take part in OHM. The perceived social pressure and the opinion of an individual's environment have an impact on behavioral intention and extrinsic motivation. Thus, we conclude:

H2a: Effort expectancy (EE) has a positive impact on behavioral intention (BI).
H2b: Effort expectancy (EE) has a positive impact on extrinsic motivation (EM).
H3a: Social influence (SI) has a positive impact on behavioral intention (BI).
H3b: Social influence (SI) has a positive impact on extrinsic motivation (EM).

Intrinsic motivation is defined as "the doing of an activity for its inherent satisfactions rather than for some separable consequence" [53, p.56]. Accordingly, it represents the extent to which employees perceive wearables in OHM, apart from other consequences, as pleasant and entertaining. Studies on consumer behavior as well as research in the field of IS have found that intrinsic motivation is an essential determinant for explaining technology acceptance [54, 55]. Furthermore, in the context of mHealth services and also in the context of wearables, it is shown that the user's intention to use mHealth services is determined by both extrinsic and intrinsic motivation [3, 29, 47, 49]. Thus, if an employee has intrinsic motivation to improve his or her health, it is all the more likely that he or she will participate in OHM activities and take greater account of the benefits provided [56]. We include intrinsic motivation in our model and state that an activity perceived as pleasant or entertaining has a positive influence on the perception of the usefulness and thus, supports a user to achieve its goals. Thus we hypothesize:

H4a: Intrinsic motivation (IM) has a positive impact on behavioral intention (BI).

H4b: Intrinsic motivation (IM) has a positive impact on extrinsic motivation(EM).

When introducing a wearable in OHM, it is crucial that the use of the device is accepted by employees as quickly as possible. So it is vital to convince employees to adopt technological innovations at an early stage. We consider employees with a high motivation to use different technologically innovative devices as gadget lovers. A gadget lover is defined as "a consumer with high intrinsic motivation to adopt and use a variety of leading-edge, technology-based goods, including the services that complement them" [57, p.330]. So far, the gadget-loving concept has yet not been integrated into acceptance research. We incorporate gadget loving as an external variable which measures the employee's personal characteristics. Hence, we postulate:

H5: Gadget loving (GL) has a positive impact on intrinsic motivation (IM).

From the perspective of the extrinsic motivation, a behavior is carried out on the basis of the expected benefit of the action or the expected advantages that an action brings [53]. Expected organizational rewards can be regarded as fundamental objectives of extrinsically motivated behavior [58]. Rewards are also often used in the OHM context to motivate employees to participate in specific measures [6]. These expected organizational rewards can range from monetary incentives, such as discounted membership in gyms, to points in competition with other employees. Thus, the offered rewards shall motivate employees' participation. Hence, we conclude:

H6: Expected organizational rewards (EOR) have a positive impact on extrinsic motivation (EM).

Furthermore, we also included the Health Belief Model in our model. It proposes that perceived barriers are subtracted from the perceived benefits [32]. The negative aspects of a health-promoting activity can act as barriers to the implementation of the recommended behavior. Consequently, if employees consider OHM activities as, for example, unpleasant or time-consuming, their motivation will decrease. On the basis of a cost-benefit analysis, the advantages of preventive measures are weighed against their disadvantages. Since the perceived benefits of the preventive measure are already taken into account by the constructs intrinsic and extrinsic motivation [4, 35], we only include the perceived barriers into our model. Thus, we hypothesize:

H7a: Perceived barriers (PB) have a negative impact on extrinsic motivation (EM).

H7b: Perceived barriers (PB) have a negative impact on intrinsic motivation (IM).

Furthermore, we integrated the effects of the perceived health threat, operationalized as perceived severity and perceived vulnerability, into our model. Perceived vulnerability is defined as the perception of an individual's vulnerability to health threats, while perceived severity is defined as the assessment of an individual as to whether a particular health threat is severe or dangerous [59]. From the perspective of extrinsic motivation, the expected benefit of an action determines the behavior. Employees are expected to value the benefits of the use of wearables in OHM more if the expected consequences of a resulting health threat are serious. Hence, we state:
H8: Perceived vulnerability (PV) of an individual has a positive impact on extrinsic motivation (EM).
H9: Perceived severity (PS) of an individual has a positive impact on extrinsic motivation (EM).

We also incorporate health motivation into our model, which "refers to consumers' goal-directed arousal to engage in preventive health behaviors" [36, p.9] and hence, refers to the internal characteristics. Studies have found that this can be associated with most health behaviors [36]. This preventive health behavior is of great importance to many individuals and represents an essential general goal in life. Hence we conclude:
H10: Health motivation (HM) has a positive impact on extrinsic motivation (EM).

According to the literature on wearables, risk has a significant influence on the behavioral intention of individuals [4, 47]. Within the acceptance research of health-related IT, the fear of unintentional secondary data use and privacy concerns are often investigated [4, 29, 49, 60]. For example, in the case of restructuring measures, employees face the risk that the employer will incorporate the gathered health data in its redundancy decision. Therefore, we define risk as the total perceived threats that employees feel when using wearables in OHM. Hence, we postulated that risk has a negative influence on behavioral intention. Thus, we conclude:
H11: The perceived risk (RSK) has a negative impact on behavioral intention (BI).

The long-term exchange of personal information (e.g., with the employer) through the use of wearables in OHM also requires a trustful relationship between the employee and its employer. In the context of eHealth technologies and also in technology acceptance studies, it is confirmed that the effect of trust is a decisive factor [60, 61]. We argue that employees, in particular, are often in a weaker position than their employers. Especially in our context, highly personalized user data is collected, and there is the chance that the employer may misuse this data. We define trust as the perception of the employee that its employer is trustworthy and wants to do something good for its employees by introducing wearables in the context of OHM. Since trust has a significant influence on the behavioral intention of individuals we thus conclude:
H12a: Trust in the employer (TRST) has a positive impact on behavioral intention (BI).
H12b: Trust in the employer (TRST) has a negative influence on perceived risk (RSK).

4 Measurement Instrument Development

The development of a suitable measurement model is crucial for the causal model's future evaluation. The development of our measurement instrument is therefore carried out in several stages [62]: (1) We identified existing measurement scales where possible and initially created new ones where necessary. The measurement scales for the latent variables are expressed by several manifested statements (items) [63]. (2) Subsequently, we adapted the identified items to our context and gained an initial item long-list. (3) Subsequently, three scientists iteratively reviewed the initial item pool and adjusted the items to fit our context and provide a common style in language and wording. (4) Following this, we conducted a card-sorting procedure proposed by Moore and Benbasat [62]. The card-sorting procedure aims to assess the construct validity of the various scales and to "attempt to identify any particular items which still may have been ambiguous" [62, p.199]. Therefore, we sent out an Excel-spreadsheet containing a VBA macro for randomization via email and asked twelve judges to sort the randomized initial item pool to the corresponding construct with given construct definitions [62, 64]. The group of judges consisted of employees in order to ensure that the items to be evaluated were understandable for future participants. In a second step, after the judges had assigned the items to the corresponding constructs, we asked them to sort the items of each construct according to their representativeness, to then identify the most appropriate items of the initial long-list, and then to send back the spreadsheet. After having received the completed card-sorting, we consolidated the filled-out spreadsheets and analyzed the results. This enables the identification of items which are not suitable to measure the underlying construct. It is assumed to exclude these items from the study [64]. After having received the results, we evaluated the construct validity of our initial item pool and removed items which were mainly sorted into an incorrect construct. (5) Finally, we pilot-tested the resulting item pool with a seven-point Likert-scale and analyzed the gathered feedback to complete our instrument. Thus, we ended up with a total of 51 items for our final measurement model. Table 1 provides the sources and number of items for the final measurement model.

Table 1. Sources of the measurement model

Construct	# of items	Adapted from
Behavioral Intention	4	[41, 65]
Extrinsic Motivation	4	[41, 66]
Effort Expectancy	4	[41, 65]
Social Influence	4	[39]
Intrinsic Motivation	4	[65, 66]
Gadget Loving	4	[57]
Expected Organizational Rewards	4	[67], own
Health Motivation	4	[68, 69]
Perceived Barriers	5	[70, 71], own
Perceived Severity	3	[70]
Perceived Vulnerability	4	[70]
General Risk Beliefs	3	[72]
Employees Trust Beliefs	4	[1]
Total	51	

5 Conclusion and Further Research

In this article, we set out to develop a literature-based measurement model to explain the behavioral intention to use wearables in OHM. As highlighted in the first section, due to demographic developments as well as changes in the spectrum of illness and in the value system of employees, health expenditures in industrialized countries like Germany have exploded. The introduction of modern, easy to use and consumer-centric IS in the workplace possibly meet these challenges. IS, such as wearables, do have the functionality to support employees' health conditions. Consequently, the crucial point of introducing wearables in the workplace for OHM purposes is the employees' behavioral intention to use the provided technologies.

As the presented work shows, many studies exist on the acceptance of several kinds of technologies. Although the possibilities of supporting the health of users by IS are highly relevant, research is surprisingly scarce. Therefore, we reviewed the current state-of-the-art of wearable technologies, health behavior, and technology acceptance from the perspective of possible applications in the workplace. Subsequently, we developed a measurement model to explain the behavioral intention to use wearables in an OHM context. The measurement model was validated by a card-sorting procedure and led to a measurement model consisting of a total of 51 items. With our model, we provide a research tool to explain the behavioral intention to use wearables in OHM. Regarding our specific next steps in this research endeavor, we deem quantitative-empirical methods as most applicable to validate our model. Therefore, we will collect data by conducting a large-scale multinational online survey study and analyze the gathered data using a structural equation model approach [73] and will subsequently strengthen our statistical analysis by conducting multi-group comparisons [74]. The survey will incorporate different kinds of wearables such as wristbands and smart clothing. Hence, differences in wearable technologies in the behavioral intention to use might be identified, and practical implications can be derived. Furthermore, we will apply the research model in different industries and different organizations to gain a deeper insight into under which conditions employees accept the implementation of wearables for OHM. To get a more comprehensive view on the intention to use wearables in the workplace, different theories (e.g., system theory) from related domains could be taken into account as OHM affects a lot of different perspectives, habitats, actors, and systems.

Understanding Patient Pathways in the Context of Integrated Health Care Services - Implications from a Scoping Review

Peggy Richter[1], Hannes Schlieter[1]

[1] Technische Universität Dresden, Chair of Wirtschaftsinformatik, esp. Systems Development, Dresden, Germany
{peggy.richter2,hannes.schlieter}@tu-dresden.de

Abstract. Healthcare systems in western countries are continuously working to achieve efficient resource allocation and to improve access to quality medical care. The implementation of standardised care processes promises better integration and coordination of care across several healthcare providers. In this context, an increasing use of the term patient pathway is recognised within official documents provided by health authorities and within scientific publications in recent years. However, a common understanding, distinguishing the term from other pathway approaches such as care- or clinical pathways, is missing. By means of a scoping review we analysed 132 publications in order to clarify key concepts and the understanding of patient pathways. Six common themes in the literature were identified and results show that individualisation and care continuity are essential descriptive characteristics. Using this motivation, we discuss the main implications for research and practice by the example of comprehensive cancer care in the European Union.

Keywords: patient pathways, care networks, scoping review

1 Introduction

Health care faces a broad spectrum of transition processes that necessitate integrated care delivery. In this context, demographic change, skilled worker shortage and an increasing number of patients with multimorbidity and chronic diseases are among the main drivers [1, 2]. For the latter, cancer is one of the most common and costly diseases in western countries [3, 4]. In order to coordinate cancer care on the national level and to increase access to quality cancer care, the implementation of Comprehensive Cancer Care Networks (CCCNs) is recommended by the European guide on quality improvement in comprehensive cancer control [5]. Such networks integrate different institutions and institutional units representing all relevant episodes for a patient's cancer care, i. e. research, prevention, diagnosis, treatment, follow-up, rehabilitation and end-of-life care [5]. One of the CCCNs' tasks is the provision of practical support tools. In this context, comprehensive, integrated patient pathways are recognised as a valuable approach [5]. Whereas the term patient pathway is often used with regard to

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

optimising cancer care processes and aligning information and communication flows, a common terminological basis is still missing. This has negative impact on the harmonisation of such big scale activities, in this case on EU level, and on the communication of their maturity in general. Hence, to further advance the utilisation of patient pathways in cancer care and beyond, clarification of the concept is necessary. It is still unclear whether patient pathways are any different from already well-established pathway approaches such as care pathways or clinical pathways. According to the definition used by the European Pathway Association, a "care pathway is a complex intervention for the mutual decision making and organisation of care processes for a well-defined group of patients during a well-defined period" [6]. Clinical pathways particularly focus on the care provision within a single institution, e. g. a hospital [7].

The article aims to examine the literature body available on patient pathways. On this basis, key concepts of patient pathways shall be clarified and implications for future research and practice shall be discussed. Therefore, three research questions are to be answered: (RQ1) How has the literature on patient pathways developed over the years and which themes are addressed in the literature? (RQ2) What are characteristics of patient pathways including characteristics that differentiate them from other pathway approaches? (RQ3) What are potential implications for practice and future research? Accordingly, the article is structured as follows: The scoping review method used to address the research questions is described in section 2. The results are presented in section 3 by describing identified themes within the patient pathway literature. Also, common characteristics of patient pathways are derived within this section. The results of the review are discussed in the context of current literature and practice in section 4. This also includes the discussion of implications for research and practice as well as limitations of our study. A conclusion is given in section 5 by summarising the results and the contributions of the presented work.

2 Method

2.1 Scoping Review

In order to answer the research questions, a scoping review was conducted. Unlike a systematic literature review, a scoping review is a review type which is used to map key concepts underpinning a research area [8, 9]. A common purpose of scoping reviews is the identification of topics for future research [10]. They are often performed to determine and represent the body of literature and available evidence on a topic [8]. Since there is yet no comprehensive literature review about patient pathways available, the conduction of a scoping review is the appropriate choice to answer our research questions. Also, the research objectives are among those, that Anderson et al. (2008) state as the key criteria for which a scoping review is reasonable, e. g. clarification of the conceptual understanding of a topic where definitions are unclear and identification of research gaps advising on future research [10].

The conduction and reporting of the scoping review follows the guidelines proposed by Peters et al. [9]. The process of developing a review protocol as well as the literature search and selection process are not different from a systematic literature review, except that there is no formal assessment of the methodological quality of the included literature [8, 9]. The developed review protocol included the definition of the search strategy, search terms, databases, screening approach, and the inclusion criteria.

In order to clarify the characteristics of the review, we draw on the established taxonomy for literature reviews described by Cooper [11] and define the focus, goal, perspective, coverage, organisation and audience as intended with the scoping review on patient pathways. The focus areas are outcomes, theories and applications. With respect to the research objective of this article, the goal of the review is twofold, i. e. it aims at the identification of central issues (see RQ1 and RQ2) as well as at the integration of existing literature (see RQ3). We take a neutral perspective in the presentation of the results and cover literature exhaustively with selected citations due to space limitations. The review is organised conceptually. The intended audiences are both scholars and practitioners in the fields of information systems and health care.

2.2 Search Strategy

The search strategy comprised a scientific database search and a google search in order to include both scientific articles and grey literature (e. g. government, business or institution reports regarding patient pathways) [12, 13]. The searches were carried out in April and May 2018. The search and review process is depicted in Figure 1.

During the screening phase, the exclusion criteria were non-scientific publication types (e. g. letters to the editors), the unavailability of an English abstract (reasonable for the results of the database search), or an extraneous topic (e. g. disease specific research aims that did not have patient pathways as a central topic). The high number of unavailable database records mostly results from unavailable poster abstracts. In such cases, the authors were contacted and asked to share their publication.

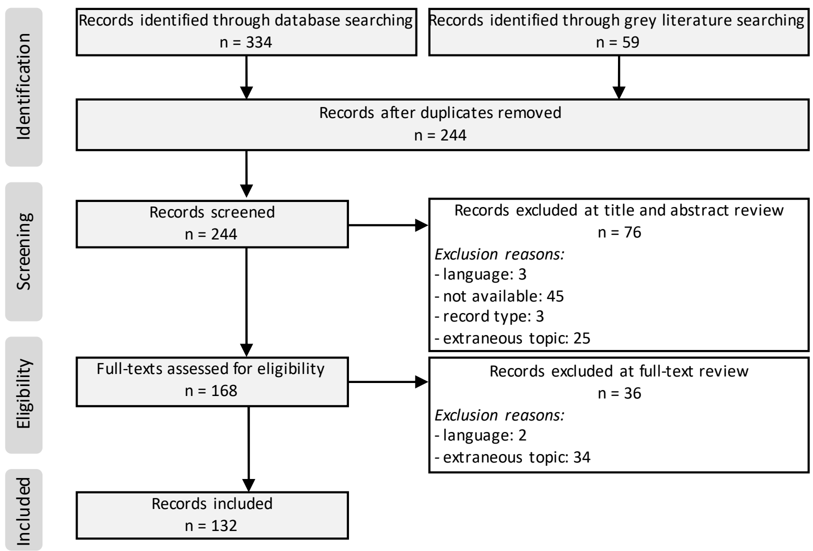

Figure 1. Scoping review process (representation mode based on [14])

During the full-text assessment, we did not restrict the analysis to full papers but also included abstracts, poster abstracts and posters, since one aim of the scoping review is the analysis of the currently available literature body on patient pathways. Included full-texts were in English or German, the latter occurring twice.

2.3 Database Search

We searched for "patient pathway" OR "patient pathways" in the titles of articles in PubMed, EbscoHost Academic Search Complete, Web of Science, and ScienceDirect. The decision to exclusively search for the term patient pathway is based on initial search term tests. These tests included potential synonyms such as clinical-, treatment-, care-, or integrated pathways and tested combinations with terms related to “definition” or “development”. The searches resulted in a large amount of irrelevant articles and since the focus of the scoping review is the examination of the term patient pathway, we decided to exclusively search for this term.

The results were screened based on titles and abstracts by four reviewers. This procedure meets the requirement for at least two reviewers necessary for a scoping review [9]. In order to create a common understanding for the screening process a pre-test was conducted. Each reviewer analysed the first 15 included records regarding the context in which the term patient pathway was used. In a consensus meeting, the findings were discussed and the authors decided on a preliminary classification of research themes in the literature on patient pathways. This classification was assessed and refined in a second pre-test by applying it to the first 25 records of the included records and another consensus meeting. Based on this revised classification, the authors mapped all included records. During this, minor iterative refinements of the classification took place, leading to its final version as described in section 3.1.

2.4 Search for Grey Literature

We searched google exclusively for the singular and plural of the term patient pathway, for the same reasons as described for the database search. The first six results pages (the first 59 results, excluding hits to language translation pages) were screened by the authors. After that, there were scarcely any more relevant hits, which justifies ending the search at this point. The literature classification developed during the pre-test with the database search results was also applied to the included grey literature.

3 Results

3.1 Themes in the Patient Pathway Literature

As a first, theme-independent result, it can be stated that the interest in the examination of patient pathways in research and practice has increased over the years. This is shown by the increase in publications per year as depicted in Figure 2.

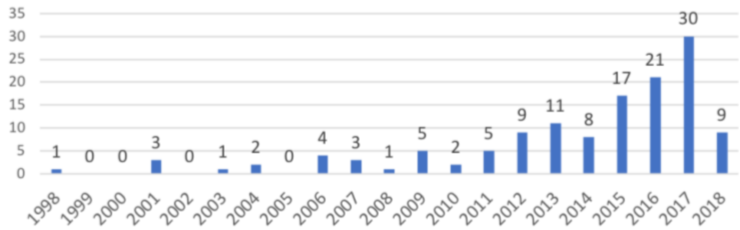

Figure 2. Number of publications per year (n = 132)

The literature can be roughly divided into publications examining patient pathways in general (n = 39) and publications addressing patient pathways for certain diseases (n = 93). For the latter, a major focus is on patient pathways in cancer care. As shown in Figure 3 (a), patient pathways for tuberculosis, heart diseases or alcoholism/drug addiction were examined much less frequently. The rest of the disease-specific literature was highly diverse. Thus, all diseases that were addressed only once or twice in the analysed patient pathway literature were summarised as others.

As described in section 2.3, during the analysis of the titles, abstracts and full-texts of the searched literature, a classification of six common research themes was developed and iteratively refined during the process. The identified themes regarding patient pathways are: definition and conceptualisation, development and implementation, analysis of patient pathways, responsibilities and roles, tool- and IT-support, and simulation. The frequency distribution of the themes is depicted in Figure 3 (b). Each theme is described in detail in the following.

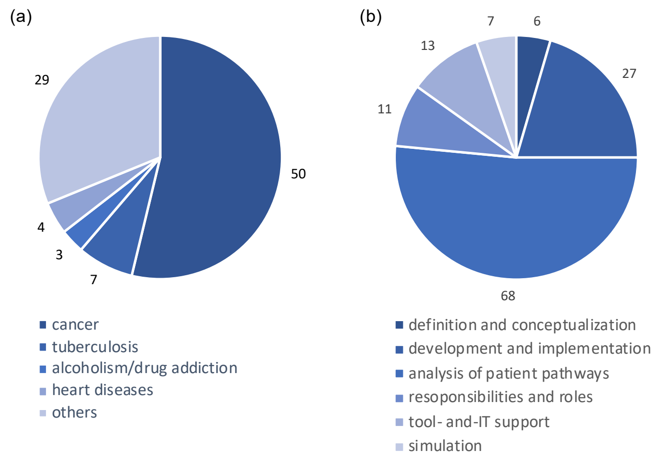

Figure 3. Results of the analyses: (a) focus of disease-specific patient pathway literature (n = 93), (b) themes in the patient pathway literature (n = 132)

Definition and Conceptualisation. Currently, there are only few articles (n = 6) examining characteristics or the notion of patient pathways. However, there is neither a comprehensive analysis of the patient pathway approach nor a common definition available. Instead, the current literature discusses single important issues in relation to the patient pathway approach. For example, Berntsen and colleagues [15] qualitatively analysed the goals of care in individual patient pathways and concluded that the alignment of functional, biological and personal goals in a network of multidisciplinary care providers is essential to support care continuity. Another issue, addressed by Salamonsen et al. [16], is the influence of disruptive health and life events on the patient pathways. Also, they argue that patient pathways are beyond the known concept of clinical pathways, because they are not solely understood as the standardised, guideline-based provision of health care for certain patient types but also address multimorbidity and patient preferences [16]. Further basic characteristics of patient pathways can be taken from the patient pathway diagram as part of the NHS Data Model and Dictionary [17]. It describes the attributes and relationships to health care activities and organisations for the patient pathway class.

Development and Implementation. There are 27 publications that address the issues of development and implementation of patient pathways. We also included publications that present concrete patient pathways for certain diseases and health situations in this theme because they indicate how patient pathways are represented in practice. The concrete patient pathways analysed for the scoping review were represented as checklists [18], flowcharts [19] or non-standardised semi-formal process models often combined with textual descriptions [20, 21]. Standards, clinical practice guidelines or the results of systematic literature reviews are the starting points for pathway development and can be complemented by expert knowledge or experiences [22, 23]. Wicke et al. [24] propose a construction process for patient pathways based on a lifecycle consisting of four phases, i. e. preparation, construction and testing (main phase), implementation, and maintenance (controlling and revision). In the context of the latter, the collection of quality, service improvement and redesign tools could be used to improve certain stages of patient pathways [25]. So far, patient pathway development is rather addressed in the context of single health care institutions (e. g. a hospital [24]) than on network level.

The development and implementation are tasks of a multidisciplinary, inter-organisational team consisting of all key stakeholders along the patient pathway, e. g. involving hospital and community staff [23, 24, 26]. The development process should include consensus team meetings in order to reach agreement between all partners [27, 28]. A prominent example for nationally implemented patient pathways are the Danish Cancer Patient Pathways that were developed with a consensus seeking model ensuring the involvement and cooperation between bureaucrats, health professionals and politicians [29]. Besides the involvement of professional and administrative staff in the development process, the patient's perspective is highlighted as well. Focus group discussions are one way to identify patients' preferences and to integrate their input in the pathway development and maintenance phases [30].

Analysis of Patient Pathways. The analysis of patient pathways was subject to more than half of the publications analysed (n = 68). This theme can be further differentiated into four sub-topics, which are (I) patient pathway analysis (n = 16), (II) the analysis of patient pathway usage (n = 27), (III) the analysis of patient pathway effects (n = 23), and (IV) the examination of data sources to be used for analysis purposes (n = 2). Patient pathway analysis (I) is an established phrase being used to describe the alignment between the care seeking patterns of patients with a certain disease and the availability of corresponding health care services [31, 32]. In this understanding, the patient pathway is not a predefined, standardised process but the actual, unplanned journey of a patient seeking health care services to address her/his health conditions. Based on this understanding, articles examining the pathways of patients before and after hospitalisation [33] or how patients decide where to seek care and what factors influence this decision [34] were also included in this sub-topic. In contrast, the analysis of the practical usage of patient pathways (II) is based upon predefined, standardised pathways. This sub-topic includes the analysis of patient characteristics for a certain patient pathway [35, 36], pathway compliance analyses [37], and process analyses (e. g. sources of delay [38, 39] or utilisation of certain activities in a pathway [40]). The analysis of patient pathway effects (III) comprises outcome studies, i.e. the analysis of the results after patient pathway implementation. Here, patient-related outcomes, such as survival and mortality, complications, quality of life and treatment-related side-effects [41, 42], and organisation-related outcomes, such as waiting times, length of hospital stay or timeliness of care [43, 44], are the focus. Another, rather minor sub-topic is the examination of data sources that can be used for analysis purposes (IV). In this context, the need for data linkage of electronic health records with clinical data registries as well as across regional borders is highlighted [45, 46]. This would increase the understanding of the complete patient pathway covering multiple involved care providers and also support national research.

Responsibilities and Roles. The responsibilities and roles of different stakeholder groups are discussed in 11 of the analysed articles. The role of nurses turned out be particularly important for patient navigation and early patient pathway optimisation, i.e. coordinating interventions, streamlining and planning the pathway, tailoring interventions to individual patient's needs and preferences [47–49]. The literature examines the relevance of nurses for patient management and for the provision of seamless care in both the acute care (clinical nurse specialists [47, 48]) and non-acute care setting (community nurses [49]). Other roles and their impact on patient pathways addressed in the literature are emergency care practitioners [50] and community pharmacists [51]. The import role of patients themselves is reflected with the patient-centred approach called user-led health care. It describes the systematic involvement of patients in the planning and execution of their individual treatment and care process and aligns patients' responsibilities with their preferences [52].

Tool- and IT-Support. Improving the utilisation and the streamlining of patient pathways by tools and information technology is a central issue for 13 of the analysed literature records. Here, patient education and patient empowerment by the online provision of information materials are typical applications. For example, there are internet-based, interactive patient pathways used as education tools for breast cancer patients [53] or to explain a forthcoming surgical journey [54], and interactive, individualised online patient pathways with detailed, personalised timelines to keep patients informed and involved [55]. Another topic in relation to tool- and IT-support is the use of telemedicine in order to streamline a patient pathway, e. g. with early tele-assessment of stroke patients [56]. Furthermore, there are triage tools to assess and allocate patients to the appropriate pathway [57] and technical solutions for tracking patient pathways [58].

Simulation. The literature addressing simulation of patient pathways (n = 7) applies it for example to predict their outcomes. Simulation models are used to produce quantified output of patients with a certain diagnosis [59] or to simulate scenarios at the population level in order to support intervention planning of public health care [60]. Furthermore, simulation is used for teaching and training purposes, e. g. by fully simulating a hospital across the entire patient pathway in order to train expert health care providers [61] or by simulating the surgical patient pathway for undergraduate students to supplement classroom medicine and clinical practice [62].

3.2 Characteristics of patient pathways

The scoping review results show that currently a common definition of patient pathways is not available. However, characteristics of this approach can be identified from the included literature by analysing their understanding of patient pathways. It was found that there are related pathway terms also used as synonyms for patient pathways. Mainly, these are care pathways [47, 49, 63–65], treatment pathways [47, 66, 67], and patient journeys [45, 68, 69]. However, the usage of these terms was not reasoned in the articles. The full-texts of the included literature were screened for statements describing characteristics of patient pathways, such as:

"[…] 'patient pathways' from a patient perspective, understood as incorporated into socioculturally constructed life courses. […] Not only 'health events', but also 'life events' are included in our understanding of patient pathways." [16]

"Based on treatment guidelines, patient pathways display an optimal sequence of staff actions in the preoperative, operative, and postoperative in- and outpatient treatment." [24]

"Patient pathways are tools that assist in providing general guidelines of care for dealing with individuals and groups of patients suffering from a wide variety of diseases." [70]

Based on the analysis of such statements and the identified themes in the literature, descriptive characteristics of patient pathways can be summarised as follows. Patient pathways are:

- stating and aligning functional, biological, and patient-related goals of care [15, 16],
- focusing on patient group and individual patient planning and -management for complex long-term conditions [16, 70–72],
- describing and sequencing key components of care to guide care provision and the patient journey [18–21, 23, 24],

- comprising the whole route a patient takes including inpatient and outpatient settings and thus, are typically inter-organisational pathways [45, 68, 71, 73] but individual stakeholders can focus on single episodes (e. g. surgery or hospital stay) [24]
- developed, implemented and used by a multidisciplinary care team consisting of professional and informal caregivers and involving the patient [23, 24, 26, 30, 52],
- evidence-based (medical guidelines, standards) and experts' experiences [22, 23],
- used for patient information, documentation, monitoring and evaluation purposes (e. g. assessment of quality and efficiency of care delivery or patient-related outcome measures) [37–44, 53, 55, 74].

4 Discussion

As the analysis revealed, more than half of the reviewed publications are related to oncological diseases. This emphasises the initial statement that patient pathways are recognised as a valuable approach in cancer care in order to create seamless care, inform the patient, plan the care process, and implement medical guidelines [5]. The results of the scoping review also show that the majority of publications addresses the analysis of various aspects related to patient pathways such as the effects of their application or their usage (see Figure 3 (b)). Still, the broad use of the term indicates some ambiguity in its understanding. Surprisingly, there are a lot of papers analysing effects of patient pathways but without referring to a common definition of this concept.

Although some papers discuss the use of patient pathway in an intra-organisational context and other focus on the inter-organisational setting, the proposed characteristics cover both aspects because patient pathways within a single institution are also embedded in the inter-organisational route of a patient. Interfaces and the relation to the overall process have to be described accordingly. Furthermore, ambiguity exists regarding the time perspective of patient pathways. Some authors focus more on the general journey of patients through the health care delivery system, analysed retrospectively for example by means of patient pathway analysis. Others rather focus on prospectively defined pathways for a patient (group) to guide the provision of care. The latter highlights the planning character of a pathway, which is also the aim of related pathway approaches such as clinical pathways and care pathways.

In the context of existing literature on other pathway approaches, patient pathways comprise the core concept of care pathways, that are already well established in the field of medical process management nowadays [75, 76]. However, patient pathways have a stronger focus on the individual patient. This is particularly apparent in form of aligning the goals of care to a patient's needs and preferences and, accordingly, tailoring the pathway to the individual. The concept of patient pathways emphasises the care process from the perspective of the patient and also includes mechanisms of empowerment and engagement. Based on the identified characteristics, patient pathways are also not equivalent to clinical pathways [7] because these typically do not cover the whole care chain across in- and outpatient settings.

The current state of literature provides several action points for future research. A consensus regarding the patient pathway understanding should be developed, e. g. by an expert panel discussing and rating the identified characteristics. From a practical perspective, a stronger methodological support for developing and implementing patient pathways is desirable. This could be achieved by providing a tool for the preparation of patient pathways, their adaption to patient-individual characteristics and to local specifics of the application environment. Latest research, e. g. on adaptive and personalised pathways [77] or on multi-perspective pathway modelling languages [78], can be exploited for this purpose. The mechanisms of reference modelling [79] might provide appropriate means to combine generic templates with intended governance for health process design. Taking up the example of comprehensive cancer care, a method for patient pathway development could allow CCCNs to prepare common templates of patient pathways for specific tumour entities. These could for example specify the main goals, phases and milestones of care for a specific patient type as well as roles and tasks within the care network. Such a template, functioning as a reference model, could then be adapted to regional conditions and patient individualities based on adaption guidelines provided along with the method. In order to increase usability, the specification of user requirements is essential, since the users have an application-oriented background being e. g. physicians, nurses or a cancer patient. In perspective, this approach could increase comparability and set process-oriented quality standards for cancer care in CCCNs. This could contribute to developing more process-oriented measures for quality and performance assessment. Thereby, insights for continuous patient pathway improvement could be gained.

Critically reflecting on the methodological approach of the presented paper, the scoping review could be broadened by expanding the database search to titles and abstracts and by adding forward and backward searches. The mapping of the literature could be enriched by a multi-disciplinary review team [10] that also involves scholars from the health care domain. Due to the nature of the scoping review it does not include a process of quality assessment of the literature and thus, has some limitations [8]. For this reason, recommendations for practice are preliminary and the understanding of patient pathways could be further examined by a systematic literature review. The conducted scoping review determined the high value and scope of such.

5 Conclusion

The article aimed at examining the current literature body available on patient pathways in order to clarify key characteristics of this approach and to discuss implications for research and practice. A systematic scoping review was conducted. It included a database and a grey literature search. An increase in the discussion of the concept in the literature was confirmed. There were six common themes identified in the current literature on patient pathways. These are definition and conceptualisation, development and implementation, analysis of patient pathways, responsibilities and roles, tool- and IT-support, and simulation. The majority of publications addresses analytical topics, such as the analysis of patient pathway usage or effects but a common definition is currently not available. However, there are typical characteristics of patient pathways that were summarised based on the reviewed literature. Patient pathways differ from other pathway approaches as they rather aim at planning care for multimorbid patients with complex health conditions. They focus on the inter-organisational setting and patients' needs and preferences. We also discussed potential implications for practice and research. Particularly, the methodological and technological support for developing and implementing patient pathways should be improved.

The presented work contributes to the knowledge base by consolidating the understanding of patient pathways and by summarising typical characteristics. As we pointed out, the patient pathway approach builds upon the core concept of care pathways. Since there are concerns regarding the feasibility of care pathways for complex health conditions that require integrated care, we see the opportunity that patient pathways drive a transition to a broader utilisation of pathways for chronic and complex health conditions such as cancer. In summary, our work informs the debate on patient pathways and is a starting point for future research and practical applications.

Understanding the Habitual Use of Wearable Activity Trackers

Annamina Rieder[1], Christiane Lehrer[1], Reinhard Jung[1]

Abstract. Given the large discrepancy between rates at which wearable activity trackers (WATs) are initially adopted and their continued use, the question concerning how sustainable use emerges arises. While IS research has found habit an important driver of sustained use, the mechanisms of habit formation have been left unexplored. To address this research gap, we conducted narrative interviews to investigate the habit-formation mechanisms behind the use of WATs. We identified two drivers of habitual WAT use and constructed five narratives that provide insights into the habit-formation processes of WAT users and possible interrupting factors. Our results provide a valuable basis for both theory and practice in explaining how sustained WAT use develops.

Keywords: Wearable, Habit, Habit Formation, Sustained Use, Continuance.

1 Introduction

The growth in the wearable industry continues as increasing sales figures and numbers of adopters of wearable activity trackers (WATs) buoy the technology's success [11, 27]. However, abandonment rates for the devices are striking [11]. A study by Endeavour Partners reported that users' minimum attrition rate is as high as 30 percent within the first six months [18]. However, sustained use is a prerequisite for inducing long-term changes in health behavior, which is most WAT devices' key value proposition. Information systems (IS) research has identified habit as a key driver of continuous IS use [e.g., 20, 3], but most of its studies of habit and post-adoption phenomena are quantitative in nature and focus on the relationship between habit and factors like continuance, leaving the underlying mechanisms of habitual IS use unexplained. Research that has investigated WATs [e.g., 1, 12] has provided only a few insights into users' perspectives and experiences. Clarifying how habitual use patterns emerge in the context of WATs and post-adoption phenomena would help in designing WATs in a way that supports users' sustainable behaviors and habits. Against this background, our research question asks, *What are the underlying mechanisms of habitual WAT use?*

We used a narrative interview technique in qualitative interviews with ten habitual WAT users to gain a longitudinal insight into the users' experiences with the devices. Eyal's (2014) IS habit formation model, which is grounded in psychology and

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

neuroscience research, provided a valuable theoretical lens through which to investigate the cognitive and behavioral processes of habitual WATs users and the factors that can interrupt habitual use.

The paper proceeds as follows. First, we discuss the theoretical background on wearables, the role of habit in IS, and the mechanisms behind habit formation. Then we present our methodology and the results of our analysis. Finally, we conclude with a discussion of our results and limitations and a proposal for further research.

2 Theoretical Background

2.1 Wearable Activity Trackers

"Wearables" refers to any electronic computing device worn on the body and that uses sensor technology so users can track their personal activities and vital parameters [32, 29]. Even though a wide range of devices (e.g., wristbands, glasses, clothing) fall under the umbrella term of wearables, we focus on wearable devices that track physical activity: WATs. Wearable devices that are designed only to track other health-related parameters, such as fertility, blood pressure, or blood glucose levels, do not fall into the category that we investigate in this paper. WATs, which usually take the form of bracelets and watches, are the most popular category of the wearables market [11]. These devices allow users to self-optimize by providing them with insights into their physical performance through self-tracking of such parameters as steps, sleep, sports activities, and food consumption [29, 10]. Users can usually interact with WATs directly over the device's screen or via mobile applications, which are typically accessible using a smartphone.

Because of the possible positive effects of WATs on personal health, the healthcare sector places considerable value on their potential. The intended behavioral outcomes of wearable use, such as increased activity levels and conscious nutrition, are key preventive measures that can improve public health and reduce strain on healthcare providers and insurers [10]. However, this promising outlook is dampened by the large discrepancy between adoption rates and sustained use. Findings from the US show that, despite adoption rates higher than 20 percent in 2014 and estimated adoption rates higher than 35 percent by 2020, attrition rates are as high as 30 percent within the first six months of use [18, 27]. Consequently, many WAT users do not reach the phase of sustained long-term use, which is a better indicator than mere adoption with which to assess the success of WATs [4]. Research has identified several issues that lead to discontinuance, including short battery life, inaccurate sensors, privacy concerns, insufficient data, and irrelevant information provided to users [6, 7, 27]. Some authors have also suggested that the design of WATs insufficiently incorporates findings from behavioral theory [21, 6, 7].

To date, research on wearables has predominantly followed a quantitative approach to examine the effectiveness of using WATs in health behavior interventions [e.g., 12], and only a small fraction of articles has focused on the experiential side of WATs and the qualitative analysis of the user's perspective [e.g., 2, 13, 24]. The majority of articles has addressed only the adoption process, so we lack qualitative experience-centric research that explores sustained WAT use in the post-adoption phase.

2.2 Habit in Information Systems Research

Research on continued IS use in the post-adoption phase has consistently highlighted the importance of habit as a key predictor of continued IS use [20, 3, 14, 22, 19]. Habit can be defined as the automatic or unthinking performance of specific behavioral sequences, such as the use of an IS artifact, to obtain a certain goal in response to environmental cues [20, 3]. Automation occurs through the processes of repetition and learning.

Studies that have investigated the effect of habit on continued IS use have shown two primary influences: a direct positive influence on IS continuance, continuance intention and satisfaction [3], and an indirect suppressing effect that moderates the relationship between continuance intention and actual continuance [20]. Bhattacherjee and Lin's (2015) findings also supported this link, corroborating the notion that automatic behavior reduces the need for intention. Limayem et al. (2007) identified four antecedents of habits in IS use: frequency of the behavior, satisfactory outcome, a stable context, and the use of various features of the IS in question (comprehensiveness of use). Building on these findings, a handful of studies have investigated continued IS use and the role of habit in specific use contexts, including participation in online communities [14], online gambling [22], mobile location-based services [19], and quitting Facebook use [31].

Whereas the extant research on habit in IS use has involved variance theory, predicting the relationships between antecedents and outcomes, Kim (2009) offered a process view on IS continuance and the influence of habit. Drawing on a process model from cognitive psychology that outlines how memory is formed, Kim sheds light on the process that drives post-adoption behaviors. However, the model does not provide a detailed explanation of the process of habit formation itself.

In summary, the extant IS research assigns habit an important role in predicting IS continuance, but it has yet yielded only a few attempts to untangle the mechanisms and processes behind habit formation. Therefore, we turn to Eyal (2014), who developed a process model to explain habit formation with digital products and services.

2.3 Mechanisms of IS Habit Formation

Process of IS Habit Formation. Eyal's (2014) process model indicates that IS habit formation takes place in four-step cycles: trigger, action, variable reward, and investment (Figure 1). This view is in line with the definition of habit from social psychology, which understands habit as automated dispositions to respond to specific cues to obtain certain goals or end-states [25, 33]. Responses are learned sequences of acts, memorized through a process of repetition that have led to satisfactory outcomes in the past [25]. Habit formation takes place when a trigger—that is, an environmental cue—instructs users in a more or less explicit way about what action to take next [33, 25]. If users are sufficiently motivated and capable of performing the behavior, they will execute the action [9]. The action always takes place in anticipation of a reward, which users expect to receive upon completion of the action [25]. After multiple repetitions, users start building associative links between the trigger and the action and between the action and the reward, which lead them to repeatedly and effortlessly perform the behavior when they are confronted with a similar context [28]. Users also typically "invest" in a specific technology by putting something of value into the system (e.g., effort, time, skill acquisitions) [8]. Along with the processes of associative learning, such investments increase the likelihood that users will repeatedly pass through the process [26]. Repeating this process with high frequency is critical to habit formation [17, 25].

Figure 1. IS habit formation model (based on [8])

Trigger. A trigger can be understood as an "actuator of behavior" [8, p. 7], the first step in the habit cycle. Triggers are goal-related in so far as they cause individuals to desire a certain reward that they expect on execution of a specific behavior [33, 8]. The literature differentiates between external and internal triggers [9, 33] such that external triggers are stimuli sent out by the technology that tells the user what behavior to perform next (e.g., a push notification that reminds the user to take a specific number of steps every hour), while internal triggers do not require a sensory stimulus but are firmly installed in users' minds and automatically activated as certain thoughts, emotions, or routines come up. Examples of internal triggers are feelings of boredom or hunger, certain weekdays, and preceding actions. Having laced up one's running shoes could serve as an internal, routine-based trigger for users to activate their WATs' sports monitoring function.

Action. Action refers to the behavior performed in response to the trigger and in anticipation of the reward [33]. Performing the action requires the user to be sufficiently motivated and able to do so [9]. Pursuing the goals or end states that result from performing the action can include seeking to achieve a positive goal but also avoiding a negative one. Ability, that is, the ease with which a user can perform an action, also influences the likelihood that the action will occur. Ability involves the user's personal capabilities and skillset, as well as contextual factors like time restrictions and the physical environment [25]. In the context of WATs, an action could include making the missing number of steps to fulfill the daily goal. Thereby, the user's motivation to execute this action could, for example, be negatively influenced by the weather, while restrictions to the user's ability could include not having sufficient time or being temporarily incapacitated due to an injury.

Variable Reward. The successful completion of the action is followed by a variable reward, a "positive reinforcer" of behavior [28, p. 89; 33]. With repeated encounters with a similar situational context, associative links between the context and response that have yielded a specific reward are established [33, 25]. Thus, what drives the user to comply with the trigger is not the reward itself but its anticipation, which causes the emission of neurotransmitters in the human brain [28]. The reward should be variable in so far as it provides the user with some degree of novelty [8]. Rewards can take a variety of forms, including social rewards, rewards that fulfill the human desire to acquire resources and information, and rewards that have intrinsic benefits. Eyal (2014) highlighted the importance of the fit among the reasons an individual uses a product, his or her internal triggers and motivations, and the reward. Related to WATs, rewards could, for example, include receiving badges, seeing an upward tendency in performance, or improvements in wellbeing.

Investment. Users' investments in a product or service (e.g., time, data, effort, social capital) influence the value they assign to it [cf. 26]. In the case of technology and software, such investments can enhance the users' experience and, thus, increase the likelihood of re-engagement [8]. Stores of value with technology can take the form of data, followers, acquired skill, content, or reputation. In the context of WATs, investments could comprise a personal training history or a network of friends and followers.

3 Methodology

Since empirical evidence of the process through which habitual WAT use is formed is scarce, we employed an inductive, qualitative approach using narrative interviews, following established principles [16, 5], to capture individual users' experiences and a longitudinal picture of the individual's use history. In this interview technique, the interviewee recalls and gives an account of a past event [16]. Typically, the interview's organization and structure are left to the interviewee, and the interviewer does not intervene with the narrative until the interviewee has recognizably ended his or her recitation. Thus, this interview technique can help to overcome common biases like social desirability, as well as patterns of interaction in the interview, issues related to the wording and placement of questions, and topics and terminology brought in by the interviewer [16].

3.1 Data Collection

We interviewed ten WAT users who were based in Switzerland, which, with a 7.6 percent market penetration in wearable devices in 2017, is one of the most advanced markets for wearables in Europe [30]. In line with the narrative interview technique, we used no interview guideline [16]; instead, we used a pre-formulated initial stimulus to ignite the interviewees' narratives: *"I would like you to tell me the story of your activity tracker. This means from the moment you got it, until today."* We did not intervene until the interviewees had recognizably finished their narratives. Then we took up topics the interviewees had mentioned in their initial narratives to trigger additional accounts. All of the interviews were held in person, and interviewees were ensured anonymity and confidentiality in the statements they made during the interview. The narratives' duration (ranging from 24 to 68 minutes, with an average length of 42 minutes) and level of elaboration varied widely. We recorded and transcribed the interviews verbatim to ensure rigorous and transparent analysis of the resulting data. Interviews and transcriptions were done in the participants' native language, either German or Swiss German dialect, and were processed by native German speakers. The quotations presented in this paper were translated into English.

As we sought depth over breadth of information, a sample of ten participants was adequate to gain rich insights into personal use histories and to identify various habit formation processes. We followed a criterion-based sampling strategy [23], taking the respondents' gender, age, and duration of use into account. Although generalizability is not a primary objective in qualitative research, we tried to distribute interviewees evenly across both genders and to cover a broad age range. Our sample consists of four females and six males whose ages range from 18 to 58 years (M=33.5), and it includes both students and professionals (Table 1). The sample slightly over-represents younger people, but younger people tend to adopt WATs more frequently than older people do [30]. We also chose continuous WAT users (i.e., those who used their devices past the trial phase) who had used their WATs for at least six months, although a few had used them for several years. The use frequency varied across interviewees and largely depended on the motivation for use. Most interviewees used the device every day and even at night, while others only wore it only when they engaged in sports. Most of them used their WATs to track their daily activity, support their sports performance, and improve their health. Some reported using the devices to explore the novel technology out of curiosity. The four functionalities used frequently and long-term by more than three participants were step-counting (nine out of ten participants), sports-activity monitoring (6 participants), competition (5 participants), and heart-rate feedback (3 participants). Fewer than three participants used nutrition tracking and sleep tracking habitually, which others used mainly on a trial basis.

Table 1. Sample characteristics

Alias	*Age*	*Gender*	*Occupation*	*Total use duration*	*# WATs used*
INT1	25	F	Student	> 24 months	2
INT2	24	F	Student	6 - 12 months	1
INT3	57	F	Project manager	12 - 24 months	2
INT4	58	M	Consultant	> 24 months	4
INT5	41	M	Entrepreneur	12 - 24 months	2
INT6	41	M	Entrepreneur	6 - 12 months	1
INT7	25	M	Student	6 - 12 months	1
INT8	20	F	Student	6 - 12 months	1
INT9	18	M	Student	12 - 24 months	2
INT10	26	M	Bartender	6 - 12 months	1

3.2 Data Analysis

The data analysis process broadly followed Chatman's (1978) recommendations. In the first step, we used narrative coding to decompose the narrative into its elements so we could extract the kernel sequence of events. According to Chatman (1978), the story of a narrative consists of *events* and *existents*. Events can be understood as changes of state that are driven by *actions* executed by significant agents (e.g., *"In the beginning, I measured my heart rate relatively consistently" (INT4)*;*"This was when I actually stood up and started walking through the apartment"* (INT1)) and *happenings* that occur but are not directly influenced by the agents (e.g., *"This fitness tracker brought to my attention what I was eating and how often I was exercising"* (INT2); *"The problem was that it just wasn't working most of the time. Then there was something* *wrong with the software, then this, then that"* (INT3)). Existents, on the other hand, are descriptive elements of the story that are constituted of *characters*, which are animate or inanimate agents that advance the plot (e.g., *"I wasn't really a sports enthusiast"* (INT9); *"My fitness tracker is a first-generation Apple Watch"* (INT5); *"The platform has more analytical functionalities, where my running coach could see my progress"* (INT4)) and the *setting*, which is the space in which the characters exist and act (e.g., *"I had two, three colleagues in school who had this too"* (INT9); *"During the semester break we took off the device when we had to study because we wouldn't even make 1,000 steps per day"* (INT1)).

We differentiated between kernel and satellite sequences of events. Kernel events are actions and happenings that advance the plot and are central to the participants' narrative. For example, kernel events were identified if the participants gave an in-depth and lengthy recounting of their use history of a key WAT functionality. Satellite events are not central to the plot, so omitting them does not alter the story. For example, satellite events include when participants mention a WAT functionality only briefly or tell how they used it only on a trial basis.

In the second step, in which we focused on the kernel sequences of events, we identified the WAT functionalities that the participants used habitually: sports-activity monitoring, heart-rate feedback, step-counting, and competitions. Indicators of habitual use patterns were long duration of use, regular use, and signs of automaticity (e.g., when a user mentioned that he or she always and unthinkingly performed certain actions). For those functionalities, we identified the underlying drivers of habitual use. While our research process was exploratory, we were sensitized by the concepts of Eyal's (2014) IS habit-formation model and used the model to identify how the steps of trigger, action, reward and investment were represented in the data along the narratives. The IS habit-formation model proved to be an appropriate theoretical lens, as the interviewees went through steps of the process when they used their devices' various functionalities.

4 Results

Our analysis revealed two drivers of habitual WAT use identifiable across narratives. On the one hand, habitual WAT use was driven by users' offline habits performed independently of WAT use, as it was the case for the functionalities sports activity monitoring and heart rate feedback. On the other hand, the technology itself fostered habitual WAT use by sending out triggers, as with step counting and competitions. Each of the following subchapters covers one of the two motors. The first subchapter illustrates habitual WAT use driven by offline habits by presenting the composed narratives for the functionalities sport-activity monitoring and heart-rate feedback. The narratives in the second subchapter on the motor habitual WAT use driven by the device, are related to the functionalities step reminders, activity statistics, and competitions. The narratives presented below follow the logic of the IS habit formation model, comprising the three impelling elements *trigger*, *action*, *reward*, as well as potential *interrupting factors* to habitual use found in the data. We purposely left out the *investment* element of the model, as we did not find any explicit mentions in relation to specific WAT functionalities.

4.1 Habitual WAT Use Driven by Offline Habits

Habitual Use of Sport Activity Monitoring

Sport activity monitoring allows users to track their exercise (mainly running) using performance indicators like distance, pace, and blood oxygen consumption. A characteristic of this functionality is the need to switch it on and off to monitor the activity while it is being performed. The interviewees who habitually used sport activity monitoring typically had already established a sports habit—usually running—or wanted to develop one before they adopted a WAT. Most had a clear focus on sports and intended to support their sporting goals using a WAT or were interested in monitoring and the data as such.

It's a Christmas gift that I asked for because I went running regularly. I basically used the tracker for running. I also wore it during leisure time and at work, but I mainly used the functionalities for running, like to measure the distance I had run. It also monitored the heart rate, which was useful sometimes, and especially the time per kilometer, which was very important to me. I w0anted to see the progress I made. (INT10)

Sport activity monitoring was in all cases cued by a pre-existing (offline) sports habit, which can be classified as an internal trigger. Intending to or preparing to engage in sports would automatically trigger the participants' subsequent action of switching on the sports tracking mode. In addition, several interviewees engaged in information retrieval after the sports training sessions and even processed the information further by, for example, sharing it with their social networks or feeding it into other data analytics platforms.

When I bought the Suunto, I started trying out the apps. I found that very exciting. There are lots of interfaces through which you can export data. My main platform is Strava, which allows me to see my activities. For example, I went skiing, and you can see where I took photos. I'm sure there are some people who would call this profile neurosis, but I think it's fun. (INT4)

Using sport activity monitoring brought the interviewees multiple kinds of rewards that were all based on the technology. The interviewees often mentioned that the statistics and history motivated them and allowed them to monitor their progress and path toward reaching their goals, which had a confirming effect. Moreover, quantification and visualization of the sports training sessions were considered rewarding in themselves because they led to insights into novel parameters. Monitoring the training sessions also gave the interviewees a sense of achievement because parameters like calories burned, time trained, and distance covered were made transparent. Sports activity monitoring also rewarded them with social recognition when they shared their achievements through social network sites and received positive responses. In addition, spending time with the monitoring data was perceived as entertaining, as they could, for example, keep track of their routes on Google Earth and add the photos they had taken during the training.

Of course, it is great at the beginning, when you're proud or when you do your ten kilometers for the first time and pass your limits for the first time, or when you do your first trail run. Of course, you do want to share this and document all of it. (INT5)

The most common cause for interruptions of the habitual use of sport activity monitoring was loss of the reward. Besides not being able to look at the statistics because of technical problems or a general lack of interest in seeing one's progress, interviewees described how the documentation lost its novelty and excitement after a time. Other such interrupting factors were changes in underlying offline habits that resulted in loss of the trigger and broken devices.

For me, it was the case that it didn't particularly motivate me anymore. It was more like you've been outside for an hour in fresh air and had a good time, so documentation wasn't that important to me anymore because I realized I felt good. You end up doing it regularly – when you move from compulsion to enjoyment. That makes the difference. (INT5)

Habitual Use of Heart-Rate Feedback

Heart-rate feedback, which provides users with close to real-time information about their heart rate, is constantly running in the background. This functionality was mainly used habitually by interviewees who also reported strong, established sports habits or wanted to develop them before adopting a WAT. Using heart-rate feedback served specific goals: improvements in distance and pace or high calorie burn.

The story of how I came across the fitness tracker was that I started to go running on a regular basis, like two to three times a week, and I had to measure my heart rate because it was not supposed to exceed 160. I think my personal trainer was afraid I would have a heart attack. (INT5)

A pre-existing (offline) sports habit serves as an internal trigger, so engaging in a habitual activity like running or doing cardio exercise automatically set the cycle in motion.

I also used the heart-rate monitor during sports. I always checked it; for example, when I went running, I would eventually have to make a cardio peak and then I always checked whether it was over 160. (INT2)

The interviewees report two subsequent actions in the case of heart-rate monitoring: constant interaction with the device during the activity to check the heart rate and immediate adjustment (e.g., breathing, pace) when the heart rate deviated from the target.

I tried to keep a lower pulse on longer distances and not go at full intensity. I also tried to slow down a bit when my pulse was at 160 or so. The tracker was really useful for when you want to improve your running performance. Sometimes, even when you don't have the impression you're going so fast, you take a look at your pulse and the pace and you say, "Oh, 170 is maybe a bit too high for a flat route—should probably slow down." (INT10)

The rewards interviewees got from using heart-rate monitoring were not usually delivered by the technology but were internal. Interviewees reported rewards that were personal in nature, such as feeling good, improving, being able to run longer in a healthier way, and getting to know their bodies.

However, through repetition and learning, interviewees felt they had acquired a subjective feeling for their bodies and heart rates, which obviated the need to use the digital heart-rate feedback provided by WATs. Changes in underlying habits that resulted in loss of the trigger, and broken devices are other factors that interrupted the habitual use of the heart-rate feedback.

Once you've reached a certain level–this was the case with me after some three months, and after half a year it got really easy–where you can run for an hour plus, you've learned to deal with it and you also feel for *yourself which pulse is good for you, then you don't need the technical support anymore to guide you. As you get to know your body better, the device becomes less informative.* (INT5)

4.2 Habitual WAT Use Driven by the Device

Habitual Use of Step Reminders

The step-counter of a WAT is always running in the background, recording each movement that is sensed as a step. Most WATs come with pre-set hourly and daily step goals or let users specify goals themselves. External triggers in the form of push notifications on the WAT screen or the user's smart phone drove the habitual use of the step-counting functionality for our interviewees. The devices reminded users to move if they were to achieve their hourly activity goals or informed them of how many steps were left to reach their daily step goals. Such push notifications triggered the interviewees to interact with their WATs and to engage in offline actions—that is, to take the number of steps that were necessary to reach a certain goal.

I always got something five or ten minutes before the hour saying, "Hey, 300 steps left for the hourly goal" or so. It was vibrating, and then you realized, "Oh, I've been sitting around for an hour looking at the computer. I'll get up and go to the toilet or somewhere else just to walk a few meters." You're always reminded when an hour passes and another hour passes, and you haven't moved at all. (INT7)

Interviewees reported various rewards upon executing the triggered behavior. Complying with the cue usually left them with the feeling of being energized and more fit during their daily activities. Moreover, as making hourly step goals also added to the overall step count, they felt that compliance contributed to overall goal achievement. With WATs that were using a different technique like a punishment logic with a red bar that appeared on screen after a certain amount of sedentary time, executing the action was perceived as a relief.

The more bars you had, the longer it took to get rid of them, so if you had one bar, you could cross your apartment two or three times before it eventually disappeared. But when you had five bars, this meant you would have to move for five or ten minutes to get rid of all of them. Yes, the red bar really annoyed me. (INT8)

The most common interruption to the habitual use of step reminders the interviewees mentioned was the loss of the trigger if users stopped wearing the WAT regularly. Even though the interviewees intended to maintain their activity levels, they reported being unaware of their hourly number of steps and so were not cued to move.

I only stand up when I really have to. If I am not made aware of it, I don't think, "Oh, I haven't gotten up for three-quarters of an hour straight." (INT9)

Habitual Use of Activity Statistics

WATs provided the interviewees with a wide variety of statistics and historical data about their physical activity, graphically represented in dashboards that were accessible via smartphone app. Unlike using step reminders, using these functionalities requires the user to access and retrieve information actively.

I was curious to see how many steps I take and how this changes over the course of the week–how this changes based on whether you're doing sports or are just at university. Even if I did not reach my step goal each day, I just concentrated on the weekly average and made sure that I got a daily average of 10,000 steps per day, and if I succeeded in that, I didn't care too much when I had a day on which I had fewer steps and another one with more. Then it was kind of balanced. (INT1)

For some functionalities, the triggers are external, but they take a passive form, as they remind users of the goals they have set and to interact with the technology when it catches their attention. For example, merely seeing the wristband on one's wrist or seeing the WAT app on the screen of a smartphone app can serve as a trigger.

Triggered actions can be comprised of only interaction with software components or can also include execution of an offline behavior. Interviewees regularly checked their numbers of steps, consulted their statistics and histories, and looked into the progress they had made toward reaching their goals. However, most interviewees used their WATs' functionalities not only by interacting with them but also by adapting their offline behavior based on their progress toward their goals. Most participants engaged in extra activity if they had not reached their step goal yet.

When you're looking at your device and you see that you have half the steps that you normally do, it's a bit shocking and you think you'll have to do something about it. (INT7)

Interviewees received a variety of rewards from the technology for executing the actions it triggered, including a sense of achievement, confirmation from an upward trend over the use history, and avoidance of "punishment" when the interviewee's goal was to prevent a downward movement in data. Engaging in offline behavior in response to the activity history also added to interviewees' well-being and their perceptions of their fitness, as it kept them active and moving.

When you went running, you quickly got 15,000, 16,000 steps, and that was great. I had days on which I had 25,000 steps–that made me proud. And then it also told you the calories, and then you saw you really burned a lot. (INT3)

For some users, learning effects decreased the interviewees' perceptions of rewards and their excitement from using the activity history functionality for a period of time.

It eventually loses its novelty value or you eventually know and get a feeling for how many steps you've walked. (INT6)

The interviewees' ability to perform the offline behavior was restrained in some cases when they faced changing schedules or lost awareness of the number of steps they had taken after discontinuing use of their WATs.

I know that I don't do a lot during the exam period, and I think that I can't because I have tons of other stuff to do. But when you have it in black and white that you have 1,000 steps over the whole day, you just don't wear the WAT at all to silence your conscience.(INT1)

Habitual Use of Competitions

WATs offer users the opportunity to compete against other users through a social network. The functionality, which is based on step-counting, lets users initiate or accept competitions and provides them with reports in the form of rankings or reminders entailing the status of the competition. Competing against other WAT users was rarely the interviewees' initial motivation to use a WAT; instead, they learned about the function when they adopted their devices and tried it out with their friends. The strength of the habit of using competitions was affected by one's social network's motivation and involvement.

In the beginning, it was fun to see how many steps I take, but then two or three colleagues at school had the device too and there was the possibility to engage in challenges against each other. I eventually started walking home from school just to win the challenge. (INT9)

Engagement in competitions was triggered external to the device when the interviewees were invited to compete against other users or initiated the competition themselves. To participate in a competition, interviewees had to take the first action of initiating or accepting an invitation. Further actions included checking the competition status and the rankings in the social network. The interviewees also often engaged in an offline behavior like taking more steps to win a competition.

It motivated me. I purposely took the stairs or, when I had to take the subway for one stop, I walked instead because I desperately wanted to beat my boyfriend. (INT2)

Rewards for participating in a competition were usually delivered by the technology. Interviewees drew social recognition from competitions, as others got to see how active and fit they were and offered admiration. Interviewees also received confirmation through winning a competition that confirmed that they were better or more active and sporty than their competitors, which served as a form of reward. Besides being entertaining, competitions also supported interviewees' fitness by prompting them to take even more steps.

I believe this is what motivates people most–comparing themselves to others. You look up on Freeletics or Linkedin what all the other people are doing and you think, "Ah, shit, I totally don't have my life under control," and then you do something about it. (INT2)

The reason for ending the habit was usually that interviewees lost interest in the rewards. Similar to step-counting, some interviewees lost interest in the function after the excitement and novelty value had vanished and rewards had become predictable.

At some point, after all these competitions were nothing special anymore, it just wasn't an advantage to me anymore. (INT2)

Other problems had to do with restricted social networks and frequently losing competitions, both of which negatively affected the rewards connected with the behavior.

With the one colleague I used it with, I didn't have any chance. Even when I thought I had done lots of steps, like 40,000 or so a day, he ended up getting 60,000. Then I thought I'd have to stop this, as it started annoying me. (INT1)

5 Discussion

This study investigates the mechanisms behind habitual WAT use. Based on narrative interviews, we identified two distinctive drivers of habitual WAT use and constructed five narratives that provide insights into WAT users' habit-formation processes and possible interrupting factors. The two drivers of habitual WAT use are pre-existing offline habits and the device itself. When offline habits drive WAT use, WAT use is embedded into existing behavioral sequences that have become habitual prior to WAT adoption. When use habits are driven by the device, users are incited to learn and perform new behaviors.

Our research contributes to the literature on habit and wearables and has implications for theory and practice. First, we contribute to the IS literature on habit [e.g., 20, 3] by unveiling the process by which use habits are formed in the context of WATs. Two drivers of habitual WAT use are pre-existing offline habits and the technology itself, but only one of the two drivers tends to be in effect with a particular user—that is, users either habitually used their WATs in response to an offline habit (INT3, 4, 5, 10) or were driven by the technology (INT1, 6, 7, 8, 9), rather than being motivated by both drivers (INT2). Moreover, taking into consideration Limayem et al.'s (2007) research, which provided insights into antecedent conditions of IS habit, our findings indicate that comprehensiveness of use is not a substantial driver of habit in the WAT context or for our sample. On the contrary, we observed a tendency toward long-term use and stronger use habits the more users were focused on only a few functionalities of the WAT. Wide adoption of WAT features was often associated with trial usage or weak habits.

Second, we contribute to research on wearables by offering insights into the experiential side of WATs, particularly by providing information about habit-formation processes and habitual use of WATs. Unlike to several other kinds of IS, WAT use cannot be conceptualized simply as interaction with the device's software components, as WATs aim to induce offline behavior, and the performance of such behavior constitutes a qualified form of WAT use. Our findings suggest that a much of what leads to interruption of sustained WAT use resides with the user, although the perspective of current WAT research predominantly allocates interrupting factors to the technological sphere.

Our research has several implications for theory and practice. First, our research suggests that it is reasonable to conceptualize habitual WAT use along its functionalities because users develop use habits for some functionalities, but not for others. Second, Eyal's (2014) IS habit-formation model is useful in explaining IS habits on a fine-grained level, as we found evidence for the stages of the model in our data. Therefore, IS researchers could apply the model to examine similar IS habit-formation processes. Third, our research offers producers clarity about the habit-formation processes that are related to WAT use and about potential interrupting factors. Building on such information, WATs designers can design them in a way that supports particular stages of the habit-formation process and that anticipates and counteracts the interrupting factors that are obstacles to long-term WAT use. Fourth, as habitual WAT use is driven in part by pre-existing offline habits, producers must shift their focus away from technology-driven behaviors to consider users' existing behavioral patterns and habits.

6 Limitations and Further Research

The present research is subject to some limitations. Because this research is qualitative, we limited the number of interviewees we used for analysis, so we may not have heard all variations of use cases in the WAT context or have covered all functionalities equally. Future research may consider interviewing users with other use cases and contexts. Although the narrative interview technique is especially valuable when it comes to exploring longitudinal, process-like issues with highly individual character, some themes could be under-represented in the data, which could be why we found no evidence of the investment element in our data. While interviewees mentioned investment-related aspects of WAT use on a general level, such as appreciating the historic data or having gained specific use skills, we were unable to relate them to specific functionalities. Future research could verify this finding and investigate the role of investment in the habit-formation process with WATs. Moreover, habits always underlie automated cognitive processes that users do not necessarily consciously perceive. Therefore, when we relied on the interviewees' memories, we had to use interpretive proxies to identify such processes. However, also other forms of qualitative studies, as well as quantitative studies, address this particular limitation, so future research could use other research methods (e.g., mining WAT use data) to triangulate and establish reliability. Finally, future research could go a step farther to look into behavior changes that result from sustained WAT use and assess how WATs are keeping up with their goal of inducing behavior changes in their users.

Abstract. Lacking regular physical activity is a pertaining problem in most western societies. Fitness apps are positioned to address this issue by offering motivational affordances to the user, which aim to enhance motivation and increase physical activity: self-monitoring, rewards, and social comparison. Yet research provides inconclusive results about their effectiveness. For clarification, this paper draws upon Achievement Goal Theory and theorizes how and why motivational affordances vary in dependence of users' motivation-relevant goals in supporting motivation and physical activity. Empirical validation among 283 fitness app users generally supports that motivational affordances need to be congruent with users' underlying goal orientations to achieve the benefits. As such, this paper contributes to fitness app research by resolving prior inconsistencies, offers a theorizing on motivational affordances and individual motivation-relevant differences, and aids practice in designing fitness apps.

Keywords: Fitness apps, Motivational affordances, Achievement goal theory.

1 Introduction

January, 12th is unofficially called the *Quitters Day* [1]. According to recent analytics of millions of fitness app users, most of them give up their New Year's resolutions to be more physically active only twelve days later [1]. This insight remarkably echoes two prevalent issues: lacking regular physical activity and questionable effectiveness of fitness apps to sustainably motivate users.

The lack of regular physical activity is a pertaining problem for most western societies [2]. Although of high importance for health and well-being, most people are not regularly physically active as recommended [3]. For instance, only 43% of the German population meets the recommended minimum of physical activity in 2018 – a serious downward trend compared to 60% who met the recommendation in 2010 [4]. Initiating and sustaining physical activity is a great challenge for health promotion [2].

Fitness tracking applications and devices aim to address this issue [5, 6, 7] and gain huge public interest [7, 8]. In 2018, about 489 million people already use a fitness

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

tracker [9]. Today, the worldwide market has an estimated revenue of 16 billion USD and is expected to increase in the next years [9]. To motivate people for physical activity, fitness tracking applications ('fitness apps') provide different 'motivational affordances' to the users: self-monitoring, rewards, and social comparison [10, 11].

Although these are expected to benefit individuals by increasing motivation and physical activity, studies draw an overall inconclusive picture about their influence raising controversial discussions about the role these affordances play [5, 6, 7]. It is known that the expected benefits do not unfold to the same extent for every fitness app user: each motivational affordance can be 'motivating' for some – but 'demotivating' for others [5, 6, 7]. Today, however, we lack an understanding as to *why* the motivational affordances are not necessarily of equal benefit for everyone. Understanding the particular effects and causes allows to tailor the motivational affordances and hence to design effective fitness apps that motivate users individually.

Although it is well-known that individuals, and hence fitness app users, can greatly differ in their underlying motives and goals for physical activity [12, 13], little attention has been paid to such motivation-relevant differences of the users and their interplay with motivational affordances in affecting the benefits gained from fitness apps. Therefore, this paper asks: *How do motivational affordances and motivational differences of the users interact in affecting the benefits gained from using fitness apps?*

To provide answers to this question, this paper develops a parsimonious theoretical understanding of how motivational affordances and motivation-relevant user characteristics interact in providing the expected benefits. Drawing upon the key tenets of Achievement Goal Theory [14, 15], we discuss that motivational affordances serve as 'goal structures' that need to be congruent with the 'goal orientations' of the users in order to provide the expected benefits. Quantitative data (N=283) generally lend support for our theoretical considerations, so that this paper contributes to 1) fitness app research by resolving parts of the inconclusive findings about motivational affordances by taking user characteristics into account [5, 6, 7, 16] and 2) by offering a theorizing on motivational affordances [17] explicating their motivation-theoretical characteristics and their interaction with individuals' motivational goals in unfolding their potentials.

The rest of this paper unfolds as follows. Next, we outline the theoretical background of motivational affordances in the context of fitness apps and introduce the key tenets of Achievement Goal Theory. Then we develop our theoretical considerations and detail our hypotheses subsequently. Finally, we lay out our methodological approach and the research results before discussing the findings, implications, and limitations.

2 Theoretical Background

2.1 Motivational Affordances within the Fitness App Context

Fitness apps – such as Strava or Nike+ Running – aim to increase motivation and physical activity. These apps record and document physical activity metrics such as distance, speed, or heart rates and can be used standalone or in combination with devices such as Fitbit wristbands [8]. To augment the recorded data, to induce motivation, and to sustain physical activity, fitness apps provide a set of 'motivational affordances' to the user [5, 6, 7, 16] that build upon self-quantification, gamification, and social network capabilities [16, 18].

The general concept of *'affordances'* is defined within the information systems (IS) research context as "*the possibilities for goal-oriented action afforded to specified user groups by technical objects*" [19, p. 622]. Affordances reflect the potential ways of using IT and aid understanding how the benefits of IT unfold [19]. Using this general notion of affordances in the motivation context, *'motivational affordances'* denote "*the properties of an object that determine whether and how it can support one's motivational needs*" [17, p. 145]. Popular motivational affordances in fitness apps (Table 1) include 'self-monitoring', 'rewards', and 'social comparison' [10, 11].

Table 1. Popular motivational affordances of fitness apps [10]

Affordance	*Definition:* The possibility to…	*Feature examples*
Self-monitoring	… systematically document and observe one's sport behavior	Logs of activity metrics (e.g., time, distance, pulse)
Rewards	… obtain cognitive or virtual rewards for physical activity	Points, badges, trophies
Social comparison	… compare one's performance against others	Leaderboards, competitions, activity reports, profiles

The *self-monitoring affordance* of fitness apps provides the possibility to systematically document and observe one's sports behavior [10] and reflects the cornerstone of the self-quantification [8]. When monitoring themselves, fitness app users seek to observe trends and patterns about their sports behavior. This includes among others whether they are making progress, to ensure that they are maintaining their physical activity or to increase self-awareness about (un)healthy behavior [10]. The *rewards affordance* provides users the possibility to obtain cognitive or virtual rewards for physical activity such as through virtual points or trophies [10] and reflects the gamification aspect of fitness apps [16]. Rewards can be given for achieving self-set activity goals and for making progress (e.g., running a certain distance) but also on normative bases, such as in leaderboards where users obtain trophies for the best sports performance [5]. The *social comparison affordance* reflects the social network aspect [16] that allows fitness app users to compare their performance against other users, for instance through leaderboards, competitions, or others' activity reports and profile pages [10].

However, little is known about the role these motivational affordances play for increased motivation and physical activity. On the one hand, prior research neglected the particular influence of these motivational affordances as fitness apps have been most often examined as a 'whole' [5]. Studies devoted to these particularities, on the other hand, give rise to skepticism about the expected benefits emerging from the motivational affordances. Here, literature reviews draw an overall inconclusive picture reporting positive, neutral, and mixed effects on benefits-related outcomes for the motivational affordances in fitness apps [cf. 5, 6, 7]. As equally accentuated by user stories [e.g., 20], it can be increasingly observed that the achieved benefit of each motivational affordance differs for users. For instance, due to the self-monitoring affordance, users report higher health awareness, higher satisfaction when achieving sports goals, and heightened sports motivation but for others, this affordance is demotivating because of not making visible progress [20, 21]. As for the rewards affordance, studies observed increases in motivation and physical activity, whilst others detected these effects only in short-term or even found no effects at all [5]. The social comparison affordance can be beneficial by inducing fun and affiliation but it also results in peer pressure, negative self-evaluations, or unwanted competition [20, 22].

Whilst research is aware that the expected benefits do not necessarily unfold for all fitness app users to the same extent [5, 6, 7], we do not know a lot about *why* this differs. Scholars point to potential motivation-relevant individual differences of the users [5, 6, 7], such as different motives [16] or goals [18], that can be influential for the motivational affordances used in fitness apps. Thus, taking motivation-relevant user differences into account may provide a more complete understanding of the role motivational affordances play in accounting for the benefits gained from fitness apps. To understand this potential interplay, we draw upon Achievement Goal Theory next.

2.2 Achievement Goal Theory

Human motivation considers the processes that give behavior its energy and direction [12]. Motivation scholars seek to understand the sources of human motivation and their resulting behavior, such as physical activity, suggesting that both the person oneself as well as her/his environment are influential [12, 23]. Achievement Goal Theory (AGT) is a dominant motivation-theoretical framework that considers these dual sources of human motivation and their influence on motivation-relevant cognition, affect, and behavior particularly in the physical activity context [13, 14, 15, 24]. AGT rests on the assumption that individuals are goal-directed beings and achievement goals guide their beliefs, decision making, and subsequent behavior in achievement contexts, such as in the physical activity context [13]. Here, 'achievement' reflects the attainment of a personally or socially valued goal that has meaning for the person, such as improving physical abilities, sports performance, or beating others [13]. AGT hence considers two major achievement goals: *mastery goals* focusing on competence development and *performance goals* focusing on competence demonstration [24]. These two achievement goals are salient within the individual – known as 'goal orientations'– but also within one's social environment – known as 'goal structures' [24].

Goal orientations are dispositional tendencies of the individual [24] where the outlined mastery and performance goals are of centrality. Individuals with a *mastery goal orientation* focus on competence development believing that effort and hard work will lead to competence and mastery [15]. These persons assign value to progress in a self-referenced manner, focusing on learning rather than on the outcome [14, 25]. Thus, fitness app users holding a mastery goal orientation may be eager to improve their physical abilities, to run faster or longer than before, and to observe the progress they made. Individuals holding a *performance goal orientation*, in contrast, define achievement on normative bases and focus on competence demonstration, to show superior ability, to outperform others, and to gain favorable judgments [15]. Fitness apps may be thus motivating and beneficial for users with a performance goal orientation as the social network functionalities allow them to compare themselves with other users, engage in competitions, and to earn trophies for their sports performance.

Goal structures, also referred to as the 'motivational climate' [14], are the achievement-relevant and goal-related emphases within the social environment of the individual [14]. They are caused by environmental practices such as specific messages sent by social actors like teachers, sports coaches, or peers [14, 24]. Equally, goal structures can have an emphasis on mastery and performance goals [24]. A *mastery goal structure* emphasizes improvement and understanding where individuals perceive that effort and learning are valued. A *performance goal structure* stresses relative ability, social comparison, and interpersonal competition [14, 24]. We theorize the role of goal structures in our context subsequently (chapter 2.3).

As goal orientations and goal structures are influential for motivation-relevant outcomes, including heightened motivation and physical activity, linkages between these two constructs have been established [13, 24]. One specific linkage considers the interaction between goal orientations and goal structures in beneficial but also detrimental ways [24]. This interactionist approach proposes a conventional *'matching hypothesis'* suggesting that the most positive outcomes are expected when goal orientations and goal structures are congruent concerning their emphasis on mastery and performance goals [24]: individuals holding a mastery goal orientation are expected to achieve higher motivational outcomes when acting within a mastery goal structure whereas individuals high in a performance goal orientation are best situated within a performance goal structure [24]. Hence, goal orientations and goal structures can reinforce or diminish each other in affecting motivation-relevant outcomes depending upon whether the same goals are emphasized [24].

Next, we discuss how the key tenets of AGT with respect to goal orientations and goal structures with differing emphases on mastery and performance goals as well as their interaction translate into the fitness app context to understand how the benefits of fitness apps to induce motivation and heightened physical activity unfold.

2.3 Theoretical Considerations

Based on these considerations, we aim to use the key tenets of AGT to better understand the role of motivational affordances in promoting the expected benefits of fitness apps.

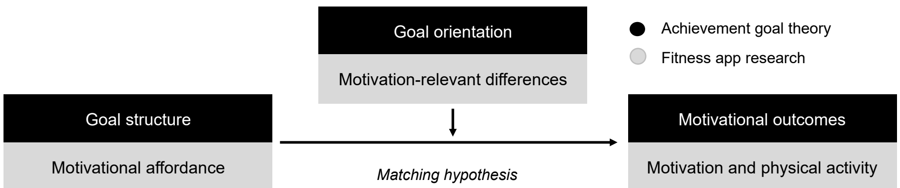

Figure 1. Theoretical considerations

As depicted in Figure 1, we observed parallel lines between fitness app research and AGT. Both fitness app research and AGT are concerned with motivation-relevant outcomes, particularly heightened motivation and increased physical activity. Moreover, fitness app research indicates the necessity to take motivational differences of the users into account which parallels individuals' goal orientations in AGT. Lastly, AGT considers goal structures as an important environmental factor which shares commonalities with the motivational affordances of fitness apps as follows. Information technology, such as a fitness app, is part of an individual's environment including its associated features and capabilities [23]. These features and capabilities, in turn, have certain qualities making them significant for human motivation [23] as posited by the concept of motivational affordances [17]. Motivational affordances can be thus generally understood as environmental factors which are important sources of human motivation [12, 23]. In terms of AGT, motivational affordances act as goal structures with different emphasis on mastery and performance goals.

In short, the *self-monitoring affordance* provides a mastery goal structure given its emphasis on understanding and improvement in a self-referenced manner [10]. The *rewards affordance* can serve as both mastery and/or performance goal structure because sports performance can be either rewarded due to own achievements and improvements but also on normative bases, such as by leaderboards [5, 10]. The *social comparison affordance* serves as a performance goal structure given its emphasis on normative evaluations of one's sports abilities and achievements [10, 16].

In line with the 'matching hypothesis', the motivational affordances are thus expected to interact with users' goal orientations where higher benefits of fitness apps emerge out of a fit between mastery and performance goal emphasis. We detail our arguments subsequently in our hypotheses development.

3 Hypotheses

Because of the inconclusive results about the role motivational affordances play in promoting motivation and physical activity in fitness apps, it is important to understand how and why these benefits do not unfold to the same extent for each user.

In IS research, the benefits gained from IT use are usually labeled as 'net benefits' [26]. As fitness apps aim to enhance motivation and physical activity, net benefits are defined in that context as the extent to which the fitness app has positive impacts on motivation and resulting physical activity. Based on our theoretical considerations just developed (cf. chapter 2.3), we now detail our hypotheses how motivational affordances pronounce mastery and performance goals and thus interact with users' goal orientations in accounting for variations of these net benefits gained.

The *self-monitoring affordance* provides a mastery goal structure to the user [10]. Because it grants the possibility to document sports behavior and to monitor progress in physical activity [8, 10], the self-monitoring affordance focuses on the user's competence and ability and hence emphasizes a mastery goal [14, 24]. As such, the self-monitoring affordance should be particularly beneficial for users holding a mastery goal orientation as it complements their striving to improve their physical abilities and to observe their progress in a self-referenced manner [14, 27]. Recent research in the strand of fitness apps has shown that users holding this mastery goal orientation [18] or pursuing related physical improvement and achievement motives [16] are more inclined towards features that allow evaluation of performance and progress as resembled in the self-monitoring affordance [16, 18]. This evidence suggests that mastery goal orientations match with the self-monitoring affordance making its positive influence even stronger. Fitness app users holding a performance goal orientation, on the other hand, seek to evaluate their sports ability and performance against other users [15]. Here, the self-monitoring affordance does not provide a complementary goal structure that satisfies their performance goals.

H1(a-c): The self-monitoring affordance a) poses a positive relationship with net benefits and this relationship is b) stronger for users high in a mastery goal orientation and c) weaker for users high in a performance goal orientation.

The *rewards affordance* provides a mastery and/or performance goal structure to the user. Rewards can be granted on self-referenced attainments when a user achieved her/his self-set goals such as running 5km, but also on normative bases where a user receives a trophy when her/his performance is better than those of others [5, 10, 16]. Hence, the rewards affordance can be particularly beneficial for users holding a mastery or performance goal orientation. For users with a mastery goal orientation, this affordance values their improvement efforts. Fitness app research tends to support this consideration as users are more attracted by reward-related features of fitness apps when they seek to compare current against past physical conditions or aim at reaching a particular activity goal [18]. For users with a performance goal orientation, this affordance makes their achievements visible to others and awards outperforming other users [5, 10, 16]. Here, fitness app research equally lends support as users high in a performance goal orientation place higher importance on reward-related features [18]. Thus, this affordance supplements mastery and/or performance goal orientations.

H2(a-c): The rewards affordance a) poses a positive relationship with net benefits and this relationship is stronger for users b) high in a mastery goal orientation and c) high in a performance goal orientation.

The *social comparison affordance* provides a performance goal structure to the users as it promotes interpersonal competition and public evaluation [14, 28] through features that allow fitness app users to compare their performance against others users' performances [10]. This affordance is thus expected to be most beneficial for users holding a performance goal orientation [24]. Users holding a performance goal orientation describe their achievements on normative bases and seek to become better than others [15]. The social network capabilities of fitness apps allow to observe other users' profile pages and activities or to enter competitions where performances are displayed within leaderboards [10]. The social comparison affordance should thus reinforce their striving for interpersonal performance comparisons. Research indicates that fitness app users pursuing social motives for engaging in sports, such as affiliation and recognition from others, as well as users pursuing competitive motives are more likely to draw upon features allowing performance comparisons against others as well as on features where they can receive recognition from their social network, such as 'likes' [16]. Similarly, performance-oriented users assign higher importance to social network features including other users' activity logs and leaderboards [18]. Mastery-oriented users, in contrast, should receive fewer benefits from the social comparison affordance because those users focus on self-referenced achievements.

H3(a-c): The social comparison affordance a) poses a positive relationship with net benefits and this relationship is b) weaker for users high in a mastery goal orientation and c) stronger for users high in a performance goal orientation.

4 Research Method

To test our hypotheses, empirical data with specific characteristics is needed. First, as the functionalities vary between apps [29], a single fitness app providing our focal affordances is required to prevent outside effects. Second, to assess the effects of the 'social comparison' affordance, users need to be connected with other users. Third, the fitness app needs to target the same class of activities, such as cardio-intense sports like running or cycling, to assess the achieved benefits (motivation and physical activity).

We chose the fitness app 'Strava' (www.strava.com), which meets above-mentioned criteria and anecdotal user stories indicate varying benefits [e.g., 20]. As a large number of users is needed, mainly to test interaction effects, we recruited respondents using an online panel of Amazon Mechanical Turk that gained widespread attraction as a viable and reliable source for research [30]. Following recent guidelines [30], we restricted our sample to the United States as such responses provide reliable results similar to regular consumer panels [30, 31]. Our study was conducted in May 2018.

As depicted in Table 2, our measurement instrument was derived from prior literature. Items for motivational affordances [10] were adapted to our context. Goal orientation items were assessed by instructing respondents to think about their sports and exercises [25, 27]. Items for net benefits were based on our definition, compiled from related studies [32], and adapted. We used a 7-point Likert scale for all items.

Table 2. Measurement instrument

Construct	*Items*
Affordances	*When I use Strava, I use features that allow me…*
Self-monitoring [10]	… to monitor my sport behavior. … to keep track of my exercise activities. … to record my physical activities.
Rewards [10]	… to make my physical activity rewarded. … to get more rewards if I try harder. … to earn virtual rewards as a token for my efforts in physical activity.
Social comparison [10]	… to compare my performance with the performance of others. … to compare myself with others regarding what I have accomplished in exercising. … to find out how I am doing in exercise compared to what others have done.
Mastery goal [25, 27]	It is important to me to perform as well as I possibly can. I prefer challenging goals so that I'll improve a great deal. I am willing to take on a difficult challenge if it helps me reach my goals.

Performance goal [25, 27]	It is important for me to perform better than others. It is important to me to do well compared to others. To be honest, I really like to prove my abilities to others.
Net benefits [32]	Using Strava has helped me being physically active. I gained motivation to exercise from using Strava. I exercise more since using Strava. Using Strava makes my sport more enjoyable.

After data collection and preparation, 283 responses were eligible for data analysis [30].[1] The dataset is characterized as follows: 60.4% are male and the average age is 32.4 years (SD 7.96 years). On average, participants use Strava already for 11.5 months (SD 14.1 months) and when it comes to sports, 63.3% use Strava 'often' or 'always'. Participants' number of followers in Strava is at a median of 16 followers. Asking about their general frequency of performing sports, 78.4% answered with 'several times a week' or 'almost every day'. As such, our sample consists of quite active sports people resonating with recent literature and studies [16, 18, 29].

5 Data Analysis

The data was subsequently transferred into Structural Equation Modelling using Partial Least Squares [33] with the software SmartPLS 3. We analyzed the measurement model including common method bias before evaluating the hypothesized relationships [33].

All constructs were modeled using reflective measurements. Evaluation involves indicator and construct reliability as well as discriminant validity (Table 3) [33].

Table 3. Measurement model evaluation

			Discriminant validity					
Construct	*CR*	*AVE*	1	2	3	4	5	6
1. Benefits	0.904	0.703	0.838					
2. Monitor.	0.863	0.678	0.667	0.824				
3. Rewards	0.903	0.756	0.397	0.237	0.870			
4. Soc. comp.	0.900	0.750	0.434	0.277	0.595	0.866		
5. Mast. goal	0.862	0.675	0.616	0.537	0.359	0.470	0.822	
6. Perf. goal	0.907	0.765	0.293	0.133	0.490	0.581	0.452	0.875

Indicator reliability was achieved as all item loadings are greater than 0.707 (0.781–0.892) and are significant ($p<0.001$). *Construct reliability* was achieved as values for Composite Reliability (CR) and for Average Variance Extracted (AVE) are above 0.7

[1] We received 624 responses whereby 514 passed the screening criteria of currently using Strava. We then removed all non-unique responses based on IP addresses and Worker IDs (N=425). To evaluate the 'social comparison' affordance, only participants who indicated being connected with other users were retained (N=293). Finally, responses with failed attention checks and more than five missing answers were dropped (N=283).

and 0.5. Construct reliability is further supported by values for Cronbach's Alpha between 0.760 and 0.859. *Discriminant validity* is supported as 1) each item loads highest on its designated construct, 2) as the Fornell-Larcker criterion is fulfilled given that the inter-variable correlations are smaller than the root of the corresponding AVE as demonstrated in the diagonal lines [33], and 3) as the heterotrait-monotrait ratio with the highest value of 0.81 is below 0.85 [34].

Common method bias (CMB) can be of concern when using self-reported data obtained through a single method [35]. To mitigate the potential influence, we stressed anonymity, the academic purpose, that there are no wrong or right answers, and randomized item ordering [35]. To evaluate its presence in our data, two tests were conducted. Results of Harman's single factor test indicate that 39.15% of the variance is attributed to one single factor which is not the majority [35]. Performing an additional test [36] by entering a CMB factor into the model containing all items and observing its respective influence on each construct, the resulting ratio of 1:685 is much smaller compared to prior research [36]. Thus, CMB is not a concern in our data.

For hypotheses testing, we first analyzed the motivational affordances on net benefits without the interactions (Figure 2). We obtained an R^2 of 52.7% for net benefits as significantly predicted by the three motivational affordances with medium to large effect sizes [33]. The results hence support hypotheses H1a, H2a, and H3a.

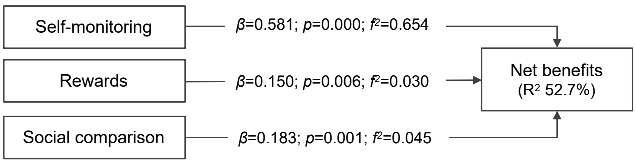

Figure 2. Direct effects of motivational affordances on net benefits

Next, we focused on the interactions of each motivational affordance with mastery and performance goal orientations in isolation. As interaction effect sizes are usually small, a conservative interpretation is 0.005 ('small'), 0.01 ('medium'), and 0.025 ('large') [37]. To aid interpretation, we plotted the significant interactions (Figure 3).

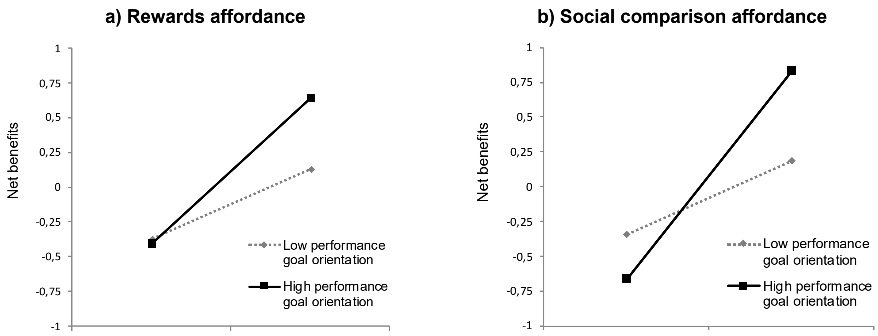

Figure 3. Interactions of a) rewards and b) social comparison affordance with performance goals

For *self-monitoring*, we did not observe significant interactions with mastery goal orientations (β=-0.070; p=0.091; H1b not supported) nor with performance goal orientations (β=-0.034; p=0.590; H1c not supported) on net benefits. For *rewards*, we found a significant positive interaction with performance goal orientations with a large effect size (β=0.138; p=0.013; f^2=0.035; H2c supported) but not with mastery goal orientations (β=0.010; p=0.879; H2b not supported) on net benefits. Lastly, for *social comparison***,** we found a significant positive interaction with performance goal orientations with a large effect (β=0.243; p=0.000; f^2=0.135; H3c supported) but not with mastery goals (β=0.048; p=0.344; H3b not supported) on net benefits. For all models analyzed, we obtained good model fits with SRMR values of 0.062 to 0.073, which are below the threshold of 0.08. We discuss the results next.

6 Discussion

Our research was motivated by the lack of regular physical activity prevailing in most western societies [2] and the inconclusive results about fitness apps and their motivational affordances to increase motivation and physical activity [5, 6, 7]. To resolve the inconsistent findings of prior research, we paid closer attention to the interplay of the self-monitoring, rewards, and social comparison affordances and users' motivation-relevant goal orientations. A quantitative study with 283 users of the fitness app 'Strava' provided support for five of our nine hypotheses. We discuss our findings next before laying out the research contributions, implications, and limitations.

The empirical data highlights the influential role of the three motivational affordances that jointly accounted for 52.7% of the variations of the benefits gained. Self-monitoring emerged to be most influential, which is not surprising as this affordance allows physical activity documentation that is integral to fitness app use [10, 29]. Rewards and social comparison appeared to be less influential, which further increased our interest to take users' goal orientations into consideration. We argued that the influence of motivational affordances varies in dependence upon users' mastery and performance goal orientations. Albeit we only found two significant interactions, these provide meaningful insights for the rewards and social comparison affordances. Because these affordances emphasize a performance goal structure, mostly through leaderboards, they complement particularly performance-oriented users' natural striving for becoming better than others [15] by making their efforts comparable and rewarded on normative bases. Although mastery goal orientations were expected to be a moderating factor as well, we did not obtain the empirical support. This absence can be explained in two ways. First, mastery and performance goal orientations are not mutually exclusive so that individuals can pursue both goals at the same time [13]. Second, Strava positions itself as 'the social network athletes' and our sample consists of quite 'athletic' users holding an above-average mastery goal orientation with little variation (mean 5.52, SD 0.93). As a result, the self-monitoring affordance poses such a strong direct effect that there is little room for variations stemming from users' goal orientations. The rewards affordance in Strava is built on the social network capabilities, particularly leaderboards, so that rewards are here much more based on normative grounds stressing performance goals rather than mastery goals.

Based on the empirical findings discussed so far, we generally note solid support for our theorized interplay of motivational affordances and users' motivation-relevant goals so that our research makes the following contributions to literature and theory.

First, our paper contributes to *fitness app research* [e.g., 5, 6, 7, 16]. As outlined above, little is known about the role motivational affordances of fitness apps play in promoting motivation and physical activity. Parts of this inhibited understanding are caused because prior research mostly examined fitness apps as 'whole' without paying the necessary attention to the particular roles the motivational affordansces play [5]. Thus, we first revealed that the reported benefits of heightened motivation and increased physical activity are generally determined by self-monitoring, rewards, and social comparison affordances. Moreover, prior research also raised awareness that each motivational affordance is not necessarily beneficial for every user – but little has been put forth to understand *why* it can differ [5, 6, 7]. To provide the needed explanations, we took motivation-relevant differences of the users, namely goal orientations, into consideration. We found that the benefits gained from the rewards and social comparison strongly depend upon the goal orientation pursued. Thus, by considering these motivation-relevant differences of the users, our paper resolves parts of the inconclusive findings of prior research [cf. 5, 6, 7]. Our considerations developed here enable further research to better understand the motivational affordances of fitness apps, such as their role in causing psychological need satisfaction and frustration [22] or in promoting continued fitness app use [38].

Second, our paper contributes by *theorizing about motivational affordances and individual differences* [17]. Although motivated by the inconsistent findings in our particular fitness app context, we developed a rather general theoretical account of motivational affordances. As detailed in chapter 2.3 and 3, we noted parallel lines with the key tenets of AGT concerning a) the consequences of interest, b) individual differences in terms of goal orientations, and c) the role of motivational affordances in terms of providing goal structures. This approach provides a refined understanding of the motivation-relevant characteristics of motivational affordances: they act as goal structures with differing emphases on mastery and performance goals. Because of this characterization, our theorizing provides explanations as to why motivational affordances interact with individual goal orientations resulting in variations of the motivational consequences. Our theorizing hereto considers that the motivational affordances and users' goal orientations need to be congruent, sharing the same emphasis on mastery or performance goals. When congruent, the positive consequences amplify yet deteriorate when incongruent. As such, our theorizing provides research with a better understanding of the interplay between motivational affordances and individual, motivation-relevant characteristics. Without this cognizance, researchers may otherwise draw insufficient or misleading conclusions about the role motivational affordances play in achieving the desired outcomes. As such, our theorizing is also useful for other contexts where motivational affordances are expected to favor anticipated outcomes, such as for organizational collaboration systems where similar affordances aim to increase employees' knowledge contributions [39].

For practice, our paper guides the application of motivational affordances in fitness apps. Fitness app vendors need to be aware that users' motivational goal orientations can greatly differ and that motivational affordances are thus not necessarily universally effective in promoting motivation and physical activity. The exposure to motivational affordances, particularly to rewards and social comparison, needs to be tailored to the goal orientations of the users. To achieve this, users' motivational goals should be assessed during initial app interactions in order to expose those affordances that provide the best fit. Then, users are expected to achieve higher benefits for motivation and physical activity so that the expected potentials of fitness apps unfold.

Despite these contributions and implications, we acknowledge some limitations. We focused on one single app offering the focal motivational affordances targeting rather intense cardio sports such as running or cycling. Although fitness app users in this context are already exercising [29], the goals and motives users pursue still differ accounting for differences in the use of cardio-targeting fitness apps [16, 18] and resulting benefits. Likewise, issues concerning the effects of motivational affordances, particularly rewards and social comparison, have also been reported in other fitness app contexts in which users are generally less motivated and in which apps target less intense physical activities such as walking [22]. Thus, to provide further confidence in the theoretical considerations developed here, future research should be carried out across a variety of fitness apps and different target groups, particularly to examine the influence of mastery goals. In this vein, our inquiry is bound to fitness apps offering social network capabilities. Although offered by many popular fitness apps, the app landscape is highly diverse and there are also fitness apps without a 'social dimension' [29], that need to be studied and compared. Hereto, other affordances such as 'exercise guidance' are available depending upon the fitness apps of interest [10, 29] and which can provide further insights. Equally, future research should also investigate other sorts of benefits achieved, such as improved health awareness, to better understand the effects of the motivational affordances provided.

Abstract. Gamification has become a popular and promising tool to positively impact the usage of health behavior change support systems (HBCSSs). Fun and engaging components are purposefully integrated in the design of HBCSSs in an effort to encourage users to employ the system in a more regular manner or over a longer period of time. Although extant research has made extensive efforts to understand the psychological and behavioral outcomes of gamification, its potential unintended side effects have been mostly neglected. We approached this gap by reviewing 33 articles on gamification in HBCSSs. We identified 16 potential unintended side effects in five categories. By taking a critical view, our research contributes to a more nuanced approach to gamification, which helps to understand how it can be utilized as a valuable tool for developers that motivates and does not harm users of HBCSSs.

Keywords: Gamification, Health Behavior Change, Literature Review, Side Effects, Negative Effects

1 Introduction

In today's Western societies the main health challenges and most important risks for mortality have been shifted from pre-modern health risks such as malnutrition and poor water quality to health risks that are generated by the modern world itself, like high blood pressure, tobacco use, high blood glucose levels, obesity, and high cholesterol levels [1]. Thus, major public health concerns are often directly linked to people's individual health behavior and modern lifestyle habits such as sedentary living, chronic stress, and intake of energy-dense foods [1]. Trying to tackle the challenge of unhealthy modern lifestyles, health behavior change support systems (HBCSSs) are a promising approach to positively influence people's health behavior [2-4]. Typical examples of such HBCSSs include systems that aim to foster healthy eating habits [5, 6], systems that motivate their users to be more physically active [7, 8], or systems that help to properly manage chronic diseases [9, 10]. HBCSSs come in many forms, such as wearables, mobile apps or dedicated software. However, recent research suggests that

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

people often do not use HBCSS frequently and over a sustained period of time [11]. As a consequence, the desired beneficial health behavior may not be maintained. Trying to address this issue, developers of HBCSS frequently employ gamification. Gamification refers to the implementation of game elements in non-game contexts [12].

In HBCSSs gamification is primarily applied to make the usage of a HBCSS more engaging and fun, thus encouraging users to use the HBCSS more regularly or promoting the completion of certain health-related activities [2, 4]. However, designing meaningful and effective gamification is associated with high complexity and extensive resource requirements [13]. In fact, researchers have repeatedly criticized practitioners and fellow researchers for oversimplifying gamification by superficially implementing single game elements such as points or badges [14]. Adding to that, recent research suggests that gamification approaches that do not consider the overall application context and gamification concept are less effective than more holistic approaches to gamification [15]. Mindless approaches to gamification might not only lack effectiveness in increasing users' motivation and engagement but additionally cause unintended side effects that could counteract the positive effects of gamified systems or even harm their users [16, 17]. Especially in a context like HBCSSs, where systems are intended to have a positive impact on peoples' health behavior, unintended side effects of gamification can have serious negative influences on users' health outcomes (e.g., by unintentionally incentivizing wrong exercising). Thus, developers of gamified HBCSSs need to be aware of potential unintended side effects in order to incorporate suitable strategies to address them into the design process. Within this research, we hence aim to answer the following research question:

RQ: What unintended side effects may occur when implementing gamification in HBCSSs?

Past research on gamification has focused on investigating the positive effects of gamification on psychological and behavioral outcomes [18, 19] or proposing theoretically grounded frameworks for designing specific gamified systems [e.g., 20]. Risks and negative aspects of gamification were only treated as side notes [e.g., 1, 21]. Some researchers have started to investigate negative aspects of gamification in general [16] or within educational systems [17]. However, those studies are based on the analysis of secondary literature and do not consider the special context of HBCSSs. This is rather problematic since (1) unintended side effects of (gamified) HBCSSs yield potential to seriously harm users' health and thus substantially differ from side effects in less serious contexts and (2) the investigated secondary literature did not thoroughly elaborate on negative aspects of gamification. In consequence, research still lacks a comprehensive overview of unintended side effects of gamification in HBCSSs. Although existing studies make first valuable contributions to the research field, a synthesis of literature is necessary to understand unintended side effects of gamification in particular with regard to specifics of HBCSSs and the serious contexts of HBCSSs.

To answer our research question, we conduct a structured review of literature to identify and analyze relevant academic publications. In particular, we review those publications that discuss and elaborate on potential unintended side effects of applying gamification to HBCSSs. An overview and explanation of unintended side effects of gamification in HBCSSs helps to (1) guide developers of gamified HBCSSs in identifying potential risks within their gamification concepts and (2) raise awareness that gamification is not a silver bullet which creates positive outcomes all by itself and without extensive design considerations.

This paper proceeds as follows. The next section provides an outline of gamification in HBCSSs as well as an overview of research on unintended side effects of gamification. Section three describes our research approach, while section four presents our results. We discuss our results in section five and briefly conclude our paper in section six.

2 Background

2.1 Gamification in Health Behavior Change Support Systems

Literature provides two prevailing definitions for gamification. Huotari and Hamari [22] refer to gamification as the process of enhancing services with motivational affordances for gameful experiences. Hamari et al. [19] advanced this conceptualization by introducing the three essential concepts in gamification research (i.e., implemented motivational affordances, resulting psychological outcomes, and further behavioral outcomes). Deterding et al., define gamification as "the use of game design elements in non-game contexts" [12]. Popular game elements used in gamification include points, badges, leaderboards, and time constraints [12]. In general, gamification aims to utilize peoples' growing passion for games to positively influence their personal motivation or perception concerning a selected action in order to make it more engaging and fun [2, 21, 23]. However, it is important to differentiate gamification and serious games. Gamified systems are no full-fledged games. In fact, game elements in gamified systems are only means to foster certain behaviors and not the main object of the system [24]. Serious games, on the other hand, are fully-developed games that serve specific non-entertainment purposes [24].

Extant research has made extensive efforts to investigate psychological and behavioral effects of gamification in various research fields such as education [25, 26], crowdsourcing [27], or enterprise systems [21]. Among these research fields, HBCSSs have emerged as one of the most relevant application areas for gamification [1, 28]. In HBCSSs, gamification is primarily applied for motivating individuals to continue using the systems more regularly or promoting the completion of activities or tasks that are associated with positive health outcomes [2, 4]. According to extant literature, there are three major groups of use contexts for gamification in HBCSSs [2]: (1) Individual lifestyle habits (e.g., fitness, food consumption, unhealthy habits), (2) chronic disease management (e.g., diabetes, cancer), and (3) support of health professionals (e.g., for educational purposes or daily habits). However, as we focus our research on unintended side effects concerning patients and users aiming to improve their health status as well as the fact that a majority of HBCSSs in group three can also be classified as educational systems, we concentrate our analysis on such HBCSSs belonging to group one and two.

2.2 Unintended Side Effects of Gamification

Extant research on gamification has primarily focused on investigating intended psychological and behavioral effects on gamification. Two studies exist that focus on shedding light on potential unintended side effects of gamification. Hyrynsalmi and Kimppa [16] conducted a meta study and reviewed existing literature reviews on gamification concerning negative impacts. They classify their results in two main groups: (1) Limiting issues and (2) harmful issues. However, they also state that most reviewed studies had only little if any discussion on the negative effects of gamification. As a result, their data basis is scarce and lacks an in-depth discussion of side effects and potential consequences. Second, Toda et al. [17] reviewed literature on gamification in education and identified four negative effects (i.e., indifference, loss of performance, undesired behavior, and declining effects). However, the results of their study are only applicable to the context of educational systems. In addition to these two studies, some research has dealt with risks or negative effects of gamification as a side note. For example, Thiebes et al. [21] have discussed four risks of gamification in information systems, and Johnson et al. [1] outline some negative aspects of gamification found in studies in health and well-being. Furthermore, Kim and Werbach [29] elaborate on ethical issues in applying gamifications such as potential for manipulation and exploitation. In summary, to the best of our knowledge, no study exists that focuses on identifying and purposefully reasoning on unintended side effects of gamification in HBCSSs.

3 Structured Literature Review

3.1 Data Collection

For the identification of publications discussing potential unintended side effects of gamification in a HBCSSs context, we applied a systematic online literature database search following the guidelines by Levy and Ellis [30]. We thus searched the scientific databases IEEE Xplore, ProQuest, AIS Electronic Library, ACM Digital Library, EBSCO Host, and ScienceDirect using the following search string: *TITLE-ABSTR-KEY (gamif*) and TITLE-ABSTR-KEY(health* OR medic* OR life* OR fitness OR well-being) and TITLE-ABSTR-KEY(risk* OR danger* OR peril* OR effect* OR negative* OR disadvantage*).*

Where possible, our search was limited to peer-reviewed publications published in 2010 or later, since gamification only gained widespread recognition by researchers and practitioners in 2010. The database search yielded a total of 212 publications, excluding duplicates. Two researchers separately assessed the relevance of each article by utilizing predefined exclude criteria. In this process, we excluded ten articles not written in English, seven articles that were not peer-reviewed, 140 articles that had no focus on gamification in HBCSSs (i.e., they dealt with related concepts such as serious games or researched gamification in a non-healthcare context), and 43 articles that did not discuss any unintended side effect of gamification. In addition, a forward and backward search was conducted on the twelve relevant articles which lead to the identification of three additional relevant publications and a set of 15 relevant articles. In a second step and in an effort to integrate scientific literature from health and medical perspectives, we searched the scientific database PubMed using our research string. Our PubMed search yielded a total of 145 additional unique publications. By screening these publications against our exclusion criteria, we excluded 104 publications that had no focus on gamification in HBCSSs and 23 publications that did not discuss any unintended side effects of gamification. Through searching PubMed, we identified 18 additional relevant publications, which led to a final set of 33 relevant publications.

3.2 Concept-centric Data Analysis

To identify unintended side effects of gamification in health & well-being, we conducted a manual content analysis. Two researchers independently coded the 33 articles with regard to unintended side effects using an open coding approach [31]. As suggested by Strauss and Corbin [31], during open coding, the data was broken down into discrete parts (i.e., text passages), closely examined, compared for similarities and differences, and coded with regard to the phenomena as reflected in the data. The results were iteratively reviewed and discussed with a third researcher to consolidate them. To improve the explanatory power of our results and to find semantically coherent groups, the identified side effects were grouped into categories if they were logically related to the same subject.

4 Results

Our review of relevant literature yielded a total of 16 potential unintended side effects due to the application of gamification in HBCSSs, which we grouped into five categories of unintended side effects. Table 1 provides an overview of the categories of unintended side effects. It also highlights for which unintended side effects we were able to find empirical support within the reviewed literature and which side effects are specific to the HBCSSs context. We describe each unintended side effect in detail below.

4.1 Adverse Motivational Outcomes

Undermining Intrinsic Motivation. Researchers often argue that gamification aims to foster users' intrinsic motivation in order to make using gamified systems more engaging and fun [32]. However, gamified HBCSSs sometimes tend to focus on extrinsic motivation and thereby even corrupt and undermine intrinsic motivation for positive health behavior change [33, 34]. As a result, users' health behavior may become dependent on the presence of the gamified HBCSSs and their motivation may immediately decrease once the extrinsic rewards are not available anymore [1, 33]. Attig and Franke [33], for example, showed in their study that motivation for physical activity can become dependent on the presence of an activity tracker as well as the related game elements and decreases in case the tracker is not available.

Table 1. Overview of unintended side effects.

Class of Unintended Side Effects	*Unintended Side Effect*	*Sources*	*Empirical support*	*HBCSS specific*
Adverse Motivational Outcomes	Undermining Intrinsic Motivation	[13, 33-42]	[33-35, 38, 40, 41]	No
	Motivation Decreasing Over Time	[15, 35, 38, 40, 43-48]	[35, 40, 43, 45-48]	No
	Unfulfilled Expectations	[36, 45, 49, 50]	[45, 49]	No
Informational Noise	Distraction from Health Purpose	[13, 15, 34, 41, 45, 51, 52]	[15, 45, 51, 52]	Yes
	Trivializing the Health Context	[1, 13, 15, 24, 36, 41, 53]	-	Yes
	Reduced Usability	[13, 15, 45, 54]	[45]	No
Reduced Integrity of Exercise	Cheating the Self	[37, 55]	-	Yes
	Rewarding Incorrect Execution	[34, 36, 56]	-	Yes
	Overuse	[13, 55, 57, 58]	[57]	Yes
Demoralization of Users	Cheating Others	[13, 37, 55, 59]	-	No
	Overemphasized Peer Pressure	[37, 38, 41, 57, 60]	[38, 41, 57, 60]	No
	Exaggerated Punishment	[37, 40]	-	No
	Feeling of Manipulation	[36, 42, 49, 57]	[49, 57]	No
	Discouragement Due to Failure	[36, 61]	-	No
Overstepping Boundaries	Privacy Infringements	[13, 36, 37, 40, 44, 55, 60]	[40, 60]	Yes
	Fostering Behavior that Harms Third Parties	[58]	[58]	No

Motivation Decreasing Over Time. An often-discussed problem with gamification is novelty effects. Novelty effects describe a situation in which users are often curious and enthusiastic for gamification at first, as it is visually appealing and something they did not experience before [15]. However, interest and enthusiasm for gamification most likely decrease in the long run when these novelty effects wear off. With it, motivation to perform healthy behaviors could decrease as well, ultimately dropping below the initial level of motivation. El-Hilly et al. [40], for instance, describe this effect in their study of a gamified HBCSS for smoking cessation where participants exhibited monotony and decreased levels of engagement as they perceived achievements as repetitive.

Unfulfilled Expectations. Gamification of HBCSSs might raise high expectations by claiming to bring fun and engagement to health activities while maintaining therapeutic effectiveness of the system. If these expectations are not met, users might be disappointed, which could lead to decreasing levels of satisfaction. To this end, Lumsden et al. [49] report that participants of their study of different web-based cognitive testing systems were disappointed of a task that had the graphical impression of a game but did not offer any actual gameplay.

4.2 Informational Noise

Distraction from Health Purpose. Sardi et al. [15] point out that gamification concepts sometimes tend to not provide "a tangible health-driven meaning in terms of the user's competence and health skills" and that game mechanics are "sometimes wrongly located on the application's display". As a result, it can be difficult for users to identify a link between the gamification concept and their health behavior and they do not understand the purpose of certain game mechanics. This effect can lead to a distraction from the core health behavior elements of the system and thus reduce the overall system's efficacy [34]. For example, Boendermaker et al. [45] conclude in their study that their gamified HBCSSs for attentional bias modification in the context of alcohol consumption contained distracting game elements that negatively influenced the systems efficacy.

Trivializing the Health Context. Developers of gamification concepts frequently aim to design visual appearances that resemble existing games [21]. Thus, gamification design is often colorful and eye-catching [1]. In some cases, exaggerated visual design might lead to perceptions that important health topics, which deserve a serious and professional tone, might be trivialized and that gamification is more of a marketing gimmick than a serious tool that supports health behavior change [36]. As a result, recent studies reported that some health professionals shy away from participating in designing gamified HBCSSs as they worry about their credibility and respect among patients [15].

Reduced Usability. Introducing gamification to a HBCSS is always associated with adding new possibilities of system interaction for the user. As a result, established paths of human-system interaction may change and users' might initially be confused as the system does not longer work the way it used to. Gamifying HBCSSs adds an additional layer of interaction complexity and, thus, might lead to an initial decrease in usability [15]. For example, Boendermaker et al. [45] observed that participants in a gamified intervention differed with regard to speed and accuracy of responses in comparison to a non-gamified intervention. They ascribe this observation to the more complex nature of the gamified intervention.

4.3 Reduced Integrity of Exercise

Cheating the Self. Gamifying HBCSSs can open the door to cheating and exploiting. Especially users that have higher interest in achieving game rewards than the actual health behavior change sometimes try to achieve a target in a way in which it was not supposed to be achieved according to the game rules [13, 37]. Users cheat by, for example, "exploiting inherent sensor-related limitations to fabricate false detection" [37]. Cheating is also promoted by the fact that most gamified HBCSSs are used while being online and without supervision by professionals, which might lower the threshold for lying [55]. Cheating the self can lead to misdirected incentives and false health behavior and might thus negatively impact health-related outcomes [55].

Rewarding Incorrect Execution. Creating gamified HBCSSs requires a great variety of different resources and expertise [34]. In particular, developers need to ensure that games' rewards and progresses adequately reflect people's health behavior. If the gamification concept is not sufficiently aligned with the desired health behavior change, users might unintentionally be incentivized for wrong or even unhealthy behavior (e.g., distributing a reward although an exercise was not performed correctly) [36].

Overuse. Gamification frequently aims to motivate people to use an HBCSS in a more regular manner. However, gamification concepts that are not sufficiently balanced but instead reward exaggerated repetitions of certain tasks might incentivize users to use an HBCSS too excessively and thus overreaching their personal limits [55, 58]. In an extreme case, gamification concepts might lead to users that are "driven by obsession rather than enjoyment […] resulting in problems relating to overtraining, overexertion and risk taking" [57]. Barrat [57], for example, reported in his study about a gamified HBCSS for cycling that some participants – driven by peer pressure and competition – ended up cycling excessively thereby negatively influencing their overall health and social outcomes.

4.4 Demoralizing Effects

Cheating Others. As stated before, cheating can be an important problem in gamified HBCSSs. When users cheat they often aim to gain an advantage over other users by exploiting certain game mechanisms in a way that should not be allowed according to the game rules [37]. Cheating can ruin the fairness of competitive game mechanisms and might even result in other users giving up [37]. As a result, dissatisfaction among users that do not cheat might increase [13]. Recent research suggests that users are more likely to cheat the more they are exposed to other users cheating [62].

Overemphasized Peer Pressure. Gamification often contains competitive game elements that, for example, enable comparing the scores of different users [37]. However, competition and social comparison is not for everyone. Recent research suggests that introverted users are likely to be demotivated by gamification that contains social comparison [60]. In addition, competitive game elements that publicly compare the scores of different users can also be discouraging to those who have low scores due to temporary setbacks or simply being new to the system [37]. Thus, studies found that social comparison can have negative effects on users' health behavior [38]. For example, Horse-Fraile et al. [41] report of collaborative health app studies in which parents complained about the possibility that their children may become demotivated if other families ranked better than theirs did.

Exaggerated Punishment. Users might also be discouraged due to the feeling of disproportionate punishment. Even regularly active users might get sick or be otherwise unable to perform desired health-related behavior (e.g., exercises), resulting in a sharp drop of their (average) score [37]. Although this drop might sufficiently represent reality, users' might perceive it as unreasonable and unrepresentative of their health behavior and thus get discouraged or even stop using the HBCSS [37].

Feeling of Manipulation. Gamification aims to foster users' motivation to perform certain activities in a specific way or in a more regular manner, for example, by applying rule-based systems. This could cause users to perceive a feeling of being manipulated or forced into performing those actions, especially if the underlying health activity is inherently unstructured and requires a great degree of autonomy. For example, Barratt [57] reports that participants in a study of a cycling application complained about negative experiences due to a restricted level of autonomy.

Discouragement Due to Failure. Gamification often relies on goal-oriented game elements. These may discourage users if they fail to meet certain goals despite putting in a lot of effort. According to extant literature, it is particularly important for more serious contexts such as heart diseases [61] that developers avoid a sense of defeat while adjusting the level of difficulty according to users' capabilities.

4.5 Overstepping Boundaries

Privacy Infringements. Information about users' health status and health behavior is often sensitive and subject to specific laws which limit the disclosure of healthcare information without explicit consent from the user [36]. Implementing gamification in HBCSSs can add another level of complexity concerning privacy and data protection [13]. Based on game elements additional health information about HBCSS users might be gathered and stored. For example, users' badge collections might disclose information about health status and past health-related behaviors. This can be particularly problematic when unknown third parties, such as employers or insurance companies, start reviewing badge collections by individuals or user groups for specific purposes [36]. Research also indicates that some users are more likely to participate in HBCSSs if they are not required to disclose personal data [60].

Fostering Behavior that Harms Third Parties. Gamification of HBCSSs might also cause unintended side effects for third parties outside of the system. This was particularly observed in GPS-based HBCSSs that aim to foster physical activity and use auto-generated outdoor locations for specific rewards. For example, in 2011 an object used in a GPS-based gamified HBCSS was placed in the Downtown Disney Park in Anaheim, CA, USA. As a result, people that not played the game were scared and triggered a bomb alarm. This led to temporary closure of the park [58]. Another example for behavior that harms third parties might be overcrowding of specific real-world places that promise special rewards as observed in the beginning of Pokémon GO.

5 Discussion

Our objective within this research was the identification and analysis of unintended side effects of gamification in HBCSSs. Building on the results described in section four, we were generally able to provide answers to our research question and thus contributed to the knowledge base on gamification. We discuss some of the most interesting findings and their implications in the following.

By intensively reviewing and discussing the 16 identified side effects, we were able to build five logically coherent groups of unintended side effects. First, adverse motivational outcomes describe those side effects which basically result in the main objective of gamification (i.e., fostering user motivation and engagement) not being achieved. Reasons for the occurrence of side effects of this group are diverse. Many researchers emphasize that applying gamification is a demanding process that requires excessive resources and expertise in order to be effective [13, 15]. When developers decide not to include game design knowledge in the design process and instead go for "cheap" gamification solutions that are based on extrinsic rewards that are easy to implement and promise short-term behavior change, their gamification approach is likely to fail in the long run. If adverse motivational outcomes occur, they are likely to negatively impact users' adoption of gamified HBCSSs. Second, informational noise describes unintended side effects that are related to a flawed visual representation and interaction concept of the gamified HBCSSs. They are often caused by insufficient consideration of the unique seriousness of the health context and thus choosing inappropriate gamification elements. If those unintended side effects occur, users' might perceive an HBCSS as being less professional and serious. Third, reduced integrity of exercise describes those unintended side effects that can directly lead to health-related disadvantages for the user. Thus, it is particularly important to prevent these side effects from occurring. They are often caused by not carefully aligning the gamification concept of HBCSSs with their core activities and thus providing users with wrong incentives. Fourth, demoralization of users describes unintended side effects that might cause users to stop using the system because they feel treated unfairly. Fifth, overstepping of boundaries describes those side effects that might lead to legal issues for developers of gamified HBCSSs. In order to prevent legal uncertainties in particular when considering the high sensitivity of health-related data, it is very important for developers to prevent these side effects from occurring.

As mentioned before, some side effects are more specific to HBCSSs than others. For example, although cheating the self might occur in any gamification context, its potential consequences are particularly critical in HBCSSs as they threaten the correct execution of health behavior and thus yield potential harm to users' health. Another side effect that is strongly linked to HBCSSs is the trivialization of the context. While colorful and eye-catching design themes might be unproblematic for less serious contexts, within HBCSSs users might perceive them as especially inappropriate and unprofessional and subsequently avoid using the system for a serious context such as healthcare.

Our research yields some implications for practice. First, by presenting and discussing our results we show that developers of HBCSSs need to be aware of potential drawbacks of gamification. In addition, developers need a set of suitable prevention strategies to address these potential side effects when designing gamified HBCSSs. However, it was beyond the scope of this work to derive such prevention strategies. Thus, we leave it to future research and to developers of gamified HBCSSs to carefully develop prevention strategies that fit the diverse application scenarios of HBCSSs. Concerning implications for research, existing frameworks for gamification of HBCSSs mostly have been created on the basis of potential positive effects of gamification. With regard to our results we think that existing frameworks should be critically reviewed and evaluated whether they adequately consider unintended side effects of gamification.

Our research contributes to the scientific knowledge base in several aspects. By synthesizing knowledge on unintended side effects of gamification in HBCSSs, we contribute to the conceptual knowledge on gamification in the context of health and well-being. In particular, although we acknowledge the various potential positive aspects of gamification, we contribute to conceptual knowledge by taking on a more critical view of gamification, which has so far been underrepresented in gamification research [16, 29]. This critical view leads to a more nuanced perception of gamification and thus contributes to a better understanding of how to apply gamification as a valuable tool that motivates and does not harm users of HBCSSs.

The limitations of this study are as follows. First, our literature base is limited to 33 articles that discuss potential unintended side effects of gamification in HBCSSs. This shows that the topic received only little attention among researchers so far. Although we carefully performed our keyword-based search, we cannot rule out the possibility that we might have missed relevant articles. Second, there are different kinds of HBCSSs with various levels of context seriousness [2]. Thus, side effects might also differ between these different types of HBCSSs. It would be interesting for future research to delve deeper and compare potential side effects of different types of HBCSSs. Lastly, interpreting literature and text passages always leave some room for interpretation. However, we aimed to address this issue by carefully performing the concept-centric data analysis and developing a common understanding of side effects while synthesizing the literature. Future research might further strengthen the knowledge base by conducting qualitative research and gathering primary data from experts of the field. Future research could also aim to delve deeper in order to understand the underlying reasons for the observed side effects and the circumstances under which they occur.

6 Conclusion

Although gamification has received tremendous attention from practitioners and researchers interested in HBCSSs, little attention has been paid to the unintended side effects that potentially come with the implementation of gamification in HBCSSs. Within this research, we have taken a first step towards closing this gap by reviewing past research on gamification in HBCSSs and synthesizing 16 unintended side effects that may occur when using gamification. Our research adds to the knowledge base on gamification by, for the first time, providing a comprehensive overview of potential unintended side effects. We also contribute to a more nuanced view of gamification, which helps relieving gamification from unrealistic expectations threatening to position it as a silver bullet rather than a valuable tool for developers of HBCSSs. Future research should delve deeper into this topic and examine in more detail under which circumstances such side effects can occur and how they can be avoided or counteracted.

Investigating the Influence of Information Incongruity on Trust-Relations within Trilateral Healthcare Settings

Marius Mueller[1], Oliver Heger[1], Bastian Kordyaka[1], and Bjoern Niehaves[1]

[1] University of Siegen, Chair of Information Systems, Siegen, Germany
{firstname.lastname}@uni-siegen.de

Abstract. Modern health information technologies (HIT) come with many benefits for healthcare, such as a decrease of necessary clinical visits or independent health monitoring. The deployment of these technologies to support medical treatments expands the traditional patient-physician relationship to a trilateral setting involving patient, physician, and HIT. Whereas patients formerly relied on health-related information given by their physician, the digitization of healthcare as well as increasing levels of individual health literacy represent new sources of information and, thus, call for investigating different forms of trust towards medical experts, technologies, and the patient's own judgements. Information incongruities, however, can lead to new forms of trust issues, thus calling for dedicated research. We propose a vignette study in the form of an online survey to investigate the influence information incongruities can have on different forms of patient-sided trust. For this, we develop hypotheses representing our expected results.

Keywords: HIT, Trust, Information Incongruity, Health Literacy, Self-efficacy.

1 Introduction

Traditional healthcare settings involve relationships between patients and one or more medical experts such as primary care physicians that are largely based on interpersonal trust, empathy, and satisfaction with treatments [1]. Patient-sided trust in physicians leads to compliance with instructions, assessments, and advices [2], which in turn increases the effectiveness of medical treatments. Whereas traditional patient-physician relationships evolve around the patient following and complying with recommendations and judgements made by the physician, a deliberative relationship model emerged throughout the last decades that calls for a higher degree of patient participation and autonomy regarding clinical processes [3, 4]. This autonomous and deliberative stance becomes more important in the light of modern developments and deployments of technologies for healthcare, often referred to as health IT (HIT) [5].

The implementation of HIT within medical processes and, thus, patient-physician relationships introduces a new source of health-related information. Hence, the medical setting becomes more complex and new relationships are formed. On the one hand, patients interact with mobile, self-managed HIT systems [6] or more complex ones that are deployed in their home environment [7, 8]. For example, they are enabled to

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

autonomously retrieve information about their health status and the potential need for interventions. Wearable sensors, for instance, can measure the patient's heart rate and cardiac status throughout the day [9]. On the other hand, physicians deploy HIT systems to support patient care, to reduce the number of face-to-face meetings through health status monitoring (gathered by wearable sensors or patient input), or to mediate therapeutic instructions using telemedical tools such as live video sessions [10]. Hence, HIT represents a new 'actor' within healthcare settings, enabling new forms of interaction. A transition from bilateral to trilateral relationships becomes apparent.

However, by dissolving former power-imbalances between patients and physicians through HIT deployment, these new forms of relationships are prone to deteriorations, for instance evoked by informational gaps and differing outcome expectations between patients, experts, and technologies [11]. Since HIT systems represent an additional source of health-related information, new issues arise. The HIT's behaviour and output might contradict the information the patient or physician have, which potentially evokes questions on whether the patient or physician might be wrong in their assessment [11]. This, in turn, might deteriorate prevalent trust-relations. From a patient perspective, three trust-forming relations can be identified, which are trust in the physician [1], trust in the HIT [12], and trust in oneself (regarding knowledge and actions) [13]. A decrease in trust can originate from different forms of information incongruity and resulting skepticism towards the source of information trusted the least [12]. As suggested by Cognitive Balance Theory, imbalances within a trilateral setting (e.g. patient trusts physician and HIT but physician and HIT contradict each other) lead to discomfort [14].

This study's goal is to shed light on the emergence of trust issues within trilateral healthcare settings evoked by information incongruity between involved actors, which delivers implications for HIT design and solutions to hamper the deterioration of trust. Consequently, this study is guided by the following research question (RQ):

RQ: *How do information incongruities within a trilateral healthcare setting influence patient-sided forms of trust (trust in physician, a HIT, and in oneself)?*

2 Trust in Physician, HIT, and Oneself

Trust is the willingness of people to be exposed in risky situations [15] and depend on another party [16]. From the patient's perspective within the trilateral setting, trust is their willingness to depend their health on 1) the physician, 2) the health information technology, and 3) their own health knowledge and capabilities.

Trust between a patient and a physician depends on many factors. Among others, significant drivers of interpersonal trust within a patient-physician relationship are perceived empathy, the patient's satisfaction with courses and outcomes of treatments [1], patient-centered communication [17], and autonomy [18] as well as perceived control [19]. Patient-sided trust in recommendations, treatment instructions, and overall assessments made by a physician is expressed through the patient's compliance [2]. Non-compliance can interfere with the patient's health and therapeutic efforts [20]. As a result, the effectiveness and outcome of therapies and medical treatments greatly depend on this relationship and emerging trust-relations.

Besides trust in the human expert, trust in HIT itself plays a role in shaping the trilateral setting. Trusting beliefs in a specific technology is shaped by trust in its functionality, reliability, and helpfulness [21]. The formation of trusting beliefs in IT can be explained by ease of use, system quality perceptions, uncertainty avoidance culture, and institution-based trust [22]. Furthermore, the formation of trust in technology is influenced by the performance, process, and purpose of the IT artifact itself [23]. Trust is not only a desirable condition within a medical setting itself, but an important precondition for a successful adoption of "risky" and novel technologies [24].

The third trust relationship of interest is the patients' trust in their own competence to assess the appropriateness of a medical treatment and/or to carry out the medical treatment by themselves (e.g. physiotherapeutic activities at home). This trust relationship can be represented by the constructs of 'self-efficacy' and 'health literacy'. Self-efficacy deals with one's "*judgment of their capabilities to organize and execute courses of action required to attain designated types of performance*" [25] (p. 391). Studies indicate that self-efficacy related to health practices shows strong relationships with health behavior [13]. Besides this, computer self-efficacy could additionally play a significant role within the trilateral setting, since the patient is expected to use technology [26]. Similarly but from a more dispositional perspective, health literacy is "*the ability to understand and interpret the meaning of health information in written, spoken or digital form*" [27] (p. 144). Health literacy is an essential factor when it comes to the deployment of HIT, since their success depends on the effective communication with different audiences, who have unique needs and capacities [28].

3 Hypotheses

Based on the trilateral setting including patient, HIT, and physician, we derived the following hypotheses (Table 1):

Table 1. Hypotheses (Pa.=Patient, Phy.=Physician; solid=congruent, dashed=incongruent)

Hypothesis	*Illustration*
H1: Information incongruity between patient, HIT and physician negatively influences trust in patient, HIT, and physician.	H2a: Information congruity between patient and HIT and information incongruity between patient or HIT and physician negatively influences trust in physician.	H2b: Information congruity between patient and physician and information incongruity between patient or physician and HIT negatively influences trust in HIT.	H2c: Information congruity between HIT and physician and information incongruity between HIT or physician and patient negatively influences trust in patient (self-efficacy).	
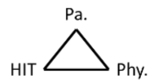
H3: Information congruity between patient, HIT and physician positively influences trust in patient, HIT, and physician.



4 Method and Outlook

To empirically test our hypotheses, we plan to conduct a between-subjects vignette study with an online survey given out to a self-selected convenient sample consisting of patients. To acquire a sample of sufficient size, we distribute the survey link via a network of regional primary care physicians as well as via social media. Each of the five conditions within the trilateral setting (cf. Table 1) is represented by two vignettes. To ensure external validity, we interview primary care physicians in a preliminary step. In doing so, we aim for constructing viable vignettes that depict common treatment scenarios that often occur among patients with chronic conditions. Since trust forms over time, the investigation of such conditions seems promising. Hence, we target participants who have experienced chronic treatments.

We aim for constructing two vignettes. The first vignette describes a scenario in which the participant is instructed by a HIT to take pills and receives congruent (or incongruent) information. The second vignette describes a more complex scenario in which the participant has to carry out a physiotherapeutic exercise. Following each vignette, the participant has to answer the same questionnaire. The two vignettes are presented in a random order. The reasons for presenting two vignettes per condition is to account for external validity and to alter the degree of scenario complexity, since trust is especially relevant in complex situations [29].

For the questionnaire, we plan to adapt the eleven items of the "Trust in Physician Scale" [19] to measure interpersonal trust between participants and the physician. For the participants' trust in HIT, we adapt the eleven "Trust Belief in Specific Technology" items from McKnight et al. [21]. For participants' trust in themselves, we adapt relevant items from the SRAHP scale [30] and the European Health Literacy Questionnaire (HLS-EU-Q) [31]. We further include demographic and control variables. For data analysis, we plan to conduct three separate 2 (simple vs. complex scenario) x 5 (trilateral trust settings depicted in Table 1) mixed ANOVAs with complexity as within-subject factor, information congruity as between-subject factor, and the three forms of trust (trust in physician, the HIT, and in oneself) as dependent variables.

Based on the results of this study, we plan to derive and empirically evaluate technology design implications to deal with the matter of trust. Although the trilateral setting described in this paper is a simplified model, we believe that considering potential information incongruities in the design of health information technologies will increase trust in and the acceptance of digital healthcare interventions.

Abstract. In der Sicherheits- und Krisenforschung stehen bislang primär Fragen der Vulnerabilität, Stärkung von Resilienz und Erhaltung bzw. Wiederherstellung kritischer Infrastrukturen (KRITIS) im Mittelpunkt; zunehmend wird auch die Bedeutung von Sozialen Medien und Krisen-Apps erkannt. Inwiefern ist die Zivilbevölkerung in Deutschland aber auf das Eintreten einer Krise tatsächlich vorbereitet? Welche Informations- und Kommunikationstechniken (IKT) werden im Alltag und bei einem potentiellen Infrastrukturausfall genutzt? Unser Beitrag stellt die Ergebnisse einer repräsentativen Umfrage mit 1024 Teilnehmern in Deutschland vor, die belegen, dass Gefahrenbewusstsein, Vorbereitung, effektives Krisenmanagement und Verbreitung von Krisen-Apps in Deutschland noch relativ gering sind, während traditionelle Kommunikations- und Informationskanäle sowie informelle Informationsnetzwerke bevorzugt werden. Die Ergebnisse stellen weiterhin die beträchtlichen Unterstützungspotentiale von IKT in derartigen Krisensituationen heraus, die zur Erhöhung des Risikobewusstseins, der Erleichterung des Informationstransfers und der Verbesserung der Kommunikation zwischen Zivilbevölkerung, KRITIS-Betreibern und Behörden und Organisationen mit Sicherheitsaufgaben (BOS) entscheidend beitragen können.

Keywords: Kritische Infrastrukturen, Informations- und Kommunikationstechnologien, Krisenkommunikation, Krisenmanagement, repräsentative Studie

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

1 Einleitung

Obgleich in Europa extreme Naturereignisse wie Hochwasser, Überschwemmungen und Stürme besonders häufig vorkommen [1], ist Deutschland aufgrund seiner Infrastruktur indes eher selten von kollektiven Krisen[1] und längerfristigen Infrastrukturausfällen von z. B. Strom und Telekommunikation betroffen [2]. Ein geringes Gefahrenbewusstsein der Zivilbevölkerung erhöht jedoch das Schadenspotential, denn das Gefühl für die eigene, potentielle Verwundbarkeit und eine entsprechende Prävention für Ausfälle scheint nicht präsent zu sein [3]. Im Krisenfall greifen die betroffenen Parteien auf verschiedene Quellen zurück, um sich Informationen zu beschaffen und diese anzubieten, die zivilgesellschaftliche Kontinuität zu wahren und unter anderem mittels Informations- und Kommunikationstechnologien (IKT) zusammenzuarbeiten [4], [5]. Während der IKT-Einsatz in Krisen vor allem seit den Anschlägen vom 11. September 2001 in New York ein eigenes Forschungsgebiet – Crisis Informatics – darstellt [4], fehlt es noch an repräsentativen Studien zu Informationserwartungen, Vorbereitungen für und Verhalten während Krisen – insbesondere in Mitteleuropa. Unsere Studie versucht, dieses Desiderat zu adressieren und beschäftigt sich mit folgenden vier Forschungsfragen:

FF1: Wie schätzen Bürger in Deutschland ihr eigenes Verhalten sowie den Grad an Vorbereitungen und Wissen bei einem Infrastrukturausfall ein?

FF2: Über welche Medienkanäle kommunizieren und informieren sie sich in Krisensituationen und warum?

FF3: Welche Arten und Kanäle von Informationen erwarten sie von KRITIS-Betreibern?

FF4: Wie kann IKT das Bewusstsein schärfen, Verhalten anleiten sowie die Kommunikation und zivilgesellschaftliche Kontinuität in solchen Situationen unterstützen?

Dazu wird in unserem Beitrag zunächst der bisherige Forschungsstand zum soziotechnischen Charakter kritischer Infrastrukturen (KRITIS) und der Krisenkommunikation analysiert (Abschnitt 2). Im Anschluss werden die Methodik (Abschnitt 3) und die Ergebnisse einer repräsentativen Umfrage in Deutschland (Abschnitt 4) geschildert, die auf die Beantwortung der zuvor gestellten Forschungsfragen zielen. In der anschließenden Diskussion und im Fazit (Abschnitt 5) werden die Ergebnisse hinsichtlich der vier Forschungsfragen reflektiert und die Implikationen für weitere Forschung und IKT-Gestaltung zusammengefasst.

Die Ergebnisse deuten auf ein geringes Bewusstsein und eine geringe Vorbereitung in Bezug auf das Risiko eines KRITIS-Ausfalls hin. Informationsbeschaffung und Kommunikation über verschiedene Medienkanäle erzeugen einen hohen Bedarf an spezifischen, zeitnahen und zuverlässigen Informationen und Handlungsempfehlungen. Zudem stellt dieser Beitrag die Potentiale der IKT-Nutzung in KRITIS-Ausfällen und Anforderungen an deren Gestaltung in Bezug auf Bedürfnisse und Eigenschaften der Nutzer heraus.

---

[1] Unter einer kollektiven Krise wird eine öffentlich wahrgenommene, beschleunigt (rapide) in Erscheinung tretende gravierende Problemsituation oder -entwicklung, die mit den üblichen Problemlösungsverfahren nicht bewältigt werden kann, verstanden [27].

2 Stand der Forschung

Eigenschaften sozio-technischer kritischer Infrastruktur. Infrastruktur kann definiert werden als ein zugrunde liegender Rahmen, welcher einer Gruppe, Organisation oder der Gesellschaft allgemein ein Funktionieren ermöglicht und aus materiellen, institutionellen und persönlichen Teilaspekten besteht [6]. In diesem Fall wird die materielle Kategorie betrachtet, vor allem die Bereitstellung von Ressourcen wie Energie und (Tele-)Kommunikation, die auch als kritische Infrastrukturen (KRITIS) bezeichnet werden. Der Rat der Europäischen Union definiert KRITIS als eine „Anlage, ein System oder ein Teil davon, die von wesentlicher Bedeutung für die Aufrechterhaltung wichtiger gesellschaftlicher Funktionen, der Gesundheit, der Sicherheit und des wirtschaftlichen oder sozialen Wohlergehens der Bevölkerung sind und deren Störung oder Zerstörung erhebliche Auswirkungen […] hätte" [7], in Form einer Unterbrechung der gesellschaftlichen und betrieblichen Kontinuität [8].

Auch wenn Infrastrukturausfälle nicht völlig vermeidbar sind, ist die Stromversorgung in Deutschland vergleichsweise stabil; Stromausfälle sind selten und relativ kurz [2]. Dies hat zur Folge, dass viele Bürger in Deutschland noch nie einen solchen Notfall erlebt haben und dementsprechend unvorbereitet sind, z. B. in Bezug auf Risiken und Sicherheitsmaßnahmen sowie Kommunikations- und Informationskanäle. Die Bürger erwarten, dass sich Behörden und Organisationen mit Sicherheitsaufgaben (BOS) um die potenzielle Krise kümmern [9]. Selbst wenn die Bürger eine Krise erlebt haben, ist die Wahrscheinlichkeit, dass sie vorbeugende Maßnahmen ergreifen, recht gering, da sie ein erneutes Auftreten für nicht wahrscheinlich erachten.

Die Vorbereitung auf eine Krise und die Stabilität einer KRITIS kann das Risiko von Zusammenbrüchen jedoch nur verringern, sodass die Reaktionen der Bürger und Behörden entscheidend für das Notfallmanagement, die Systemkontinuität und den Wiederaufbau sind. Diese „soziale Resilienz" beinhaltet allerdings nicht nur die Vorbereitung der Bürger auf eine mögliche Krise, sondern auch das Ermöglichen einer effektiven Ausbildung, Rahmenvereinbarungen und Kommunikation zwischen Experten, Behörden, Infrastrukturbetreibern, Medien, Einsatzkräften, Freiwilligen und Bürgern [8]. Hier entsteht „menschliche" oder „soziale Infrastruktur" [10], d.h. Organisationen, Teams oder Gruppen von Menschen, die gemeinsam agieren, sich unterstützen, kommunizieren und Informationen austauschen. Heutzutage werden diese Zusammenschlüsse zunehmend durch die Benutzung von sozialen Medien etabliert und tragen dazu bei, bestimmte Infrastrukturfunktionen und öffentliche Sicherheit aufrechtzuerhalten und effizienter wiederherzustellen [11].

Krisenkommunikation und Voraussetzungen für IKT. Krisenkommunikation bezieht sich meist auf die One-to-Many-Kommunikation und das öffentliche Image einer Organisation [12] – in unserem Fall das des KRITIS-Betreibers. Zusammen mit offiziellen Informationsquellen werden informelle Mittel in hohem Maße sowohl von Bürgern als auch von Einsatzkräften genutzt – insbesondere wenn zentrale Informationen fehlen –, um aktuelle Informationen zu sammeln und auszutauschen, um den Überblick zu behalten, Hilfe zu organisieren, mit Freunden und Familie in Kontakt zu bleiben und aktive oder moralische Unterstützung anzubieten [5]. Neben sozialen Medien, die seit ihrem Aufkommen verstärkt in Krisen genutzt und untersucht werden, unterstützen Multikanalsysteme die Verbreitung von Notfallwarnungen, z.B. via SMS, E-Mail und RSS [13]. Eine aktuelle Studie ergab indes, dass 16% der Bürger in Deutschland Krisen-Apps benutzen [14]. Mit einer wachsenden Anzahl an Medienkanälen und einer schnellen Verbreitung von Inhalten besteht jedoch die Gefahr einer Informationsüberflutung und Fake News, unklarer Quellen und unvollständiger Informationen [5], [15]. Die Benutzerfreundlichkeit und Glaubwürdigkeit eines Kommunikationskanals haben einen großen Einfluss auf dessen Nutzung [5]: Betroffene Parteien nutzten primär traditionelle Medien wie TV, Radio und Zeitungen, da diese im Allgemeinen als glaubwürdigste Quellen gelten [5], [16]. Auch direkte Kommunikation durch persönliche Gespräche, Telefonate und SMS werden als wichtig empfunden [5].

Um bei einem Infrastrukturausfall die gewünschte Reaktion einzuleiten, müssen KRITIS-Betreiber die Menschen über aktuelle Entwicklungen auf dem Laufenden halten, einen Dialog herstellen und während der Krise ehrlich, ansprechbar und glaubwürdig erscheinen. Zudem sollten ihre Mitteilungen mit vertrauenswürdigen Referenzen übereinstimmen [12]. Menge, Art, Medium und Quelle von Informationen haben einen großen Einfluss auf die Wahrnehmung der Krise, der dahinterstehenden Organisation sowie auf die Resonanz der Bevölkerung [5], [15]. Während einer Krise sollten Aktualisierungen bzw. Statusmeldungen, vor allem über die Dauer des Ausfalls, möglichst schnell erfolgen, um emotionale Strapazen, negative Reaktionen, Missverständnisse und unvorhersehbares Verhalten zu vermeiden – vor allem bei Widersprüchen zwischen den Quellen [17]. Eine Umfrage in vier europäischen Ländern zeigt, dass je mehr Teilnehmer soziale Medien nutzen, desto höher die Erwartung dieser Personen ist, dass KRITIS-Betreiber solche Plattformen verwenden, um Informationen bezüglich des anhaltenden Infrastrukturzusammenbruchs zu teilen [16]. In der Studie konnte ein signifikanter Altersunterschied in Bezug auf die Nutzung sozialer, nicht aber traditioneller Medien festgestellt werden.

Forschungsdesiderate. Wenn KRITIS ausfallen, konzentriert sich die Forschung vor allem auf die komplexen Auswirkungen und die Bewältigung des Ausfalls, aber auch auf die Kontinuität und Widerstandsfähigkeit der betroffenen Bevölkerung. Während es Studien darüber gibt, auf welche Art Notfallinstitutionen wie z. B. Polizei und Feuerwehr kommunizieren und auf Infrastrukturzusammenbrüche reagieren, wurde die zivile Kommunikations- und Kontinuitätsaufrechterhaltung – insbesondere in Mitteleuropa – nicht umfassend untersucht [16]. So ist beispielsweise nicht hinreichend erforscht, inwieweit die Öffentlichkeit in diesen Bereichen über ihre lokale Infrastruktur und Krisenmaßnahmen – insbesondere alternative Infrastrukturen – informiert ist. Auch welche Art von Informationen die Öffentlichkeit vom KRITIS-Betreiber erwartet und über welche Kanäle diese kommuniziert werden, erfordert eine genauere Betrachtung. Zudem liegen viele relevante Studien bereits über ein Jahrzehnt zurück, weshalb Bedarf an einer Betrachtung im Kontext aktueller technischer Entwicklungen und entsprechender Einstellungen der Nutzer besteht. Eine Studie, die ähnlichen Fragen nachging, bildet allerdings die europäische Bevölkerung nicht demografisch ab [16]; dies wollen wir durch eine repräsentative Studie ergänzen, indem wir ein möglichst breites Spektrum an Teilnehmern verschiedener Alters- und Einkommensgruppen, Bildungsgrade und verschiedener Herkunft (Bundesländer) befragt haben.

3 Methodik

Die Daten dieses Beitrags stammen aus einer repräsentativen Onlinebefragung, die wir im Juli 2017 in Deutschland unter Nutzung des ISO-zertifizierten Panelproviders GapFish (Berlin) durchgeführt haben. Zur Beantwortung der Forschungsfragen verwenden wir drei geschlossene und eine offene Frage (siehe Anhang), die sich bzgl. der Fragen zu Stromausfällen bei [18] sowie bei Fragen zu Erwartungen Infrastrukturanbietern gegenüber bei [16] orientiert haben, und sich auf das Verhalten und die Mediennutzung während eines Infrastrukturausfalls beziehen. Die Teilnehmer wurden zur Nutzung verschiedener Medienkanäle in Krisensituationen befragt (Q1) bzw. welche Art der Kommunikation sie von KRITIS-Betreibern bei einem Ausfall erwarten (Q2). Überdies sollten sie ihre Kenntnisse in Bezug auf die von Behörden ergriffenen Maßnahmen im Falle eines Notrufausfalls angeben (Q3). Die letzte, offene Frage bot Raum zur Beschreibung des eigenen Verhaltens im Notfall (Q4). Da Krisen durch Infrastrukturausfälle selten sind, konnten die Fragen auch hypothetisch beantwortet werden – unabhängig davon, ob eine solche Situation schon erlebt wurde oder nicht.

Studienteilnehmer. Die Stichprobe der Befragten (N=1.024) wurde an die Verteilung von Alter, Region, Bildung und Einkommen entsprechend der allgemeinen deutschen Bevölkerung [19–21] angepasst. Entsprechend dieser Statistik bestand unsere Stichprobe aus 49,5 % weiblichen und 50,5% männlichen Befragten zwischen 18 und 64 Jahren, von denen fast die Hälfte 45 Jahre und älter war (48%). Wir befragten Teilnehmer aus allen Bundesländern, wobei die größten Teilnehmerzahlen aus Nordrhein-Westfalen (22%) und Bayern (16%) stammten. Nur 1% der Teilnehmer hatte keinen Schulabschluss; 15% besaßen einen Hochschulabschluss. Die Mehrheit verdiente monatlich zwischen 1.500€ und 3.500€ brutto. Ebenso erhoben wir Gewohnheiten zur Techniknutzung mittels einer Fünf-Punkte-Skala (von „stündlich" bis „niemals"). Für das Smartphone gaben fast die Hälfte aller Teilnehmer an, dieses täglich zu nutzen (49%). Ein ähnliches Ergebnis fanden wir bezüglich der täglichen Nutzung von sozialen Medien, z.B. Facebook (46%), Messengern (43%) und YouTube (28%). Insgesamt 33% gaben sogar eine stündliche Nutzung von Smartphones und Messengern an.

Datenanalyse. Für unsere Analyse haben wir zunächst unvollständige Datensätze eliminiert und die Teilnehmerzahl von N=1.069 auf N=1.024 reduziert. Zudem haben wir demografische Variablen wie Alter und Einkommen zu Kategorien zusammengefasst, um einen besseren Vergleich zu ermöglichen. Im Anschluss haben wir die Häufigkeit und Prozentsätze der Antworten auf die geschlossenen Studienfragen in Microsoft Excel berechnet. Zur statistischen Analyse der Daten haben wir das Softwarepaket IBM SPSS Statistics 25 verwendet. Nichtparametrische Tests wurden auf Grundlage von Ordinaldaten ausgewählt. Die Chi-Quadrat-Tests dienten dazu, signifikante Unterschiede zwischen den demografischen Merkmalen sowie den Gewohnheiten und Einstellungen zur Mediennutzung zu untersuchen. Korrelationen zwischen Variablen wurden unter Benutzung des Spearman-Rangkorrelationskoeffizienten bestimmt. Für die qualitative Analyse der offenen Frage wurde die Methode des Open Coding [22] angewandt. Die daraus resultierenden Erkenntnisse stellen eine wichtige Ergänzung der Ergebnisse aus der quantitativen Analyse dar. Nachfolgend werden die Befunde unserer Analysen entsprechend der Forschungsfragen präsentiert.

4 Ergebnisse

4.1 Mediennutzung während Krisen

Eine unserer Fragen bezog sich darauf, welche Informationsquellen die Befragten in einer von ihnen erlebten Krisensituation genutzt haben bzw. welche für sie besonders nützlich waren (siehe Tabelle 1). Für ein Drittel der Teilnehmer (34%) war das Fernsehen eine sehr hilfreiche Quelle während einer Krise, gefolgt von Radio (30%), sozialen Medien (20%), persönlicher Kommunikation (17%) und Notrufdiensten (15%). In der Summe nutzen die meisten Personen den Fernseher (82%) und führten persönliche Gespräche mit Freunden, Familie und Nachbarn (74%). Weitere 74% hörten Radio und 61% führten Telefonate. An fünfter Stelle standen soziale Medien, die von 55% der Befragten genutzt wurden, dicht gefolgt von Zeitungen und Zeitschriften (54%). Andere Medien wurden von weniger als der Hälfte der Befragten verwendet. Krisen-Apps waren der am wenigsten genutzte Medienkanal (25%).

Tabelle 1. Ergebnisse zu Q1: Welche der folgenden Möglichkeiten haben Sie in einer akuten Krisensituation (als Sie selbst betroffen waren / als Sie Helfer(in) waren) genutzt, um sich über die Ereignisse zu informieren, und welche waren für Sie sehr hilfreich?

	Ja, war sehr hilfreich	*Ja, habe ich genutzt*	*Nein*
Fernsehen	34%	48%	18%
Persönliche Gespräche	17%	57%	26%
Radio	30%	44%	27%
Telefonische Gespräche	14%	47%	38%
Soziale Medien	20%	35%	46%
Zeitungen/Zeitschriften	12%	42%	46%
Andere Internetangebote	12%	31%	58%
Kontakt zu Hilfsdiensten	15%	22%	63%
Informationen vor Ort	9%	25%	66%
Krisen-App	10%	15%	74%

Alle Quellen korrelierten signifikant miteinander ($p<.01$). Auch hinsichtlich demografischer und soziotechnischer Faktoren konnten wir signifikante Einflüsse auf die Antworten finden. Dazu fassten wir die Antwortmöglichkeiten in drei Gruppen zusammen: traditionelle Medien (Fernsehen, Radio und Zeitung/Zeitschriften), digitale Medien (soziale Medien, Krisen-Apps und Webseiten) und persönliche Kommunikation vor Ort (Informationen vor Ort, persönliche Gespräche und Hilfsdienste, siehe Tabelle 2). Geschlecht und Region hatten keinen signifikanten Einfluss auf die Nutzung der Informationskanäle, Alter und Bildung dagegen schon: Insbesondere ältere Teilnehmer nutzen das Radio in deutlich höherem Maße ($r=.104$), zeigten aber gleichzeitig eine geringere Tendenz zur Nutzung von sozialen Medien ($r=-.335$), Webseiten ($r=-.205$) oder persönlichen Gesprächen mit Freunden und Familie ($r=-.181$). Die Faktoren junges Alter ($r=.157$), höherer Bildungsabschluss ($r=.053$) und niedriges Einkommen ($r=-.0.58$) führten zu einer größeren Tendenz, sich auf lokale Quellen zu verlassen. Weiterhin hatte die Nutzung von Smartphones einen positiven Effekt auf die Nutzung von Informationen vor Ort (r=.129) und digitalen Medien (r=.296). Häufige Nutzer sozialer Medien nahmen lokale (r=.283) und traditionelle Quellen (r=.115) häufiger in Anspruch. Die Häufigkeit des Postings beeinflusste sowohl die Nutzung von traditionellen (r=.152), digitalen (r=.365) als auch örtlichen Medien (r=.260).

Tabelle 2. Signifikante Ergebnisse der Chi-Quadrat-Tests zur Mediennutzung in Krisen (*p<.05, **p<.01, N=1024)

	Trad. Medien	***Digitale Medien***	***Vor-Ort-Komm.***
Alter		$\chi^2(30,N)=121.64^{**}$	$\chi^2(40,N)=70.32^{**}$
Bildung		$\chi^2(30,N)=53.16^{**}$	$\chi^2(40,N)=64.81^{**}$
Einkommen (EK)			$\chi^2(24,N)=37.62^{*}$
Smartphone-Nutzung (SP)		$\chi^2(24,N)=111.75^{**}$	$\chi^2(32,N)=49.00^{*}$
Social-Media-Nutzung (SM)	$\chi^2(180,N)=274.15^{**}$		$\chi^2(240,N)=424.12^{**}$
Posting-Verhalten (PV)	$\chi^2(24,N)=63.69^{**}$	$\chi^2(24,N)=171.76^{**}$	$\chi^2(32,N)=126.68^{**}$

4.2 Erwartungen an KRITIS-Betreiber in Krisen

Zudem wollten wir herausfinden, welche Informationen die Teilnehmer im Falle eines Infrastrukturausfalls von KRITIS-Betreibern erwarten (siehe Tabelle 3). Die meisten Befragten nannten Mitteilungen über traditionelle Medien (72%) und die Webseite des KRITIS-Betreibers (70%). Darüber hinaus erwartete die Mehrheit eine SMS (60%), eine Nachricht über soziale Medien (59%), einen Anruf (58%) oder eine persönliche Ansprache vor Ort (57%). Zwei-Wege-Kommunikation erachteten die meisten (60%) als neutral oder unnötig. Die zentralsten Erwartungen an den Inhalt der Informationen umfassten Instruktionen (83%), die Ursache des KRITIS-Ausfalls (80%) sowie die voraussichtliche Dauer der Störung (78%). Für 70% war die Quelle der Informationen von Relevanz.

Alle Antworten korrelieren signifikant sowohl untereinander als auch mit den vorherigen Fragen (p<.0001). Die Nutzung von sozialen Medien während Krisen (r=.388, p<.0001) beeinflusste die Erwartungen einer Mitteilung auf den sozialen Kanälen des KRITIS-Betreibers maßgeblich. Das gleiche Ergebnis fand sich auch in Bezug auf traditionelle Medien, z.B. Zeitungen (r=.070, p<.05), Fernsehen (r=.105, p<.0001) und Radio (r=.159, p<.002). Zudem konnten wir feststellen, dass ein jüngeres Alter die Erwartungen eines Telefonanrufs (r=-.098) und einer Nachricht in sozialen Medien (r=-.114) erhöht, jedoch das Gegenteil für eine Meldung in traditionellen Medien gilt (r=.160). Je älter die Teilnehmer waren, desto mehr erwarteten sie, dass der KRITIS-Betreiber Anweisungen veröffentlicht (r=.088), die Quelle der Information angibt (r=.089) und Informationen über die Dauer des Ausfalls zur Verfügung stellt (r=.102). Zudem fanden wir auch Einflüsse des Einkommens und Bildungsstatus: Speziell auf Mitteilungen über traditionelle Medien (r=.099 und r=.085) und Webseiten (r=.116 und r=0.94) gab es einen signifikant positiven Einfluss. Ein höheres Einkommen erhöhte auch die Informationserwartung, insbesondere über die Dauer des Ausfalls (r=.115). Alle signifikanten Ergebnisse der Chi-Quadrat-Tests sind in Tabelle 4 zu finden.

Tabelle 3. Ergebnisse zu Q2: Was erwarten Sie bei Ausfällen der Infrastruktur (z.B. Strom, Gas oder Telekommunikation) seitens des Betreibers (z.B. Telekom, Energieversorger)?

	Starke Zust.	***Zust.***	***Neutral***	***Abl.***	***Starke Abl.***
Instruktionen	45%	38%	15%	2%	1%
Informationen zum Grund	45%	35%	17%	3%	1%

4.3 Maßnahmen während eines Ausfalls der Notrufnummer

Überdies wollten wir herausfinden, über welches Wissen die Teilnehmer in Bezug auf Maßnahmen während eines KRITIS-Ausfalls verfügen. Die Mehrheit wusste, wo sich die nächste Polizeistation (70%) und andere Verwaltungsgebäude befinden (68%), kannte den Standort der nächstgelegenen Rettungswache (55%) und des Feuerwehrgerätehauses (55%). Mehr als die Hälfte war über die Tatsache, dass Medien über alternative Maßnahmen berichten (56%) und die Polizei ihre Aktivität im betroffenen Gebiet erhöht (51%), informiert. Hingegen war der Standort des nächstliegenden Gebäudes des Technischen Hilfswerks (THW) nur 27% der Befragten bekannt, und knapp ein Viertel (23%) der Teilnehmer wusste, dass ein Fahrzeug der Feuerwehr an Orten ohne

Feuerwehrwache auf einem zentralen Platz anzufinden ist. Nur 19% waren sich der Tatsache bewusst, dass im Krisenfall die Feuerwachen durch BOS besetzt sind.

Tabelle 5. Ergebnisse zu Q3: Bei einem Ausfall der Notrufnummer 112 werden verschiedene Maßnahmen getroffen, um der Bevölkerung weiterhin die Möglichkeit zu geben, einen Notfall zu melden. Zu welchem Grad sind Ihnen die folgenden Maßnahmen bzw. Standorte bekannt?

	Sehr bek.	*Bek.*	*Neutral*	*Unbek.*	*Sehr unbek.*
Standort Polizeiwache	29%	41%	14%	10%	7%
Standort Verwaltung	31%	37%	16%	10%	7%
Alternativen in Medien	13%	43%	22%	14%	8%
Standort FW-Gerätehaus	24%	31%	18%	16%	10%
Standort Rettungswache	22%	33%	21%	15%	10%
Verstärkte Polizeipräsenz	13%	38%	20%	18%	12%
Standort THW	10%	17%	21%	34%	17%
Orte ohne FF oder BF mit FW-Fahrzeugen besetzt	6%	17%	17%	35%	25%
FW-Gerätehäuser besetzt	7%	12%	15%	36%	30%

Die Antworten für alle Maßnahmen korrelieren signifikant miteinander und mit der Nutzung aller Kommunikationskanäle in Krisen ($p<.0001$). Das Verlassen auf Telefongespräche, persönliche Kontakte und Hilfsdienste zeigte die höchste Korrelation ($r=.289$, $r=.282$ und $r=.273$). Zur Untersuchung des möglichen Einflusses von demografischen Faktoren sowie der Nutzung sozialer Medien auf die Antworten wurden diese zu einem einzigen Wert zusammengefasst und darauf basierend Chi-Quadrat-Tests durchgeführt. Hier beobachteten wir einen signifikanten Einfluss von Bildung ($\chi^2(180, 1024)=225.51$; $p<.05$; $r=.006$) und Einkommen ($\chi^2(108, 1024)=1407.23$; $p<.0001$; $r=.047$), obwohl ein Trend aufgrund schwacher Spearman-Korrelationen nicht eindeutig festzustellen ist. Die Nutzung von Smartphones ($\chi^2(144, 1024)=178.25$; $p<.05$; $r=.037$) und sozialen Medien ($\chi^2(1080, 1024)=225.51$; $p<.05$; $r=.202$) als auch die Häufigkeit von Postings in sozialen Netzwerken ($\chi^2(144, 1024)=224.53$; $p<.0001$; $r=.141$) wiesen dagegen eine signifikante Korrelation mit dem Wissen auf.

Etwa ein Drittel der Teilnehmer (n=344, 33,59%) hatten im Durchschnitt eine geringe Kenntnis der Maßnahmen (neutral oder schlechter). Im Vergleich zur Gesamtstichprobe sind die demografischen Werte dieser Gruppe sehr ähnlich verteilt, ein t-Test für unabhängige Stichproben zeigte dabei einige signifikante Unterschiede: Diese Gruppe war etwas älter ($t(1022)=2.47$, $p=.014$), benutzte soziale Medien seltener ($t(1022)=5.09$, $p<.000$) und postete weniger häufig darin ($t(1022)=2.39$, $p=.017$).

4.4 Antizipiertes Verhalten in Krisensituationen

Um Lösungen für eine bessere IKT-Unterstützung und effektive Kommunikationsstrategien für KRITIS-Betreiber im Falle von Infrastrukturausfällen zu erarbeiten, haben wir die Teilnehmer gebeten, ihr Verhalten in Krisensituationen detailliert in einer offenen Frage zu beschreiben (siehe Anhang). Anhand des Open Coding [22] haben wir Antworten einem oder mehreren Codes zugewiesen, die die Aussage beschreiben und iterativ verfeinert wurden. Am Ende der Kodierung zeichneten sich 41 individuelle Codes ab, die wir in sieben Kategorien, im Folgenden kursiv hervorgehoben, zusammengefasst haben. Die Gesamtzahlen der Aussagen in den einzelnen Kategorien sind wie folgt: Kommunikation: 692; Information: 646; Persönliche Sicherheit: 490; Keine Antwort: 209; Materielle Sicherheit: 145; Probleme: 140; Passives Verhalten: 112.Im Hinblick auf *persönliche Sicherheit* gab etwa ein Fünftel (n=178) an, dass sie Schutz suchen oder zu Hause bleiben würden, sofern dies sicher sei. 10% der Befragten nannten auch Familienmitglieder, um die sie sich kümmern würden. Darüber hinaus würden 158 Teilnehmer auch anderen außerhalb der eigenen Familie, wie etwa Nachbarn, Hilfe anbieten und beispielsweise nach gefährdeten Menschen Ausschau halten. Auch die Warnung anderer – ob persönlich, per Anruf, Nachricht oder in sozialen Netzwerken – war eine weitverbreitete Reaktion. In Bezug auf die *materielle Sicherheit* spielte die Versorgung mit Lebensmitteln und anderen Ressourcen für 78 Individuen eine wichtige Rolle. Insgesamt 13 der Befragten waren sich der Notwendigkeit der Vorbereitung bewusst. Der zweite Aspekt dieser Kategorie setzte sich aus persönlichen Gegenständen zusammen, z.B. Dokumenten und Schlüsseln (n=67).

In der Kategorie *Kommunikation* stand die Warnung Angehöriger und Weiterleitung von Informationen im Vordergrund. Darauf folgte die Kontaktaufnahme mit anderen Menschen im Allgemeinen (n=63). Familie (n=176), Freunde (n=81) und Nachbarn (n=65) waren hierbei häufig genannte Adressaten, um vor allem den Sicherheitsstatus auszutauschen. Nach Rat zu fragen, Zusammenarbeit anzubieten und Informationen auszutauschen (n=47) waren weitere Gründe zur erweiterten Kontaktaufnahme. In der Kategorie *Information* fanden wir heraus, dass mehr als die Hälfte der Teilnehmer (n=447) Informationen über die jeweilige Krise sammeln würden. Von denjenigen Befragten, die einen bestimmten Medienkanal angaben, nannten 189 Personen traditionelle, während etwas weniger die Nutzung digitaler Medien erwähnten (n=136). Zusätzlich gaben 69 Teilnehmer an, dass sie Passanten oder Helfer vor Ort befragen oder Lautsprecherdurchsagen Gehör schenken würden. Andere würden sich direkt an Notfallorganisationen, Regierungsvertreter oder KRITIS-Betreiber wenden (n=44). Währenddessen erklärten 83 Teilnehmer explizit, dass sie auf durch die Medien und Hilfsdienste kommunizierte Anweisungen warten und diese befolgen würden.

In den letzten drei Kategorien fassten wir Codes zusammen, welche keine Handlungen enthielten, die die Teilnehmer im Falle einer Krise unternehmen würden. Leere Antworten und Aussagen wie „Keine Ahnung“ oder „Weiß ich nicht“ wurden in eine eigene Kategorie *keine Antwort* aufgenommen. Unter *passives Verhalten* fiel etwa nichts tun (n=32) und Ruhe bewahren (n=77). Darüber hinaus stießen wir auf *Probleme*, welche die Teilnehmer bei der Beantwortung der offenen Frage hatten. Die Teilnehmer wiesen darauf hin, dass ihr Handeln von der Art der Krise abhängen würde (n=106). 22 Befragte gaben ausdrücklich an, noch nie zuvor eine Krise erlebt zu haben und deshalb keine qualifizierten Antworten geben zu können. Ebenso verwiesen neun Menschen darauf, dass sie in einem tatsächlichen Krisenfall anders reagieren würden und sie ihre Reaktionen deshalb nicht vorhersagen könnten.

5 Diskussion und Fazit

Der Ausfall kritischer Infrastrukturen beeinträchtigt viele Ressourcen- und Kommunikationskanäle, behindert den Transfer notwendiger Informationen und verursacht wirtschaftlichen Schaden [23]. Obwohl sich die Forschung mit den Eigenschaften, der Resilienz sowie den kooperativen und technischen Aspekten von KRITIS [15] beschäftigt hat, wurde die Einstellung von Bürgern gegenüber KRITIS-Ausfällen und IKT-Nutzung zu deren Ausgleich in Mitteleuropa noch nicht repräsentativ untersucht. Unsere Studie trägt daher mit spezifischen Aspekten des Bewusstseins, Verhaltens und der Kommunikation der deutschen Bevölkerung in KRITIS-Ausfällen dazu bei. Auch wenn unsere Stichprobe nur hinsichtlich demografischer Aspekte repräsentativ ist, ergeben sich aus unseren Ergebnissen in einem wenig beachteten Feld aktuelle und unter verschiedenen Gesichtspunkten untersuchte Aussagen, die helfen können, ein Gesamtbild zum Nutzen von Medien in KRITIS-Ausfällen in Deutschland zu zeichnen und weitere Forschung anzuleiten.

Bewusstsein und Verhalten in KRITIS-Ausfällen (FF1). Frühere Studien zeigten bereits, dass die Mehrheit der Bürger noch keinen schwerwiegenden KRITIS-Ausfall miterlebt hat [3], [24]. Etwa 10% unserer Teilnehmer hatten keine Antwort auf die Frage, was sie in einem Notfall tun würden, während andere glaubten, dass die Maßnahmen abhängig von der Art der Krise und damit nicht vorherzusagen seien. Dennoch können wir ein steigendes Gefahrenbewusstsein beobachten, vor allem bedingt durch Terrorattacken. Auf die Frage zu ihrem Krisenverhalten gaben die meisten Teilnehmer an, auf bekannte Medienkanäle zurückgreifen, um Informationslücken zu füllen und Handlungsempfehlungen zu bekommen. Im Fall einer Krise haben die eigene Sicherheit und die der Angehörigen, der Austausch von Informationen und die gegenseitige Hilfe oberste Priorität. Da die effektive Vorbereitung und Bewältigung von Krisen in Deutschland in den Händen der Behörden und Einsatzkräfte liegt, ist deren Aufgabe vor allem, die Bevölkerung für potenzielle Gefahren zu sensibilisieren, anzuleiten und einen großen Schaden durch mangelnde Vorbereitung und Risikobewusstsein zu vermeiden [3]. Hingegen kennen viele unserer Teilnehmer Gebäude und Maßnahmen, die sie im Fall eines KRITIS-Ausfalls nutzen können. Dies korreliert sogar mit der Nutzung sozialer Medien und anderem Verhalten wie dem Kontaktieren von Hilfsdiensten und der Kommunikation mit anderen per Telefon. Dies zeigt, dass diese Medien effektiv zur Krisenvorbereitung genutzt werden könnten.

Kommunikation und Information durch Medienkanäle (FF2). Im Vergleich zu sozialen Medien und Webseiten waren traditionelle Medien wie Fernsehen und Radio die am häufigsten genannten Informationsquellen [5]. Dies ist vermutlich darauf zurückzuführen, dass sie als offiziell, aktuell und vertrauenswürdig wahrgenommen werden, was einigen Teilnehmern wichtig war. In Übereinstimmung mit einer qualitativen Studie [15] tendierten viele Befragte dazu, Augenzeugen vor Ort zu vertrauen, und persönliche Kommunikation wurde von über 70% aller Teilnehmer praktiziert. Dennoch wird letztere selten als sehr hilfreiche Quelle genannt – im Gegensatz zu sozialen Medien. Im Vergleich zu einer Studie aus 2017 nahmen die Probanden soziale Medien in dieser Befragung sogar häufiger in Anspruch (55%), während die Nutzung von Krisen-Apps auf von 16% auf 25% anstieg [9]. Obwohl diese noch nicht weit verbreitet sind, nahmen 40% ihrer Nutzer sie als sehr hilfreich wahr. KRITIS-Betreiber könnten in solchen Apps daher über Institutionen, Maßnahmen und mögliche Risiken informieren als auch darauf hinweisen, wie man sich vorbereiten und verhalten sollte. Einflüsse der Demographie und IKT-Nutzung in Krisensituationen, die in bisherigen Arbeiten gefunden wurden [16], konnten in dieser repräsentativen Stichprobe für diese und die folgende Frage repliziert werden. Jedoch war das nicht der stärkste Einfluss: Je häufiger Bürger bestimmte IKT im Alltag und in Krisen nutzten, desto stärker sahen sie ihren Mehrwert in Krisen. IKT dienen vor allem dazu, Informationen zu sammeln, Familie und Freunde zu kontaktieren sowie Informationen und Sicherheitsstatus auszutauschen.

Erwartungen an KRITIS-Betreiber (FF3). Bezüglich der Kommunikation mit KRITIS-Betreibern schätzten die Befragten fast jede Art von Medien und über die Hälfte der Teilnehmer erwartete, dass KRITIS-Betreiber soziale Medien in Krisensituationen nutzen. Die Bereitstellung von Informationen, insb. Handlungsempfehlungen, sowie Dauer und Ursachen der Krise, wurde als wichtiger bewertet als die Etablierung einer Zwei-Wege-Kommunikation [9].

Implikationen für Design und Einsatz von IKT (FF4). Unsere Ergebnisse zeigen, dass es ein starkes Bedürfnis nach Informationen über und zur Sensibilisierung für Krisen gibt. Traditionelle und soziale Medien werden als hilfreiche und zuverlässige Kanäle für die Verbreitung dieser Informationen angesehen. Jedoch erlaubt in bestimmten Infrastrukturausfällen (z. B. Strom) die Akkulaufzeit von Smartphones weiterhin eine begrenzte Nutzung von Krisen-Apps, welche mitunter Checklisten und Verhaltensinformationen vor, während und nach verschiedenen Arten von Notfällen beinhalten [14]. Daher kann eine Verbreitung geeigneter IKT die soziale Widerstandsfähigkeit und Bewusstsein für Verhaltensmaßnahmen erhöhen [8]. Zudem könnte dies auch das generelle Verständnis von Infrastrukturen als wichtige Basis für viele Bereiche der Kooperation erhöhen [11], [23]. Da demografische Eigenschaften und Techniknutzung einen Einfluss auf die Antworten haben, sollten Kommunikationskanäle und Informationen an ihre jeweilige Zielgruppe angepasst werden [10]. Gleichzeitig sollte verstärkt auf schnelle, zugängliche, korrekte, vollständige und belegte Information geachtet werden, um mithilfe von IKT eine effektivere Krisenbewältigung und Kooperation zwischen KRITIS-Betreibern, Behörden und Bürgern aufzubauen.

Abschließende Betrachtungen. Zu einem hohen Grad unterstützen unsere Ergebnisse die Aussagen bisheriger Studien. Im Vergleich zu bestehenden Untersuchungen liefern wir jedoch aktuelle Einblicke in den wenig erforschten Bereich der Einstellung, Erwartung und Nutzung bezüglich Medien in Ausfällen stabiler KRITIS anhand einer demografisch repräsentativen Stichprobe aus ganz Deutschland. Unter Einbezug diverser Faktoren wie der alltäglichen Techniknutzung bietet unsere Forschung eine Grundlage für Vergleiche unter anderem mit weiteren Arten von Zielgruppen, Krisen, Einflussbereichen und Ländern. Bei einem Ausfall bestimmter Kanäle kann die Relevanz anderer zunehmen bzw. diese vorübergehend ersetzen. Dabei gilt es, möglichst viele Kanäle abzudecken und auch die Instruktionen je nach Art der Krise anzupassen. Dabei wurde deutlich, dass IKT für Krisenkommunikation in folgenden Bereichen sinnvoll eingesetzt werden kann:

- Information über potentielle Gefährdungen (Risikokommunikation) und Verbesserung der Resilienz der Zivilbevölkerung (Handlungsempfehlungen für persönliche und materielle Sicherheit, Notbevorratung, etc.).
- Während eines KRITIS-Ausfalls: Kommunikationsunterstützung zwischen Akteuren (BOS, KRITIS-Betreiber, Zivilbevölkerung) auf multiplen Kanälen.
- Während und nach einem Ausfall der Infrastruktur: Bereitstellung aktueller, lokaler, spezifischer, vertrauenswürdiger und zielgruppenorientierter Informationen durch BOS und KRITIS-Betreiber.

Die Studie unterliegt einigen Limitationen: Da Krisen wie Infrastrukturausfälle in Deutschland selten sind, waren unsere Fragen hypothetisch gestellt, sodass empirisch geprüft werden muss, inwiefern sie mit tatsächlichem Krisenverhalten übereinstimmen. Bei bestehenden Studien zu tatsächlichen Infrastrukturausfällen wurde etwa bereits mangelnde Vorbereitung seitens der Bürger und erhöhter Informationsbedarf festgestellt [25]. Eine Antwortoption für Teilnehmer, die noch nicht von Krisen betroffen waren, sollte ergänzt werden, um genauere und valide Ergebnisse zu erzielen. Ein Fokus auf bestimmte Ereignisse, in diesem Fall KRITIS-Ausfälle, ist außerdem notwendig, um Verhalten und Erwartungen in verschiedenen Situationen abzugrenzen. Weiterhin würden Begriffserklärungen und klarere Abgrenzung von Skalen zum besseren Verständnis der Fragebögen beitragen. Die Tatsache, dass wir unsere Probanden online befragt haben, schränkt zudem die Repräsentativität ein. Daher müsste die Befragung offline und mit Teilnehmern unterschiedlicher Technikaffinität durchgeführt werden. Darüber hinaus könnte man die Gründe hinter dem Verhalten und der Mediennutzung, die in der offenen Frage angedeutet werden, genauer untersuchen, um die Intentionen und Bedürfnisse der Betroffenen besser zu verstehen.

Danksagung: Diese Arbeit wurde durch das Bundesministerium für Bildung und Forschung (BMBF) im Rahmen von KontiKat [26] (13N14351), teilweise im Rahmen von HyServ (01IS17030B) sowie durch die DFG innerhalb des SFB 1053 MAKI finanziert. Zudem hat Marius Brüser an der Konzeption des Fragebogens mitgewirkt.

Anhang: Fragen

Q1: Welche der folgenden Möglichkeiten haben Sie in einer akuten Krisensituation (als Sie selbst betroffen waren / als Sie Helfer(in) waren) genutzt, um sich über die Ereignisse zu informieren, und welche waren für Sie sehr hilfreich? (Ja, sehr hilfreich; Ja, habe ich genutzt; Nein): 1. Zeitungen und Zeitschriften | 2. Fernsehen | 3. Radio | 4. Persönliche Gespräche (z.B. mit Familie, Freunden und Nachbarn) | 5. Telefonische Gespräche (z.B. mit Familie, Freunden und Nachbarn) | 6. Kontaktaufnahme zu Rettungsdienst, Feuerwehr, Polizei oder Krankenhaus) | 7. Informationsmöglichkeiten vor Ort (z.B. Aushänge, Flugblätter und Lautsprecherdurchsagen) | 8. Soziale Medien (z.B. Facebook, Twitter, Instagram und YouTube) | 9. Andere Internetangebote | 10. Eine Krisen-App (z.B. KATWARN oder NINA) | 11. Keine | 12. Weiß nicht

Q2: Was erwarten Sie bei Ausfällen der Infrastruktur (z.B. Strom, Gas oder Telekommunikation) seitens des Betreibers (z.B. Telekom, Energieversorger)? (Starke Zustimmung; Zustimmung; Neutral; Ablehnung; Starke Ablehnung): 1. Persönliche Ansprache vor Ort | 2. Anruf | 3. SMS-Nachricht | 4. Nachricht auf sozialen Medien | 5. Meldung auf der Website | 6. Meldung in traditionellen Medien | 7. Zwei-Wege-Kommunikation | 8. Informationen zur Dauer | 9. Informationen zum Grund | 10. Informationen, was ich tun soll | 11. Quelle der Information

Q3: Bei einem Ausfall der Notrufnummer 112 werden verschiedene Maßnahmen getroffen, um der Bevölkerung weiterhin die Möglichkeit zu geben, einen Notfall zu melden. Zu welchem Grad sind Ihnen die folgenden Maßnahmen bzw. Standorte bekannt? (Ist mir sehr bekannt; Ist mir bekannt; Neutral; Ist mir nicht bekannt; Ist mir überhaupt nicht bekannt): 1. Durch die BOS werden Feuerwehrgerätehäuser im betroffenen Gebiet besetzt. | 2. In Ortschaften ohne Feuerwehrgerätehaus wird ein Fahrzeug der Feuerwehr auf einem zentralen Platz positioniert. | 3. Die Polizei verstärkt ihre Aktivität im betroffenen Gebiet. | 4. Durch die Medien werden weitere Alternativen gemeldet. | 5. Standort der nächstliegenden Rettungswache (Standort Krankenwagen etc.) | 6. Standort des nächstliegenden Feuerwehrgerätehauses | 7. Standort des nächstliegenden Gebäudes des Technischen Hilfswerks (THW) | 8. Standort der nächstliegenden Polizeistation | 9. Standort der nächstliegenden Verwaltungsgebäude (z.B. Rathaus, Kreishaus)

Q4: Beschreiben Sie möglichst detailliert, wie Sie in einer außergewöhnlichen Lage (Krise, Katastrophe) vorgehen oder vorgehen würden? Welche Tätigkeiten führen Sie durch oder würden Sie durchführen?

Fake News Perception in Germany: A Representative Study of People's Attitudes and Approaches to Counteract Disinformation

Christian Reuter, Katrin Hartwig, Jan Kirchner, and Noah Schlegel

Technische Universität Darmstadt,
Science and Technology for Peace and Security (PEASEC), Germany
reuter@peaesec.tu-darmstadt.de

Abstract. Fake news has become an important topic in our social and political environment. While research is coming up for the U.S. and European countries, many aspects remain uncovered as long as existing work only marginally investigates people's attitudes towards fake news. In this work, we present the results of a representative study (N=1023) in Germany asking participants about their attitudes towards fake news and approaches to counteract disinformation. More than 80% of the participants agree that fake news poses a threat. 78% see fake news as harming democracy. Even though about half of the respondents (48%) have noticed fake news, most participants stated to have never liked, shared or commented on fake news. Regarding demographic factors, our findings support the view of younger and relatively educated people being more informed about fake news. Concerning ideological motives, the evaluation suggests left-wing or liberal respondents to be more critical of fake news.

Keywords: Fake news, disinformation, citizens' perceptions, representative survey, counteraction, Germany

1 Introduction

Information systems play a crucial role regarding peace and security [1], also with regard to interactive systems [2]. Since the 2016 U.S. presidential election, the term *fake news* is widely known and has found its way into both scientific and public debates. In Germany, the 2017 parliamentary election was accompanied by discussions about fake news. However, research shows that there was no major fake news during the campaign which had any impact on the election results [3]. Although there were many cases of fake news during the U.S. election, scholars argue that they did not have any impact on its outcome [4]. These observations suggest that the perception of fake news influencing people's attitudes diverges from its actual impact. As fake news is apparent online, it may shape users' social media experiences to varying degrees, potentially influencing important social dynamics [5–7]. Thus, we ask for a clearer picture of the population's perception of and interaction with fake news. In the context of this study, fake news is

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

to be understood as "all forms of false, inaccurate, or misleading information designed, presented and promoted to intentionally cause public harm or for profit" [8].

Our paper tries to find answers to the following questions: *(1) What **attitudes** do people have towards fake news? (2) Have they ever noticed fake news or **interacted** with it? (3) How do they evaluate possible approaches to **counteract** fake news?* Therefore, we conducted a representative study (N=1023) and analyzed our results referring to demographic factors as well as to perceptions of threats to peace (i.e., ideological standpoints) to ask for influential factors regarding the perception, interaction, and counteraction of fake news. This allowed us to focus on attitudinal and behavioral patterns of different groups. While it is certainly important to examine actual fluctuations of fake news, humans' respective perception may constitute an essential factor for their behavior online or in cases of counteraction. We focus our work on one country permitting a differentiated analysis and presentation of results which may prove relevant with respect to other countries across Europe. Germany is an important European country and just recently had the 2017 parliamentary elections, introducing a right-wing populist party into parliament. Therefore, we performed a study representative of the German adult population under 65 on their opinion on fake news. First, we elucidate the phenomenon of fake news and discuss relevant work (section 2). Next, we introduce the representative survey, describing our approach and methodology (section 3) and presenting the results (section 4). Last, we discuss the results and draw a conclusion (section 5).

2 Background and Related Work

2.1 Fake News as a Social Phenomenon

Before 2016, fake news mainly referred to satirical news shows; the perception changed when a lot of fake news went viral, starting to affect political parties globally and influencing opinions on a larger scale than before [9]. While being such a popular and frequent term, it is often mingled with other phenomena [3]. Its fuzzy meaning facilitates misuses of the term to discredit undesired news [10]. Furthermore, in German debates, its meaning is often mixed with hate speech [3]. Allcott and Gentzkow [4] define fake news as "news articles that are intentionally and verifiably false and could mislead readers". In contrast, misinformation refers to "information that is false but not created with the intention of causing harm" [11]. Fake news often deals with controversial issues like migration, child abuse, or war [12]. Although there is no consensus in science as to whether social media encourages the emergence of "digital echo-chambers" – that is to say: a system that amplifies and reinforces ideas of beliefs at the expense of competing vies – its popularity has been proven to facilitate the spread and success of fake news [13]. Nowadays, many people use social media instead of mainstream media as a source of information [14]. Consequently, the important role of journalism as a gatekeeper has shifted to individuals who must decide on their own whether a report is reliable [15], [16]. Well-studied occurrences of fake news appear in the context of elections although studies show that it had little overall impact on them [3], [4]. Yet, fake news may be used to manipulate public opinion and debate. According to the

German investigative journalism collective *Correctiv*, most fake news in Germany has originated from supporters and politicians of the right-wing populist party *Alternative f r Deutschland* (AfD).[1] Also, radicalization on social media has been observed [17].

As a reaction to the massive fake news spread, most social networks have enabled methods to take care of the potential harms by curating, deleting and censoring content [18]. Thus, independent platforms now take the role of an information gatekeeper [19]. In 2018, the European Commission has appointed a "High Level Group on fake news and online disinformation". In October 2017, a German law came to force called *Netzwerkdurchsetzungsgesetz* (NetzDG; Network Enforcement Act). It attempts to fight fake news and hate speech by forcing platforms to quickly delete illegal contents but has been widely criticized for threatening freedom of speech.

2.2 Related Work

Over the last years, research on fake news has been emerging. Work focused on how fake news is received by individuals and potential factors determining whether fake news is considered true. Light has been shed on a cognitive heuristic called *Confirmation Bias* [20], describing the selective choice of (news) messages on the basis of matching ideologies. Marwick and Lewis [21] showed in several studies that individuals tend to forget the original source of information (*Sleeper Effect*). Subsequently, having forgotten about the untrustworthy source, the false information might be taken as true when fitting one's ideology [22]. Polage [23] described the *Truth Effect*, showing that content which is repeated often and by multiple sources tends to be taken for real at some point, independent from initial considerations.

A study by Del Vicario et al. [24] determined that (fake) news is spread especially within homogeneous groups of users with similar ideologies. In a Twitter analysis, Starbird [25] examined alternative narratives which she describes as a special kind of fake news, neither fitting one side of the conventional left-vs. right-wing cleavage but motivated by anti-globalism (e.g., criticism on the role of the US in world politics).

To investigate perception and handling of fake news by individuals, Barthel et al. [26] carried out a representative survey of 1,002 U.S. adults. According to the findings, about one third (32%) of U.S. adults "often see political news stories online that are made up" and 64% say fake news "cause[s] a great deal of confusion about the basic facts" [26]. Additionally, there are 23% who stated that they have shared a made-up story with 14% knowing it was fake. Furthermore, the participants were asked to state their opinion on responsibilities to prevent the spread of fake news. While 45% said government, politicians and elected officials have a great deal of responsibility, 43% held the public responsible, 42% social networking sites and search engines. The authors detected age as a determining factor: "Americans aged 50 and older are more likely to place a great deal of responsibility on the government" [26].

Allcott and Gentzkow [4] collected fake news headlines circulating during the U.S. election campaign. They asked 1,208 survey participants whether they had seen those headlines and whether they had initially accepted them as true. They found that 15% of

[1] https://correctiv.org/echtjetzt/artikel/2017/09/25/wahlcheck17-zieht-bilanz-den-fake-news-keine-chance/

the participants stated they had seen fake news headlines while 8% also believed them [4]. According to the authors, Democrats, heavy media consumers, people with higher education, and of higher age tend to “have more accurate beliefs about news” [4].

Sängerlaub [3] conducted a representative survey of 1,037 participants shortly after the German parliamentary elections in 2017. His results show that 61% of the participants had the impression that there were many cases of fake news during the election campaign. Interestingly, those who voted for the right-wing, populist party AfD agreed more to this statement than others (71%). Regarding fake news dealing with migration, right-wing supporters were often found to believe them. Besides partisanship, other factors like gender, age, income, and education had less influence on the results [3]. Lewandowsky et al. [27], [28] follow the assumption of ideology being a decisive factor, focusing on correlations between perceptions of fake news and worldviews. Reuter et al. found that 73% of the German population perceive false rumors in social media as a barrier for its use in emergencies [29].

Regarding the question of how to counteract fake news, Lewandowsky et al. [27] focused on building new narratives based on their examination of psychological dynamics with respect to the interaction with (fake) news. Other scholars introduced tools useful for detection and the individuals’ ability to assess news as untrustworthy [30–32]. A study by Neudert [33] on the issue of computational propaganda in Germany revealed a rise in junk news generated by social bots in the context of “the skeptical political zeitgeist” [33] in Europe. The authors further suggest junk news often to be disseminated by right-wing populist actors.

2.3 Research Gap

We aim for a deeper understanding of the highest populated and economically important European country with respect to fake news. While the country’s discourse is marked significantly less by fake news than debates around US elections are [34], it has, like many other societies, experienced a polarization of political attitudes in recent times, introducing the issue and providing fertile ground for the creation of fake news [35]. While a few studies have investigated fake news in Germany concerning specific election events [3], [34], there are no studies that analyzed the perception of fake news in Germany independently of specific events. With respect to possibilities of counteraction, we offer a first glance at a population’s general opinion on this issue. Reviewing related work, we propose to encounter the lack of research about citizens’ perceptions of countermeasures. These findings may contribute to the development of practical policies, as the success of ICT governance strongly depends on the willingness of non-state actors [36]. This may prove to be relevant as German decision-makers have been active in this field, introducing the Network Enforcement Act. We suggest our analysis to be helpful as survey answers are analyzed by both demographic and ideological characteristics, valuably pointing out different degrees of sensitivity in perception. Our findings concerning Germany’s population may not only be useful with respect to this single case but contribute to an understanding of fake news interaction in other European countries with similar media-cultural conditions and political polarization [34]. Instead of following US case studies and their binary ideological categorization of left- (Democratic) or right-wing (Republican) partisanship, we analyze the survey results according to demographic factors considered relevant by the surrounding academic discourse and test for correlations corresponding to ideological statements.

3 Approach

We intend to give an overview of the situation of fake news in Germany by finding answers to questions of attitude, interaction, and counteraction with respect to fake news. For these three topics, we also investigate differences between demographic subgroups and ask for correlations with more general attitudes regarding perceived threats to peace. To find answers to these questions, we conducted a representative survey of adults in Germany and analyzed the results. Using data of a representative survey, we compile a descriptive quantification about the belief of Germans.

3.1 Survey Design

We conducted a representative online survey (N=1023) of the adult German population in July 2017, using the ISO-certified panel provider GapFish (Berlin). They guarantee panel quality, data quality, and security, as well as survey quality through various (segmentation) measurements for each survey within their panel of 180,000 active participants. Our overall survey included 30 questions and also covered other topics, such as [37], [38]. In this work, we investigated three survey questions targeting the subject of fake news and selected on the basis of previous work. Each question consisted of multiple items which were answered on a three- or five-step Likert scale (see Appendix). The first question aimed at participants' attitudes towards fake news and their ramifications. The ten items comprised statements about fake news, which participants had to agree or disagree with on a five-step Likert scale. For example, the statements were about fake news posing a threat, or influencing public actors and population. In the second question, we asked whether and how participants had contact with fake news. On seven items, they had to state, among others, if they have perceived, liked, commented on, shared or created fake news on a 3-step Likert scale. Additionally, we asked for their opinion regarding the handling, i.e., counteracting of fake news. Participants were told to assess six suggested approaches to counteract fake news responding on a 5-step Likert scale. We selected several additional question items which we expected to hold interesting relations to fake news, including demographic positions and ideological statements.

3.2 Characteristics of Survey Participants

The conducted survey is representative of the German population stratified according to gender, age from 18 to 64 years, and federal state. This means that on these variables, the collected data shows no significant differences from the target population. Furthermore, we ensured a wide spread of the survey sample in terms of education and income which could not be tested for representativity due to the lack of appropriate national statistics. The χ^2-test on gender reveals no significant differences to the German population between 18 and 64 years (χ^2 (df= 1) = 0.031, p= .860). The collected sample consists of 50.4% male and 49.6% female participants (Germany: 50.7% male and 49.3% female) and, therefore, is representative. The participants' age was gathered in groups of 18 to 24 years, 25 to 34 years, 35 to 44 years, and 45 to 54 years. All group sizes correspond to the target population (χ^2 (df= 4) = 1.928, p= .749). We precluded one participant from analysis who stated to be 65 years or older, thus analyzing answers of 1,023 participants. Also, all sixteen German federal states are represented proportionately (χ^2 (df= 15) = 3.832, p= .998). Survey participants were paid a small allowance, recruited online, and able to take part once via the research agency's platform.

Most of all participants stated using a smartphone on a daily (49%) or hourly (43%) basis. Facebook is used less frequently than smartphones. A large majority (67%) does not use Twitter at all. Instagram is less popular than Facebook but more popular than Twitter, with 24% using it daily or hourly. All items concerning smartphone and social media use are highly influenced by the age of the participants (e.g., χ^2 (df= 4) = 195.2, p= .0000 for smartphone use), with younger respondents being more active.

3.3 Analysis

We examined the obtained survey data using R for data preparation and statistical methods, and Tableau for visual analytics and creation of data figures. For each question, we calculated the basic frequencies and created Diverging Stacked Bar Charts. Significant differences between participants of different demographic groups were determined using χ^2-tests of independence. Further, we investigated relationships to selected items of the extended question catalog. We calculated the Kendall rank correlation coefficient (Kendall's τ) for each pair of items, forming a correlation matrix and tested the correlations for non-zero coefficients.

4 Empirical Results

4.1 Attitude towards Fake News

The responses show that a large majority of participants concedes the risks of fake news (see Fig. 1). More than 80% agree that fake news poses a threat and can manipulate the population's opinion. But almost the same number of participants believes that public players like politicians can be manipulated as well. 78% see fake news harming democracy. In contrast, there are fewer (but still a significant amount of) people who see a threat in social bots and state censorship. Furthermore, there is a large number of participants who are indecisive about social bots. About 24% believe that fake news is annoying but does not pose a threat. There is no clear tendency, and there are widespread answers to the question of fake news being a pretext to fight system-critical actors. Most of the participants (82%) see the platform operators responsible for preventing fake news. 70% believe it is the state's task.

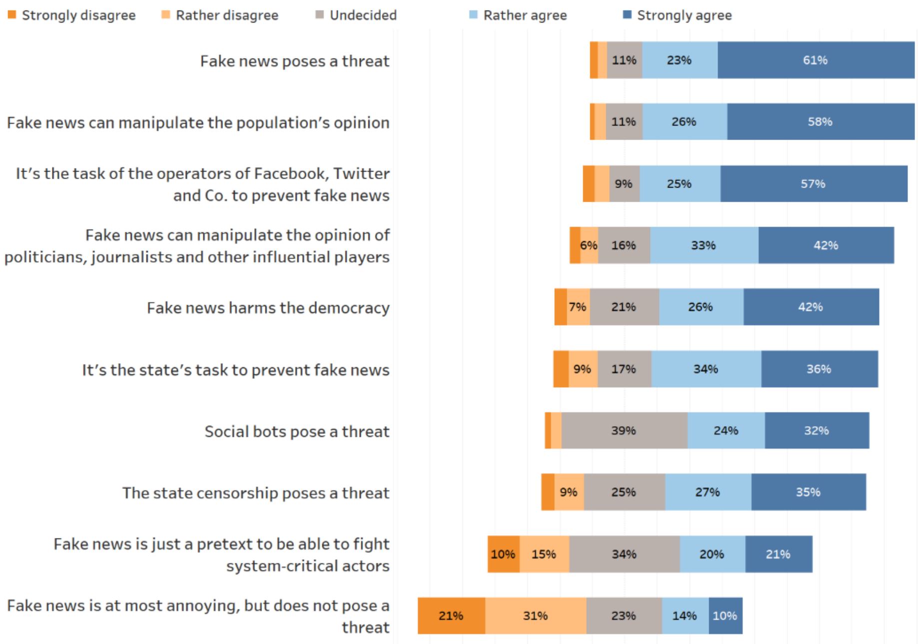

Fig. 1. Responses to the ten items of the first question ("Please indicate to what extent you agree to the following statements on fake news"). The responses are visualized in a *Diverging Stacked Bar Chart.* The level of agreement on an item is indicated by the horizontal shift.

Demographic Aspects. There are significant differences between female and male participants on several items: While about half of all women (47%) are undecided about a threat of social bots and 50% agree (or strongly agree) on it, male participants are more decisive (χ^2 (df= 4) = 34.168***[2], τ = -0.100***). 37% of male participants strongly agree (and 24% agree), and only 31% are undecided. There are also more male participants who disagree with it (7% male and 3% female). Regarding the threat of state censorship, men agree with this statement more strongly than women (41% vs. 29%, χ^2 (df= 4) = 25.394***, τ = -0.071*). Female participants clearly agree, that it is the state's task to prevent fake news (74%, disagree 9%, χ^2 (df= 4) = 21.029***, τ = 0.103***). Men are less consensual (65%) and more hostile (18%) to this statement. Most female participants are undecided (40%) whether fake news is just a pretext to fight system-critical actors (χ^2 (df= 4) = 24.366***, τ = 0.031). Male participants are less undecided (29%) and more disagreeing (30% vs. female 20%). However, there are fewer female participants who strongly agree (18% vs. male 23%) and more who just agree than men (22% vs. 18%). Furthermore, there are significant differences between different age groups on this item (χ^2 (df= 16) = 33.63**, τ = 0.065**). Older participants are less undecided than younger ones (e.g., 30% of 55 to 64 years vs. 40% of 25 to 34 years). The group of 55 to 64 years is also more disagreeing on this item than others (34% vs.

[2] (p<.001)***;(p<.01)**; (p<.05)*

15% of 18 to 24 years). In addition, the youngest group (18 to 24 years) is more agreeing than others (51% vs. e.g., 37% of 25 to 34 years).

The educational level has an important impact on many questions. For example, on the item of social bots (χ^2 (df= 20) = 65.714***, τ = 0.095***), participants with a university degree or university of applied sciences degree are mainly strongly agreeing to a threat of social bots (43%). However, participants with a high school diploma or secondary school degree are mainly undecided (38%, 47%). The item of social bots is also influenced by income (χ^2 (df= 12) = 23.864*, τ = 0.062*) which slightly correlates with educational level: Kendall's τ = .0748**. The majority of those with an income of more than €3,500 strongly agree that social bots pose a threat. Other income groups are mainly undecided (38% to 41%).

Correlations with Additional Survey Items. The correlation matrix generally revealed a high number of significant relationships while we consider only the most significant and compelling links to other survey items. We found that the question about the assessment of social media advice had significant non-zero coefficients especially for the item of correcting wrong information ("When you find or share wrong information, correct it."). This item correlates to multiple items about fake news: For example, the response on this item has influence on responses towards fake news posing a threat for democracy (τ = .21***, z = 7.87). There also is a quite strong connection to stating that fake news manipulates the population's opinion (τ = .31***, z = 11.10). A smaller (but still significant) link can be found regarding fake news manipulating the opinion of politicians, journalists and other influential players (τ = .23***, z = 8.65). The item stating that "all information controlled by the state should be made publicly available, even if posing a risk to public safety" shows a correlation with the attitude towards fake news being at most annoying and not posing a threat (τ = .21***, z = 8.45). Similarly, they rather disagree with the item stating that fake news poses a threat (τ = −.13***, z = −4.93) and they more often think that fake news is just a pretext to fight system-critical actors (τ = .18***, z = 7.20). We could also find a negative link to the item of fake news manipulating the population's opinion (τ = −.15***, z = −5.58) and another negative coherence regarding the responsibility of social media operators to prevent fake news (τ = −.11***, z = −4.10). On the items about what poses a threat to the peace in Germany, the analysis revealed some significant correlations. Seeing other states as a threat to peace is positively correlated to assessing fake news posing a threat (τ = .12***, z = 4.65) and harming democracy (τ = .10***, z = 3.84). We found a similar connection to the threat of social bots (τ = .10***, z = 3.75). Interestingly, a threat of social bots correlates with seeing a threat in nationalism (τ = .19***, z = 7.29). The items on the threat of nationalism and capitalism also show a significantly positive coefficient on fake news harming democracy (τ = .21, ***, z = 7.82 and τ = .10***, z = 3.82). There also might be an opposing link between the item of multicultural coexistence posing a threat to peace and the item regarding a threat of fake news (τ = −.08**, z = −3.06). Furthermore, the analysis revealed correlations with the statement that fake news is just a pretext to be able to fight system-critical actors: There are significantly positive coefficients for the item on a threat of globalization (τ = .21***, z = 8.14) and other states (τ = .19***, z = 7.50).

4.2 Interaction with Fake News

While almost half of all participants (48%) stated they had perceived fake news, the majority says they had not interacted with fake news in any of the suggested ways (see figure 2). In general, the number of participants who affirm interaction with fake news is between 23% ("deleted or reported fake news") and 2% ("created fake news"). The responses of *only* those participants who have perceived fake news are slightly higher: There are 38% saying they have deleted or reported fake news and 23% who affirmed commenting and disliking fake news, respectively. About 7% state they had shared fake news and 4% say they had created fake news themselves. However, due to the social desirability bias, these numbers are probably not accurate and might be higher. Since fake news has a negative social standing, not everyone would respond honestly and admit e.g., sharing or creating fake news.

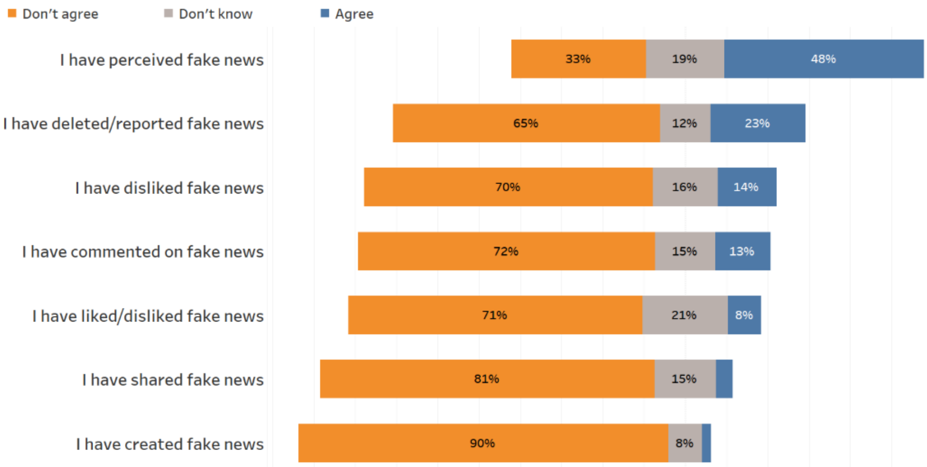

Fig. 2. Responses to the seven items of the second question ("How did you have contact with fake news on social networks?").

Demographic Aspects. Regarding gender, there are no significant differences in interaction with fake news. However, age has an important impact on most questions. For example, 63% of the participants aged 18 to 24 and 59% aged 25 to 34 say they have perceived fake news while only 33% of participants aged 55 to 64 agree (χ^2 (df= 8) = 52.356***, τ = 0.140***). Additionally, younger participants are more likely to have liked, disliked (τ = 0.021) or commented (τ = 0.044) on fake news. Furthermore, younger participants stated significantly more often than older participants to have deleted or reported fake news (46% aged 18 to 24 vs. 11% aged 55 to 64, χ^2 (df= 8) = 78.881*** τ = 0.149***). The educational level corresponds significantly with the perception of fake news (χ^2 (df= 8) = 37.012***, τ = 0.141***, ignoring the minority without graduation) but not with the interaction with it. 67% of participants with a university degree state to have perceived fake news while only 41% of participants with a secondary degree agree. A significant impact of income on the interaction with or perception of fake news could not be shown.

Correlations with Additional Survey Items. Again, we found several links to additional survey items using rank-based correlation. Unsurprisingly, items on social media usage show a correlation with the interaction with fake news. For example, posting messages on social media correlates with commenting on (τ = .22***, z = 7.88), sharing (τ = .12***, z = 4.29) and reporting (τ = .20***, z = 7.30) fake news. Thus, a higher activity in social networks often comes along with more interaction with fake news. A possible (but weak) indicator for the item on fake news creation is the belief that globalization is a threat to peace (τ = .08**, z = 2.92). Responses to the item on public safety having priority over information access show a minor correlation to the item about perceiving fake news (τ = −.06*, z = −2.19). In contrast, the item on unrestricted information access shows a significantly positive coefficient to the item on fake news creation (τ = .13***, z = 4.57).

4.3 Counteracting Fake News

Most participants agree with all suggested ways to deal with fake news (see: figure 3). For all items, the numbers of participants who agree vary between 80% ("quick reactions of the authorities") and 72% ("establish state IT centers of defense"). The amount of neutral responses ranges from 14% to 21%, while very few participants do not agree with the suggested approaches (between 3% and 7%). Compared to the other items, the idea of a state IT center managing fake news has the lowest compliance. It has the lowest number of supporting answers and the highest numbers of neutral and disagreeing answers. However, the reported deviations are altogether relatively small. For gender, age, educational level, and income, no significant differences could be found in the answering patterns.

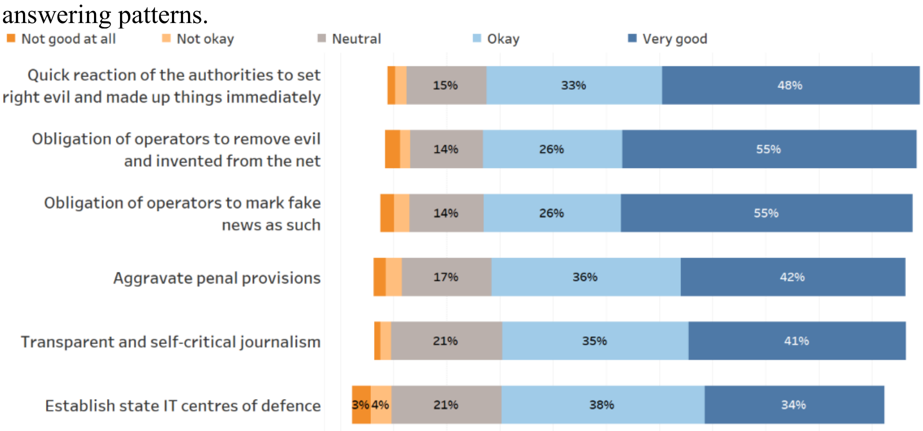

Fig. 3. Responses to the six items of the third question: ("How do you rate the following suggestions for dealing with fake news?"), visualized in a Diverging Stacked Bar Chart.

Correlations with Additional Survey Items. The correlation revealed significant connections to the items on an obligation of operators to remove fake news and to mark fake news as such. The social media advice on correcting false information has positive coefficients towards obligation to remove fake news (τ = .36***, z = 13.11) and to mark fake news ($\tau = .34^{***}$, $z = 12.38$). The same links can be found for the advice to verify information before publishing (obligation to delete fake news: $\tau = .41^{***}$, $z = 14.65$ and obligation to mark fake news: $\tau = .39^{***}$, $z = 13.89$).

5 Discussion and Conclusion

5.1 Scientific Contribution & Policy Implications

In sum, the analysis has shown that a large majority of participants concedes the risks of fake news. More than 80% of the participants agree that fake news poses a threat, and 78% see fake news as harming democracy. Even though almost half of all participants (48%) stated that they had perceived fake news, the majority claims not to have interacted with them in any of the suggested ways. Only 2% admitted having created fake news. Moreover, most participants agreed with all suggested ways to deal with or counteract fake news.

We analyzed survey results with respect to common demographic factors. While studies did not make any differences between male and female respondents, we point out to respective diverging attitudes [39], with women stressing the state's responsibility to deal with fake news and men increasingly pointing out to the danger of state censorship. Our results propose future policy-making to be sensitive towards this issue by ensuring to enhance a more differentiated view considering *gender*. Yet, one may put this into perspective, as our findings do not suggest a correlation between gender and any item regarding interaction or counteraction with respect to fake news. The same applies for *income* as a potential factor. Further, we can assume only the highest income group, slightly correlating with education, to be critical of social bots. Thus, to allow for overall informed opinions and decisions regarding fake news, it may be useful to raise awareness to this phenomenon. In contrast, *age* and *education* influence not only attitudes regarding fake news but also people's considerations of interaction with them. Our findings support the view of younger and relatively educated people being more informed and sensitive about fake news due to their relatively frequent and differentiated internet usage, contradicting other studies [4]. Thus, educational approaches may specifically target older generations and focus on easy and appealing access to necessary information [40]. Yet, it should be kept in mind that across correlations between demographic factors and survey items, we could mostly make out only small effects.

We analyzed respondents' answers according to ideological motives, testing for correlations with statements reflecting perceived threats. Respondents who believed globalization to pose a threat to peace in Germany also shared the attitude of perceiving the phenomenon of fake news used as a pretext to fight system-critical actors and showed a weak link to the action of creating fake news. Following Starbird's assumption of online anti-globalist narratives being often (re-)produced by nationalist populist groups [25] and the findings of Allcott et al. [4] pointing out to right-wing or republican ideology as a motivation for creating fake news, we suggest both the creation and playing down of fake news to potentially symbolize the respective populist political view. Similarly, respondents who possibly downplayed fake news to be no threat and just an excuse to fight against system-critical actors perceived multicultural coexistence to be threatening. This fits with Sängerlaub's result on AfD-related appreciation of fake news [3]. Future regulative implementations might, therefore, reflect awareness of diverging attitudes across political camps. Our findings also indicate German respondents to not associate fake news with mainstream media as apparently as in the US, diverging from study results focused on the immediate aftermath of elections [3]. Respondents who perceived nationalism as well as capitalism to pose a threat also found fake news to harm democracy while the first group also perceived social bots to be problematic, suggesting relatively left-wing or liberal respondents to be more critical of fake news. Assuming a perceived dualism of freedom and security, respondents who prioritized unrestricted access to information over public safety shared the attitude of fake news not posing a threat and legitimizing actions against system-critical actors as well as showed to be responsible for the creation of fake news. Participants who prioritized public safety demanded control with respect to fake news by social media operators. Policies may consider this regarding burden-sharing. Again, effects between ideological standpoints and survey items were not great, yet, stronger relationships compared to demographic factors and items were proposed.

5.2 Limitations & Future Work

This work has limitations: (1) Our results were acquired using a survey. This method of data collection implies the risk of participants being more technophile, not responding honestly, being influenced by social desirability biases, which is very likely on such a controversial topic. To find more reliable numbers, other techniques than a survey need to be utilized. (2) Furthermore, the study relies on self-reported behavior. It is likely that people interact with fake news without knowing it. (3) Also, it must be mentioned that the concept of fake news – as a result of the term's ambiguous nature and changing meaning in the current political and societal discourse – might have been interpreted differently by each survey participants. (4) Also, the correlations to other survey items are all lower than $\tau = .5$ and thus, cannot be considered strong. However, although the given correlations are weak, they are statistically significant and reveal existing tendencies. (5) Our panel excluded teenagers younger than 18 years; a group which might have yielded important results regarding the perception of fake news. Future research may test for correlations between the three respective topics to gain deeper insight into causal relationships between general perception, perceived interaction and opinion on counteraction while targeting various groups defined by demographic and ideological factors. Worldview-related variables may contribute to a more accurate understanding of variations in perceptions regarding fake news and of a diversity of fake news conceptions.

Appendix: Survey Questions

#15) Attitude towards Fake News. Please indicate to what extent you agree to the following statements on fake news. (strongly agree, rather agree, undecided, rather disagree, strongly disagree): *1. Fake news poses a threat. | 2. Social bots pose a threat. | 3. It's the state's task to prevent fake news. | 4. It's the task of the operators of Facebook, Twitter and Co. to prevent fake news. | 5 Fake news harms the democracy. | 6. Fake news can manipulate the opinion of politicians, journalists and other influential players. | 7. Fake news can manipulate the population's opinion. | 8. Fake news is just a pretext to be able to fight system-critical actors. | 9. The state censorship poses a threat. | 10. Fake news is at most annoying but does not pose a threat.*
#16) Interaction with Fake News. How did you have contact with fake news on social networks? (agree, don't know, don't agree): *1. I have perceived fake news | 2. I have liked/disliked fake news | 3. I have commented on fake news | 4. I have shared fake news | 5. I have deleted/reported fake news | 6. I have disliked fake news*
#17) Dealing with Fake News. How do you rate the following suggestions for dealing with fake news? (very good, okay, neutral, not okay, not good at all): *1. Establish state IT centers of defense | 2. Aggravate penal provisions | 3. Transparent and self-critical journalism | 4. Quick reaction of the authorities to set right evil and made up things immediately | 5. Obligation of operators to remove evil and invented from the net | 6. Obligation of operators to mark fake news as such*
Further questions:
#1) Please state how often you perform the following activities. (hourly, daily, more than once a week but less than daily, less than once a week, never): *1. Using a smartphone | 2. Using Facebook | 3. Using Twitter | 4. Using YouTube | 5. Using other forms of social media | 6. Posting messages to social media*
#13) In your opinion, should federal authorities in Germany have the right or not to guarantee public safety? (definitely yes, rather yes, neutral, rather no, definitely no): *1. All information controlled by the state should be made publicly accessible, even if posing a risk to public safety. | 2. The public safety should have priority, even if this restricts the access to information controlled by the state.*
#18) In your opinion, what poses the greatest threat to peace in Germany? (very great, great, neutral, little, very little): *1. Other States | 2. Nationalism | 3. Multicultural coexistence | 4. Climate change | 5. Social injustice | 6. German politics | 7. Left-wing extremism | 8. Religious fanaticism | 9. Capitalism | 10. Globalization*
#23) How do you assess the following advice for using social media during crisis situations? (very important, rather important, neutral, rather unimportant, very unimportant): *1. When you find or share wrong information, correct them.*
#25) How do you assess the following aspects of social media usage during crisis situations? (strongly agree, agree, neutral, disagree, strongly disagree): *1. You are responsible for your postings, please consider possible consequences. | 2. Verify your information before publishing.*

Analyzing the Potential of Graphical Building Information for Fire Emergency Responses: Findings from a Controlled Experiment

Abstract. To better support firefighters during emergency response processes, novel information technologies are frequently being presented in research and practice. While such approaches are often technology-driven in nature, we present a task-centered approach to identify the actual information demand during emergency response scenarios. As an important example, we examine the search and rescue task. Combining the theory of situation awareness with findings from cognitive science, we hypothesize that providing graphical information about the building and the location of victims increases firefighters' task performance in comparison to a verbal briefing. Findings from a controlled experiment that was developed in cooperation with a state firefighting academy show that such information might indeed facilitate the task performance. A continuous access to such information during the entire mission was found to be less effective, though. Our findings have implications for the development of novel information technologies and call for an adaption of current working routines.

Keywords: Firefighter information technologies, Situation awareness, Cognitive Science, Laboratory experiment.

1 Introduction

Newly emerging firefighter information technologies (FITs) such as digital plans [1, 2], unmanned aerial vehicles [3, 4], on-site emergency response systems [5, 6], augmented reality devices [7, 8], or intelligent protective clothing [9, 10] open up novel opportunities to gather, process, and present real-time information about the site of a fire emergency. They are hence supposed to bear a significant potential to facilitate the making of context-dependent decisions and, accordingly, to support the emergency response process. Currently, however, novel FITs are developed and proposed mainly based on their innovative capabilities and the presumably resulting potential to support the emergency response process. Recent studies indicate that such technology-driven approaches run a risk to neglect the specific nature of emergency response processes and might miss the actual demand for information [11].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

During emergency responses, firefighters make time-critical decisions in a dynamic environment. By improving the information base, new and emerging information technologies might facilitate the decision-making process. However, there also exist tight constraints, for instance with respect to the time and the margin for error. The provided information hence needs to be succinct, easy to process and straightforwardly understandable without distraction. To make sure that firefighter information technologies indeed meet the demand that exists on site, it appears thus necessary to investigate, (i) which kind of information is effective in enhancing the performance of firefighters during their operations and (ii) how information technologies should be designed to deliver the information adequately. Yet, so far literature hardly discusses under which circumstances (and subject to which task-specific requirements) novel FITs are viewed as beneficial by prospective users.

With the work at hand, we intend to contribute to the closure of this literature gap. Narrowing the scope, we focus on examining, which kind of information is effective in supporting the search and rescue task. This task was identified as an appropriate study object during a roundtable discussion with instructors of a firefighting academy for several reasons: first, the task frequently occurs during daily emergency responses. Second, firefighters typically suffer from an insufficient information basis during this task. Third, emerging FITs like digital plans and on-site emergency response systems are proposed in literature to better support this task (among others). In our study, we examine the following research questions: "*Does an up-front presentation of a graphical building plan and the location of a victim during the mission briefing improve the search and rescue task compared to a verbal description? Does the continuous availability of a graphical plan during the mission further improve the task?*"

To achieve rigorous results, we conducted a controlled experiment, in which 69 firefighter squads were provided with information about the building and the victim location in different formats and with different forms of availability. The experiment was conducted in cooperation with a Bavarian firefighting academy, which made available a building that has been designed for fire emergency response training purposes and resembles a typical small apartment house in Germany. The design of the experiment is informed by findings from cognitive science on the processing of information formats and on cognitive overload. The experiment results indicate in how far graphical building information is effective in enhancing typical fire emergency response operations. Accordingly, they provide an empirically grounded basis for the design of firefighter information technologies such as digital plans, on-site emergency response systems, or augmented reality devices, which shall make available such information to firefighters during the emergency response. As domains with high stress levels, strict timing constraints, and low margins for error hardly have been in the focus of research so far, the results of our study furthermore complement existing findings from cognitive sciences.

In section 2, we discuss the background of our study. Furthermore, we develop the hypotheses and the research model underlying the design of our experiment. In section 3, we describe the experiment design. Section 4 presents the obtained results. We discuss the results and the implications for academia and practice in section 5. In section 6, we conclude by summarizing the findings and outlining future research directions.

2 Background, Hypotheses, and Research Model

During fire emergency response operations, firefighters make time-critical decisions in highly dynamic situations. Because of the existing time constraints, they often must decide on a basis of insufficient information. Improving the information basis and increasing the so-called situation awareness is hence supposed to be a critical success factor to achieve better and/or quicker decisions [12, 13]. The theory of situation awareness can be applied to various domains, in which actors make time-critical decisions in stressful situations. Besides emergency responders like firefighters, it has also been applied to pilots and soldiers. Generally, situation awareness is established in a three-level process of perception, comprehension, and projection [12]. In the perception phase, the actor must capture all relevant aspects of the situation. In a simplified example, a firefighter would have to realize that there is smoke coming from an open window on the second floor or that the house door is closed. In the comprehension phase, the actor must try to connect the different aspects to build a holistic understanding of the situation. The firefighter would have to understand that there is a fire, which could be reached by breaking the door or using a ladder to reach the window. Finally, based on perception and comprehension, the actor can make projections about the near future. The firefighter could predict that the fire might spread to other rooms and could be reached faster through the window. All three levels of situation awareness demand qualitatively and quantitatively sufficient information. In this context, information technologies such as the FITs mentioned in the previous section can be an effective means to deliver this information. Looking at the research conducted on situation awareness in emergency response management, however, there is a strong focus on large-scale phenomena like the handling of extraordinary disasters or the coordination of multiple agencies [14, 15]. To our best knowledge, the theory has not yet been applied to study daily routines of firefighters such as search and rescue of victims.

2.1 Development of Hypotheses

To identify how information needs to be presented in such a scenario to increase situation awareness, we consulted relevant literature of cognitive science. Various studies in this field indicate that especially graphical information can be used to effectively and understandably provide information to humans. The graphical format often proved to be superior to other forms of presentation like natural language or written words. Generally, humans seem to better recall pictures and other graphical information than the identical information coded in words [16-18]. As an explanation for this, Kaplan, Kaplan and Sampson [16] showed that the human brain double-codes pictures (i.e., both verbally and visually). This mental connection between graphics and words enables people to better recall the information. A special form of graphical information are diagrams. Due to the support of numerous perceptual interferences and the grouping of related information, they can further improve comprehensibility [19]. Mousavi, Low and Sweller [20] showed that another improvement can be achieved by connecting the graphical information with corresponding verbal explanations. According to Mayer and Sims [21], these effects specifically apply to inexperienced persons. Since firefighters typically are not acquainted with the concrete situation and environmental conditions when responding to an emergency (in our scenario the apartment they will be operating in), they can also be characterized as inexperienced. Deducing from the above findings of cognitive science, we assume that firefighters with access to graphical information about a building shall be able to better recall this information during a mission. Accordingly, they should also be able to perform search and rescue tasks better. With our study, we apply the general findings of cognitive science to the practical and very special domain of firefighters. Firefighters typically work under high emotional stress and time pressure in chaotic situations. Yet, according to instructors of the firefighting academy who supported this study, the use of graphical information during responses has by now hardly been identified as a means to overcome these problems in practice. By applying existing findings of cognitive science to this special and comparably unexplored domain, we hence test (and might further increase) their general validity.

The specific characteristics of the firefighter domain, however, also imply a risk that firefighters' cognitive abilities might not suffice to process all information they are receiving. This problem is referred to as cognitive overload [22]. In an emergency, responders are confronted with countless environmental and emotional impressions that need to be processed. Once reaching the point of cognitive overload, they may not be able to completely perceive and memorize information like the graphical building plan examined in our study. For these reasons, we assume that making graphical information available continuously during the mission further enhances the task performance as the information would not have to be memorized but could be looked up when needed. We hypothesize that such a higher degree (of availability) of graphical information will have a positive effect on its usability and, accordingly, the task performance.

2.2 Research Model

To capture the background of our study more precisely, we integrate our assumptions into a research model. We postulate that different degrees of graphical information provide differing support for firefighters during their tasks. Particularly, we expect the different degrees of information to have an impact on their usability for firefighters. Usability as such can be further operationalized into three aspects: the effectiveness (i.e., the accuracy with which a task is fulfilled), the efficiency (i.e., the effectiveness in relation to the effort needed to complete a task), and the satisfaction (i.e., the users' comfort while performing a task) [23, 24]. Following this definition, we concretize our three hypotheses as follows (the resulting research model is summarized in Figure 1):

- **H_1**: Firefighters provided with a higher degree of graphical building information will be able to perform the task more accurately.
- **H_2**: Firefighters provided with a higher degree of graphical building information will need less time to perform the task accurately.
- **H_3**: Firefighters provided with a higher degree of graphical building information will be more satisfied while performing the task.

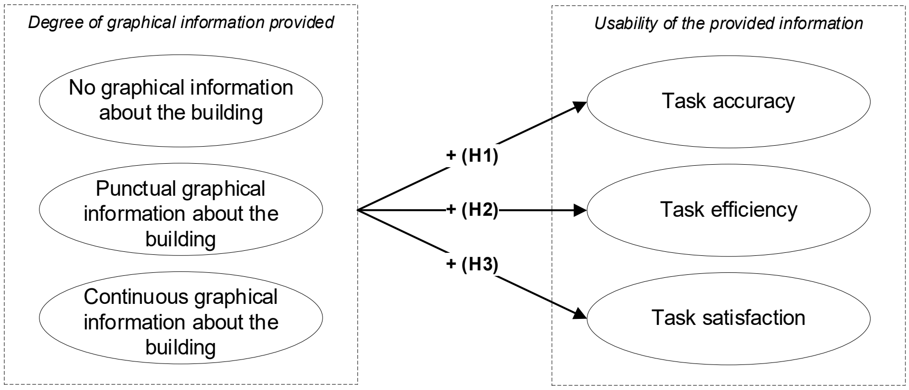

Figure 1. Research model

3 Research Procedure

To examine H_1-H_3, we conducted a controlled laboratory experiment. Next, we present the design of this experiment to evaluate H_1 and H_2. Thereafter, we describe the questionnaire that accompanied the experiment and was used to examine H_3.

3.1 Controlled Laboratory Experiment

Our experiment was developed and conducted in cooperation with the Bavarian state firefighting academy in Würzburg, Germany. In this academy, firefighters from all over Bavaria are trained in several tasks like salvage rescue, firefighting, and incident command. By means of the academy's specialized training facilities, we were able to simulate a realistic scenario under safe conditions. Despite providing a realistic scenario, the environment nevertheless allowed us to control surrounding factors in order to conduct a laboratory experiment following the guidelines given by Cox and Reid [25].

The experimental setting was developed in a collaboration with a group of instructors of the firefighting academy. Beginning with a roundtable session in late 2017, we identified various everyday tasks in which firefighters typically suffer from a lack of information. As one of the most critical of these scenarios, the instructors introduced the search and rescue of a victim during an apartment or house fire. Based on this scenario, we developed our concrete experiment in a second roundtable session.

In our experiment, a squad of firefighters responded to an apartment fire in the basement of a two-story building. The building was represented by the academy's fire training building (cf. Figure 2). It emulates a typical residential building and was specifically designed to simulate apartment fires by means of remotely controlled gas-fires and simulated smoke from fog machines. Inside the burning apartment, a life-size dummy depicted a missing, unconscious person. The squad responding to the apartment fire consisted of a squad leader and a team of two firefighters. The squad leader commanded the response by first investigating the scene and then briefing the team. In the experiment, the squad leader was represented by a member of our research team. In so doing, we could control the equality of the briefings. The team's performance, consequently, was not influenced by the abilities of its squad leader but only by the received information. The firefighter team got a briefing on the situation and was then commanded to enter the burning apartment to search and rescue the missing person. The positions of the team were taken by random firefighters wearing self-contained breathing apparatuses (SCBA). Other positions of a real-life squad like the operator of the fire engine and a second team of firefighters on standby have not been included in the experiment, because they would have had no connection to our experimental interventions.

The subjects who acted as team members were retrieved from firefighting courses, which took place from March to July 2018. Due to capacity restrictions, places in those courses are limited and distributed among all Bavarian fire departments. This resulted in a diverse, random sample of subjects. Each team consisted of two subjects and was randomly assigned to one of three equally sized groups [25]: G_0, G_1, and G_2. $\mathbf{G_0}$ was the control group. Teams of this group received a verbal briefing and command without any graphical resources, which represents the current state of the art for such rescue missions. The teams were briefed with the following standardized phrase: "There's an apartment fire in the basement, one person is missing but we know their presumable location. Heading down the stairs, there are four doors: one ahead, two on your left, and one at your left back. To reach the person, you must take the farer left door. Then cross the following corridor straight ahead. In the room after the corridor, you must go to the right around a room divider. There, you should find the person. Intervention team for search and rescue with the first hose line to the basement via the stairs, go!"

$\mathbf{G_1}$ was the first treatment group. As treatment, teams of this group received punctual access to a sketch-map of the apartment during the briefing. As shown in Figure 2, the map contained the apartment's layout including stairs, walls, doors and the victim's location. The squad leader briefed them with the identical phrase that was also used in the control group. This time, however, he visualized the verbal information in the map, for example by pointing toward the doors the team was supposed to go through. After the briefing, the team entered the building without any further access to the sketch-map.

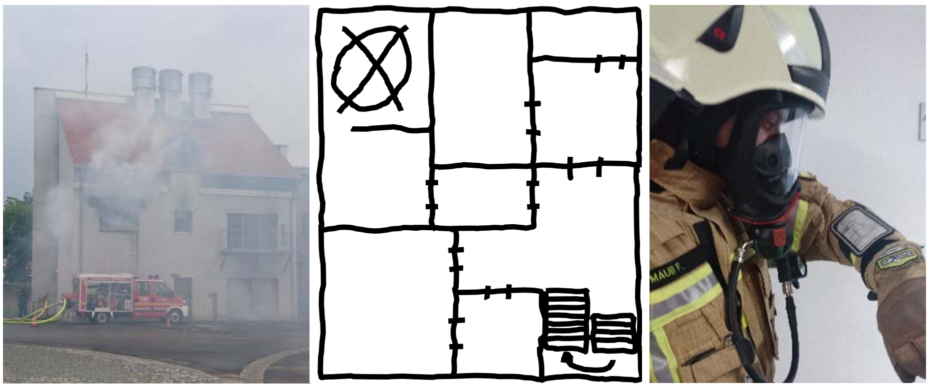

Figure 2. Fire training building (left), sketch-map (middle), and small-scale copy on the team leader's sleeve for continuous access (right)

G_2 was the second treatment group. The treatment received by teams of this group was continuous access to the before-mentioned sketch-map. Like the teams of G_1, they were briefed with the standardized phrase supported by the graphical information of the map. In addition, they also took the graphical information with them during the rescue mission. To simulate an information device, they were equipped with a small-scale copy of the sketch-map that was wrapped in a protective cover and fastened on the team leader's sleeve (cf. Figure 2). As discussed in section 5, the real-world application of our treatments – especially the continuous access to the map – will inevitably require the use of information technology. As an approximation to measure the resulting effects, however, we decided to stick with the paper-based solution.

To examine **H_1**, we compared the average task completion rates of the three groups. A task was rated as completed if the team could find the dummy and bring it outside. To examine **H_2**, we took the time the firefighters needed to complete the task. Precisely, we took the time the teams needed to find the dummy inside the apartment. The period began once the first team member crossed the door sill and ended once the first team member reached the dummy. Since there was no visual contact with the team, an instructor (who was following the team for security reasons anyway) radioed to the squad leader once the dummy had been found. By comparing the average times needed to find the dummy for the three groups (task completion time), we could test **H_2**. Finally, to examine **H_3**, we captured the task satisfaction of the participants by means of a questionnaire as described in the next subsection. Tables 1 and 2 summarize the experimental design.

Table1. Summary of the different groups

Groups
G_0: verbal only information
G_1: verbal + punctual graphical information
G_2: verbal + continuous graphical information

Table 2. Summary of the tests of Hypotheses

Test of Hypotheses
H_1: task completion rate
H_2: task completion time
H_3: After-Scenario Questionnaire (cf. 3.2)

Following the requirements of a laboratory experiment, we took several measures to ensure the internal and external validity of our results [25]. Regarding internal validity, we tried to make our treatments the only varying factor between the different groups. Consequently, we controlled the surrounding conditions as far as possible. First, all teams had to perform the identical task. The dummy had been positioned at the identical spot in the same room for all teams. The doors on the way were equally closed, and the rooms had been equally filled with smoke. All in all, the briefing at the beginning of the task was the only varying factor between the groups.

Also, the search and rescue task was chosen with the goal to ensure internal validity in mind. In a firefighting task, for example, several other factors like hose management and extinguishing technique might have affected the task completion time much more than our treatments. In our scenario, on the other hand, the teams' orientation abilities inside the apartment were the major determinant for how long it took to find the dummy. As another measure, we ensured that the participants had no prior knowledge of the apartment or the task. The teams were separated and not allowed to watch other teams during their briefings or the tasks itself. This way, we could rule out learning effects and keep the conditions equal for all teams. Finally, we captured several control variables like the firefighters' experience, age, and other in the questionnaire to rule out differences based on those factors (cf. Section 3.2).

We maximized external validity mainly by choosing the fire training building as a realistic site. Since it was specifically designed to simulate apartment fires, the task could be reproduced as realistically as possible under safe and controlled conditions. Remotely controlled gas-fires provided heat and real flames. Multiple fog machines simulated realistic smoke and limited the sight to only a few centimeters. Loudspeakers played acoustic stimuli like the crackling of the fire. All in all, the surrounding conditions of the experiment were closely comparable to those of a real-world emergency. Besides, the scenario itself was developed in roundtable sessions with instructors of the firefighting academy and characterized as a realistic everyday scenario for firefighters. Furthermore, the sample of subjects contributed to ensuring external validity. All participants were firefighters that also conduct this kind of tasks in real operations. We hence assume that our results are transferable to comparable real-life emergency operations of firefighters.

3.2 After Scenario Questionnaire

To capture feedback from our participants and assess their task satisfaction, we used a questionnaire. In its first part, we asked about general and demographic information. This way, we wanted to record several control variables that could have an influence on our results. To assess the firefighters' experience, we asked both team members for how long they have been members of a fire department and for how long they have been trained to wear SCBA. Besides that, we captured the average number of emergencies and SCBA-operations they are responding to per year. Furthermore, we asked for the command level they are normally working in and the type of fire department they are working for. Finally, the age and gender of our participants were captured. This first part of the questionnaire was filled out prior to the task.

In the second part of the questionnaire, we wanted to assess the participants' task satisfaction to examine $\mathbf{H_3}$. This part was filled out by the firefighters right after completing their task. Due to previous experiences in questioning firefighters in or shortly after stressful situations, we wanted to keep this part as short and simple as possible. Consequently, we decided to use the easy, yet well-established After-Scenario Questionnaire (ASQ) [26]. The ASQ consists of three items that we slightly adapted:

- Overall, I am satisfied with the ease of completing the task in this scenario
- Overall, I am satisfied with how long it took to complete the task in this scenario
- Overall, I am satisfied with the available supporting information when completing the task in this scenario

All three items had to be rated by the teams on a seven-point scale ranging from 1 (strongly disagree) to 7 (strongly agree), as well as an n/a-point. To gather additional qualitative feedback, we included open-ended questions about what the firefighters perceived as positive and negative about the available information.

4 Results

During the experiment, we observed the performance of 150 firefighters that were composed to 75 teams. We could, however, not use all 75 observations for various reasons. For example, one team already knew the fire training building from a previous visit, another accidentally activated an emergency shutdown button, and one team was interrupted by a technical fault. All in all, we had to delete six observations from our initial sample, which resulted in an adjusted sample of 69 teams. Those remaining teams were equally distributed among the three groups, resulting in 23 observations per group.

Regarding our control variables, the participants were 27 years old on average, mainly male (>98%), have been members of a fire department for 12 years, and trained to wear SCBA for 7 years. On average, they respond to 26.48 emergency operations per year. Of those operations, they are wearing and actually applying SCBA 3.62 times a year. Looking at the command level, 24 of our participants had a team member qualification, 56 had a team leader qualification, 50 had a squad leader qualification, and the highest qualification of eight was the one of a platoon leader. Finally, most of our participants (>98%) were members of voluntary fire departments. To rule out possible influences, we calculated the correlation coefficients between our control and dependent variables. None of those coefficients are significant, however.

As stated before, our dependent variables are the task completion rate, the task completion time, and the three items of the ASQ (satisfaction with ease, satisfaction with time needed, and satisfaction with available information). We summarize the means and standard deviations of those factors for the three groups in Table 3. For all factors, there are first impressions of superiority for $\mathbf{G_1}$ and $\mathbf{G_2}$, which had graphical information available. Most dominantly, the means of the task completion times of $\mathbf{G_1}$ and $\mathbf{G_2}$ were lower than that of $\mathbf{G_0}$. Looking at the ASQ items, $\mathbf{G_1}$ showed the highest agreement, whereas $\mathbf{G_0}$ showed the lowest. Interestingly, it was not $\mathbf{G_2}$ with continuous graphical information that showed the best results, as our hypotheses implied. Instead, $\mathbf{G_1}$ with only punctual access to graphical information performed better.

Table 3. Descriptive summary and test statistics

	Group 0		*Group 1*		*Group 2*		*t-tests (p-values)*		
	mean	*SD*	*mean*	*SD*	*mean*	*SD*	*G_0 vs G_1*	*G_0 vs G_2*	*G_1 vs G_2*
Task completion rate (0 or 1)	0.87	0.34	0.96	0.21	0.87	0.34	0.15	0.50	0.15
Task completion time (sec.)	340	100	285	78	289	67	0.02*	0.03*	0.41
ASQ 1	4.30	1.74	5.22	1.59	4.61	1.62	0.04*	0.27	0.10
ASQ 2	4.43	1.38	5.17	1.40	4.57	1.50	0.04*	0.38	0.08
ASQ 3	5.52	1.73	5.96	1.58	5.83	1.56	0.19	0.27	0.39

Legend: ASQ items from 1=disagree to 7=agree; *: $p < 0.05$, one-tailed testing, N=69, each group n=23)

To examine the statistical significance of those impressions, we employed t-tests to check for differences between the groups. Since our hypotheses implied an increased task completion rate, decreased task completion time, and increased task satisfaction for $\mathbf{G_1}$ and $\mathbf{G_2}$, we used one-tailed, unpaired t-tests. The test results are summarized in Table 3. As can be seen, there were no significant differences between the groups regarding task completion rate. Consequently, $\mathbf{H_1}$, which implies that a higher degree of graphical building information would help firefighters to perform their task more accurately, cannot be accepted. We could not identify any significant differences between control group $\mathbf{G_0}$ and treatment groups $\mathbf{G_1}$ and $\mathbf{G_2}$.

For task completion time, Table 3 indicates that the teams of both treatment groups $\mathbf{G_1}$ and $\mathbf{G_2}$ were significantly faster than the teams of control group $\mathbf{G_0}$. However, a significant difference between the two treatment groups could not be observed. For a more detailed insight into the task completion times, we generated boxplots that are shown in Figure 3. The more robust measures of the boxplots confirm the beforementioned results. The medians and quartiles of $\mathbf{G_1}$ and $\mathbf{G_2}$ are consistently below the ones of $\mathbf{G_0}$. The only visible difference between the treatment groups is the slightly higher median of $\mathbf{G_2}$. Overall, $\mathbf{H_2}$, which implies that firefighters provided with a higher degree of graphical building information would need less time to complete their task, can be partially accepted. Both forms of graphical information did make a significant difference compared to the verbal instruction. The degree of graphical information (i.e., punctual or continuous access) showed no further impact.

Looking at the task satisfaction, there are two significant differences in the ASQ item values (cf. Table 3). Members of $\mathbf{G_1}$ were more satisfied with the ease of completing the task and the time needed to complete it than members of $\mathbf{G_0}$. On the other hand, there were no significant differences regarding the satisfaction with the available information. In addition, the values of $\mathbf{G_2}$ show no significant difference to the other groups at all. Consequently, $\mathbf{H_3}$, which implies that a higher degree of graphical building information increases firefighters' task satisfaction, can again be partially accepted. The punctual access to graphical information during the briefing did raise the task satisfaction, while the continuous access to graphical information during the mission did not.

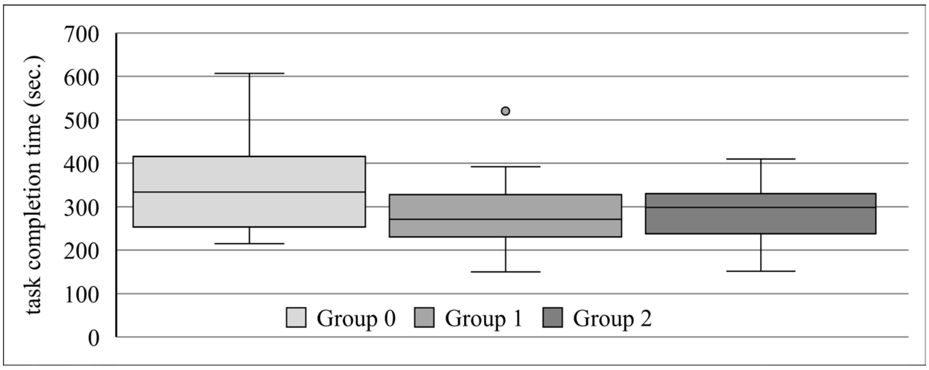

Figure 3. Boxplots for task completion time by groups

5 Discussion

In this section, we discuss our results in more detail. The discussion is informed by qualitative feedback gathered during the experiment, insights from reviewing the results with instructors of the firefighting academy, and scientific literature.

As shown in the previous section, our results only partially support the hypotheses. Regarding the task completion rate, there were no significant differences between the groups at all. Looking at the firefighters' qualitative feedback, all teams that were not able to complete their task stated physical exhaustion as the reason. They all managed to find the dummy but had to give up on their way out. None of the tasks failed due to insufficient information or lost orientation. Consequently, it seems that there has been no impact of our treatments toward the task completion rate.

With punctual graphical information, however, the firefighters could perform their task faster and were more satisfied than with verbal information. This outcome also corresponds to qualitative feedback from the participants. In $\mathbf{G_0}$, they criticized that they received *"too much information in a short time"* and that the information was *"misleading."* In $\mathbf{G_1}$, on the other hand, they praised the *"short overview"* that was *"well understandable"* and allowed a *"better orientation."* Opposed to our hypotheses, the continuous access to the graphical information did not bring further improvements. The firefighters belonging to $\mathbf{G_2}$ could perform their task faster than those of $\mathbf{G_0}$. The task satisfaction, however, was not significantly different. Between $\mathbf{G_1}$ and $\mathbf{G_2}$, there were no differences, at all. Possible reasons for this can again be found in the qualitative feedback. In $\mathbf{G_2}$, the firefighters saw a too strong *"distraction"* and *"fixation"* to the map that led to the problem of *"blindly relying on it"* and *"overlooking things."* Consulting the instructors of the firefighting academy, we identified the low complexity of the building as an additional explanation why there were no advantages in the continuous access to the graphical information. The layout of the apartment and the way to the dummy as it is displayed in Figure 2 might have been simple enough that the firefighters did not experience cognitive overload [22]. According to the instructors, though, a real-world apartment fire is rarely more complicated. It seems that for the scenario of apartment fires, a short look on the map simply suffices. In larger events with more complicated layouts like multiple burning apartments or a burning hospital, however, they see potential in the continuous access to the information.

Looking at the practical adoption, our experiment did not include the creation of the sketch-map. Since we wanted to provide the teams with standardized briefings for internal validity, the squad leader position was taken by a member of the research team. In reality, the squad leader would have to ask the house owner or neighbors for information about the building and draw the map according to it. The time effort of drawing must, of course, be opposed to the time gained by completing the task faster. According to the instructors, however, the squad leader would question knowledgeable attendants anyway. He would also have some short time to draw a map while the team is grabbing their equipment and preparing to enter the building. Of course, the much more favorable solution would be that the graphical building information is available already in advance to an emergency. This would save time and is not depending on the availability of attendants. One solution would be that house owners provide their local fire department with building plans and the department stores them in a database.

As stated before, the application in practice might benefit from using information technology. Of course, the first treatment of punctually presenting the graphical information may also work with simpler means like pen and paper. It is, however, unclear if the squad leader could be able to draw a sketch-map faster with electronic means like a drawing software on a tablet computer which provides predefined design elements. This should be examined in further experiments. In the previously discussed case that the graphical information might be available prior to an emergency, the pure amount of data would call for the use of information technology. Corresponding FITs that are discussed in literature are digital plans [1, 2] and on-site emergency response information systems [5, 6]. Making the information available continuously will, however, require the use of additional, more intricate information technologies. On the one hand, the information would have to be duplicated in real-time. While the sketch-map is given to the team, another instance of it should remain with the squad leader for his commanding duties on site. On the other hand, the map taken by the team would have to be heat-resistant, waterproof and readable in dark smoke. Instead of the paper approximation that we used in our experiment (cf. Figure 2), different FITs might be used in practice. Displays could be integrated into the sleeves of intelligent protective clothing [9]. Also, augmented reality systems could be used to display the graphical information in the firefighters' breathing masks [7]. A third approach was proposed by one of the participants. For the search for fires and victims, firefighters often carry infrared cameras with them. The displays of those cameras could also be used to show the sketch-map. This way, the firefighters would not have to carry any additional devices with them but could use systems they are already used to. It might indeed be the simplest, yet most acceptable solution for the practitioners. The performance of all those technological solutions should be examined in future research.

All in all, our results hold several implications for both academia and practice. Regarding academia, we present a task-centered approach to identify information potentials for a specific scenario and propose suitable technological solutions for firefighters. This constitutes an alternative approach compared to the mostly technology-driven development of FITs. The overall procedure can be transferred to many other problems. First, other scenarios from the firefighter domain can be examined in a similar way. From salvage rescues after car accidents to forest fires, there are many possible scenarios. Besides, the procedure can be applied to scenarios of other first responders like police or rescue departments as well. In the work at hand, we build on the theory of situation awareness. While this theory is well established in emergency management, it has by now mainly been used to examine higher levels of severity. In our study, we demonstrate its applicability in a comparably small-scale and everyday scenario. To increase situation awareness, we furthermore combine this theory with findings from cognitive science. In so doing, we also show the applicability of those findings in the special domain of firefighting and could even partly confirm them.

Regarding implications for practice, we showed a potential adaption of the firefighters' conventional procedure of getting to work as fast as possible, even with insufficient information. In our experiment, we could demonstrate the positive effects of improved situation awareness. By providing the firefighters with suitable and easy to process information like a sketch-map, the task completion time could be significantly reduced. Consequently, it might make sense for the squad leaders to take a little more time to establish situation awareness in order to gain overall time advantages. The involved instructors of the firefighting academy also support the findings of the experiment. They meanwhile integrate those findings into the squad leader courses held at the academy. They try to sensitize the firefighters for the importance of situation awareness even in time-critical operations and discuss how it can be established. All in all, our study demonstrates the potential of specific information for the firefighters. The developers of FITs can use our findings to provide firefighters with such information.

Although we implemented several measures to ensure internal and external validity, there are some limitations. First, we concentrated on the specific scenario of an apartment fire. Accordingly, our results will only be transferable to real operations of this type. By now, we only used paper approximations to display the information. Employing information technologies might increase or decrease the identified effects. Therefore, as a point of future research, the graphical information should be implemented in according technologies and analyzed in additional experiments. As stated above, the scenario was realistic but not very complex. To examine the potential of continuous access to the information in detail, more complex scenarios than search and rescue during an apartment fire should be analyzed. Furthermore, 98% of our subjects were members of a voluntary fire department. While voluntary and professional firefighters perform equal tasks in Germany, there might still be differences regarding the fitness level or training frequency. To strengthen our results, an additional experiment with professional firefighters might be wise. Finally, our sample of subjects consisted of firefighters from all over Bavaria. Since firefighting tasks and training are comparable in Germany, our results can be transferred to German firefighters. Due to differences in the organization of fire departments and emergency response processes, however, we cannot straightforwardly transfer the results to other countries.

6 Conclusion and Outlook

In an attempt to facilitate the design and implementation of suitable information technologies that provide adequate support for firefighters during critical everyday missions, we presented the results of a controlled experiment, in which we examined the efficacy of different kinds of information during the search and rescue task. During the planning of our study, the search and rescue task was identified as an important task, in which the performance might be affected negatively due to an insufficient information base. At the same time, various FITs have been suggested to also facilitate this task. In our study, we found indications that certain kinds of information about the building and the victims might be effective in enhancing the task performance. However, our findings also provide indications that the continuous access to such information (as it is, for instance provided with augmented reality devices) might not provide a further improvement. Judging from the findings of our study, the design of FITs hence ought to be carefully aligned to the task that is to be supported and the information demands.

In future iterations, we plan to strengthen both the theoretical implications and the conceptual foundations of our research. To examine the robustness of our findings, we will further increase the sample size. Moreover, we plan to re-evaluate our results in different scenarios and settings, for instance with varying building and situation complexity, with members of other types of departments (such as professional firefighters), or in settings where the squad leader only has ambiguous or incomplete information. Based on the gathered results, we plan to implement and test FITs that provide theoretically grounded and empirically proven support for the search and rescue task. To better guide the implementation of such FITs, we also intend to connect our findings to existing literature about indoor-navigation, wearable IT, and other domains, which might deliver additional insights for the task-centered design of FITs.

Although we have not formally tested it, we believe that the proposed procedure to examine the existing information demand and to explore ways to provide an adequate information basis before designing and implementing FITs based on their technological capabilities can also be used to support other tasks during the fire emergency response process. In future iterations, we therefore also intend to deduce a generally usable methodology to design FITs based on relevant theories and empirical evidence. With the presented study, we hope to provide a starting point to change the development of FITs from a primarily technology-driven into a mainly demand-driven process.

Towards a Taxonomy of Platforms for Conversational Agent Design

Stephan Diederich[1], Alfred Benedikt Brendel[1], Lutz M. Kolbe[1]

[1] University of Goettingen, Chair of Information Management, Goettingen, Germany

{abrendel, lkolbe}@uni-goettingen.de

Abstract. Software that interacts with its users through natural language, so-called conversational agents (CAs), is permeating our lives with improving capabilities driven by advances in machine learning and natural language processing. For organizations, CAs have the potential to innovate and automate a variety of tasks and processes, for example in customer service or marketing and sales, yet successful design remains a major challenge. Over the last few years, a variety of platforms that offer different approaches and functionality for designing CAs have emerged. In this paper, we analyze 51 CA platforms to develop a taxonomy and empirically identify archetypes of platforms by means of a cluster analysis. Based on our analysis, we propose an extended taxonomy with eleven dimensions and three archetypes that contribute to existing work on CA design and can guide practitioners in the design of CA for their organizations.

Keywords: Conversational agent, chatbot, design science, taxonomy, cluster analysis

1 Introduction

As artificial intelligence, particularly machine learning, increasingly permeates and impacts our daily private and professional lives, it drives a new wave of technological change and unprecedented automation of cognitive tasks [1]. One phenomenon in this wave are continuously improving conversational agents (CAs) which benefit from expanding functionalities and the diffusion of powerful and connected (mobile) devices. The presence of CAs is more and more increasing, such as in the form of Apple's Siri, Amazon's Alexa or in-car assistants. Basic CAs conduct information search for us, send messages or enter meetings in a calendar. Similarly, more and more companies use CAs for different purposes, such as automation and innovation in customer service or marketing and sales [2–7]. CAs can be distinguished from other software by their ability to interact with users based on natural language. This language can be spoken, as for example in the case of Amazon's Alexa, or written, often referred to as chatbots. In recent years, CA capabilities significantly expanded from simple rule-based systems to seemingly intelligent assistants [5, 8, 9] as a result of advances in machine learning and natural language processing.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

In research, CAs attracted increasing interest in the last few years with different foci, such as information disclosure of users [10, 11], human performance improvement [12] or user authenticity perception [8]. In parallel with increased research interest in the IS community, organizations have started to experiment with and introduce CAs, often in the context of larger artificial intelligence initiatives [4, 8, 13]. However, many CAs fell behind expectations and often disappeared due to flaws related to their design, thus successful design remains a complex challenge in practice where various aspects need to be addressed [5, 14, 15].

With the popularity of CAs in both research and practice, a variety of enterprise CA platforms has emerged, supporting the design of CA with different functionality [16]. This includes both offerings of established technological players, such as Google's DialogFlow, as well as start-ups specialized in CAs such as ManyChat. While several studies can inform CA design through principles of form and function [5, 17, 18], the platforms that are used to actually designing CAs, providing both possibilities as well as constraints for the implementation, have not been studied in the past to the best of our knowledge. In order to gain a better understanding of these novel platforms, we first study along which dimensions CA platforms can be categorized (RQ1). Building on these dimensions and empirical data, we then aim to identify archetypes of platforms and their distinctive characteristics (RQ2). To address these research questions, we first develop a taxonomy of CA platforms, both conceptually from a literature review and empirically through the iterative classification of platforms. We then perform a cluster analysis to identify archetypes and gain a better understanding of commonalities and differences between the platforms.

We continue by describing the research background on CAs and presenting our research approach, i.e. taxonomy development followed by a cluster analysis. Finally, we present and discuss our results, particularly the developed taxonomy and identified archetypes, and close by suggesting directions for future work on CAs.

2 Research Background

The basic idea of a CA is to interact with users using natural language just like in a human-to-human conversation [19] and exchange information through verbal communication about a common topic [20]. This idea dates back decades to the 1960s when the first CA, called ELIZA, was developed by Joseph Weizenbaum [21]. Since then, a variety of CAs emerged (and often disappeared) that used simple pattern matching to provide a set of responses to the users [5, 22]. With recent technological advances, particularly in the fields of machine learning and natural language processing, as well as the diffusion of powerful, connected devices, the capabilities and potential of CAs increased significantly and they moved from rule-based systems to seemingly intelligent agents [22, 23]. Due to this development, CAs regained momentum in research and practice in the past few years and a variety of new CA offerings emerged.

In order to organize this variety that is available today, Gnewuch et al. [5] provide a simple taxonomy that consists of two dimensions including primary mode of communication and context (see Table 1). As natural language can be written or spoken [24], the mode of communication indicates the primary way in which users interact with a CA. For example, Apple's virtual assistant Siri is accessed using voice commands whereas Spotify's messenger bot works using digital text messages. CAs with text-based input are often referred to as chatbots in research as well as practice [2, 25, 26], while CAs with speech-based input are described as virtual or digital assistants [25, 27]. Because voice input can be quite easily transferred to written input in most cases, the boundaries between the mode of communication are often blurred as bots offer both spoken and written language as input. For example, a customer can request a ride with Lyft both via chat, e.g. Facebook Messenger or Slack, and by voice command, for example with Amazon Echo [28].

The second dimension, context, indicates whether the CA serves a specific domain such as a task or business function, or can interact on any topic with its users [5, 29]. General-purpose CAs like text-based Cleverbot [30] and Mitsuku [31] can have a conversation about any topic and continuously learn as they interact with users. For speech-based, general-purpose CAs the most prominent examples are from private life, such as Siri or Google Assistant.

Table 1. Classification of CA according to Gnewuch et al. [5]

		Context	
		General-purpose	**Domain-specific**
Communi-cation mode	**Text-based***	ELIZA, Cleverbot, Chatterbot, Mitsuku, …	Enterprise-class CAs, IKEA's Anna, Starbucks Chatbot, …
	Speech-based**	Apple's Siri, Amazon's Alexa, Google Assistant, …	SPECIES [29], in-car assistants, speech-based service agents, …

*Text-based: Chatbot, chatterbot, dialogue system, etc.
**Speech-based: (Virtual) personal assistant, digital companion, smart agent, etc.

Domain-specific CAs include a wide variety of CAs, for example in a professional context for internal and external purposes, such as customer service [4, 8], IT service desk tasks, product marketing [3], and e-commerce [14]. Further exemplary domains from private life include museums [32, 33] and healthcare [34].

In order to design a CA, a variety of development platforms exists to model a bot's behavior and to deploy them, for example on Facebook or by embedding the CA in the company website. Such platforms are characterized by an extensible technological foundation, i.e. the natural language processing and machine learning capabilities, created by a platform owner, on top of which developer can build platform-augmenting applications [35], such as conversational agents for a specific domain and organization.

The development platforms offer different ranges of functionality regarding aspects such as the bot's implementation, continuous training, analytics or hosting. With regard to the implementation for example, the platform Chatfuel [36] offers to quickly model a bot's behavior within a few minutes using a web interface while Twyla [37] uses supervised learning to automatically learn from existing data, such as customer service conversations or product catalogues. Concerning analytics, the functionality of CA platforms ranges from basic analysis (e.g. number and length of conversations) to advanced approaches, such as automatic sentiment and topic detection. Overall, a large number of enterprise platforms exists that allows building and introducing both text- and speech-based CA for general-purpose or specific domains.

3 Research Approach

In order to determine the distinct characteristics of CA platforms (RQ1) and to empirically identify archetypes (RQ2), we develop a taxonomy and perform a cluster analysis after classifying the respective platforms. The role of taxonomies is well recognized in information systems (IS) as they provide structure and organize knowledge in a field [38–41]. Within IS research, a multitude of taxonomies has been developed, covering for example business models of FinTechs [42], (mobile) health IT [43, 44] or cybercrime [45]. In particular in a diverse, emerging research area, taxonomies can provide useful insights into the grouping of objects based on their common characteristics [41].

To create our taxonomy, we follow the method proposed by Nickerson et al. [41] which iteratively develops a taxonomy based both on existing conceptual knowledge as well as empirical observation. This method clearly defines the necessary steps and ending conditions, providing a rigorous and useful approach for the systematic creation of a taxonomy, and to avoid the risk of defining and altering dimensions and characteristics through ad-hoc changes. The Nickerson method has been successfully applied to develop a variety of taxonomies, such as for collaborative applications [46] or carsharing business models [47]. Our complete research approach consists of three phases and is summarized in Table 2.

Table 2. Research approach phases

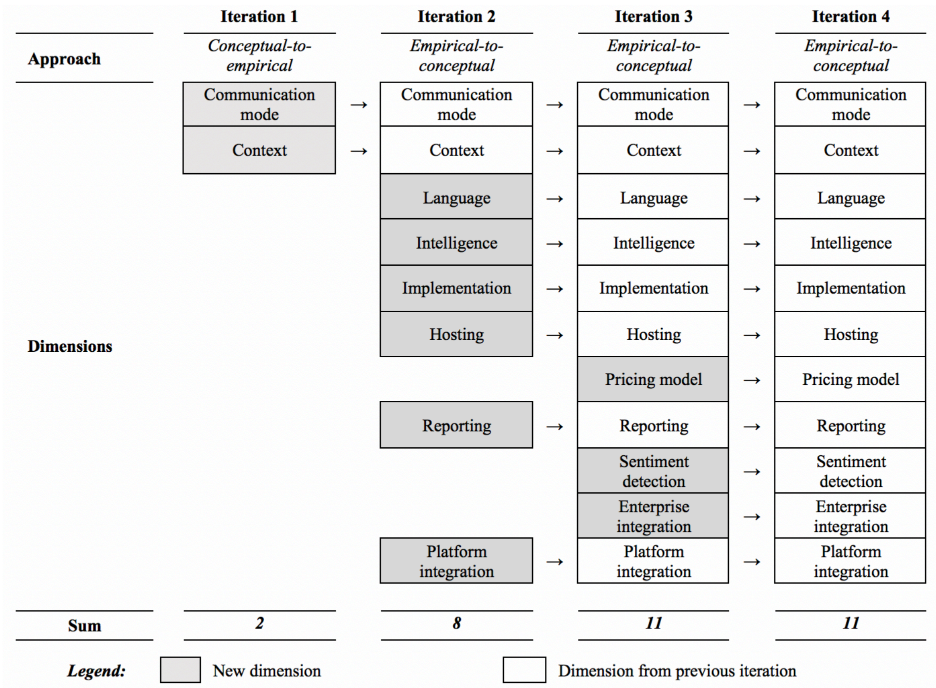
	Phase 1: Create database	**Phase 2: Develop taxonomy**	**Phase 3: Conduct cluster analysis**
Steps	• Search for CA platforms in CrunchBase and on the web • Request additional information where required	• Define meta-characteristic for the taxonomy • Iterate through taxonomy development until ending conditions are met	• Determine useful number of clusters • Specify the companies belonging to each cluster
Method	Lit. review, desk research	Taxonomy development	Clustering algorithms
Source	CA lit., blogs, practice reports, CrunchBase	CA literature, CA platform database	Taxonomy of CA platforms with empirical data
Results	Database with 51 CA platforms	Taxonomy of CA platforms with 11 dimensions	Three identified CA platform archetypes

Phase 1: Set up database: The first research phase aimed at the creation of a database with CA platforms that were operational in May 2018. For this we examined existing literature on CA, searched the world's largest startup database (CrunchBase), a variety of blogs (e.g. https://chatbotsjournal.com), and industry reports (e.g. Oracle [13]). For our search, we used the terms "conversational agent" with the synonyms "chatbot" and "digital assistant" in combination with "design" and "platform". Platforms that were not operational (i.e. actively providing the option to create a CA) were excluded from the database. Missing or incomplete data, particularly on pricing models, was gathered via e-mail requests. At the end of the first research phase, we created a database with 51 platforms for CA design.

Phase 2: Develop taxonomy: The objective of the second phase was to create a taxonomy of CA platforms that contains the most important dimensions along which the platforms differ based on the method described by Nickerson et al. [41]. For our research, we defined CA development platforms as the meta-characteristic for the taxonomy from which all subsequent dimensions follow. Regarding the ending conditions that indicate whether the taxonomy development process is completed, we used the eight objective (such as all objects have been examined and no new dimension or characteristics were added in the last iteration) and five subjective ending conditions (concise, robust, comprehensive, extendible and explanatory) from Nickerson et al. [41]. We started the taxonomy development with a conceptual-to-empirical iteration. In this initial iteration we added two dimensions (CA primary mode of communication, CA context [5, 29]) that were identified in our literature review (see Table 1). The following three iterations were empirical-to-conceptual and added nine dimensions in total, such as pricing model, implementation mode or hosting (see Figure 1). After all platforms in our database were successfully classified and both subjective and objective ending conditions were met, we considered the taxonomy final.

Phase 3: Perform cluster analysis: The objective of the third research phase was the empirical identification of CA platform archetypes (RQ2). For this purpose, we conducted a cluster analysis. Cluster analysis aims at grouping objects where objects in one group are as similar as possible and as dissimilar as possible from objects in other groups [48]. Following the recommendations by Punj and Stewart [49] to first determine the number of clusters and subsequently use an iterative partitioning technique like k-means, we chose a two-stage clustering approach: First, we defined the number of clusters with Ward's method. With this method we agglomeratively clustered (i.e. repeatedly combined the two closest objects into one group until all objects belong to the same group [50]) the CA platforms using SPSS version 25 and squared Euclidean distance. We then reviewed the descriptive data on these iterations, i.e. the coefficient distance, the dendrogram and the scree plot using the elbow rule. These indicated that a three cluster would be most useful. In the second step, we used the chosen number of groups for a k-means clustering procedure. The procedure used three iterations until no significant enhancements were achieved.

Figure 1. Iterations of our taxonomy development



4 Results

In the following, we present our taxonomy for CA platforms (RQ1) and provide examples for platforms to demonstrate their respective characteristics. We then continue with describing the archetypes of platforms we identified in the two-step cluster analysis (RQ2).

4.1 Taxonomy for CA platforms

The resulting taxonomy consists of 11 dimensions with two to four characteristics each (see Table 3). The first two dimensions were found in existing literature [5]. Each platform was assigned one characteristic for each dimension. We omitted dimensions that were the same across all platforms (representation of the CA with an avatar, assigning a name to the CA) as we aim to distinguish them by their main characteristics.

The first dimension, *Communication mode*, refers to the primary way with which a user communicates with a CA and may more broadly described as the user interface, i.e. text-based, speech-based or both [5]. For example, platforms such as ManyChat, pandorabots, or Recime exclusively offer building text-based CAs (referred to as Chatbots) whereas aivo and The Pullstring Platform focus on agents that interact with its users via speech. Furthermore, platforms such as Nuance and IPSoft offer to build and integrate CA that interact via both text and speech. The dimension *context* indicates in which task or business domain a CA built on the respective platform can be used [5]. For example, SurveyBot offers to build specific CAs that conduct surveys and collect their results or Octane AI's CA that provides sales optimization by interactively engaging with users that abandon their digital shopping carts. The dimension *language* refers to the language(s) supported by the CA where platforms offer support for single languages (mostly English, e.g. botmother) or multiple languages (e.g. ChatClub). *Intelligence* indicates whether a CA is primarily based on rules that perform rather simple pattern matching, such as ChatbotsBuilder, or has the ability to self-learn, such as Twyla, enabling the CA to improve over time as it converses with its users.

Existing dimension

New dimension

The dimension *Implementation* indicates how a bot is built, whether via programming (actually writing code), modeling (modeling typical user conversations in a flow chart), supervised learning (training the CA with labeled conversations), or with the help of a hybrid approach (e.g. modeling in combination with supervised learning). Popular platforms for creating a bot via programming are wit.ai, and Zenbot. With regard to modeling, the most common platforms used to build bots include Massively, ManyChat, and LeadFlip. In contrast to programming and modeling, some platforms such as Twyla rely on training a CA with existing user interactions (supervised learning) while others like Creative Virtual and gupshup use a combination of these implementation approaches. *Hosting* refers to the deployment of CAs where platform offerings range from on-premise (e.g. botpress), public cloud (e.g. ChatterOn or Converse), and both methods combined. *Pricing* refers to the pricing model that is used by the platform. The models we observe in our data include usage-based (i.e. based on number of interactions, such as Microsoft Azure Bot), user-based (i.e. based on number users, such as MobileMonkey), instance-based (i.e. based on number of CA, such as ChatbotsBuilder) and free (such as It's Alive).

Reporting indicates whether a CA platform offers reporting functionality to monitor the CA's interactions and usage, such as number of conversations or unique users (for example provided by reply.ai and Lex). *Sentiment detection* indicates whether a platform allows automatic detection of user sentiment during an interaction. Finally, *Enterprise integration* indicates whether a CA platform offers pre-built interfaces or APIs to let CAs access different enterprise systems such as a CRM for information that is used in a conversation with a user. For example, Microsoft Azure Bot Service can automatically retrieve information from its Dynamics CRM in a user interaction via a standardized interface. Other platforms, for example pandorabots or Rasa, can retrieve data from enterprise systems via API calls.

4.2 Archetypes of CA platforms

The three clusters contain 18 (cluster 1), 19 (cluster 2), and 14 (cluster 3) platforms from our database (Table 4). Each cluster has different centers along the dimensions of the taxonomy developed in this study. As the characteristics within the taxonomy are mutually exclusive and collectively exhaustive, we describe the clusters with a crosstab analysis showing percentages for each characteristic within a cluster (see Figure 2). For example, 22% of all CA platforms in cluster 1 support a single language whereas 78% offer multi language support. In the following, we describe the clusters, highlight their distinctive characteristics, and provide illustrative examples.

Archetype 1 – Multi-language, integrative CA platform with advanced analytical functionality: The first cluster contains platforms that mainly support multiple languages, self-learn over time, and integrate with different enterprise systems, such as CRM software, as well as various platforms, such as social media. All platforms within this cluster offer reporting functionalities and the majority of platforms has built-in sentiment detection. These platforms include the CA offerings of major technology players, such as Oracle Intelligent Bots, Microsoft Azure Bot Service, IBM Watson Assistant or Amazon Lex, and large technology companies that strive to automate tasks particularly in customer service, IT operations as well as product and marketing like IPSoft or Nuance. CA platforms in this cluster support text-based and speech-based communication and include CAs for various purposes. Whereas platforms in cluster 2 and 3 mainly focus on the modeling of typical conversation flows as an implementation approach, platforms in this clusters also offer supervised learning (allowing to train a CA with a set of historical, labelled data) and hybrid approaches (i.e. a combination of modeling and supervised learning). Regarding deployment, many platforms offer cloud or cloud and on-premise hosting and pricing depends on actual usage.

Archetype 2 – General-purpose, cloud-based CA platform with single language and API support: The second cluster includes platforms that focus on CAs for different purposes, support a single language (in most cases English), and are primarily hosted in the cloud. With regard to integration with other enterprise software, these platforms typically offer APIs to program the automatic retrieval of data from existing systems, such as CRM. Examples of platforms in this cluster include pandorabots, Recime and Xenioo. These platforms mostly use modeling as the implementation approach, as in the first cluster. Regarding the analytical functionality, none of the platforms provide sentiment detection, while about two third of the platforms in this cluster offer reporting features. Regarding the integration of CAs with target platforms, the companies within this cluster are split between single-platform (e.g. TalkBot for Facebook) and cross-platform support (e.g. pandorabots).

Figure 2. Cross tab analysis

Dimension	Characteristics	Archetype 1	Archetype 2	Archetype 3
	Number of platforms in cluster	*18*	*19*	*14*
Communication mode	Text-based	33%	68%	100%
	Speech-based	33%	5%	0%
	Both	33%	26%	0%
Context	General-purpose	83%	100%	21%
	Domain-specific	17%	0%	79%
Language	Single language	22%	89%	93%
	Multi language	78%	11%	7%
Intelligence	Rule-based	0%	0%	50%
	Self-learning	100%	100%	50%
Implementation	Programming	6%	11%	0%
	Modeling	50%	84%	100%
	Supervised learning	33%	5%	0%
	Hybrid	11%	0%	0%
Hosting	On-premise	11%	0%	7%
	Cloud	39%	89%	93%
	Both hosting	50%	11%	0%
Pricing model	Usage-based	89%	79%	50%
	User-based	6%	5%	14%
	Instance-based	0%	5%	14%
	Free	6%	11%	21%
Reporting	Without reporting	0%	26%	50%
	With reporting	100%	74%	50%
Sentiment detection	Without sentiment	39%	100%	93%
	With sentiment	61%	0%	7%
Enterprise integration	None	0%	0%	71%
	API	11%	95%	29%
	Pre-build interface(s)	89%	5%	0%
Platform integration	Single-platform	0%	47%	79%
	Cross-platform	100%	53%	21%

Archetype 3 – Text-based, domain-specific CA platform with modeling functionality: The third and final cluster contains platforms that show different distinctive characteristics: First, these platforms exclusively offer text-based CAs, which tend to be chatbots that are used in specific domains and mostly on single platforms. For example, SurveyBot can conduct interactive surveys and collect their results via Facebook Messenger. CA platforms in this cluster typically host their CA in their own clouds and pricing is based on actual usage. With regard to the capability for integration of data from other enterprise software, the majority of platforms in this cluster does not offer an API or pre-built interfaces connecting the CA to existing systems.

Table 4: Clustered platforms

Archetype 1	Archetype 2	Archetype 3
[24]7 AI	BotEngine	ChatbotsBuilder
aivo	botmother	ChatClub
BotCore	Botsify	ChatterOn
botpress	Chatfuel	E.D.D.I.
Creative Virtual	Conversation one	HubSpot / motion.ai
Dialogflow	Converse	It's alive
gupshup	Flow xo	LeadFlip
IBM Watson Assistant	Landbot.io	ManyChat
inbenta	pandorabots	Massively
Interactions	Parlo	MobileMonkey
IPSoft	Rasa	Octane AI
Lex	Recime	rebot.me
Microsoft Azure Bot Service	Sequel	Surveybot
Next IT	Smooch	Zelp
Nuance	TalkBot	
Oracle Intelligent Bots	The PullString Platform	
reply.ai	Wit.ai	
Twyla	Xenioo	
	Zenbot	

5 Discussion

In the following, we discuss the developed taxonomy and identified archetypes against the background of existing research, followed by a description of limitations of this study, and an overview of opportunities for future research.

5.1 Taxonomy and Archetypes

The taxonomy and archetypes from our analysis underline the versatility of CA platforms and indicate three types of platforms. The cross-cluster comparison shows that CA platforms range from high-end offerings (cluster 1), mainly by large technology providers such as IBM or Microsoft that offer a variety of analytical features and options for integration as well as provide CAs both for speech- and for text-based communication, over mid-range general-purpose CA platforms (cluster 2) like pandorabots or Chatfuel that primarily focus on single platforms for deployment and require implementing an API for integration to highly standardized CA platforms (cluster 3) that offer mainly domain-specific CA with a limited set of functionality, such as SurveyBot or MobileMonkey. These archetypes and the underlying taxonomy contribute to theory in different ways. The taxonomy we developed extends the existing, basic classification of CAs according to communication mode and context [5] through the empirical observation of CA design platforms by adding further dimensions. These dimensions describe CAs in greater detail as the existing classification, for example by taking into account the implementation approach, integration capabilities or the intelligence a CA possesses, which in turn provides possibilities and constraints for implementing CAs based on design principles formulated in previous studies [5]. Furthermore, we provide an overview of the state-of-the-art of platforms for conversational agent design through the taxonomy and classified platforms that can be used in future design-oriented research on CAs. For example, studies that investigate empathetic behavior of chatbots in customer service, such as the work by Hu et al. [51], could select a platform that offers built-in sentiment analysis for text-based CA to design their CA. Thus, in the context of design-oriented research, this study contributes to the growing knowledge base on CA [52].

In addition to the aforementioned contributions, our study provides two main insights for practitioners that intend to design CAs. First, the taxonomy can be used to select a vendor for a specific use case, for example by defining the desired characteristics along the 11 dimensions and then choosing a suitable platform. For example, a company that seeks to design a text-based CA with multi language support, on-premise hosting, and built-in analytics functionality could select a platform such as inbenta, Creative Virtual or IBM Watson Assistant. Or, a company that would like their CA to specifically conduct text-based customer surveys on a single platform, Facebook, can use SurveyMonkey for their implementation. The cross-cluster comparison shows that CA platforms range from high-end offerings (archetype 1), mainly by large technology providers such as IBM or Microsoft that offer a variety of analytical features and options for integration as well as provide CAs both for speech- and for text-based communication, over mid-range general-purpose CA platforms (archetype 2) like pandorabots or Chatfuel that primarily focus on single platforms for deployment and require implementing an API for integration to highly standardized CA platforms (archetype 3) that offer mainly domain-specific CAs with a limited set of functionality, such as SurveyBot or MobileMonkey.

Second, the platform database and identified archetypes underline the wide spectrum of CA platforms ranging from basic text-based CAs for single platforms to high-end, adaptive CAs that integrate in existing systems and can communicate with customers both via speech and text. Thus, managers can use the archetypes to strategically decide what type of CA platform they require. Furthermore, the analysis revealed that some platforms address different departments. Whereas multiple platforms can directly be used for design by the department that intends to introduce a CA, such as marketing and sales, as they deliver it based on simple modeling of typical conversation flows and convenient hosting in the cloud, other platforms address and require the IT department to customize, integrate and deploy their solutions.

5.2 Limitations and Opportunities for Future Research

Our study is not free of limitations and offers opportunities for future studies. First, the taxonomy that was developed both from existing CA literature and empirical data (i.e. the platforms in our database) cannot be considered comprehensive in terms of explaining platforms in detail but is helpful for understanding and delineating CA platforms as shown our analysis. As Nickerson et al. [41] highlight a taxonomy can never be perfect but is at best useful to explain the nature of objects under study. We initially demonstrated the usefulness of our taxonomy, but it can benefit from validation and expansion in future studies. A second limitation is that some dimensions might mutually exclude one another. We did not systematically identify these inter-dependencies in our work, yet it would be useful to address this point in the future. The third limitation results from the market dynamics that exist with regard to CA platforms. Present acquisitions, such as Motion.AI acquired by HubSpot, underline that the current CA platform landscape is subject to change which in turn limits the validity of our analysis over time. Similarly, CA platforms might add different functionality over time and provide new interfaces to enterprise software which would reduce the accuracy of our database. However, as the cluster analysis indicated a rather equal distribution of platforms to cluster, we would argue that the three typical CA platforms will still remain applicable even in the light of acquisitions and feature changes.

We suggest two main opportunities for future research: First, the taxonomy created in this paper can be evaluated in the field with organizations that plan to introduce CA for innovation or automation. Incorporating the views from organizations that seek to introduce a CA can be useful to validate and potentially extend the dimensions or characteristics in the taxonomy. Second, engaging with organizations introducing CA can also be helpful to reach a better understanding regarding the reasons for or against selecting specific archetypes as well as with regard to different characteristics. For example, comparing the two implementation approaches modeling of conversation flows with training of a CA based on existing and labeled data (supervised learning) concerning the impact on CA performance is a promising research endeavor not only in the context of CA, but also within the broader spectrum of innovative approaches for task or process automation.

6 Conclusion

In this study, we set out to develop a taxonomy of CA platforms (RQ1) and identify their archetypes (RQ2) in order to better understand the variety of platforms to design natural language agents for organizations. Based on existing CA literature as well as the analysis of 51 platforms, we derived a taxonomy with 11 dimensions which describes CA platform characteristics alongside their implementation and hosting approaches, pricing models, analytical features, and options for enterprise software integration. Afterwards, we empirically identified three archetypes of CA platforms with different ranges of functionality. Our work contributes an overview of the state-of-the-art of platforms for CA design and outlines possibilities and constraints for the implementation of design knowledge on conversational agents. In addition, our results can practically guide CA platform selection through the analysis of platforms based on the taxonomy and outlining aspects to be considered in the design process, such as the need for multi-language support or built-in sentiment analysis.

Abstract. Chatbots are software-based systems designed to interact with humans using text-based natural language and have attracted considerable interest in online service encounters. In this context, service providers face the challenge of measuring chatbot service encounter satisfaction (CSES), as most approaches are limited to post-interaction surveys that are rarely answered and often biased. As a result, service providers cannot react quickly to service failures and dissatisfied customers. To address this challenge, we investigate the application of automated sentiment analysis methods as a proxy to measure CSES. Therefore, we first compare different sentiment analysis methods. Second, we investigate the relationship between objectively computed sentiment scores of dialogs and subjectively measured CSES values. Third, we evaluate whether this relationship also exists for utterance sequences throughout the dialog. The paper contributes by proposing and applying an automatic and objective approach to use sentiment scores as a proxy to measure CSES.

Keywords: online customer service, chatbot, sentiment analysis, service encounter satisfaction, correlation analysis

1 Introduction

Digital communication technologies have become an integral part for organizations to interact with their customers [1]. Many companies offer online services via live chat interfaces, which enable customers to directly interact with customer service employees [2]. This type of text-based service encounter is a cost effective service solution and often the preferred way of communication for young people [3]. One technology which is often deployed to assist service employees in online service encounters are chatbots [1]. Chatbots are software-based systems designed to interact with humans via text-based natural language [4, 5] and can be found across industries (e.g., airlines, energy provider). Gartner predicts that by 2020, 25% of all customer services organizations will integrate this technology [6].

Despite their great potential, many customer service chatbots did not meet customer expectations and led to service failures [7]. As a result, many service providers retired their chatbots, as unsatisfactory online service encounters have negative effects on

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

word-of-mouth, loyalty, and intention to repurchase a product [8]. Ignoring customer frustrations can strongly impede the performance of customer service encounters and carries the risks that the service chatbot is perceived as cold, socially indebt, untrustworthy, and incompetent [9]. Therefore, service providers should identify service encounters that were below customer's expectations [10] and trigger service recovery procedures (e.g., offering compensation). Such procedures can help to recover from almost any service failure and increase trust, perception of fairness, and service experience [10]. However, most approaches to identify dissatisfied customers in a text-based online environment (e.g., chat, social media) are limited to post-interaction surveys [11]. This is problematic as self-reported data can hardly be retrieved during an interaction, is influenced by various biases [12], and only few users are willing to provide this kind of information [8, 11]. Therefore, we propose that an automated method to measure chatbot service encounter satisfaction (CSES) during a customer-chatbot interaction could help service providers to deal with these issues.

To develop such a method, we want to take advantage of the fact that written text is associated with a person's thoughts, emotions and motivations [13–15]. Humans write differently when they are happy or frustrated and thus, written text by itself conveys much information about a human [14]. Users who are less happy with a chatbot use less assent, fewer positive, and more anger-related words and thus, express more negative sentiments [16]. The analysis of such opinionated text can provide valuable information about the user as opinions are "*key influencers of our behaviors*" [17, p. 2] and "*sentiment and tonal polarity are inherent properties of human-human communication and interaction*" [18, p. 1367].

As a manual analysis of expressed polarity in written text does not scale well to larger datasets [19], automated sentiment analysis methods have been developed. These methods are capable of automatically extracting positive or negative polarity expressed in written text [20]. Moreover, current sentiment analysis methods have been found to be very accurate and thus, seem to be a valid approach [21, 22]. However, research has rarely applied sentiment analysis in human-computer interaction (HCI) so far [20, 23]. Most HCI studies focus on auditory and visual signals of humans as these transmit the majority of communication-related information [20]. Moreover, most sentiment analysis studies focus on the method itself [23]. As a result, there is a lack of understanding on how to apply sentiment analysis in online chatbot service encounters to obtain valuable information about the user and her/his CSES. Therefore, we investigate the application of sentiment analysis methods for chatbots in online service encounters by drawing on research that text-based communication by itself is rich in informative signals [24] and that written language is influenced by emotions, intentions, and thoughts [13–15]. More specifically, we argue that sentiment analysis of dialog data can be used as an easy-to-use and objective proxy to measure CSES. Therefore, our research project addresses the following research question:

How to measure service encounter satisfaction with a chatbot using sentiment analysis methods?

To address this research question, we first compare different sentiment analysis methods on an empirical level by analyzing the calculated sentiment scores for two datasets. Next, we test for a potential correlation between sentiment scores and CSES values that were measured using a survey-based approach in an online experiment. In doing so, we first investigate this potential relationship on a dialog level and second on an utterance level (i.e., single messages). This paper contributes by proposing and applying an automatic and objective approach to use sentiment scores as a proxy to measure CSES. Our proposed approach enables researchers and practitioners, such as online customer service providers, to objectively and automatically retrieve valuable information after and during an online service encounter.

2 Related Work

2.1 Customer Service Chatbots

Recent advances in technology and great business potential have led to an increased interest in the development of conversational agents [5, 25]. Conversational agents are software-based systems designed to converse with a user via natural language [4, 5]. Thereby, the user interacts with the conversational agent in a natural dialog and does not use a predefined set of keywords or command phrases [4]. They can offer both speech- and text-based interfaces and can also be visualized and animated (i.e., embodied conversational agent) [4]. Conversational agents that interact with the user primarily via a text-based interface are often referred to as chatbots [5]. Chatbots can be deployed on various communication channels, such as instant messaging platforms (e.g., Line, Telegram, WeChat), websites, or on social media (e.g., Facebook, Twitter) and are accessible from various devices (e.g., PCs, mobile phones) [4]. Since Weizenbaum developed the first chatbot named ELIZA in 1966, much research has been conducted and various chatbots have been deployed across industries [4, 5].

One of the reasons why both research and practice are increasingly using this technology is the fact that chatbots interact in a human-like interaction style (i.e., use natural language) and offer great business potential (i.e., 24/7 availability at lost costs) [4]. Therefore, chatbots are increasingly implemented in online service encounters as many companies communicate with their customers via live-chats on their website or on social media platforms [1, 2]. Chatbots could help to automate online customer service, save costs, and enhance online experience [1, 26]. For example, instead of a customer calling or chatting with a service employee, customers are now communicating with a service chatbot [26]. In addition, chatbots can also take the role of first tier support agents and assist customer service employees. Therefore, chatbots can first start an online service encounter and then seemingly handover the conversation to a human agent when required. This can lead to a great reduction of routine requests usually handled by service employees.

2.2 Chabot Service Encounter Satisfaction

Satisfaction is an often applied construct in information systems (IS) research to evaluate the success and effectiveness of a system and it is particularly critical for the success of service systems [27]. It reflects whether customers perceive a service as pleasurable with regard to its consumption-related fulfilment [8]. High customer satisfaction values are important to achieve long-term success, especially in highly competitive markets, and therefore should have priority for any organization [8, 28].

Customer satisfaction is strongly impacted by the service encounter satisfaction, which refers to the post-consumption evaluation of a service encounter [29, 30]. A successful service encounter makes a company's product incrementally more effective and easier to use [28], influences the customer's choice independent whether a service is provided offline or online [31], and is linked to several desired outcomes such as word-of-mouth, loyalty, and intention to repurchase a product [8, 32]. Thus, service encounter satisfaction is a critical indicator for any organization [8, 28].

Service encounter satisfaction is influenced by several antecedents such as the customization and flexibility in service encounter, effective service recovery when failures occur, and spontaneous delights (i.e., pleasing experiences customers do not expect) [32]. In addition, various design elements of a chatbot influence the CSES such as verbal communication cues (i.e., being polite, responsive, and show mutual understanding), level of expertise (i.e., a core attribute of a service employee), or visual cues (i.e., such as an avatar) [29]. In an online context, the measurement of CSES is often limited to follow-up surveys [11, 29]. Thus, CSES cannot be retrieved in real-time, is often biased, and the surveys are only answered by a few users [11, 12]. Moreover, customers have a general "*reluctance to share their sentiments with firms*" [8, p. 359] and thus, companies are often not able to react fast enough to dissatisfied customers using service recovery procedures [10]. Failing to recover can result in lost customers, negative word of mouth, decreased loyalty, and less profits [28, 32].

2.3 Sentiment Analysis Methods

A common method within the natural language understanding literature is the analysis of opinions and sentiments expressed in written text. This becomes meaningful as research has shown that written text is clearly impacted by the user's emotions, intentions, and thoughts [13–15]. Consequently, written text says something about us and can be used as a proxy for information about the author. Therefore, various methods have been developed to analyze the opinions and sentiments expressed in written text [21]. These methods are named and defined in many different ways (e.g., sentiment analysis, opinion mining, see [33]). As it is the most common name, we follow [17, 33] and define sentiment analysis as the computational analysis of written language to identify the user's perceived positive or negative valence towards a certain entity (e.g., product, service, event). Sentiment analysis has recently witnessed great attention, because of the large availability of opinion-rich resources on the Internet (e.g., online reviews) and advances in artificial intelligence [17]. Consequently, many of the major technology companies offer sentiment analysis solutions (e.g., IBM, Google) and also various open source solutions are available (see [21]). This led to the development of many available and precise methods (see [20, 21]).

Sentiment analysis methods can be generally distinguished into two broad but also overlapping approaches, namely the application of semantic rules or statistical methods [20]. Methods of the first category compare sentiment-related expressions with sentiment lexicons that contain the semantic orientation of words [34]. One of the greatest challenges of these methods is that the semantic orientation of individual words does not necessarily correspond to the contextual polarity of the whole sentence [34]. Therefore, it is necessary to extract additional linguistic patterns of the text by conducting morpho-syntactic text analyses (i.e., wordform, lemma, part of speech tags) [20]. Too specific extraction patterns, however, limit the application range to a specific domain. Methods of the second, more recently applied category use unsupervised or supervised machine learning algorithms including support vector machines and Bayes classifiers [20]. These methods enable the development of more generic models, but require labeled data for training purposes. Consequently, the quality of such models is heavily influenced by the reliability of sentiment annotations [20].

Today's applications of sentiment analysis are manifold. Sentiment analysis can be used to predict the success of political campaigns [35], identify interaction problems within a conversation corpus [11], or even to scan the dark web in an intelligence context [36]. Nevertheless, only a few studies analyzed sentiments in a chatbot context yet as most studies are focusing on the method itself [20, 23]. One reason is the difficulty to classify rather short informal chat messages, which include a high degree of language creativity, spelling mistakes, and the expression of sentiments without real intentions [19]. Another reason are the differences and ambiguities in human mood coding which make it difficult to create a gold standard [37] and thus, it is difficult to develop user-independent prediction models [38]. However, some related research has already applied sentiment analysis to infer the customer satisfaction from product reviews for shopping websites and mobile services [23, 39].

3 Research Method

To answer our research question, we first selected suitable dialog corpora and sentiment analysis methods to run our analyses. Then, we defined a three-step research approach to analyze the corpora in order to answer our research question.

3.1 Dialog Corpora and Sentiment Methods

First, we collected one dialog corpus from an online experiment in a customer service context [40]. The participants (n = 79, mean age = 28.835, SD age = 6.388) were given a fictive mobile phone bill and the experimental task was to find a more suitable mobile phone plan through interacting with a customer service chatbot. The chatbot asked several consumption-related questions and was capable of responding interactively to given user queries. After the interaction, all participants were asked to complete a questionnaire measuring CSES using an established measurement instrument on a 7-point Likert scale [29]. The construct displayed a sufficient composite reliability (CR) above 0.8 (CR = 0.814) and the average variance extracted was above 0.5. All measurement items had factor loadings above 0.7 and the mean CSES value was 4.924 (SD = 1.179). The complete experiment, all dialogs, as well as the questionnaire were in English. The complete dialog corpus consists of 79 user dialogs with a total of 1416 user utterances. We removed 353 utterances because they consisted of only mobile contract related numbers. The final corpus included 79 dialogs and a total of 1063 utterances with an average of 13.456 utterances per dialog (SD = 8.312). We refer to this dialog corpus as "ExpCorpus" in the remainder of this paper.

In addition to ExpCorpus, we used a second, publicly available dialog corpus (without CSES values) in order to have a greater basis for the comparison of different sentiment analysis methods. Therefore, we selected the "ConvAI" dialog corpus [41]. 500 volunteers chatted with ten chatbots and the dialog set is freely available as a JSON-File. The dataset includes 2778 dialogs from which we excluded 441 human-human dialogs, 102 empty dialogs, 54 bot only dialogs, and one numbers-only dialog. This resulted in the extraction of 2180 human-chatbot dialogs, which were neither empty nor contained only numbers. Finally, we extracted all 12482 human written utterances. We refer to this dialog corpus as "ConvAI" in the remainder of this paper.

To select appropriate sentiment analysis methods for our study, we reviewed two benchmark analyses [21, 42]. We followed the benchmark analysis of [21], which compared 24 open source methods, as well as the benchmark analysis of [42], which also included sentiment analysis methods from major technology companies (e.g., IBM, Microsoft). The benchmark analyses reveal that there is no superior sentiment analysis method because all tools perform differently depending on the specific context they are applied on or depending on the corresponding data source on which they were trained [21]. Consequently, both benchmarks reveal several suitable methods depending on the respective context and the training data [21]. The benchmark of [21] reveals that two of the best sentiment analysis methods providing numerical polarity for negative, neutral, and positive sentiments are VADER [43] and AFINN (i.e., an extension of ANEW [44]) [21]. VADER and AFINN are rule-based sentiment analysis methods, which use rules and heuristics to match the analyzed texts to sentiment lexicons. Both lexicons were developed and trained on social media content and Twitter data [21, 43]. The benchmark analysis of [42] reveals that the sentiment analysis methods by IBM Watson, Google Cloud, and Microsoft Azure perform best with varying types of datasets [42]. These sentiment analysis methods leverage machine learning classification algorithms in order to predict the sentiment score. Therefore, all three providers trained their algorithms on an extensive body of sentiment annotated text databases [42]. To cover both types of sentiment analysis techniques, namely semantic rules and statistical methods [20], we selected the following methods for our study: two open source methods using rule-based sentiment analysis methods (i.e., VADER, AFINN) and three commercial methods using machine learning classification algorithms (i.e., IBM Watson, Google Cloud, and Microsoft Azure). We calculated the sentiment scores for each of the open source methods using the web service ifeel 2.0 provided by [22] and for each of the commercial methods using their Node.js APIs.

3.2 Research Approach

In this section, we present our three-step research approach (see Table 1) to answer our research question and to investigate the potential correlation between sentiments and CSES. All analyses were conducted using R 3.5.0.

Table 1. Research approach

Step	Research method	Dialog corpora	Sentiment methods
1.	Comparison of sentiment analysis methods	ConvAI (dialog & utterance level), ExpCorp (dialog & utterance level)	VADER, AFINN, IBM, Microsoft, Google
2.	Correlation analysis between sentiment scores and CSES values	ExpCorp (dialog level)	VADER, AFINN, IBM, Microsoft, Google
3.	Exploratory analysis of sentiment scores and CSES values	ExpCorp (utterance level)	IBM

In the first step, we compared all selected sentiment methods because the accuracy of sentiment analysis method are highly context and data dependent. Therefore, we investigated whether sentiment scores from each tool are similar on a dialog and utterance level by calculating the sentiment scores for each dialog and each single utterance of both corpora with all five methods. Next, we tested for potential correlations among the five sentiment scores. We do this analysis on a sentence and utterance level as sentiment analysis methods seem to perform better on "*carefully authored, lengthier content, but often struggle when faced with informal online communication*" [19, p. 318]. Consequently, we assume that some sentiment methods may struggle to predict the sentiment score of rather short utterance level and that the methods perform quite differently on both levels.

In the second step, we tested for a correlation between sentiment scores and CSES values. Therefore, we standardized the sentiment scores to -1 (i.e., negative) and +1 (i.e., positive) and subsequently tested for a correlation between sentiment scores (from all five methods) and CSES values using the dialogs and satisfaction data of ExpCorpus. By doing this, we aimed to reveal whether sentiment scores are a valid proxy for CSES values.

In the third step, we investigated the minimum number of utterances required to show a correlation between sentiment scores and CSES values. For this analysis, we used IBM's sentiment method because it yielded the highest correlation in the previous step. Therefore, we extracted utterance sequences of each dialog, calculated their sentiment scores, and tested for a correlation between sentiment scores and CSES values. Next, we investigated whether these findings also hold for utterance sequences throughout the whole dialog. This analysis provides insights whether sentiment scores can be used as a proxy for CSES during a customer service encounter.

4 Results

Step 1: Comparison of Sentiment Analysis Methods

In the first step, we started our analysis by comparing the calculated sentiment scores of selected sentiment analysis methods for both dialog corpora (ConvAI and ExpCorpus). Table 2 contains the correlation analysis between sentiment scores of both corpora for each dialog and single utterance calculated by all five methods.

Table 2. Pearson correlation analyses among sentiment scores of different methods

Corpus	Method	AFINN	VADER	IBM	Microsoft	AFINN	VADER	IBM	Microsoft
ConvAI	AFINN	-				-			
	VADER	.605***	-			.322***	-		
	IBM	.385***	.317***	-		.387***	.357***	-	
	Microsoft	.368***	.356***	.533***	-	.300***	.311***	.604***	-
	Google	.369***	.295***	.504***	.395***	.414***	.388***	.600***	.497***
		n = 2180 dialogs				n = 12482 utterances			
ExpCorpus	AFINN	-				-			
	VADER	.719***	-			.597***	-		
	IBM	.508***	.512***	-		.505***	.169***	-	
	Microsoft	.473***	.467***	.600***	-	.383***	.201***	.615***	-
	Google	.516***	.366***	.521***	.537***	.653***	.439***	.625 ***	.487***
		n = 79 dialogs				n = 1063 utterances			
*** $p < .001$									

The results reveal that sentiment scores of dialog data from both corpora are at least moderately positively correlated with each other [45] (ConvAi $.295 \leq r \leq .605$, $n = 2180$, $p < .001$, ExpCorpus $.366 \leq r \leq .719$, $n = 79$, $p < .001$). The strongest correlation for ConvAi dialogs were identified between VADER's and AFINN's sentiment scores ($r = .605$, $n = 2180$, $p < .001$) and the weakest between Vader's and Google's sentiment scores ($r = .295$, $n = 2180$, $p < .001$). The strongest correlation for ExpCorpus was again identified between VADER's and AFINN's sentiment scores ($r = .719$, $n = 79$, $p < .001$) and the weakest one between Vader's and Google's sentiment scores ($r = .366$, $n = 2180$, $p < .001$). All sentiment scores on an utterance level were significantly positively correlated, but some correlations were weaker among some methods than they were on a dialog level ($.169 \leq r \leq .653$, $p < .001$). All in all, the findings reveal that sentiment methods using similar methodologies to identify the expressed polarity in a given text provide rather similar results. Thus, methods using semantic rules such as VADER and AFINN are strongly correlated on a dialog level. Moreover, methods using machine classification algorithms such as IBM's, Microsoft's, and Google's methods are at least moderately correlated on a dialog and utterance level.

Step 2. Correlation Analysis Between Sentiment Scores and CSES Values

In the second step, we tested for a correlation between sentiment scores and CSES values using the dialogs and CSES values of ExpCorpus. The results and the corresponding scatterplots are displayed in Figure 1. The analysis reveals a significant moderate to strong correlation between sentiment scores (from all five methods) and CSES values ($.405 \leq r \leq .513$, $n = 79$, $p < .001$) [45]. Thus, we conclude that there is a moderate positive correlation between sentiment scores and CSES values for four sentiment analysis methods and a strong positive correlation for IBM's sentiment method ($r = .513$, $n = 79$, $p < .001$) [45]. Moreover, it becomes visible that sentiment scores seem to be primarily a better predictor for positive than for negative CSES values. Moreover, semantic rule based algorithms seem to calculate sentiment scores of the dialogs generally more positive.

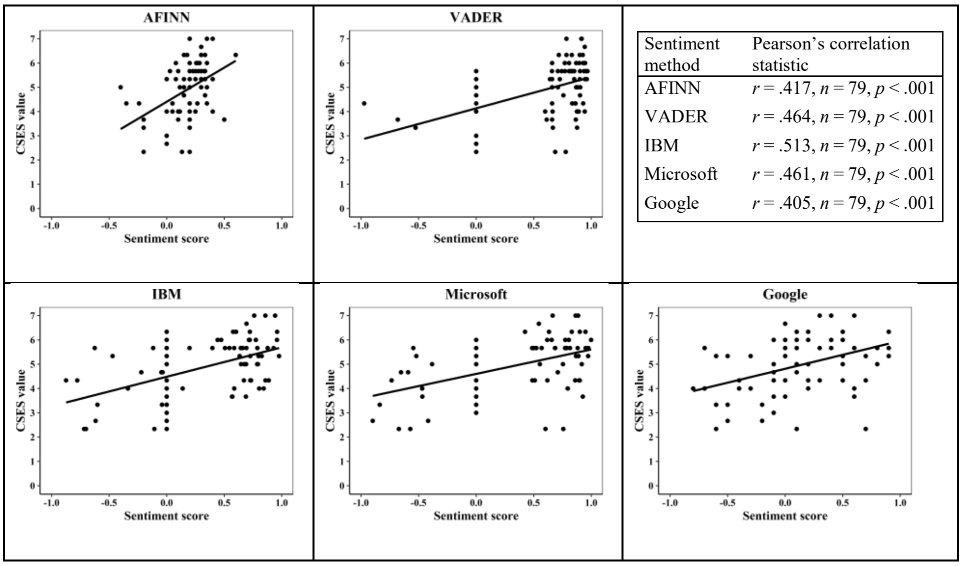

Figure 1. Correlation analyses between sentiment scores (of dialogs) and CSES values for ExpCorpus

Step 3: Exploratory Analysis of Sentiment Scores and CSES Values

In the third step, we investigated the minimum number of utterances required to show a significant positive correlation between sentiment scores and CSES values. Therefore, we combined the first ten utterances (u_i, i = 1, … ,10) into ten different utterance sequences (US_i, i = 1, …, 10), calculated their sentiment scores, and tested for a correlation with CSES values. The results are summarized in Table 3.

Table 3. Correlation analyses between sentiment scores (of utterances sequences) and CSES values for ExpCorpus

Analysed utterance squence	Included dialogs	Included utterances	Included words	Pearson' s correlation statistic
$US_1 = \{u_1\}$	79	79	739	$n = 79, r = .018, p = .872$
$US_2 = \{u_1, u_2\}$	79	158	1086	$n = 79, r = .133, p = .244$
$US_3 = \{u_1, u_2, u_3\}$	79	237	1360	$n = 79, r = .234, p = .038$
$US_4 = \{u_1, …, u_4\}$	79	316	1574	$n = 79, r = .251, p = .026$
$US_5 = \{u_1, …, u_5\}$	79	395	1779	$n = 79, r = .372, p < .001$
$US_6 = \{u_1, …, u_6\}$	75	450	1989	$n = 75, r = .437, p < .001$
$US_7 = \{u_1, …, u_7\}$	74	518	2159	$n = 74, r = .480, p < .001$
$US_8 = \{u_1, …, u_8\}$	68	544	2350	$n = 68, r = .443, p < .001$
$US_9 = \{u_1, …, u_9\}$	58	522	2495	$n = 58, r = .506, p < .001$
$US_{10} = \{u_1, …, u_{10}\}$	46	460	2633	$n = 46, r = .503, p < .001$
All dialogs with all utterances	79	1060	3431	$n = 79, r = .513, p < .001$

Please note that not all dialogs included up to ten user utterances. As a consequence, the number of analyzed dialogs decreases with increasing sequence length. The last row analyzes all dialogs including all utterances of each dialog.

The analysis reveals that the sentiment scores of US_1 and US_2 have no significant correlation with the CSES values. However, the correlation increases with an increasing number of utterances combined in each sequence. Our results show a significant weak positive correlation between sentiment scores and CSES values after the analysis of the first three utterances ($r = .234$, $n = 79$, $p = .038$). Moreover, we revealed a significant moderate positive correlation ($r = .372$, $n = 79$, $p < .001$) after the analysis of the first five utterances [45]. To provide a greater understanding of these findings, Table 4 provides some exemplary utterance sequences, their sentiment scores, and the measured CSES values.

Table 4. Exemplary utterance sequences including the first three utterances

Utterance sequence	Sentiment score	CSES value
{"*Hi*", "*Nice to meet you. I'm interested in a cheaper phone plan. Can you help me?*", "*I think it is SuperMobile*"}	0.769	6
{"*Hey, I'm currently on the mobile phone plan Yellow Basic 1000 and I received an unexpectedly high mobile phone billl last month.*", "*Are there any better mobile phone plans for me?*", *"It's SuperMobile Yellow Basic 1000"*}	0.488	6
{"*My bill is too high*", "*Help me to find a new mobile phone plan*", "*I dont know*"}	-0.566	4,333

Having shown that at least the first three utterances of a dialog are required to find a significant positive correlation between sentiment scores and CSES values, we further investigated whether this correlation can also be found for all utterance sequences throughout the whole dialogs. Therefore, we extracted all consecutive utterance sequences consisting of three or five utterances within the first ten utterances of each dialog. This extraction resulted in eight consecutive utterance sequences for dialogs that were at least that long (e.g., *Seq-1* = {*u1*, *u2*, *u3*}, *Seq-2* = {*u2*, *u3, u4*}, *Seq-9* = {*u1*, *u2*, *u3*, *u4*, *u5*}). Then we calculated the sentiment scores and tested for a correlation between sentiment scores and CSES values (see Table 5).

Table 5. Correlation analyses between sentiment scores (of consecutive utterance sequences) and CSES values for ExpCorpus

Sequence	Included utterances	Pearson' s correlation statistic
Seq-1	{*u1, u2, u3*}	$n = 79$, $r = .234$, $p = .038$
Seq-2	{*u2, u3, u4*}	$n = 79$, $r = .243$, $p = .031$
Seq-3	{*u3, u4, u5*}	$n = 79$, $r = .289$, $p = .010$
Seq-4	{*u4, u5, u6*}	$n = 75$, $r = .350$, $p = .002$
Seq-5	{*u5, u6, u7*}	$n = 74$, $r = .410$, $p < .001$
Seq-6	{*u6, u7, u8*}	$n = 68$, $r = .267$, $p = .029$
Seq-7	{*u7, u8, u9*}	$n = 58$, $r = .501$, $p < .001$

Please note that not all dialogs included up to ten user utterances. As a consequence, the number of analyzed dialogs decreases with increasing utterance position.		

The analysis shows that sentiment scores of all utterance sequences throughout the whole dialog are positively correlated with the CSES values. All correlations are significant at least at a $p < .05$ level. The correlation strength varies among the different sequences between weak and strong correlation. However, the minimum and maximum value of the correlation strength is higher for sequences consisting of five consecutive utterances, which always had at least a moderate positive correlation with CSES values.

5 Discussion

In this paper, we investigate whether sentiment scores from textual input can be used as a proxy to measure CSES in a customer-chatbot interaction. Therefore, we followed a three-step research approach: first, we compared five sentiment analysis methods by testing the relation of sentiment scores from two dialog corpora. Second, we tested for a correlation between sentiment scores and CSES values. Third, we analyzed this correlation in detail at the utterance level. Results of step 1 reveal a significant positively correlation among sentiment scores from all selected sentiment analysis methods. Results of step two reveal that sentiment scores of complete dialogs are significantly positive correlated with the subjectively measured CSES values. Results of step three reveal that this relation is not only valid for the analysis of an entire dialog, but also for any sequences of at least three consecutive utterances throughout the entire dialog. Thus, we conclude that sentiment scores can be used as an automatic and objective proxy to measure CSES in an online service encounter. Therefore, our findings further contribute to existing research that states "*sentiment analysis corresponds surprisingly well with emotional self-report*" [15, p. 87].

The results of our analysis have implications for the design of customer service chatbots. As customers may express their frustrations in written language, future chatbots could continuously perform sentiment analyses and use sentiment scores as a proxy to identify dissatisfied customers (by analyzing at least three consecutive utterances). In this way, service providers can intervene to reduce the risk of service failures. For example, a customer service chatbot could recognize that the current conversation with a customer is turning towards a negative sentiment score. In this case, several strategies could be triggered. The chatbot could seamlessly handover the conversation to a trained human service agent, automatically trigger service recovery procedures, or express certain verbal utterances such as excuses [46, 47]. Research has shown that these immediate reactions can reduce the level of frustration [46] and can lead to an increased interaction length [47]. Furthermore, service providers can use this data in post-interaction analyses to retrieve valuable information about CSES. This information cannot only be used for service recovery, but also for identifying general weaknesses in the service quality of the chatbot.

Although we aimed to ensure a high rigor in our research, some limitations should be considered. First, many sentiment analysis methods exist and they all may evaluate a given text differently depending on the context and type of a message [21]. This becomes even more meaningful when applied to rather short and informal chat data. Therefore, a different selection of sentiment methods may have led to different results.

Consequently, we tried to minimize this risk by starting with a selection of five sentiment methods based on benchmarks and compared them with each other by applying them on two dialog corpora. Even though all sentiment analysis methods had a moderate to strong correlation to CSES, some sentiments methods were rather weak predictors for users having low CSES values. Therefore, it "*is important that researchers and companies perform experiments with different methods before applying a method*" [21, p. 27]. Second, we analyzed a dialog corpus, which measured the CSES using a post-interaction survey. However, data of a survey-based approach might be influenced by various biases [12]. To reduce this risk, we reviewed all dialogs and verified that participants followed the experimental task and did not answer with straight line responses. Third, we only analyzed the relationship between sentiments and CSES based on a dialog corpus from a hypothetical online service task (i.e., finding new plan) in a specific context (i.e., mobile contract) in one language (i.e., English). Therefore, it is unclear whether our findings also hold for other customer service tasks (e.g., book ticket) in other contexts (e.g., airlines) in other languages (e.g., German). Fourth, we conducted correlation analyses between sentiment scores and CSES values to reveal a correlation between these two variables. Even though we found a strong positive correlation and propose sentiment scores as a proxy for CSES values, this analysis does not provide the explanation for this relation and does not indicate a cause-and-effect relationship [48]. Thus, results need to be applied with care as we cannot predict CSES based on sentiments scores or vice versa [48].

Considering these limitations, we identify several avenues for future research. First, future work can replicate our analyses on additional dialog corpora from different contexts, doing different tasks, and in different languages. This could further strengthen the applicability of sentiment analysis as a proxy to measure CSES in several domains and languages. Second, future studies could investigate adaptive reaction strategies based on real-time analyses of at least three consecutive user utterances. This could enable chatbots to recognize user frustrations and supports the development of chatbots that act more socially [46, 47]. Moreover, future research could investigate the application of more trivial text analysis methods, such as word count and length of dialogs, as well as more complex methods, such as topic modelling, as proxies to predict customer satisfaction. Integrating these techniques into a chatbot can lead to even greater understanding of the user and enables more precise reactions by the chatbot.

6 Conclusion

In this paper, we investigate the application of sentiment analysis methods in an online service encounter with a chatbot and show that sentiment scores can serve as a proxy to measure CSES. This enables researchers and practitioners, such as online service providers, to objectively and automatically retrieve user information during and after an online service encounter. This information can be used not only to trigger service recovery procedures, but also to identify weaknesses in the service quality and to analyze the user in real-time. Therefore, our results contribute towards the design of user adaptive service chatbots.

Abstract. The usage of wearable self-tracking devices has emerged as a big trend in lifestyle and personal optimization concerning health, fitness, and well-being. In this context, gamification elements have the potential to contribute to achieving desired user behavior. However, it is not fully understood to which extent the users perceive their self-tracking motivations as being fulfilled through the usage of a wearable self-tracking device, and how gamification affects the interplay of self-tracking motivations, wearable self-tracking device usage, and motivation fulfillment. To address this research gap, we develop a conceptual model and validate it with survey research and structural equation modeling. We find that self-tracking helps users to unexpectedly fulfill motivations without previously striving for them and that significant differences exist between the gamification users and non-users with respect to their motivations by self-entertainment and self-design.

Keywords: Self-tracking, gamification, wearable self-tracking devices, motivation fulfillment, five factor framework of self-tracking motivations

1 Introduction

The engagement in self-tracking has recently emerged as a big trend in personal optimization and lifestyle [1]. Self-trackers regularly gather data about themselves – often related to their bodily functions and everyday habits – and then analyze the data to produce statistics and other analyses, such as images and diagrams [2], [3]. Devices used for this practice include for example smartphones, tablet computers, and so-called wearables. These wearable self-tracking devices benefit from sensors getting smaller as well as more compactly integrated [2]. Wearable self-tracking devices are, for example, smartwatches, wristbands, patches, clip-on devices, and jewelry or textiles with embedded sensors which measure bodily functions or physical activity [4]. The hype about self-tracking is also driven by the fact that "the new possibilities through

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

technology have opened up a world that offers new ways to get to know oneself and to gain a profound, fact-based understanding of collected self-related data" [5, p. 13].

In this regard, research on self-tracking has also emerged as a distinct stream within the IS community in recent years, studying various facets of the phenomenon [3], [6–8]. One of these facets is dedicated to understand the role of the user's motivations to engage in the practice of self-tracking. Therefore, Gimpel et al. developed a five factor framework of self-trackers' deep underlying motivations [5], while Baumgart and Wiewiorra [6] analyzed what motivations to start self-tracking drive different self-tracking activities and how different levels of self-control influence the tracking behavior of consumers and their expenditures. However, from an end-to-end perspective, a still unanswered question is to which extent the user's initial motivations are actually fulfilled through the practice of self-tracking. We therefore aim to advance this research path by investigating to which extent the users actually perceive the motivations to self-track as being fulfilled by using their wearable self-tracking devices:

RQ1*: How does the usage of wearable self-tracking devices influence the user's perceived fulfillment of the initial motivations?*

In the context of self-tracking motivation and motivation fulfillment, the practice of gamification should be considered. Gamification is a powerful method for motivating and influencing people [9]. Its term arose from the digital media industry [10] and describes the idea of using game design elements in non-game contexts [10]. One might think that gamification relates to only the motivational factor self-entertainment – below we do however argue theoretically and show empirically that gamification also significantly relates to other motivational factors. Within self-tracking experience, the application of gamified elements has the potential to change the user's behavior [11]. For example, gamification elements such as rewards, levels, leaderboards, goal-setting, and feedbacks [11], [12] are attributed to facilitate the attractiveness of monotonous physical activities [13] and therefore motivate users to become more active [12]. Consequently, when investigating self-tracking motivations and motivation fulfillments, the concept of gamification should be considered as it can be expected to influence the relationships between Gimpel et. al's [5] self-tracking motivations, actual wearable self-tracking device usage, and fulfillment of the initial motivations. Therefore, we also strive to answer the following research question:

RQ2*: How does the usage of gamification elements within the wearable self-tracking device influence the interplay of self-tracking motivations, wearable self-tracking device usage, and motivation fulfillment?*

To answer our two research questions, we develop and test a conceptual model based on the research models of Gimpel et al. [5] as well as Baumgart and Wiewiorra [6]. Further, we investigate the influence of the motivational factors of the five factor framework on the self-tracking usage and ultimately the influence of usage on the motivation fulfillment. Finally, we integrate gamification usage as a moderator to test the effect on the interplay of self-tracking motivations, wearable self-tracking device usage, and motivation fulfillment.

2 Foundations

2.1 Wearable self-tracking device usage and motivations

Wearable self-tracking devices can be assigned to the category of personal information and communication technology (ICT) devices since they are mobile (used on, e.g., the user's wrist), are adopted by individuals for their own personal usage, and enable users to engage in various activities with one device [14], [15]. To understand the users adoption of these devices, device-specific research was conducted for smartwatches [16], [17] and for fitness-trackers [18].

Further, on a more comprehensive level, Pfeiffer et al. examined what factors drive the user's pre-adoption of wearable self-tracking devices, showing perceived usefulness, perceived enjoyment, social influence, trust, personal innovativeness, and perceived support of well-being to be the major drivers for the intention to use wearable self-tracking technologies [1]. In addition, Buchwald et. al. extended research in this area by developing a model explaining post-adoption of self-tracking devices and showed that self-tracking device usage is influenced by continuance as well as discontinuance factors [19].

In contrast to these adoption models which focus on the user's perceptions about the characteristics of the self-tracking technology and its usage, Gimpel et al. developed a five factor framework of self-tracking motivations. This comprehensive study identifies and characterizes the deeper underlying motivations of users to engage in the practice of self-tracking [5]. Those five motivations are:

- **Self-entertainment:** Being motivated by the fun and ludic aspects of self-tracking. Key drivers are the enjoyments of getting lost totally in self-tracking activities, forgetting about time while doing so or playing around with numbers, statistics etc.
- **Self-association:** Being motivated by self-individualizing aspects within a community as well as the prospect of community membership. Respective reasons causing self-tracking activities are such as the urge of comparing own results to others, helping or inspiring others, and presenting oneself to them.
- **Self-design:** Being motivated by the chances of self-optimization such as the desire to control, optimize or even manipulate certain aspects of one's life or the enjoyment of being one's own master.
- **Self-discipline:** Being motivated by the self-gratification possibilities of self-tracking. Decisive aspects are the facilitation of one's self-discipline, the motivation to keep on working for a goal and the chance to reward oneself.
- **Self-healing**: Being motivated by the possibilities of self-tracking to take care of one's own health. Major factors are the aspiration of being independent from traditional medical treatments and the distrust in the healthcare system as well as classical therapies.

Gimpel et al.'s results show on the one hand that more self-tracking motivation on any of the single factors enhances the number parameters tracked as well as the time spent on self-tracking. These two constructs are defined by Gimpel at. al as self-tracking activity. On the other hand, motivation from every factor is rather independent from demographic factors (age, gender) and of personality traits (e.g. openness, conscientiousness or extraversion). Baumgart and Wiewiorra [6] further analyzed how different levels of self-control influence the tracking behavior of consumers and their expenditures for self-tracking software and hardware as well as what motivations to start self-tracking drive different self-tracking activities. They found out that the motivation of increasing one's performance as well as the number of tracked physical parameters are the key drivers of self-tracking usage frequency and accumulated expenditures. Further, customers that started self-tracking out of pure curiosity spend significantly more on self-tracking software, services and hardware and are at the same time more likely to track parameters from a wider variety of categories. Finally, they also showed that higher levels of self-control increase the odds of consumers tracking physical parameters and spending more on self-tracking software and hardware.

2.2 Gamification in the context of self-tracking

Gamification is the use of game design elements in non-game contexts [10] for changing people's behavior and driving participation as well as engagement [9]. Gamification, often interchangeably called "gamified services" [20], "gamefulness", or "gameful design" [21], also aims at the enhancement of positive patterns in service use like increasing quality and productivity of user actions, social interactions, or user activity [22].

Gamification can be reached by integrating game mechanics or elements and game dynamics. These terms are closely related and sometimes used synonymously [9]. Game elements are composed of multiple facets of "game play" [23] in the form of various actions, behaviors, and control mechanisms. While literature offers a wide range of different gamification elements [12], [23–25], rewards, levels, leaderboards, goal-setting, and feedbacks are specific gamification elements particularly considered in the context of self-tracking [11], [12]. They are the means which are used to create a compelling and appealing user experience [9] and ensure the user's engagement and his continuance in system usage [23]. Thereby, game dynamics, e.g., status, altruism, or achievement, are defined as the desires and motivations triggered by game elements. They are the universal human needs across genders, cultures, demographics, and generations which appropriate sets of game mechanics aim to satisfy [9]. Overall, gamification elements can be seen as the means which are used to satisfy game dynamics and thus, ultimately, fulfill the inherent underlying self-tracking motivations.

As mentioned before, self-trackers strive for optimizing certain aspects of their lives [5]. Especially with challenging and difficult behavior patterns for such self-optimization, users' motivation needs to be maintained in the long run. This is where gamified self-tracking applications which are designed to change the users' behavior [11], [26] come into play. One possible underlying intention could be to motivate them to become more active by making physical activity more enjoyable [12]. For example, monotonous physical activities such as running workouts can gain attractiveness by more intensively integrating the user into the application [13]. Gamification is also able to contribute positively to the usage of self-tracking apps as long-term goals can be broken down into sub-goals that can be attained more quickly. The gamification element challenges, for example, allows the user to repeatedly achieve short-term targets set by the application and might reward the user afterwards. A user planning to lose 20 kg by running might feel discouraged at first due to the long way to go. But as the application motivates the user to do single and short workouts step-by-step, the sub-goals are easier to realize. This supports the user's motivation to continuously strive for his goals [27].

Next to positive impacts of gamification on motivation in the context of self-tracking applications, also negative aspects have been identified. According to the self-determination theory of human motivation [28], competence, relatedness, and autonomy are the three innate psychological needs that determine motivation. On the one hand, intrinsic motivation gets enhanced when these needs are satisfied, but on the other hand, they diminish intrinsic motivation when they are thwarted [12]. Generally, game-play is voluntary as well as free of consequences and hence facilitates perceived autonomy, which is intrinsically motivating. But when it comes to gamified systems offering rewards or social comparison (e.g., leaderboards), their use is not necessarily voluntary or free of consequence. This might thwart perceived autonomy and hence intrinsic motivation [29]. Taken to a more general level, Nicholson [30] claims that by artificially integrating gamification elements into non-game activities, motivation will be reduced in the long run.

Besides the influence of gamification on motivations, Wellmann and Bittner [27] as well as Gal-Oz and Zuckerman [12], expanded the research stream by investigating the influence of gamification on the user's absolute, measurable goal achievement. They examined whether a gamified version of a smartphone app can affect self-tracker's physical activity. Wellmann and Bittner discovered that gamification elements within a running app can increase the user's movement behavior as their running distance was significantly larger [27]. In contrast, Gal-Oz and Zuckerman concluded that their gamified application which measures walking is only as effective as the version excluding gamification elements [12].

3 Conceptual development

3.1 Motivations and usage

IS usage can be described as the "degree and manner in which an IS is utilized by its users" [31, p. 6]. While perceptions of characteristics of an information system (e.g. perceived ease of use or usefulness) in general and self-tracking-specific influencing factors of usage have been extensively studied before (e.g., [1], [19], [32–35]), we deliberately focus on the user's underlying motivations and assume that those influence the usage behavior of a wearable self-tracking device as well. For example, the desire for self-design concerning sleep-optimization can be fulfilled by an ongoing monitoring of sleeping patterns with a sleep-tracker, thus inducing its usage. Therefore, we adapt the previously described five motivational factors identified by Gimpel et al. [5] and hypothesize:

The motivations for self-entertainment (H1.1), self-association (H1.2), self-design (H1.3), self-discipline (H1.4), and self-healing (H1.5) have a positive effect on the usage of wearable self-tracking devices.

3.2 Motivation fulfillment

After the initiation of wearable self-tracking device usage through self-tracking motivations, we assume that the continuous usage of a wearable self-tracking device leads to the perceived fulfillment of the initial motivations. For example, the initial motivation for self-discipline causes an ongoing usage of a device in terms of setting and controlling testable goals like the number of steps walked or calories burned. With the ongoing feedback of the device on these measures, the user feels his need for self-discipline being fulfilled by the device. In this regard, we define motivation fulfillment as the perceived fulfillment of the intrinsic desires reflected in the manifestation of a motivation. We further stay with five factor framework of self-tracking motivations [5], but now do consider the motivations fulfillment and hypothesize:

Wearable self-tracking device usage positively affects the user's motivation fulfillment of self-entertainment (H2.1), self-association (H2.2), self-design (H2.3), self-discipline (H2.4), and self-healing (H2.5).

3.3 Moderating effect of gamification usage

Gamification has often shown to have positive effects on motivation [9], [11–13], [27] and distinct goal achievement [27] in the context of self-tracking. A literature analysis as well as a self-conducted analysis of the top 20 iOS applications within the category of health and fitness has shown that levels, rewards, challenges, and leaderboards can be considered as the most relevant gamification elements [11], [12]. To adapt this characteristic of gamification to the context of self-tracking, we conjecture a moderating impact of gamification usage, which influences the effect of motivations for self-tracking on the actual wearable self-tracking device usage. Consequently, we suppose the positive effects of gamification on motivation to be predominant and posit:

Gamification usage positively moderates the effect of the motivations self-entertainment (H3.1.1), self-association (H3.1.2), self-design (H3.1.3), self-discipline (H3.1.4), and self-healing (H3.1.5) on wearable self-tracking device usage.

As gamification can also, in general, enhance system usage [13], we adapt this characteristic of gamification to the self-tracking context. We assume that the user's continuous usage of wearable self-tracking devices leads to a satisfaction of her or his motivations and therefore hypothesize gamification usage to also moderate the effect of wearable self-tracking device usage on motivation fulfillment. Again, we suppose the positive effects of gamification on motivation fulfillment to be predominant and hypothesize:

Gamification usage positively moderates the effect of wearable self-tracking device usage on the motivation fulfillment of self-entertainment (H3.2.1), self-association (H3.2.2), self-design (H3.2.3), self-discipline (H3.2.4), and self-healing (H3.2.5).

4 Survey design and procedures

We chose a quantitative-empirical research approach to validate our conceptual research model because it allows for a statistical generalization on the basis of results which are representative of the whole population at a lower cost than collecting the data for the whole population [36]. To this end, we crafted a survey instrument. We began this process by using, wherever possible, established and validated measurement scales and adapted them if necessary to ensure that the focus of our study is centrally reflected in each of the statements. Each of the item statements was measured with a seven-point Likert scale [37]. All constructs are measured reflectively.

To further enhance the survey instrument's comprehensibility and validity, we conducted a pretest with six researchers and incorporated their qualitative feedback. Ultimately, we used our survey instrument to collect empirical data via an online-survey tool.

4.1 Construct operationalization

We measure both self-tracking motivation (M) and motivation fulfillment (F) based on the five factors self-entertainment (SE), self-association (SA), self-design (SDe), self-discipline (SDi), and self-healing (SH) [5]. We utilize all items from [5] to measure both the current self-tracking motivation and motivation fulfillment. For the measurement of current self-tracking motivation, the items represent answers to the originally proposed question "I am self-tracking because…" (Table 1 lists all items) and range from "strongly disagree" to "strongly agree". For each item, this question regarding self-tracking motivation was immediately followed by an evaluation of the phrase "I actually fulfill this goal by self-tracking." to capture motivation fulfillment. The answer-options range from "not fulfilled as I expected" to "fulfilled way more than I expected". In addition, we added the scale item "not applicable as not a goal of mine" in the motivation fulfillment.

Table 1. Operationalization of self-tracking motivation [5]

Constructs	Items
	I am self-tracking because…
Self-entertainment (SE)	... I enjoy getting lost totally in self-tracking activities.
	... I like playing around with numbers/statistics etc.
	... I like playing around with my smartphone/technical device etc.
	... I enjoy forgetting about time while doing so.
	... it is fun and entertaining.
Self-association (SA)	... I want to help/inspire others.
	... the way I'm doing it is interesting for others/might help others.
	... I want to compare my results to others.
	... I want to present myself to others.
Self-design (SDe)	... I want to control what I'm doing with my life.
	... I try to manipulate certain aspects in my life.

	... I enjoy being my own master.
	... I'm interested in how certain things in (my) life interact.
	... it helps me to optimize the way I'm living.
Self-discipline (SDi)	... it motivates me to keep on working for a goal.
	... It allows me to reward myself.
	... it facilitates my self-discipline.
Self-healing (SH)	... I don't trust in the healthcare system/classic therapies.
	... I want to be independent from traditional medical treatments.

Further, we self-developed two measurement items for wearable self-tracking device usage (WSTDU) based on Burton-Jones and Straub [38], Davis et. al [39] as well as Venkatesh and Davis [40]. The answer-options range from "Less than few times a month" to "Almost 24 hours a day". Regarding gamification usage, we differentiate between active self-tracking users if they at least use one of the four considered gamification elements rewards, levels, leaderboards, and challenges and those who do not engage with any of these elements. Thus, gamification usage represents a binary variable. The final operationalization of wearable self-tracking device usage (WSTDU) and gamification usage is shown in Table 2.

Table 2: Operationalization of wearable self-tracking device usage (WSTDU)

Constructs	**Items**
WSTDU	On average, how frequently do you (passively) collect data with your wearable self-tracking device?
	On average, how frequently do you actively engage with your wearable self-tracking device (e.g., for data analysis)?
Gamification usage	Do you use the gamification element *Rewards / Levels / Leaderboards / Challenges* within your wearable self-tracking device? [Four items, one each for the four gamification elements]

4.2 Data collection

We collected data by administering our survey instrument to current active users of wearable self-tracking devices. This means that it was a prerequisite that the users actively use their device to track their fitness, health, or well-being to increase the validity of the responses. Users who do not yet use or have already stopped using their devices were excluded from the survey. We explained to the participants the concept of self-tracking and the function of the different gamification elements to receive more valid responses. To gather our data, we offered English and German versions and distributed the invitation message to participate in our study in online social networks (e.g., Facebook), online business networks (e.g., Xing and LinkedIn), instant-messaging services (e.g., WhatsApp), and the e-learning system of one of the authors' universities. We decided to openly circulate our invitation to allow for a snowball effect within social media. Overall, we received 359 responses. We excluded non-self-tracking users and incomplete answers (270 in total) which left us with 89 remaining responses. Of these 89 respondents, 53% indicated that they are actively using at least one of the four gamification elements. The average time of usage for the wearable self-tracking devices was 20 months. 84% use smartphone apps for self-tracking, 33% an activity tracker, 17% a smartwatch and 10% another form of device or application. On a seven-point Likert scale ranging from light user (1) to heavy user (7), 52% of the sample group consider themselves as medium self-tracking user type (4) or higher. On a seven-point Likert scale ranging from strongly disagree (1) to strongly agree (7), 64% either agree (6) or strongly agree (7) to be interested in trying out new technical devices. 57% agree or strongly agree that they actively take care of their health and well-being and 51% that they see themselves as sportive.

5 Data analysis and results

We tested measurement properties and hypotheses with a partial least squares structural equation modeling approach (PLS-SEM) and multi-group analysis (MGA) [41], [42] using the software SmartPLS Version 3.2.6 [43]. Even though PLS-SEM has its limitations [44], we chose it as an established approach in the IS research discipline and for our study especially due to the relatively small sample size [45], [46].

5.1 Measurement model

Concerning outer loadings, we set the critical threshold at 0.70 [47]. The outer loadings of the fourth item of self-entertainment motivation and motivation fulfillment, the second item of self-discipline motivation and motivation fulfillment, and the third item of self-design motivation and motivation fulfillment are lower than 0.70. We excluded them from our measurement model. The first two items of self-association motivation and the last two items of self-association motivation fulfillment exhibit lower outer loadings than 0.70 as well. Due to the nature of our measurement model, dropping these items would lead to an asymmetric inconsistency between the constructs. We therefore further examined the data and the operationalization of the construct. The results suggest that the operationalization may describe two different facets of self-association, one more directed towards altruism, the other more towards self-presentation. Hence, we decided to not further consider the results of self-association. Furthermore, the first item of self-entertainment motivation and the first and fifth item of self-entertainment motivation fulfillment do not reach the critical threshold of 0.70. But as they still exceed 0.60, which is deemed high [48], we considered them as marginal and did not exclude them from our measurement model. All other items, including active as well as passive use frequency of the construct wearable self-tracking device usage are greater than the critical threshold. Adhering to standard validation guidelines [49–51], we tested the reflective measurement model in terms of internal consistency reliability, indicator reliability, convergent validity, and discriminant validity. The internal consistency reliabilities (composite reliability) of multi-item scales modeled with reflective indicators is 0.81 or greater, suggesting that scales were reliable. In addition, the Cronbach's Alpha values are, except for self-association, 0.70 or greater, hence showing a good internal consistency of our scale. The average variance extracted is consistently greater than the critical threshold of 0.50. Hence, we conclude that convergent validity has been established. Further, to check for discriminant validity, we applied the Fornell-Larcker Criterion as a conservative measure [52]. The square root of each construct's AVE is greater than its highest correlation with any other construct, hence discriminant validity has been established, too.

5.2 Structural model

To assess the significance levels of our structural model including the MGA, we applied bootstrapping with 5,000 sub-samples (no sign changes). Table 3 presents the results for the entire group and for the sub-groups of gamification users and non-users. Relating to the 20 hypotheses posed, 4 could not be tested due to measurement problems with self-association. Of the remaining 16 hypotheses, 7 are supported by the data. These seven hypotheses are discussed in the following. In that, we apply a 10% significance level which appears reasonable given the relatively small sample size, especially in the subgroups. Our data support that the motivation for self-entertainment increases the wearable self-tracking device usage and the latter positively influences the user's self-entertainment motivation fulfillment (H1.1 and H2.1). Further, the multi-group analysis of gamification users and non-users shows a significant difference between the two groups, with a significantly higher effect of motivation for self-entertainment on usage within the group of gamification users (H3.1.1).

Table 3. PLS-MGA results

Hypothesis	Complete		Non-gami-fication users	Gamification users	Group delta
	n = 89		n = 42	n = 47	
	Path coefficients	R^2	Path coefficients		
M-SE → WSTDU	0.276 **	0.163	0.092	0.428 **	0.337 +
M-SDe → WSTDU	0.195		0.423 +	0.041	0.382 +
M-SDi → WSTDU	0.115		0.027 +	0.137	0.110
M-SH → WSTDU	-0.076		-0.248	0.044	0.292 +
WSTDU → F-SE	0.242 *	0.058	0.238	0.297	0.059
WSTDU → F-SDe	0.326 ***	0.106	0.491 ***	0.235	0.256
WSTDU → F-SDi	0.321 ***	0.103	0.434 ***	0.218	0.215 +
WSTDU → F-SH	0.139	0.019	0.244 *	0.168	0.076
Significance levels: + 10%, * 5%, ** 1% *** 0.1% | n = number of cases					

Self-design shows significant results as well: Wearable self-tracking device usage significantly increases the user's self-design motivation fulfillment (H2.3). Additionally, within the multi-group analysis, the influence of motivation for self-design on usage is significantly higher in the group of non-gamification users (H3.1.3).

Also, our results reveal that wearable self-tracking device usage significantly increases the self-discipline motivation fulfillment (H2.4). Finally, the multi-group analysis results show that the influence of wearable self-tracking device usage on the self-discipline motivation fulfillment is significantly higher in the non-gamification group (H3.2.4).

6 Discussion

Taking a comprehensive look at our results, we acknowledge the relatively low R^2 values of the dependent variables. However, the results are reasonable since our study specifically only aims on the user's deeper underlying motivations of self-tracking and does not take the user's perceptions about the characteristics of the self-tracking technology and its usage into account which were analyzed in other dedicated acceptance studies [1], [19]. Looking further into the details of our results, self-entertainment is the key motivation to engage in the practice of self-tracking as it is the only effect on wearable self-tracking device usage that is significant. Users seem to be driven by the entertainment possibilities which allow them to experience fun and play around with their collected data and statistics. Concerning the multi-group analysis, the effect is even more pronounced among gamification users and significantly differs from that of non-gamification users. This observation confirms that the playful elements of gamification reinforce the urge to self-track due to ludic motivation.

In contrast, the motivations self-design, self-discipline and self-healing are not found to drive wearable self-tracking device usage per se. However, the MGA shows that the motivation for self-design has a significantly higher influence on usage for non-gamification users. A potential reason could be, that non-gamification users who pursue control and optimization engage in these activities with a more serious mindset, thus deliberately ignore playful gamification elements because they might not support or even distract them.

Moving on to the relationships between wearable self-tracking device usage and motivation fulfillment, results show that usage significantly increases the perception that the preexisting desire for self-entertainment is fulfilled. The users of wearable self-tracking devices feel that their wishes to entertain themselves are met in the process of self-tracking. For self-design and self-discipline, however, we observe significant positive effects of usage on perceived motivation fulfillment without significant preexisting connections between their motivation and usage. Hence, users might not necessarily start self-tracking due to a striving for self-design or self-discipline. Nevertheless, as soon as they are active wearable self-tracking device users, they seem to realize positive effects such as being able to take control of and optimize their lives, gaining knowledge about interactions of certain things within their lives (self-design), facilitating their self-discipline, or being motivated to keep on working on goals (self-discipline). A further look at the group of non-gamification users reveals that they clearly and highly significantly perceive their motivation for self-discipline as better fulfilled than gamification users. This fact seems counterintuitive; however, a possible explanation here might also be that gamification elements do not support motivation fulfillment but rather distract the users from it.

7 Conclusion

The purpose of this study was to create a basis for future research regarding the analysis of the interplay of self-tracking motivations, usage and motivation fulfillment. Therefore, our paper investigates how Gimpel et. al's [5] motivational factors for self-tracking influence the actual usage of wearable self-tracking devices, to which extent the users actually perceive these motivations as being fulfilled in the process of using them, and how gamification affects this interplay of self-tracking motivations, wearable self-tracking device usage, and motivation fulfillment. We found the motivation for self-entertainment to represent the crucial driver of wearable self-tracking device usage and ultimately usage as important driver for the motivation fulfillment of the three factors self-entertainment, self-discipline, and self-design. Further, both the motivation as well as the motivation fulfillment are moderated by gamification usage. Gamification users are more motivated by self-entertainment, non-gamification users more by self-design. In addition, non-gamification users tend to have higher levels of motivation fulfillment, except for self-entertainment. Hence, in designing self-tracking devices and apps and potentially integrating gamification elements, one should carefully consider the diverse effects of gamification.

Our study has three main limitations: First, as common in research on motivation, survey responses are self-reports. Second, our results are based on a relatively small sample size of 89 respondents which may distort the results. Future research on this topic should be built on a broader database which enables more precise and refined results. Additionally, multiple surveys at different points in time would enable empirically validated statements on continuous usage. Lastly, the influence of gamification is only explained based on the distinction between gamification users and non-users. For future research, the differentiation between the four major gamification elements would allow for more detailed insights of the influence of gamification use. Additionally, coming research could combine the research on self-tracking motivations with the research on the user's perceptions about the characteristics of the self-tracking technology which might further increase the understanding of the phenomenon.

Generally, our research contributes to the domain of self-tracking and gamification as it advances the understanding how the usage of wearable self-tracking devices influences the user's perceived fulfillment of the initial motivations, and how gamification elements affect this interplay. Thereby, we found evidence that next to the motivation of increasing one's performance [6], striving for self-entertainment is a key driver for using wearable self-tracking devices, and that the usage ultimately increases the perceived fulfillment of the user's motivations for self-entertainment, self-discipline as well as self-design. Furthermore, gamification elements might not support motivation fulfillment but rather distract users of wearable self-tracking devices from it. Our findings have three additional main practical implications: First, potential users of wearable self-tracking devices should be aware that self-tracking might help them to fulfill motivations which they have not previously been aware of. Second, we suggest that designers and manufacturers of wearable self-tracking devices consider addressing the entirety of motivational factors. This might improve their product attractiveness and let them reach more customers. Lastly, the use of gamification elements should be up to the user as their mandatory usage might not always support usage and motivation fulfillment.

{lgravemeier,lisa.berkemeier,oliver.thomas}@uni-osnabrueck.de

Abstract. Nachdem die Leistungsentwicklung von mobilen Endgeräten der letzten Jahre die Nutzung von Augmented-Reality-Anwendungen dem Massenmarkt zugänglich gemacht hat, sind diese nun gängiger Bestandteil der App Stores. Es besteht jedoch eine Forschungslücke im Hinblick auf klare Gestaltungsrichtlinien für Augmented-Reality-Applikationen. Rezensionen in den App Stores bieten an dieser Stelle eine wertvolle Einsicht in das Nutzererlebnis. Zur Identifikation von Erfolgsfaktoren wird ein Review Mining mit den Nutzerkommentaren zu 20 Augmented Reality Applikationen durchgeführt. Durch eine Sentiment Analysis werden positive und negative Nutzererfahrungen voneinander getrennt, um darin wiederholt auftretende Lob- und Kritikpunkte durch ein Topic Modeling zu erkennen. Die Erkenntnisse erweitern die Wissensbasis durch die Identifikation von Adoptionstreibern und Entwicklungsfeldern für die Gestaltung von Augmented-Reality-Applikationen. Insbesondere technische Zuverlässigkeit und Kompatibilitätsprobleme wurden als Entwicklungsbedarf identifiziert, während die volle Ausnutzung des Potenzials des Augmented Reality Interface Designs sich als klarer Treiber zeigt.

Keywords: Augmented Reality, User Experience, Review Mining, Sentiment Analysis, Topic Modeling

1 Einleitung

Applikationen (Apps) können das Konzept Augmented Reality (AR) auf verschiedenen Endgeräten umsetzen, indem sie digitale Objekte in die reale, wahrgenommene Umgebung des Nutzers integrieren. Nach der erfolgreichen Einführung der App „Pokémon Go" werden nun verschiedene AR-Apps entwickelt und konsumiert. Neben der Anwendung in der Spieleindustrie werden AR-Apps auch in klassischen Branchen wie der Möbelindustrie und im Bildungssektor entwickelt. Hierzu stellte Apple Inc. [1] auf der World Wide Developer Conference im Juni 2017 das ARKit vor, im September antwortete Google LLC [2] im Rahmen des Google Developers Day mit der Ankündigung des ARCore. Sie dienen als Entwicklungswerkzeuge für AR-Apps und bereiten den Weg für die weitere Verbreitung von Mobile-Augmented-Reality-Apps (MAR-Apps) in den gängigen App Stores.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

Obwohl die ersten Überlegungen zu Augmented bzw. Virtual Reality bereits lange zurückliegen [3], weitet sich damit erst jetzt ihre Verwendung auf eine Vielzahl von Endnutzern aus. Folglich befindet sich die wissenschaftliche Forschung zu Design und Konzeption von MAR-Apps mit Berücksichtigung des Nutzerverhaltens und deren Umsetzung derzeit noch in ihren Anfängen [4–6]. Allerdings ist die Erhebung von Nutzerdaten durch Usability- und User-Experience-Experimente mit hohen Kosten verbunden und bisher vorliegende Untersuchungen weisen häufig noch Qualitätsdefizite auf [7]. Für herkömmliche Apps stehen zwar bereits Richtlinien zur Interfacegestaltung auf Basis wissenschaftlicher Forschung zur Verfügung (z.B. [8]), allerdings können diese aufgrund der besonderen Interaktionsmöglichkeiten nur begrenzt auf AR-Apps übertragen werden.

Die Technologie eröffnet neue Möglichkeiten zur Dienstleistungserbringung seitens der Industrie und schafft neue Nutzungserlebnisse für den Endkunden. Diese Erfahrungen werden in Form von Bewertungen auf entsprechenden Plattformen, wie den App-Stores von Apple und Google, rezensiert. Diese unstrukturierten Daten können wertvolle Erkenntnisse für die Entwicklung von AR-Apps beinhalten. Ziel dieses Beitrags ist die Identifikation von Erfolgsfaktoren, aufgegliedert in Adoptionstreiber bzw. Entwicklungsfelder, die aus Rezensionen mittels Text Mining abgeleitet und analysiert werden. Die Untersuchung wird strukturiert durch die Forschungsfrage (FF) *Welche Aspekte von AR-Apps werden wiederholt positiv bzw. negativ zurückgemeldet und können daher als Erfolgsfaktoren von AR-Apps gewertet werden?* Dazu werden in Kapitel zwei zunächst die theoretischen Grundlagen der AR und des Review Mining (RM) als zentrale Konzepte erläutert. Anschließend wird in Kapitel drei die Durchführung und verwendete Methoden des RM beschrieben, um eine Rekonstruierbarkeit zu gewährleisten. In Kapitel vier werden die erzielten Ergebnisse umfassend dargestellt und in Kapitel fünf diskutiert. Abschließend wird in Kapitel sechs ein Fazit gezogen und ein Ausblick auf weiteren Forschungsbedarf gegeben.

2 Theoretische Grundlagen

2.1 Anwendungsgebiete und Interfaces von Augmented Reality Applikationen

AR beschreibt die Integration virtueller Elemente in die reale Umwelt. Der nahtlose Übergang virtueller Objekte in die reale Umgebung wird als Erweiterung der Realität verstanden. Dabei wird eine vermischte 3D Realität erzeugt, mit der in Echtzeit interagiert werden kann [9, 11]. MAR, d.h. die Verwendung von AR auf mobilen Geräten [12], wird von Smartphones geprägt [5], [13]. Smartphones stehen einer breiten Masse an Anwendern zur Verfügung und können im Gegensatz zu spezifischen Endgeräten, wie AR-Brillen, die Weitergabe der AR-Technologie von einer forschungszentrierten Entwicklung hin zum Endnutzermarkt beschleunigen. AR-Apps werden in der Regel nach Anwendungsfeldern kategorisiert [vgl. 4]. Über verschiedene Klassifikationen hinweg finden sich AR-Apps mit Bezug zu Bildung, Gesundheit, Marketing, Bauwesen und Fertigung, Gaming und Entertainment, Militär, Visualisierung, sowie Navigation und Tourismus [4], [9], [14–17].

Im Rahmen dieser Anwendungsgebiete werden AR-Apps sich nur durchsetzen können, wenn sie im Vergleich mit herkömmlichen Apps Vorteile bieten. Dabei nutzt AR das Potential der Immersion, um das Nutzererlebnis zu verbessern. So wird z.B. beim Online-Shopping mit der IKEA AR-App die Anordnung virtueller Produkte im tatsächlichen Raum und somit eine bessere Entscheidungssituation ermöglicht. Die vielfältigen Interaktionsmöglichkeiten der AR-Technologie ermöglichen neue User Interfaces (UI). Insbesondere tragbare MAR-Geräte können als „magic lens" [17] bezeichnet werden, durch die der Benutzer die Realität erweitert wahrnimmt. Die Interaktion mit den darin sichtbaren virtuellen Objekten kann in einem tangible UI [18] direkt durch die Manipulation der korrespondierenden realen Objekte erfolgen. Zusätzlich dient ein kollaboratives UI mehreren Benutzern als Basis für einen ausgeführten Prozess, sodass gemeinsam nicht nur mit realen, sondern auch mit virtuellen Objekten interagiert werden kann [19], [20]. Generell wird die Zusammenführung verschiedener Interaktionsmöglichkeiten und somit ein hybrides UI angestrebt, um eine möglichst realitätsnahe Erfahrung zu erzeugen [17]. Um die Schnittstelle zwischen Anwender und AR-System noch lebendiger zu gestalten, kommen multimodale UIs zum Einsatz. Hier werden mehrere Sinne des Benutzers für die Verarbeitung des In- und Outputs des AR-Systems verwendet [17].

2.2 Review Mining

Die Analyse von Reviews zur Zusammenfassung verschiedener Produkteigenschaften und Nutzereindrücke wird abgeleitet vom Text Mining als RM bezeichnet [21] und als Tool zur Analyse von Apps eingesetzt [22], [23]. Durch die Betrachtung von Einschätzungen der Nutzer stehen vor allem die Methoden des Opinion Mining bzw. der Sentiment Analysis (SA) im Vordergrund. Die Abgrenzung der Begriffe Opinion Mining und SA ist umstritten [24], allerdings dienen beide der Analyse von Texten mit subjektiven Inhalten im Gegensatz zu klassischen Text Mining Anwendungen [21], [25].

Eine zentrale Komponente der Analyse subjektiver Daten ist die Einschätzung ihrer Polarität bzw. der Richtung, der darin ausgedrückten Empfindungen. Diese Klassifikation kann durch verschiedene Methoden erreicht werden: mithilfe von Lexika, in denen Sentiment-Werte für enthaltene Wörter bereits definiert sind, aber auch gestützt durch maschinelle Lernverfahren wie das Natural Language Processing [25]. Diese Lernverfahren benötigen bereits klassifizierte Datensätze, um davon eine systematische Einteilung abzuleiten. Um möglichst genaue Ergebnisse zu erzielen, werden domänenspezifische Trainingsdaten benötigt. Allerdings ist die manuelle Generierung individueller Datensätze für jedes neue Anwendungsgebiet mit einem hohen Aufwand verbunden und daher werden auch domänenübergreifende Ansätze verfolgt [26]. Meist wird die Polaritätseinschätzung auf Basis des gesamten Textdokuments durchgeführt, es kann jedoch auch auf Ebene von Sätzen oder sogar Aspekten differenziert werden. Die erhöhte Granularität ermöglicht auf der einen Seite eine klarere Zuordnung der subjektiven Einschätzung zum Meinungsgegenstand, kann aber durch den Verlust von Kontext auch unerwünschte Effekte hervorrufen [27].

Zusätzlich zur Polarität der ausgedrückten Meinungen, muss auch der inhaltliche Gegenstand der Reviews ausgewertet werden. Um wiederkehrende Themen und ihre Zusammenhänge zu kategorisieren, werden Topic Modeling Methoden genutzt [28], [29]. Häufig wird Latent Dirichlet Allocation (LDA) angewandt, das übergeordnete Themen und assoziierte Inhalte in Textquellen identifiziert [30], [31]. Klassische LDA Verfahren fordern dabei eine Angabe der Topicanzahl, während das hierarchische LDA diese dynamisch selbst erlernt [32].

3 Analyse von Rezensionen über Augmented Reality Applikationen mit dem Review-Mining-Verfahren

Im Rahmen dieser Arbeit wird ein RM mithilfe der oben erläuterten Methoden durchgeführt. Hier wird zunächst der konkrete Untersuchungsablauf beschrieben, der zum Überblick in Abbildung 1 dargestellt ist. Zuerst wurden die zu untersuchenden Daten ausgewählt und extrahiert. Mit dem Ziel möglichst viele Reviews zu erfassen, wurden Daten aus den Apple App Stores aller Nationen mit Englisch als Muttersprache berücksichtigt: die Vereinigten Staaten, Kanada, das Vereinigte Königreich, Irland, Australien, Neuseeland und Südafrika [33]. Als Indikator für eine möglichst hohe Reviewdichte wurden die 20 Apps mit der höchsten Anzahl an Benutzerbewertungen im App Store der Vereinigten Staaten ausgewählt. Daten zu Download- oder Reviewanzahl können im App Store nicht eingesehen werden. Die Extraktion der Daten wurde mittels eines PHP-Skripts (modifiziert nach [34]) durchgeführt, das Datum, Rating, Titel, Inhalt und weitere Metadaten des Reviews gescrapt hat.

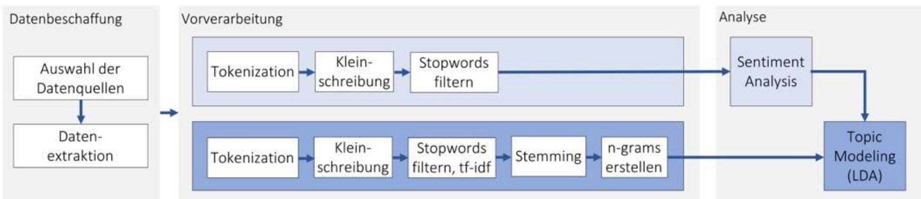

Abbildung 1. Ablauf des durchgeführten RM

Zur Analyse der Daten wurde das Tool RapidMiner Studio (Version 8.2.000) verwendet. Im ersten Schritt wurden durch das Scraping oder Spam entstandene Duplikate entfernt, wonach mit 130.262 Datensätzen gearbeitet werden konnte. Deskriptive Daten zur initialen Stichprobe sind in Tabelle 2 im Anhang dargestellt.

Als Grundlage der SA dienen die textuellen Bestandteile der gescrapten Daten, d.h. Reviewtitel und -inhalt. Diese wurden in ihre einzelnen Wortbestandteile aufgeteilt (Tokenization) und in Kleinbuchstaben umgewandelt. Zusätzlich wurden sogenannte Stopwords herausgefiltert, d.h. in der englischen Sprache grundsätzlich gehäufte Worte oder auf den App-Inhalt bezogene Worte ohne Relevanz für die ausgedrückte Meinung. Anschließend wurde auf Basis der verbliebenen Tokens eine SA durchgeführt. Da kein domänenspezifisches Training Set zur Verfügung stand, wurde ein Sentiment Score mit dem domänenübergreifenden Tool SentiWordNet 3.0 [35] berechnet.

Vorbereitend für das Topic Modeling Verfahren wurde der Datensatz zunächst verkleinert, um eine ausgewogene Zusammensetzung der Daten zu erreichen. Zuvor lag der Reviewanteil der drei führenden Apps bei 91,18% und Pokémon Go dominierte mit 86.217 von 130.262 Dateneinträgen. Um einen zu starken Einfluss dieser drei Apps zu verhindern und gleichzeitig die Stichprobe nicht unnötig zu verkleinern, wurden per Zufallsauswahl jeweils nur 5.000 ihrer Reviews zur Untersuchung ausgewählt und damit insgesamt noch 26.495 Reviews berücksichtigt. Anhand des Sentiment Scores wurden drei Gruppen gebildet: positive (Sentiment Score ab 0,2), negative (Sentiment Score bis -0,2) und neutrale Reviews. Der Sentiment Score nimmt keine kategorische Einteilung vor und somit wurden für eine möglichst fehlerfreie Einteilung die positive und negative Gruppe nicht im Nullpunkt der Sentimentskala getrennt. Die Vorverarbeitung der Daten umfasste ebenfalls den Prozess der Tokenization, die Umwandlung in Kleinbuchstaben und das Herausfiltern von Stopwords. Zusätzlich wurde das „Term Frequency-Inverse Document Frequency"-Verfahren angewandt, um nicht untersuchungsrelevante Terme zu entfernen. Daraufhin wurden die Tokens auf ihre Stammform reduziert und in N-Gramme mit einer maximalen Länge von 3 zerlegt. Anschließend wurde ein Topic Modeling per LDA angewandt. Da kein hierarchisches LDA Tool zur Verfügung stand, wurden Verteilungen mit 5 bis 30 Themen getestet, um interpretierbare und möglichst aussagekräftige Topic Models zu erhalten. Dabei wurden in 1.000 Iterationen reproduzierbare Topic Models mit jeweils 15 zugehörigen assoziierten Termen (Top Words) pro Topic erzeugt. Für die Bestimmung der Hyperparameter α bzw. β wurde eine Heuristik angewandt und sie wurden automatisch iterativ optimiert, was der gängigen Praxis entspricht [28].

Um möglichen Qualitätsdefiziten des Datensatzes entgegenzuwirken, wurden weitere Ausschlusskriterien durchgesetzt. Als Ausgleich möglicher Ungenauigkeiten in der SA durch das domänenübergreifende Vorgehen wurden die Ratings als weiterer Indikator für die Einteilung der finalen Untersuchungsgruppen genutzt. Aus den positiven Reviews wurden danach nur noch Reviews mit 4 oder mehr Sternen, aus den negativen Reviews Einträge mit 2 oder weniger Sternen betrachtet.

4 Identifikation von Erfolgsfaktoren für AR-Applikationen

4.1 SA und Teilung des Datensatzes in Untersuchungsgruppen

Nach dem beschriebenen Verfahren wurde die Stichprobe anhand einer SA in drei Gruppen geteilt. Als Indikator für die Validität der durchgeführten SA wird zunächst der Zusammenhang zwischen Sentiment Score und dem vergebenen Rating des Reviews betrachtet. Das Rating wird auf einer Skala von 1 (schlechteste Bewertung) bis 5 (beste Bewertung) vergeben. Ein hoher Sentiment Score geht mit einem hohen Rating einher, r (26.495) = 0,377, p < 0,001 und Tabelle 1 zeigt klare deskriptive Unterschiede im durchschnittlichen Rating zwischen den Untersuchungsgruppen.

Tabelle 1. Rating und Sentiment Score der vorläufigen Untersuchungsgruppen

	Reviews in Stichprobe	*Negative Gruppe*	*Neutrale Gruppe*	*Positive Gruppe*
Anzahl	26.495	1.330	15.291	9.874
Durchschnittliches Rating	4,079	3,009	3,777	4,690
Durchschnittliches Sentiment	0,143	-0,357	0,05	0,354

Insgesamt weist dies auf eine erfolgreiche Einteilung des Sentiments hin. Allerdings enthält die negative Untersuchungsgruppe viele Reviews mit positivem Rating (siehe Abbildung 2). Da von einem positiven Inhalt eines Reviews mit 5 Sternen auszugehen ist, könnten diese einen störenden Einfluss auf die Ergebnisse nehmen. Daher wurde die positive bzw. negative Untersuchungsgruppe um Reviews mit zu niedrigen bzw. hohen Ratings gekürzt. Nach dieser Einteilung werden die Untersuchungsgruppen separat betrachtet und davon ausgegangen, dass ihr Inhalt Aufschluss über Erfolgsfaktoren von AR-Apps geben kann.

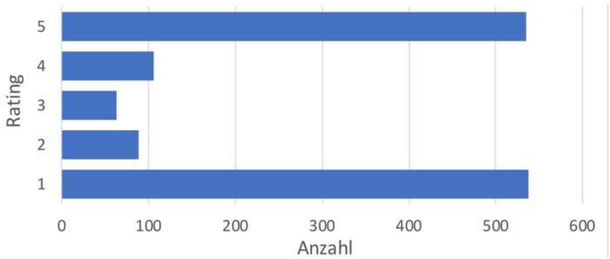

Abbildung 2. Rating der Reviews in negativer Untersuchungsgruppe

4.2 Topic Modeling in negativer Untersuchungsgruppe

Die Untersuchungsgruppe mit negativen Reviews umfasst nach dem oben beschriebenen Ausschlussverfahren 626 Datensätze, davon gehören 397 zur App „Pokémon Go“. Mit einem durchschnittlichen Rating von 2,669 und Sentiment Score von 0,014 im ungekürzten Datensatz gehört diese App nach beiden Kriterien zu den schlechtesten. Eine starke Repräsentation im negativen Datensatz ist damit nicht zu vermeiden, jedoch wird bei der Interpretation eine Abstrahierung von App-Inhalten angestrebt. Als Grundlage für die Auswertung dient ein per LDA generiertes Topic Model mit 10 vorgegebenen Topics (siehe Tabelle 3 im Anhang), wobei sinnvolle Top Words in Kombination mit hochassoziierten Reviews interpretiert werden.

Die Betrachtung dieses Topic Models fasst wiederkehrende Inhalte in negativen Reviews zusammen und macht somit Problemfelder deutlich. Hierunter befinden sich auch einige Themen, die keinen eindeutigen Bezug zu AR haben. So wird allgemeine Unzufriedenheit ausgedrückt mit beispielhaften Reviewinhalten wie „huge regret downloading“. Zudem wird das Preis-Leistungs-Verhältnis in negativen Reviews als nicht ausgeglichen wahrgenommen und die jeweilige App z.B. als „a waste of money“ bezeichnet. Der hohe Stellenwert von RM für Hersteller konkreter Anwendungen wird durch die direkte Adressierung der Entwickler und den Bezug auf bestimmte Updates und Softwareversionen deutlich. Hier werden fundamentale funktionale Probleme wie „cannot log in after update“ oder „new update makes this game unplayable“ zurückgemeldet. Dies bestätigt die besondere Rolle von Reviews, in denen Benutzer den Austausch mit den Verantwortlichen suchen, um Probleme anzumerken. Daher bietet RM vor allem für Entwicklungsteams einzelner Anwendungen die Möglichkeit, schnell auf Nutzerbeschwerden aufmerksam zu werden [22].

Zudem werden gehäuft Softwarefehler und Bugs, Server Probleme und App Crashs sowie ein hoher Batterieverbrauch bemängelt. AR-Apps analysieren die Umwelt durch ein Tracking System und benötigen daher Zugriff auf verschiedene Sensordaten. Die Erhebung und Verarbeitung dieser Daten in Echtzeit stellen hohe Anforderungen sowohl an die Hardware der mobilen Geräte, als auch an die Serverleistung [14]. Daher sollten diese Problemfelder als AR-bezogene Faktoren interpretiert werden.

Eine unmittelbare Relevanz für die Umsetzung von AR zeigt sich in der Beanstandung von fehlendem oder fehlerhaftem Tracking; beispielsweise wird „i think there is something wrong with the compass“ zurückgemeldet. Wie oben erläutert ist das Tracking der Umwelt zentrale Voraussetzung für die erfolgreiche Umsetzung eines AR Erlebnisses. Als fundamentales Problem wird zudem ein fehlender oder funktionsloser AR Modus bemängelt, häufig in Zusammenhang mit Kompatibilitätsproblemen bestimmter Geräte oder Betriebssystemversionen: „AR doesn’t work for the 7“.

Nach den Erkenntnissen dieses Topic Models liegen die Quellen von Unzufriedenheit bei Nutzern von AR-Apps vor allem in technischen Grundlagen.

4.3 Topic Modeling in positiver Untersuchungsgruppe

Nach der Filterung der Stichprobe anhand des Sentiment Scores und Ratings stehen noch 9.149 Reviews mit positiven Nutzereindrücken für die Untersuchung zur Verfügung. Diese Auswahl wird von Apps dominiert, die die Erkundung des Nacht- und Sternenhimmels thematisieren: Reviews zu Apps in diesem Themenbereich machen insgesamt 3.942 der Einträge in der Untersuchungsgruppe aus. Auch hier wird die Interpretation des Topic Models soweit wie möglich unabhängig von konkreten App-Inhalten durchgeführt. Die Darstellung der Ergebnisse basiert auf der Interpretation eines 20 Topics umfassenden Topic Models, das in Tabelle 4 im Anhang dargestellt ist. Darin werden erneut sinnvolle Top Words und assoziierte Reviewinhalte zur inhaltlichen Einordnung berücksichtigt.

Analog zur negativen Untersuchungsgruppe werden hier als AR-unabhängige Faktoren ein ausgewogenes Preis-Leistungs-Verhältnis gelobt und eine allgemeine Zufriedenheit und Empfehlung ausgesprochen: „Totally worth it!“, „I would advise this to all my friends“. Ebenso beziehen sich auch die positiven Rückmeldungen gehäuft auf bestimmte Updates und richten sich direkt an die Anwendungsentwickler, was sich in Reviewinhalten wie „The addition of the X-Ray vision improves this already brilliant app“ zeigt. Dabei werden sogar konkrete Verbesserungs- und Erweiterungsvorschläge gemacht, die in der Regel durch „Please add…“ oder „Can you add…“ eingeleitet werden. Dies macht erneut den hohen möglichen Nutzen von RM als Evaluationstool von spezifischen Apps deutlich.

Die Originalität und der Unterhaltungswert der Apps werden wiederholt positiv zurückgemeldet, z.B. mit „fun and addicting“ und „This is probably the most unique app in the App Store“. Während der reine Spaßfaktor keinen deutlichen AR-Bezug aufweist, kann die Neuartigkeit der Umsetzung von App-Inhalten mithilfe der AR-Technologie einen positiven Einfluss auf die wahrgenommene Originalität bedeuten. Besonders häufig wird zudem die erfolgreiche Umsetzung von Bildungsinhalten in positiven Nutzereindrücken festgehalten, z.B. „This app is making kids love astronomy“ und „all the information is very clear and to the point“. Dies könnte auf den hohen Anteil an Apps mit Bildungsinhalten zum Thema Himmel in der untersuchten Reviewgruppe zurückzuführen sein. Allerdings gehören edukative Anwendungen zu den besonders erfolgversprechenden Kategorien von AR-Apps, zu denen bereits weiterführende Studien zum Nutzerverhalten durchgeführt wurden [4]. Die besondere Eignung und fortgeschrittene Gestaltungsrichtlinien von AR für die Umsetzung von Lernumgebungen kann somit auch zur Erklärung der gehäuften positiven Reviews in diesem Bereich beitragen. Dies gibt Anlass dazu, experimentelle Nutzerdaten auch für andere Anwendungsbereiche zu erheben, um die Nutzererfahrungen auch hier anhand von evidenzbasierten, auf AR-Umgebungen zugeschnittenen Gestaltungsrichtlinien verbessern zu können.

Zentraler Inhalt positiver Rückmeldungen mit eindeutigem Bezug zu AR sind das Interface und die Benutzerfreundlichkeit, was die besonderen Möglichkeiten der AR-Technologie für die Implementierung intuitiver Schnittstellen unterstreicht. Reviews beziehen sich mit Aussagen wie „The way this all was designed and implemented seems incredible“ und „amazingly accurate and intuitive“ auf die grundsätzlichen Stärken der Interfaces. Darüberhinaus werden aber auch multimodale Ansätze gelobt („love this app and also the music“) und trotz spezifischem Bezug zur App „Pokémon Go“ wird der Wunsch nach lokaler Interaktion mit anderen Nutzern deutlich, was die Implementierung kollaborativer AR-Interfaces bekräftigt. Auch der AR-Effekt an sich wird von Nutzern positiv zurückgemeldet. Assoziierte Reviewinhalte wie „This app is my (…) window on the real sky“ und „makes pics come alive!“ zeugen von einer erfolgreichen Umsetzung der „magic lens“ nach Gervautz und Schmalstieg [36].
Zusammenfassend legt dieses Topic Model die Ausnutzung der vielfältigen UI-Gestaltungsmöglichkeiten als zentralen Adoptionstreiber dieser Technologie nahe.

5 Diskussion

Die Topic Models decken Quellen von Lob und Kritik der Nutzer von AR-Apps auf und lassen damit Rückschlüsse zu den Erfolgsfaktoren von AR-Apps zu. Das negative Topic Model verdeutlicht die wiederholte Beanstandung von technischen Problemen: die Umsetzung des Trackings, sowie Verfügbarkeits- und Kompatibilitätsprobleme. Hingegen werden Aspekte der Benutzerschnittstelle nicht kritisiert. Im Einklang damit heben die Ergebnisse des positiven Topic Models die Implementierung eines benutzerfreundlichen Interface als wesentlichen Adoptionstreiber hervor. Die

Ausschöpfung der Interaktions- und Darstellungsmöglichkeiten der AR-Technologie kann somit eine vorteilhafte Mensch-Computer-Schnittstelle erreichen.

Die Durchführung der vorgestellten Untersuchung ist mit Limitationen verbunden. Das Format von App Store Reviews geht mit einer geringen inhaltlichen Qualität der Datengrundlage einher, die in der Verarbeitung und Analyse kompensiert werden muss, sodass trotzdem aufschlussreiche Erkenntnisse gewonnen werden können [22], [37]. Im Hinblick auf die inhaltliche Datenqualität könnten die Untersuchung ergänzt werden, indem die bewertete Nützlichkeit der Reviews berücksichtigt wird. So könnten Reviews, die von mindestens fünf anderen Nutzern als „hilfreich" bewertet wurden, gesondert ausgewertet werden. Darüber hinaus könnten abwägende Reviews mit mittleren Bewertungen und ohne Zuordnung zu den polaren Untersuchungsgruppen konstruktive Kritik enthalten und sollten daher ebenfalls betrachtet werden.

Wie oben bereits erwähnt, bestätigt die Untersuchung einen hohen Nutzen von RM einzelner Apps für Anwendungsentwickler. Damit können Trends in den Nutzerrückmeldungen schnell erkannt und entsprechende Anpassungen umgesetzt werden. Im Rahmen dieser Untersuchung wurde jedoch angestrebt, allgemeine Schlussfolgerungen in Bezug auf bestimmte App-Eigenschaften zu ziehen. Um dies erfolgreich umzusetzen, hat ein ausgeglichener Datensatz einen hohen Stellenwert. Im hier untersuchten Fall der AR-Apps stehen zum Zeitpunkt der Untersuchung jedoch noch nicht genug Reviews in vielfältigen AR-App-Kategorien zur Verfügung, sodass einzelne Anwendungen wie „Pokémon Go" und „Sky Guide" die Analyseergebnisse dominieren. Sobald eine ausreichende Datengrundlage besteht, könnten weiterführende Untersuchungen eine Aufgliederung der Analyse nach den oben angegebenen Kategorien von AR-Apps vornehmen. Darüber hinaus adressieren die identifizierten Faktoren nicht nur spezifische Eigenschaften von AR, sondern auch allgemeine Aspekte, die es in der App-Entwicklung zu berücksichtigen gilt.

Auf methodischer Ebene würde die Interpretierbarkeit der Ergebnisse von einer SA auf dem Level von Aspekten profitieren, sodass verschiedene inhaltliche Bestandteile eines Reviews einzeln klassifiziert werden. Zudem würde die Anlage und Verwendung eines domänenspezifischen Training Sets die Treffsicherheit der Einteilung erhöhen. Das Topic Modeling wurde in dieser Untersuchung mittels eines klassischen LDA Verfahrens durchgeführt, da in der gewählten Data Analyse-Umgebung kein kostenfreies hierarchisches LDA Verfahren verfügbar war. Damit könnten allerdings die Trennschärfe zwischen den Topics und die allgemeine Interpretierbarkeit des Topic Models erhöht werden. Aufgrund der grundsätzlich geltenden eingeschränkten inhaltlichen Qualität von App Reviews und methodischer Einschränkungen kann ein RM in keinem Fall die Ergebnisse einer wissenschaftlichen Nutzerstudie ersetzen.

6 Fazit und Ausblick

Durch die Durchführung eines RM wurden Rezensionen über AR-Apps analysiert. Die Untersuchung trägt mit Erkenntnissen zu den Erfolgsfaktoren von AR-Apps zur Erweiterung der Wissensbasis im Bereich der Applikationsentwicklung bei. Durch die Auswertung von Nutzerbewertungen begegnet diese Untersuchung einer aktuellen

Forschungslücke in der Betrachtung der User Experience von AR-Technologien [38]. Mithilfe von SA wurden Topic Models zu positiven und negativen Benutzerrückmeldungen generiert. Dabei werden vor allem Defizite in den technischen Grundlagen wie dem Tracking System und der Gerätekompatibilität als Entwicklungsfeld identifiziert. Eindeutiger Adoptionstreiber von AR-Apps ist die Umsetzung eines intuitiven Interface mithilfe der AR-Technologie. Die erfolgreiche Anwendung dieses Vorgehens schließt an den von Panichella et al [39] skizzierten Forschungsbedarf zum Einsatz von Topic Modeling in der Reviewauswertung an.

Die Analyse und Auswertung wurde von Wissenschaftlern aus Sicht der App-Entwicklung vorgenommen. Die vorausgehende Erfahrung in der Entwicklung eigener Applikationen stärkt die Validität der Ergebnisse (vgl. [37]). Die identifizierten Erfolgsfaktoren tragen zur Wissensbasis der Entwicklung von AR-Apps bei und sind damit von wissenschaftlicher und praktischer Relevanz. Die gewonnenen Erkenntnisse tragen Implikationen zur Erforschung des Nutzererlebnisses von AR-Applikationen bei (vgl. [40]). Weiterhin unterstützen die vorgestellten Erkenntnisse die erfolgreiche Optimierung und Neuentwicklung von AR-Applikationen.

Die identifizierten Faktoren adressieren auch Gestaltungsempfehlungen, die nicht AR-spezifisch sind. Dies impliziert die weiterhin gegebene Relevanz grundsätzlicher Charakteristika der App-Entwicklung für AR-Anwendungen. Im Einklang mit Forderungen der Wissenschaft sollte darauf aufbauend eine Erweiterung und Adaption vorhandener Gestaltungsrichtlinien für spezifische Technologien vorgenommen werden (vgl. [41]). Die spezifischen AR-Faktoren liefern dazu wertvolle Implikationen für die Entwicklung einer Gestaltungstheorie für AR-Applikationen. Die Ergebnisse können unter anderem im Rahmen von Design Science Research im Bereich der Entwicklung von AR-Anwendungen genutzt und ausgebaut werden [42], [43]. Die Erkenntnisse können durch eine Erweiterung der Analyse auf Nutzerreviews von weiteren Plattformen und neuerscheinenden Applikationen ausgebaut werden. Weiterer Forschungsbedarf besteht hinsichtlich der Übertragbarkeit der Erkenntnisse auf AR-Apps für andere Endgeräte, beispielsweise AR-Glasses.

Designing Dynamic Decision Support for Electronic Requirements Negotiations

Annika Lenz[1]

[1] University of Hohenheim, Department of Information Systems I, Stuttgart, Germany
annika.lenz@uni-hohenheim.de

Abstract. Decision support in software development is particularly important for requirements negotiations to help assessing requirements and their different implementation alternatives. Changes related to requirements are likely, which impede decision making. To keep an overview of the assessment of requirements and to keep this assessment up-to-date throughout a software development project, flexible decision support processes are needed. In this paper, we design interactive dynamic decision support, which can handle changes related to requirements dynamically. The designed support component is compared to two state-of-the-art approaches for decision support in requirements negotiations.

Keywords: Dynamic decision support, requirements negotiation, dynamic preference measurement

1 Introduction

To keep an overview of the various requirements in large software development projects is a great challenge, even if requirements management systems are employed. It gets even more challenging, if negotiations must be conducted, to determine, which requirements are actually implemented and how. Requirements negotiation is an "iterative process of communication and decision-making between [stakeholders] who have the overall goal of agreeing on a software development process and outcome" [1, p. 304]. In such coordination and reconciliation processes, requirements to be implemented, their development cost, and the delivery schedule are negotiated [2].

Decision support in such scenarios enables the quantification of requirements and possible alternatives of their implementations and thus makes them comparable [3]. In negotiations, in which various stakeholders (e.g. customers, developers, project managers, product owners) have a say, knowing one's own position and expressing this position quantitatively provides enormous benefits to enforce one's own interests.

A drawback is that software development is an industry characterised by a high degree of dynamics [4]. Especially in large software development projects, new information regarding requirements is obtained or disclosed throughout the project, so changes in requirements are likely [5]. An existing set of requirements must be refined in subsequent iterations of the requirements negotiation process in terms of additional requirements, omitted requirements, and/or changes in existing requirements' scope [2,

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

6], which illustrates the high degree of uncertainty and incompleteness of information [7].

Moreover, negotiations underlie process dynamics which influence the negotiators' preferences [8, 9]. In general, preferences are unstable due to new preference formation, learning or fatigue [10]. This effect is amplified by the negotiation partners' exchange during the negotiation process. By the negotiation partners' reciprocal behaviour they gain new information or achieve clarity about the negotiation issues or values, which influences their preferences [11].

Thus, preference changes in requirements negotiations may stem from agenda changes [12] or from the reciprocity of the negotiation process itself. In both cases, existing measurement of preferences must be efficiently adjusted to provide meaningful decision support. Dynamic decision support takes the perspective of time into consideration. It considers an unstable negotiation agenda (i.e. requirements or their implementation solution changes), and unstable preferences themselves.

From a requirements engineering perspective, decision making in requirements negotiations is supported by multi-criteria decision analysis approaches [e.g. 13], which methodologically consider a dynamic perspective in their requirements negotiation process, however, do not carry it to the decision support process. Negotiation research delivers decision support dealing with incomplete information [e.g. 14]. However, literature, which integrates insights of both domains is still scarce [2, 15]. There is no comprehensive approach that focuses on supporting decisions in requirements negotiations on a dynamic, interactive level to allow for adjustment of preferences [cf. 15], although the necessity of dynamic methodologies for requirements negotiations is present [e.g. 6, 11].

Against this background, our aim is to design efficient dynamic decision support in requirement negotiations integrating a requirements engineering and negotiation research perspective. Dynamic decision support enables continuously accurate preferences, which allows an accurate negotiation analysis [16], i.e. analysis of own and the negotiation partner's requirements specification offers and concessions. To this end, the aim of our paper is two-fold: (1) to design a dynamic decision support component for requirements negotiations; (2) to evaluate its suitability by comparing it with state-of-the-art decision support in electronic requirements negotiations using a scenario-based approach [17, 18].

2 State-of-the-Art

In negotiations, the two perspectives of individual decision making and plural decision making are relevant [16]. Decision analysis takes an individual perspective and focuses on a normative and prescriptive approach for an individual negotiator or a single negotiation party, while negotiation theory as a perspective of plural decision making assumes joint decision making. Negotiation theory describes how real people could make better collaborative decisions. Both perspectives are integrated in asymmetric negotiation analysis, which supports a negotiator's position considering the partner's behaviour [14] to support achieving the best outcome [16]. Thus, decision support takes an individual decision making perspective in a joint decision making context, whose result and benefit is asymmetric negotiation analysis.

Prerequisite is that the individual preferences of the negotiating parties are measured beforehand. A multitude of preference measurement methods exists to quantify the decision makers' preferences. As terminology differs in the field of preference measurement methods, we refer to measuring preferences for attributes and alternatives. In self-explicated approaches [19], the decision makers elicit their preferences directly. The preference measurement can thus be carried out quickly and easily and the cognitive complexity can be kept low for the decision maker. For example, Adaptive Self-Explication (ASE, [20]) comprises of three different user dialogue steps: (1) the alternatives are rated on a scale from 0 to 1; (2) the attributes are ranked regarding their importance; (3) pairwise comparisons of attributes are conducted, for which two attributes are presented to the decision maker, who enters a ratio of how much more important one attribute is compared to the other. Another popular preference measurement methods is TOPSIS [21], which uses linguistic terms to determine the attribute weightings.

Electronic negotiation systems aim to support the three phases of a negotiation, namely the planning phase (or pre-negotiation or preparation), the actual negotiation phase, and the post-settlement phase. Negotiation support systems have an inherent characteristic of providing decision support [22]. They help decision makers to understand the problem and assess the implications of their decisions. To do so, preference measurement methods are applied to calculate the utility of single offers using multi-attribute utility theory [23] based on the importance weightings of negotiation issues (= attributes) and issue values (= alternatives) [e.g. 24–26]. The resulting utility model forms the basis for negotiation analysis [16].

Requirements engineering distinguishes between requirements and their implementation solutions [17]. Using the terminology of preference measurement, requirements refer to attributes and solutions refer to alternatives. In requirements negotiations, three types of issues are negotiated: i) design related issues, ii) contract related issues, iii) technological issues and for each implementation solutions respectively options to resolve the issue [2, 27, 28]. For the sake of better reading, we refer to all types as requirements and their solutions.

Involved negotiation parties cover success critical stakeholders of the software development project [6], who typically pursue mismatching goals: Future end users desire numerous features, a high service level, or fast delivery, buyers may also wish timely delivery, however are also interested in cost within budget, or compliance, while developers prefer stable requirements and flexible contracts [2]. Typically, only a relevant subset of these stakeholders are actually involved in the respective negotiation, which results in different negotiation constellations [29]. Although requirements negotiation is an iterative process [2], which is not a one-time episode but an on-going process in general, its instantiation characteristics depend on several factors such as the software development method deployed (e.g. traditional, agile, or hybrid software development), the project type, the collaboration situation [2], involved stakeholders [29], the project stage (beginning or completion of the project), negotiation scope (i.e. requirements and solutions, technologies, or contract aspects), or frequency. Thus, their structure may differ. Requirements negotiations can be performed in independent phases, each including respective stakeholders and resulting in a (partial) agreement [29].

Nonetheless, in almost every software development project, requirements negotiations are present in some way, and in each requirements negotiation, decisions must be made. Decision support accordingly is required for stakeholders' conflicting requirements perspectives in the actual negotiation phase. We consider negotiations, in which preference measurement is supported electronically and analysis is provided based thereon. Preference measurement can jointly be conducted in face-to-face negotiation workshops [e.g. 6] or be applied asynchronously for an individual decision maker to prepare the requirements negotiation [e.g. 30].

The most widely used methodology in the area of interactive requirements negotiation support is the WinWin methodology [6, 15], which aims to achieve a fair agreement among all involved stakeholders by attempting to meet the win conditions of each stakeholder [6]. Dealing with various stakeholders, group recommendation technologies, such as IntelliReq [31], dedicatedly aim to support collaboration and enable group decision making [15]. Based on the stakeholders' preferences, recommendation technologies are applied to reach a joint decision on which requirements to implement (first).

The presented existing approaches follow a dynamic paradigm and provide decision support, however dedicated preference adjustment mechanisms are missing. Applying dynamic preference measurement to the domain of requirements negotiations can improve such approaches substantially. Our work addresses the depicted gap by designing and evaluating such a concept.

3 Methodology

The methodology applied in this paper covers the design of dynamic decision support for requirements negotiations, DynaDeS, and the evaluation of the designed component, both based on scenarios to be captured [17, 18, 32].

We design the component to fulfil the goal of providing dynamic decision support to handle preference changes efficiently. To do so, scenarios are considered, for which the design goal must be fulfilled [17, 18]. The scenarios affecting preference information changes, which must be supported, stem from volatile requirements [2] and negotiation process dynamics [8, 11], see Table 1. When requirements or solutions change during the negotiation process, the decision support component is intended to provide a process to adjust their preferences accordingly. Thus, it must consider (A) a new requirement with new solutions, (B) a new solution without a new requirement and adjust their preferences. Moreover, preferences are unstable and may change over time despite of requirements or solution changes, thus the decision support component must handle (C) preference changes for requirements and (D) preference changes for solutions.

To reach the overall aim of handling preference changes efficiently, the design process conducts the following steps: (1) Existing decision support of negotiation research is adapted to requirements negotiations; (2) the preference measurement is extended to allow dynamic preference adjustment; (3) the decision support processes are adapted to meaningfully use the adjusted preferences.

Table 1. Scope of preference adjustment for dynamic decision support in requirements negotiations

#	*Scenario*	*Cause*
A	New requirement	Unstable requirements
B	New solution	Unstable requirements
C	Changed requirement preference	Negotiation process dynamics
D	Changed solution preference	Negotiation process dynamics

The designed DynaDeS is implemented in the web-based negotiation support system Negoisst [26, 30] to exploit the benefits of an integrated system. DynaDeS is evaluated by means of a scenario-based [17, 32] comparison to analyse whether the designed dynamic decision support component meets its design goals for requirements negotiations. Scenarios illustrate how design goals are satisfied [17]. Thus, we compare DynaDeS to existing decision support w.r.t. to their suitability for the required scenarios (cf. Table 1). Furthermore, as the WinWin methodology is the methodology most commonly used for electronic requirements negotiations [15], we include decision support within the WinWin methodology [6, 33]. Moreover, we compare IntelliReq [31], which provides dedicated group decision support in requirements negotiations. Although the support components to compare are heterogeneous in different characteristics, they coincide in taking a dynamic perspective on decision support for requirements negotiations.

4 Design of the Dynamic Decision Support Component

The decision support component is not intended to replace requirements elicitation processes or requirements refinement processes. It starts when an initial set of requirements and their implementation solutions is determined. This set may be rudimentary at the beginning and be refined during the superordinate negotiation process, however, requirements and solution refinement is not meant to be part of the decision support component. In contrast, the decision support component is supposed to handle the required scenarios of changes of the environment.

4.1 A Concept for Dynamic Decision Support

In the following, we will (1) adapt existing decision support of negotiation research to requirements negotiations; (2) enable dynamic preference adjustment; (3) design processes to meaningfully use the adjusted preferences.

(1) For decision support during requirements negotiations without a dynamic perspective, information about the agenda (i.e. requirements and solutions to negotiate) is gathered in the planning phase. The problem definition takes place based on the

project goals and the project phase [cf. 34]. At a very early stage, requirements negotiation involves negotiation issues on a high-level, while negotiation in a later stage of the software development project focuses on specific aspects or sub-projects. Requirements that are elicited at an early stage allow for a wide range of implementation solutions that will be specified later. Furthermore, in the planning phase success critical stakeholders' individual goals are collected. These goals may concern high-level issues, general system functions, budget, schedule, or technical issues, such as the development environment. Having extracted the initial agenda to negotiate, the negotiation issues and values are elicited. Subsequently, still during the planning phase, an initial preference elicitation is performed, resulting in a (tentative) utility model, which is required to provide asymmetric analysis in the actual negotiation phase.

During the actual negotiation phase, the agreement takes place. The stakeholders exchange offers and counteroffers to find a mutually beneficial and acceptable solution. Analytical support is provided to assess own offers or offer drafts as well as the negotiation partner's offers based on the preferences measured.

(2) To provide dynamic preference adjustment, we choose ASE [20] as basis preference measurement method, since it performs very well regarding its efficiency, validity, and cognitive complexity [35]. Furthermore, although it is a one-shot preference measurement method as is common in multi-criteria decision analysis, it provides the potential to be adopted for dynamic contexts [35], since it uses scarcely dependencies between preference information and allows to separate preference information measured and a utility model calculated based thereon. In this paper, we incorporate DynASE, which extends ASE by dynamic preference mechanisms, into DynaDeS.

For the dynamic preference adjustment, similar user dialogues as in the initial preference elicitation are applied, namely rating of the desirability of all solutions, ranking of the requirements according to their importance, and pairwise comparison of all requirements [20]. After a bundle of pairwise comparisons is conducted, a utility model can be calculated. An adaptive selection of pairwise comparisons facilitates to ask for the greatest possible information gain. If the resulting utility model is sufficiently precise, the preference adjustment process terminates. Otherwise, further pairwise comparisons are conducted until a pre-defined number of comparisons is reached, or all issues are compared at least once.

(3) The decision support process is adapted to react to negotiation process dynamics and to embed subsequent activities in the actual negotiation phase. It allows to adjust preferences and to re-calculate the utility model during the actual negotiation phase and shifts thereby activities of the planning phase into the negotiation phase (similar to agenda negotiations, cf. [12]), see Figure 1. Focus of the dynamic preference adjustment is the interaction of preference measurement and the utility model calculation. Most preference measurement methods do not separate the pure measurement of preferences from the calculation of the utility model. However, to enable efficient dynamic decision support, the possibility of separation is inevitable. The preferences resulting from the initial preference elicitation must be saved

independently of the utility model calculated to reuse still valid preferences in the case of changes.

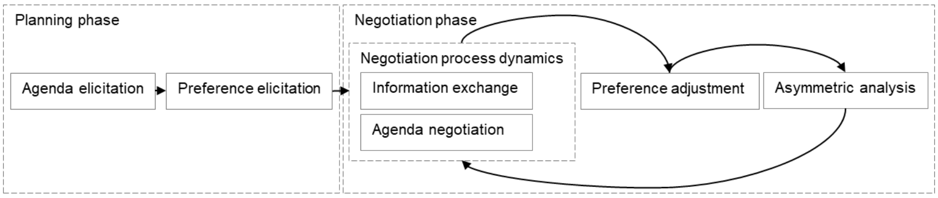

Figure 1. Dynamic decision support in the negotiation phases

In DynaDeS, the dynamic aspect comes into effect if new information is obtained, which result in (A) requirements, (B) solutions, (C) requirement preference, and/or (D) solution preference changes, see Figure 2. The planning phase is entered again in all scenarios. In the scenarios of A and B, additionally the agenda is adjusted. Subsequently in all scenarios, preferences are adjusted as well, dependent on the information gained: Solution ratings are maintained from the existing preference information if it is still valid. This can be facilitated because the solution ratings of one requirement do not relate to the ratings of other solutions. Except for scenario C when only requirement preference information changes, the first step of the preference measurement is repeated for (A) solutions of the new requirement, (B) a new solution, or (D) the outdated solution preference information. In the scenarios B and D where no requirement information has changed, the user dialogue is already completed and a renewed accurate utility model is calculated based on existing valid preference information and newly gathered preference information, which can be used in the stakeholder's analysis. For the scenarios of A and C, the preference adjustment process continues, presenting the existing requirements ranking to the user, in which (A) the new requirement must be sorted respectively (C) the rank of the respective requirement must be corrected. Preference information of paired comparisons of all other requirements is reused. Thus, based on the ranking and valid paired comparisons, a renewed utility model is calculated again. If the utility model is not yet sufficiently precise, additional pairwise comparisons involving the respective requirement can be performed. Optionally, an interactive check allows the stakeholders to view and validate their utility model and initiate preference adjustment in case the utility model does not fit their preferences (anymore). Again, based on a newly calculated utility model, precise analytical support can be provided.

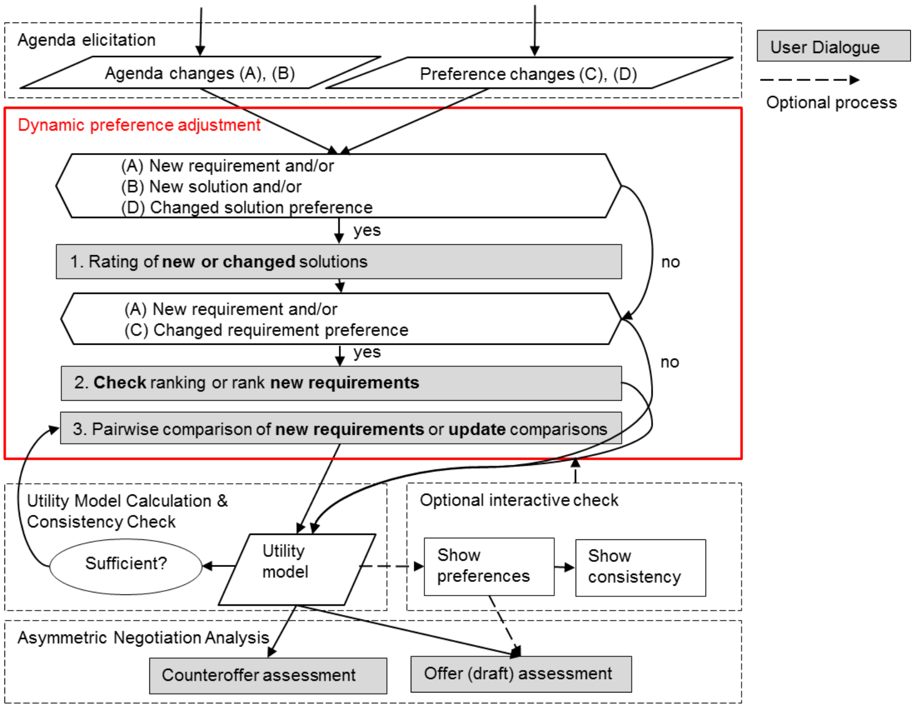

Figure 2. DynaDeS

4.2 Instantiation of Dynamic Decision Support in a Negotiation Support System

The designed dynamic decision support is implemented in the negotiation support system Negoisst [26, 30] as it already offers holistic negotiation support. Negoisst is a web-based support system, which provides decision support, communication support, and document management. One aspect of its communication-orientation is to support the offer exchange by semi-structured message exchange, which allows to send unstructured text messages along with a structured, formal offer. To make binding offers, the negotiators send each other semi-structured messages in an alternating order.

Negoisst provides extensive analytical features for decision support [e.g. 14]. The analytical features enable to assess offers quantitatively based on the negotiators' preferences by utility values. The utility of offers can be analysed by each negotiator. The history graph serves as visual support of the negotiators' convergence during the negotiation process, depicting the utility of offers over time. Concessions and gains can be analysed visually. Negoisst provides analytical support during the phases of planning (e.g. preference elicitation) and in the phase of negotiation (e.g. offer assessment and analysis). The implementation of the preference adjustment within DynaDeS covers the following three user dialogues: (1) rating of solutions; (2) ranking of requirements; (3) comparing requirements pairwise by using a slider or input fields, see Figure 3.

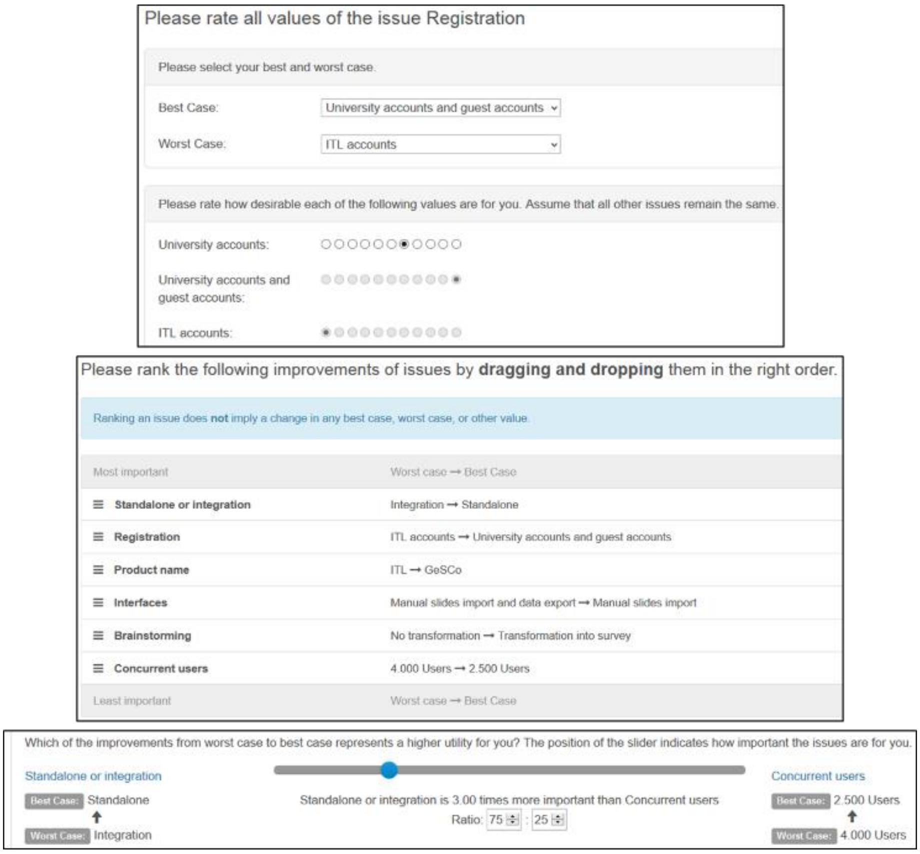

Figure 3. Preference adjustment in Negoisst: Rating of solutions, ranking of requirements, and pairwise comparison of requirements.

5 Scenario-Based Comparison of Dynamic Decision Support for Requirements Negotiation

In the following, we will analyse in a scenario-based [17, 32] comparison as to whether DynaDeS meets its design goals for requirements negotiations. DynaDeS will be compared with decision support based on the WinWin methodology [33] and IntelliReq [31].

5.1 Characteristics of the Decision Support Components to Analyse

The three decision support components all quantify the assessment of requirements and/or solutions. However, they use different assessment bases to provide decision support. In a late incorporation of the WinWin methodology, subsequently called WinWin, TOPSIS is used, which assesses strategic business goals and requirements based on ease of realisation, their business value, and relative penalty [33], while IntelliReq requests the user to rate one of the solutions for a requirement as the preferred solution [31]. Requirements are not assessed. In contrast, DynaDeS uses utility functions to assess requirements and their solutions. It assesses the requirements relatively dependent on all requirements, while the solutions are assessed independently determining one most preferred, one least preferred solution and rating all other solutions directly on a scale from 0 to 1 per requirement.

Regarding the actual support for the negotiators to make their decisions, WinWin focuses on making well-informed decisions based on cost, benefit, and penalty. It additionally considers the requirements' contribution to business goals and performs a relative assessment, so requirements and their solutions can be compared with each other. IntelliReq provides a recommendation for the group of stakeholders, which is based on the preferences of all group members. The stakeholders' assessments do not relate to each other, nor do the assessment of the requirements relate to each other. DynaDeS assesses solutions for requirements under consideration in terms of utility based on the solution preferences and the relative importance of a requirement to facilitate utility analysis [16, 36].

The process for requirements negotiations using the WinWin methodology follows an iterative spiral model. Adjustments can be conducted in each iteration and decision support is correspondingly provided in each iteration when the win conditions are reconciled [6]. IntelliReq is intended to be used in any existing requirements negotiation process model. Since it is not embedded in a process, stakeholders can change their preferences any time as long as the process has not completed resulting in a group recommendation. DynaDeS allows an iterative refinement throughout the negotiation process. Preference adjustments can be conducted at any time to provide updated accurate decision support when asymmetric analysis in the negotiation process is needed.

The concept of requirements and solutions is viewed differently in the three decision support components. The WinWin methodology elicits and negotiates win conditions, issues, and options. To consolidate terminology, we refer to issues as requirements and options as solutions. IntelliReq uses requirements and decision alternatives. Here, we refer to decision alternatives as solutions, too. DynaDeS emerges from general electronic negotiation support. Here, negotiation issues are referred to as requirements and issue values are referred to as solutions.

5.2 Comparison of the Decision Support Components

In the following (see Table 2), we analyse WinWin, IntelliReq, and DynaDeS based on the scenarios from Table 1. Following the WinWin extensions of the spiral model [6], for scenario A, in each iteration a new requirement can be added. The subsequent steps need to be performed, which are to generate solutions to cover the requirement and to jointly agree upon both the new requirement and its solutions. The new requirement has to be assigned to business goals to correctly assess its value. The preference measurement must be repeated. A new solution for a requirement (B) can also be added in each iteration. The solution possibly makes agreements obsolete, so in the same iteration, agreements possibly need to be dissolved and a new agreement must be made involving the new solution. Scenario B does not impact decision support, since solutions are not assessed. The process does not foresee that a stakeholder's preference may change after a requirement is assessed as required in scenario C. A repetition of the assessment and calculation is required. If a stakeholder's preference for a solution (D) has changed, is not applicable in WinWin, since solution preference information is not elicited and included in decision support.

Table 2. Comparison of Decision Support Components for Requirements Negotiations

	Scenario A	*Scenario B*	*Scenario C*	*Scenario D*
WinWin [33]	Repeat preference measurement	No impact on decision support	Repeat assessment for the respective requirement	Not applicable
IntelliReq [31]	Repeat recommendation process	Repeat recommenda-tion process	Not applicable	Repeat recommenda-tion process
DynaDeS	Rate solutions of new requirement; insert requirement into ranking; optionally conduct two requirement comparisons; repeat calculation of utility model	Rate new solution; repeat calculation of utility model	Check requirements ranking; conduct two requirement comparisons; repeat calculation of utility model	Assess solution; repeat calculation of utility model

In IntelliReq, adding a new requirement (A) is not designed. However, adding requirements to the agenda should be possible as long as the superordinate negotiation process is not concluded. For the new requirement solutions have to be entered and all stakeholders must utter their preferences for the best solution. The recommendation process must be repeated from scratch including the new requirement, so decision support can be provided. A new solution (B) is also not foreseen but should be possible to be added at any time. As in scenario A, all stakeholders must consider if the new solution is their most preferred solution and enter it accordingly. The recommendation process must be repeated again. Scenario C is not applicable since requirements are not assessed in IntelliReq. Thus, decision support regarding requirements is not provided. Stakeholders can add or change (D) preferences for solutions at any time. IntelliReq does not use a preference measurement method, but asks for the most preferred solution, while the remaining solutions are not assessed. Thus, changes can be made very easily and quickly. Subsequently the recommendation process must be repeated again.

In DynaDeS, in case of a new requirement (A), all solution preferences can be maintained. Only the solutions of the new requirement have to be assessed. The existing requirements ranking can be reused, too. The ranking is presented to the stakeholder who only must sort in the new requirement. All paired comparisons can be kept. At this point, a utility model can already be calculated, because the relative importance weight of the new requirement can be interpolated based on the requirements ranking. The usual criteria terminate the adjustment process, i.e. two comparisons including the new requirement can be performed if desired. If a new solution is added (B) to an existing requirement, which does not replace the best or worst solution of the respective requirement, it is rated as in scenario A. The partial utility value of the newly rated solution is included in the utility model. In case the preference information for a requirement changes (C), the requirements ranking must be checked respectively corrected and all related paired comparisons must be adjusted. Based thereon, the utility model can be re-calculated. If the preference information of an existing solution has changed (D), the preference adjustment process is the same as in scenario B. The respective requirement and its solution ratings is presented to the stakeholder, who corrects the respective assessment.

6 Discussion and Conclusions

The scenario-based evaluation shows that although both decision support components besides DynaDeS follow dynamic approaches, they do not support preference adjustment reusing the existing assessment. It is required to repeat preference measurement instead of only adjusting changes. Consequentially, the applied preference measurement methods require repeated information input. This is the major advantage of DynaDeS: The analysed decision support component based on the WinWin methodology cannot deal with changes efficiently. Using DynaDeS, the correction of the requirement ranking is already sufficient to measure the relative importance of an issue based on valid relative importance weightings of other requirements. If a more accurate importance weighting is desired, two pairwise comparisons are sufficient.

The main contributions of this paper are the dynamic concept and the proposed decision support process to integrate it. The adjustment of preferences during the requirements negotiation process provides a more accurate basis for decision making that improves the effectiveness and efficiency of the requirements negotiation process. An increase in effectiveness is reached by incorporating new or changing information during the process. Key concepts are both the separation of preferences and utility and relating preferences only to one other object. The general concept can be used and adopted by existing approaches for decision support in requirements negotiations to extend their work. The scenario-based evaluation shows the general applicability of a dynamic perspective as an improvement to decision support. Implications for practice relate to the facilitation of quickly adjusting single preferences, representing the stakeholders' interests, and thus relying on accurate decision support.

Future research could address integrating dependencies between requirements and assumptions of multi-attribute utility theory, since it requires attributes must be independent of each other. Another extension to this work could address an additional level of criteria. Stakeholders may use various criteria to assess requirements or their implementation solutions. For example, customers may evaluate requirements according to their importance, the budget, or the time of delivery, while developers use profitability and availability of resources. Dynamic decision support could enable individual criteria.

Moreover, research proposes that visualisation of information respectively the decision problem should both match the individual's cognitive style and the decision task characteristics [37]. The decision maker's experience could be considered as well [38]. Future studies could investigate, which type of visualisation in requirements negotiation is the most appropriate one. Different types of visualisation and information input could be provided so that an individual decision maker can pick the most appropriate one, e.g. regarding the presentation of the pairwise comparisons in the preference adjustment process. Additionally to different input types, the ratio of the comparison could be provided in numbers, in bars or in a bar chart.

Who is Stressed by Using ICTs? A Qualitative Comparison Analysis with the Big Five Personality Traits to Understand Technostress

Katharina Pflügner, Jens Mattke, and Christian Maier

University of Bamberg, Information Systems and Services, Bamberg, Germany
{katharina.pfluegner,jens.mattke,christian.maier}@uni-bamberg.de

Abstract. The purpose of the current study is to reveal personality profiles that predispose to the experience of techno-stressors within an organizational setting. These insights are useful because techno-stressors lead to considerable costs and adverse health effects. We use the theoretical lens of the transaction-based model of stress to study the effect of the Big Five personality traits on techno-stressors. We distributed a self-rating questionnaire among 221 individuals and analyzed data using fuzzy set Qualitative Comparison Analysis. The results reveal that six different personality profiles lead to the experience of techno-stressors. The study contributes to research by revealing that personality traits need to be investigated in profiles when studying their role in technostress and that different profiles of the Big Five predispose to techno-stressors. The results are useful for practitioners as they allow the prevention of techno-stressors and negative consequences by detecting users who are at risk at an early stage.

Keywords: technostress, personality profiles, Big Five, fuzzy set Qualitative Comparison Analysis (QCA), configurations

1 Introduction

In today's society, people heavily depend on information and communication technology (ICT). Nowadays, living and working without them is hardly conceivable. However, using ICTs can be stressful [1], which is known as technostress [2]. The term was first defined as a disease of adaptation that results from an insufficient dealing with new computer technologies [3]. In current Information Systems (IS) literature, it refers to "*stress that individuals experience due to their use of information systems*" [4, p. 2]. Stress in the workplace leads to substantial costs for organizations and the national economy as well as considerable health impairment for employees. Researchers estimate the annual costs of workplace stress, e.g. by reduced productivity, absenteeism, and compensation, at \$300 billion in the United States, and €20 billion in the EU-15 countries [5]. Technostress depicts an important aspect of stress in the workplace [6]. It is caused by different stimuli, called techno-stressors [2, 7]. In order to diminish financial costs of technostress and adverse consequences like health impairment, it is exceptionally relevant to understand what factors (e.g. personality traits of the user)

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

predispose to the experience of techno-stressors. Such knowledge allows detecting at an early stage, which employees with what personality traits are at risk. Based on this detection, preventive measures and interventions for the reduction of techno-stressors for employees at risk can be implemented even before negative consequences arise.

IS research has mainly focused on evaluating consequences of techno-stressors [2, 7–10] and *environmental or technological characteristics* that precede techno-stressors [1, 10]. The investigation of preceding *characteristics of the user* that increase or decrease techno-stressors has received little attention [4]. This is the case although other research strands beyond technostress inform us that if an individual experiences stressors does not only depend on environmental or technological characteristics, but also characteristics of the individual [11]. Findings suggest that characteristics of the individual include personality traits, which means that personality traits predispose to the level of stressors [12–14]. In line with that, first results from IS research indicate that personality traits are relevant to technostress [8, 9]. The findings reveal that personality traits influence the reaction to techno-stressors and the consequences of techno-stressors [9]. However, the depicted technostress research has two shortcomings: (1) It was not focused on personality traits as predisposing factors to techno-stressors [4] and (2) it has examined personality traits independently, which may only reveal '*half of the picture*' or even lead to false conclusions of the role of personality on techno-stressors [15]. Every user is characterized by various personality traits that coexist, forming a personality profile [16]. Thus, the current study aims to answer the following question: **Which profiles of personality traits predispose to techno-stressors?**

To answer the research question, we base on the transaction-based model of stress [11] and focus on employees working in organizations and experiencing techno-stressors as part of their daily work. Regarding personality traits, we focus on the Big Five personality traits, which reflect higher-level factors [15, 17]. They capture user personality on the most general level and cover most facets of a user's personality. The investigation of Big Five personality traits is analogous to other research in the field of IS [8, 9].

By addressing the research question, we contribute to IS research in the field of technostress and personality. Despite the relevance of technostress and even though we know that personality traits influence the reaction to techno-stressors, personality traits as *predisposing factors* to techno-stressors have not been studied so far in a comprehensive way, referring to premier journals and conferences. Moreover, we highlight the importance of investigating personality profiles within personality research. If a user experiences techno-stressors does not depend on the pure presence of absence of a single personality trait. Instead, it depends on his or her profile of personality traits. We refer to profile of personality traits (equivalent to personality profile) as the specific bundle of the Big Five personality traits. Users have different personality profiles and within each profile, these five personality traits are present to a varying degree. Finally, this research also contributes to practice by revealing personality profiles of how ICTs can evoke techno-stressors and thereby pave the way to reduce the experience of techno-stressors, e.g. through interventions, preventive measures, or sensitization of executives.

2 Theoretical Background

To study how personality profiles predispose to techno-stressors, the transaction-based model of stress [11] guides our research. The theoretical model has been widely used in plenty of different research streams, including technostress literature [2, 4, 18] (for an overview of theories in technostress research see also [19]). Based on that, we introduce the concepts of techno-stressors and personality traits, before depicting the current state of research in these two areas.

2.1 Techno-stressors and Personality in the Transaction-Based Model of Stress

Techno-stressors in the Transaction-Based Model of Stress. The increasing use of ICTs at work as well as daily life expects users to permanently adapt to new functionalities, applications, and work flows. In fact, ICTs act as a new source of stress, which is referred to as technostress [2, 10]. In line with the transaction-based model, *technostress* is a process that results as a combination of a stimulation condition (techno-stressor) and a user's response to the condition (strain). Thus, *technostress* is referred to as the overall process, including techno-stressors, strain, and appraisal as well as coping processes. *Characteristics of the environment* (e.g. organization or technology) and *characteristics of the user* (e.g. personality) precede and influence techno-stressors through appraisal processes [4]. *Techno-stressors* (also called *technostress creators*) are stressful situations caused by ICTs that result in strain [7]. Alleviating factors mitigate the relationship of techno-stressors and strain [4] through coping processes [4, 11, 20]. *Strain* refers to the consequences of techno-stressors. It is the result of being exposed to techno-stressors [10] (see Figure 1).

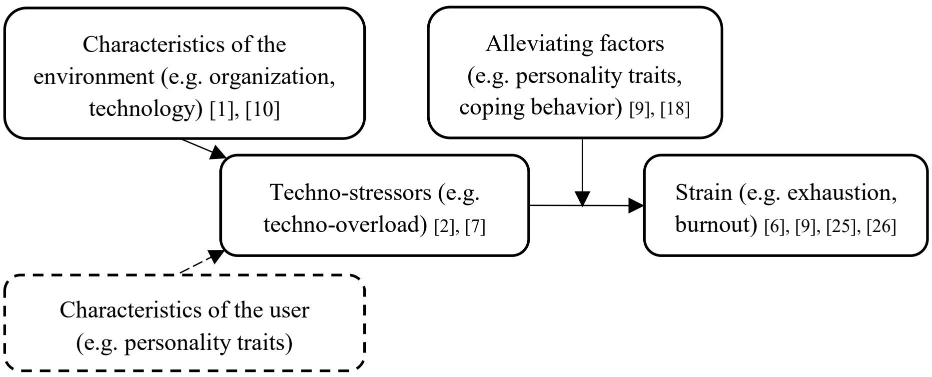

Figure 1. Overview of aspects of technostress and relevant literature. Dotted lines refer to the research gap addressed by the current study.

Personality Traits in the Transaction-Based Model of Stress. Psychological literature informs us that stressors are preceded by characteristics of the individual [11, 20]. Additionally, previous IS research informs us that personality traits as characteristics of the user play an important role in IS contexts as they influence user beliefs and behaviors (for a review see: [21]). The overall tenet thereby posits that personality traits can be captured on different hierarchical levels, whereby these differ regarding their breadth and stability [17]. Broad traits reflect user personality at the highest hierarchical level. At this level, the well-known Big Five personality traits [22] describe elements of an individual's personality. The Big Five personality traits include *neuroticism* (the tendency to experience unpleasant emotions such as anxiety easily), *extraversion* (the tendency to seek the stimulation of others), *openness to experience* (the tendency to prefer new experiences over routines), *conscientiousness* (the tendency to act in a planned and duty-oriented manner), and *agreeableness* (the tendency to cooperate with others) [23]. These five traits are commonly seen as context-free and stable and are useful to understand beliefs and behaviors across different situations [17]. Since the Big Five as broad traits capture user personality on the most general level and cover most facets of a user's personality, we focus on that level.

We have now introduced the concepts of techno-stressors and personality traits and depicted how these are connected. The transaction-based model of stress helps us to understand that personality traits as characteristics of the user precede and influence if an employee experiences techno-stressors. Based on that knowledge, we will now illustrate relevant research findings from the technostress and personality stream. By that, we will reveal research gaps and clarify where the study at hand extends existing research.

2.2 Research Findings Regarding Technostress and Personality

In the following, results from the technostress literature will be explained first, followed by a linkage to personality traits with a focus on IS literature.

Findings Regarding Techno-stressors. Previous research has discussed five techno-stressors. The techno-stressor *techno-overload* describes situations in which users face an increase of work amount and speed due to ICTs. *Techno-invasion* refers to situations where users feel the need to be permanently connected to work and where the line between work and personal life becomes blurred due to ICTs. *Techno-complexity* describes situations where ICT-related complexity leads users to the feeling of inadequate skills and to spend time as well as effort to understand the different aspects of ICTs. *Techno-insecurity* refers to situations where users fear losing their job due to other employees with better ICT skills or due to the replacement by an ICT. Finally, *techno-uncertainty* describes situations where users feel uncertainty because of ongoing changes in ICTs and where they are constantly forced to adapt, learn, and educate themselves about new ICTs [2, 7]. The five mentioned techno-stressors are commonly used in IS research [2, 9, 10].

Findings Regarding Strain. The exposition to techno-stressors leads to increases in strain that are non-beneficial consequences of techno-stressors [10] (for a review see: [4, 24]). In this context, techno-stressors have been linked to adverse job-related consequences like decreases in satisfaction with the ICT, performance, innovation, job satisfaction, and commitment [2, 7, 10]. Additionally, techno-stressors lead to adverse well-being-related consequences like exhaustion, burnout, overall strain, and lower work engagement [1, 6, 8, 9, 18]. These quantitative results are supplemented by qualitative results, suggesting that techno-stressors lead to problems in concentration, sleep, identity, and social relation [25]. It is worth noting that consequences of techno-stressors do not only manifest on a behavioral or emotional level, but also on a biological level [24]. Stress that arises from the use of ICTs even leads to physiological changes. Research in a laboratory experimental setting revealed that the experience of techno-stressors, induced by a system breakdown or high frequency of instant messages, results in endocrinological changes in terms of an incidence in stress hormones [26, 27].

Findings Regarding Preceding and Alleviating Factors. Research has examined technology characteristics that precede techno-stressors, e.g. usefulness, reliability, and presenteeism [1]. Recently, the interest in examining coping strategies that help dealing with techno-stressors has increased. In line with that, aspects of personal control that influence the effect of techno-stressors on strain have been investigated [18].

Findings Regarding User Personality and Technostress. With regards to personality research in IS, research has among others used the Big Five personality traits to show that these influence technological beliefs in terms of perceived usefulness and ease of use [28] as well as user behavior [29]. From the strand of technostress, research informs us about two aspects. First, we see that the Big Five personality traits, such as extraversion and neuroticism, influence how users react to techno-stressors [8]. This means that users high on neuroticism or low on extraversion are more exhausted from using ICTs. Second, we know that the Big Five determine how techno-stressors influence job burnout and job engagement [9]. This means that whether a user is high or low on extraversion determines, among others, if a given level of techno-stressors produces job burnout. In Figure 1, we have summarized the mentioned concepts and have linked them to relevant technostress literature with a focus on studies that have investigated predisposing or alleviating factors to techno-stressors. Moreover, the leverage point of the study at hand is shown dashed.

To sum it up, previous research on technostress emphasizes that there are different techno-stressors that lead to wide-ranging non-beneficial consequences and are preceded by specific technological and organizational characteristics. However, it remains a research gap that no knowledge exists about which personality traits precede whether a user experiences techno-stressors (as shown dashed in Figure 1) (referring to premier journals and conferences). In latest IS literature, there is the claim to investigate how personality traits influence if a user experiences techno-stressors [4] to understand what factors increase the likelihood that ICTs are experienced as stressful. In addition to this research gap and claim, existing studies do not account for the effects of coexisting personality traits, building personality profiles. We know that the Big Five form distinct personality profiles. This suggests that multiple profiles exist, which differ in their personality traits, but all predispose to techno-stressors. Thus, there might be profiles that predispose to techno-stressors, but there might also be profiles of personality traits that do *not* predispose to techno-stressors. Thus, if a user experiences techno-stressors might not depend on the pure presence or absence of a single personality trait. Instead, it might also depend on the presence or absence of other personality traits that coexist and form employees' personality profile. Yet, so far, research has not considered which different personality profiles predispose to techno-stressors. This knowledge is essentially important to prevent, intervene, and foster the handling of techno-stressors.

To address the mentioned research gaps, we apply a configurational approach using fuzzy set Qualitative Comparison Analysis (fsQCA) [30]. Previous research on user personality emphasizes that there are three different hierarchical levels. Thereby, it is recommended to initially focus on broad traits, particularly if no previous research exists that identifies other, more specific, narrower traits [31]. Therefore, we focus on the Big Five personality traits [16] to explain how personality profiles predispose to experiences of techno-stressors. Having in mind that techno-stressors result in adverse consequences like decreased performance and IT use, the results allow the drawing of propositions to positively react to techno-stressors and related adverse effects.

3 Method

We next describe the data collection process as well as the used measures, and outline the validity and reliability of the measurement model. We then explain our data analysis using fuzzy set Qualitative Comparison Analysis (fsQCA) [30], which has been successfully used in IS research to examine different personalities using individual level data [32, 33].We use this approach to reveal which configurations of different personality traits lead to the same outcome (techno-stressors). Here, configurations are equivalent to profiles of the Big Five personality traits. Thus, each configuration encompasses the five personality traits that are pronounced with varying degree.

Data Collection. The sampling strategy is to get a broad spectrum of participants who are familiar to work with IS on a regular basis as their profession. Therefore, we chose to invite cloud workers using Amazon Mechanical Turk (mTurk). Those participants professionally work with IS and mostly have additional occupations in organizations [34]. We prepared an online survey and used mTurk, which has become an established approach in IS research and is equal to traditional data collection approaches [35]. To ensure a high quality of our data, we embedded two attention tests in our survey. Overall, 239 individuals participated, however, we removed 18 participants as they failed the attention tests. The final sample consists of 221 participants. Thus, the sample size is large enough, as the ratio of conditions (here: the Big Five) to number of participants should be smaller than 0.2 and in this study we have a ratio of 0.022. This means fsQCA only requires a sample of 25 observations, yet our sample size is eight times as large [36]. Individuals who successfully participated in the survey received $ 0.20. The characteristics of the final sample are shown in Table 1.

Table 1. Sample characteristics (in per cent) of 221 participants

Age (in years)	< 20	1.0	ICT use (hours per week)	< 10	10.9
	20-29	40.1		10-19	12.5
	30-39	40.7		20-29	16.2
	40-49	12.5		30 – 39	16.1
	> 49	5.7		> 39	44.3
Sex	Female	39.1	IT professional	No	64.6
	Male	60.9		Yes	35.4

We followed recommendations for self-reported data [37] and tested for common method bias. For this, we applied Harman's single factor test, which reveals that one factor only explains 37 percent of the variance, which is below the recommended threshold of 50 percent [38]. Additionally, we examined the correlation matrix (see Table 4), which does not reveal any high correlations [39]. In summary, we can state that common method bias is not an issue in this study.

Measures. To measure the Big Five personality traits, we base on existing items [9]. For openness to experience we used three items, yet one item was removed because the loading was below the recommended threshold [40]. For neuroticism, we used three items and for agreeableness three items, but one item was removed due to a low loading. To measure conscientiousness and extraversion, we used three items each [9]. To measure techno-stressors, we used the five techno-stressors and measured overall techno-stressors as a second-order construct resulting of the five stressors [2]. Therefore, we base all techno-stressor items on Ragu-Nathan [2]. We measured techno-overload by five items, but we removed one item because of a low loading. We used four items to measure techno-complexity and again removed one item due to a low loading. We used five items for techno-complexity, four for techno insecurity, and four for techno-uncertainty. All items were measured on a 7-point Likert-type agreement scale, ranging from 1 (completely disagree) to 7 (completely agree) (see Table 2).

Table 2. Measures

Techno-overload [2], $\alpha = 0.86$	I am forced by ICTs to work much faster. [0.795] I am forced by ICTs to do more work than I can handle. [0.882] I am forced by ICTs to work with very tight time schedules. [0.881] I have a higher workload because of increased ICT complexity. [0.743]
Techno-invasion [2], $\alpha = 0.79$	I have to be in touch with my work even during my vacation due to ICTs. [0.896] I have to sacrifice my vacation and weekend time to keep current on new ICTs. [0.900] I feel my personal life is being invaded by ICTs. [0.720]
Techno-complexity [2], $\alpha = 0.86$	I do not know enough about ICTs to handle my job satisfactorily. [0.721] I need a long time to understand and use new ICTs. [0.962] I do not find enough time to study and upgrade my ICT skills. [0.741] I find new recruits to this organization know more about ICTs than I do. [0.719] I often find it too complex for me to understand and use new ICTs. [0.787]
Techno-insecurity [2], $\alpha = 0.86$	I feel constant threat to my job security due to new ICTs. [0.853] I am threatened by coworkers with newer ICT skills. [0.891] I do not share my knowledge with my coworkers for fear of being replaced. [0.800] I feel there is less sharing of knowledge among coworkers for fear of being replaced. [0.725]
Techno-uncertainty [2], $\alpha = 0.83$	There are always new developments in the technologies we use in our organization. [0.745] There are constant changes in computer software in our organization. [0.846] There are constant changes in computer hardware in our organization. [0.803] There are frequent upgrades in computer networks in our organization. [0.852]

Openness [9], α = 0.87	I see myself as creative. [0.961] I see myself as imaginative. [0.921]
Neuro-ticism [9], α = 0.75	I see myself as moody. [0.799] I see myself as easily upset. [0.846] I see myself as anxious. [0.817]
Agreeable-ness [9], α = 0.75	I see myself as sympathetic. [0.728] I see myself as kind. [0.991]
Conscien-tiousness [9], α = 0.74	I see myself as dependable. [0.761] I see myself as self-disciplined. [0.714] I see myself as organized. [0.909]
Extraver-sion [9], α = 0.85	I see myself as extraverted. [0.894] I see myself as enthusiastic. [0.851] I see myself as talkative. [0.880]

Measurement Model. To ensure content validity we only used items that have been used and validated in previous research. Each item used in this study has a loading above 0.707, which attests indicator reliability [2]. We can attest construct reliability because the average variance extracted (AVE) of each construct is higher than 0.50 and the composite reliability (CR) is higher than 0.70. Furthermore, we can attest discriminant validity, as we conducted the heterotrait-monotrait (HTMT) ratio, which is 0.68 and consequently below the threshold of 0.85 [41]. The square root of the AVE is higher than the corresponding correlations of the constructs [42, 43] (see Table 4).

Data Analysis Using fsQCA. To analyze which configurations of the five personality traits predispose to techno-stressors, we take a configurational approach [44]. More precisely, we use fuzzy set Qualitative Comparison Analysis (fsQCA) [30], which enables us to study techno-stressors as the result of a configuration of personality traits. In this study, a configuration refers to a specific bundle of the five personality traits which can predispose to techno-stressors and where each personality trait is expressed through a fuzzy set. Using fuzzy sets allows us to express the degree to which a measure belongs to a personality trait.

The *data analysis of configurations sufficient for techno-stressors* consists of four subsequent steps [30, 45]. First, for the *calibration* of the survey data into fuzzy sets, we applied the direct calibration, as recommended in QCA literature [44, 45]. For this, we used three recommended qualitative anchors (value 1 for full non-membership, value 4 for the crossover point, and value 7 for full membership) and calibrated the survey data [44, 45]. The resulting fuzzy sets are used in the subsequent steps of the analysis. Second, based on the fuzzy sets, we perform the *construction of the truth table*, which lists all possible configurations of the five personality traits. Third, after constructing the truth table, we applied the recommended thresholds to reduce the truth table to *meaningful configurations* [46]. In line with previous research [45, 47], we applied a frequency threshold of three, meaning that all configurations with less than three observations are dropped from further analysis. In conformity with QCA literature [46], we applied a *consistency threshold* of 0.90, meaning that only configurations with a consistency of at least 0.90 are considered in the analysis. Consistency is a measure that captures the extent to which a configuration leads to the studied outcome [30]. This means that the extent to which a configuration of personality traits predisposes to the sum of techno-stressors is measured. By applying those two thresholds, we reveal configurations that are sufficient in bringing about techno-stressors [45]. Sufficient means that every time the configuration of these personality traits is present, the experience of techno-stressors is present as well.

4 Results

In this section, we will outline the findings of the analysis of configurations sufficient for techno-stressors.

Six Different Configurations of Personality Traits Predispose to the Experience of Techno-stressors. Results reveal six alternative configurations of personality traits sufficient for predisposing to techno-stressors. We draw on graphical illustration of the configurations for readability reasons (see Table 3).

Table 3. Configurations of personality traits predisposing to the experience of techno-stressors

Configuration / Conditions	*The neurotic-agreeable personality profile* *C1*	*The neurotic-conscientious personality profile* *C2*	*The agreeable-conscientious personality profile* *C3*	*The neurotic-agreeable and conscientious personality profile* *C4*	*The open-extraverted and agreeable personality profile* *C5*	*The open-neurotic personality profile* *C6*
Openness to experience			⊗	⊗	●	●
Neuroticim	●	●		●	⊗	●
Agreeableness	●	⊗	●	●	●	⊗
Conscientiousness	⊗	●	●	●	⊗	
Extraversion	⊗	⊗	⊗		●	⊗
Raw coverage	0.38	0.36	0.36	0.37	0.37	0.36
Unique coverage	0.03	0.01	0.02	0.02	0.03	0.01
Consistency	0.90	0.90	0.90	0.90	0.91	0.91
Solution coverage	0. 60					
Solution consistency	0. 81					

Note: Black circles (●) indicate the presence of a personality trait, white crossed-out circles (⊗) the absence of a personality trait, and blank spaces indicate a *don't care* situation. In this case, the trait plays a subordinate role and may be either present or absent. C means configuration.

The configurations are translated in the following way: Black circles indicate the presence of a personality trait, white crossed-out circles the absence of a personality trait, and blank spaces indicate a '*don't care*' situation. In this case, the trait plays a subordinate role and may be either present or absent. The configurations (C1 – C6) are named based on their main characteristics, e.g. neurotic-agreeable personality profile (C1), as users with this configuration show high levels of neuroticism and agreeableness. In summary, we identified the following configurations (personality profiles): Neurotic-agreeable (C1), neurotic-conscientious (C2), agreeable-conscientious (C3), neurotic-agreeable and conscientious (C4), open-extraverted and agreeable (C5), and open-neurotic (C6).

The solution coverage of 0.60 indicates the degree of how much of the outcome (here: techno-stressors) is covered by the six configurations. Thus, the six configurations account for 60 percent of the membership in the outcome, which illustrates a high explanatory power of the configurations [48]. In line with recommendations in QCA literature [46], the solution consistency of 0.81 as well as the consistency of each configuration exceed the minimum value of 0.80. The raw coverage of the six configurations expresses the "*proportion of membership in the outcome explained by each term of the solution*" [49, p. 86], which means the extent to which the configuration covers the cases of the outcome, and ranges from 0.36 to 0.38. The six unique coverage values range from 0.01 to 0.03, expressing the unique contribution of each configuration under exclusion of the contribution of other configurations [30].
Each of the Six Configurations that were Identified Substantially and Equally Contribute to Experiencing Techno-stressors. Comparing the six configurations, the raw coverage scores and unique scores are comparable, meaning that the configurations explain techno-stressors to an equivalent extent. Furthermore, the configurations have comparable relative importance for explaining techno-stressors. To further assess the mentioned results, we discuss them in the following section, providing theoretical and practical relevance as well as future research directions.

Table 4. Descriptive statistics

Constructs	M	SD	CR	AVE	1	2	3	4	5	6	7	8	9	10
1 Open	5.39	1.34	0.94	0.89	0.94									
2 Neuro	3.95	1.32	0.86	0.67	-0.06	0.82								
3 Agree	5.43	1.11	0.85	0.74	0.19	-0.17	0.85							
4 Cons	5.29	1.21	0.83	0.63	0.16	-0.14	0.09	0.79						
5 Extra	4.28	1.47	0.91	0.76	0.27	-0.16	0.32	0.16	0.87					
6 TO	3.88	3.88	0.90	0.70	0.06	0.20	0.06	-0.04	0.10	0.84				
7 TInv	3.97	3.96	0.87	0.69	0.17	0.10	0.05	0.08	0.11	0.60	0.83			
8 TC	3.12	3.12	0.89	0.63	-0.10	0.09	-0.02	-0.02	0.15	0.35	0.28	0.79		
9 TU	3.08	3.10	0.89	0.66	0.22	0.13	-0.08	0.10	0.13	0.29	0.37	0.23	0.81	
10 TIns	4.73	4.73	0.89	0.61	-0.09	0.19	-0.04	-0.04	0.04	0.51	0.41	0.65	0.28	0.78

Note: square root of AVE is listed on the diagonal of bivariate correlations; techno-stressors are calculated as the sum of constructs 6 to 10, Open = openness, Neuro = neuroticism, Agree = agreeableness, Cons = conscientiousness, Extra = extraversion, TO = techno-overload, TInv = techno-invasion, TC = techno-complexity, TU = techno-uncertainty, TIns = techno-insecurity, M = mean, SD = standard deviation; CR = composite reliability; AVE = average variance extracted

5 Discussion

Using information and communication technologies (ICTs) can lead to the experience of techno-stressors, which in turn results in negative consequences for organizations, e.g. reduced productivity, and for users, e.g. emotional exhaustion [7, 9]. For both sides, knowledge about what factors predispose to this type of stress is relevant to address and deal with it. The aim of the paper at hand is to provide a better understanding of the interplay of personality traits influencing users' experience of techno-stressors. We base on the transaction-based model of stress [11, 20] to explain that personality profiles influence the level of techno-stressors that employees experience, which in turn influences health and organizational consequences [9, 10, 26]. To answer the research question, we test for different personality profiles leading to techno-stressors, and discovered six profiles of the Big Five personality traits by the application of fsQCA. In the following, we outline the theoretical and practical implications followed by limitations and possible areas of future research.

Theoretical Contributions. The current research contributes to the two research strands of technostress and personality as illustrated in the following.

Up to now, personality traits as predispositions to techno-stressors have gained little attention (see Figure 1). Personality traits are characteristics of the user. Existing literature revealed personality traits to directly influence the consequences of techno-stressors, e.g. exhaustion [8], and to moderate the relationship between techno-stressors and consequences like burnout and job engagement [9].

Thus, the study at hand adds the importance of personality traits, especially profiles of personality traits, as predispositions to techno-stressors to existing literature (as shown dashed in Figure 1). The findings illustrate that there is not one single personality profile, which leads to techno-stressors. Instead, there are multiple profiles leading to the experience of techno-stressors. We see that neuroticism plays a major role in four personality profiles (C1, C2, C4, C6). However, in two of the profiles (C3, C5) neuroticism plays a subordinate role or must even be absent. We see that being neurotic is not the only way towards experiencing techno-stressors. In the open-extraverted and agreeable personality profile (C5), neuroticism even has a negative influence on techno-stressors. Similarly, four of the personality profiles encompass the absence of extraversion (C1, C2, C3, C6). However, in two of the profiles (C4, C5) extraversion does not have any influence at all or can even have a positive influence on techno-stressors. Based on that, we see that there are different profiles of personality traits that lead to the experience of techno-stressors and that they explain techno-stressors to an equivalent extent. It is highlighted that certain personality traits do not necessarily have a positive or negative influence and that it rather depends on the combination of traits if they predispose to techno-stressors.

Practical Contributions. This research contributes to practice as the findings enable the early detection of users who are at risk, even before negative consequences arise. The findings can be used for preventing that employees are stressed by using ICTs. This is relevant based on the fact that techno-stressors negatively affect employees' health and organizational factors [7, 9, 26, 27].

Who might incorporate and contribute from the research findings? First, employees themselves may use the findings for self-insight. They may evaluate themselves based on the depicted profiles of personality traits, which allows them to identify if they are at risk. This self-insight is the first, but very important step to take action for mitigating and preventing techno-stressors. Based on that self-insight, they may e.g. change their ICT work habits, seek support, or engage in stress management practices.

Second, the depicted research findings may sensitize leaders for the risk of techno-stressors. More concretely, the findings highlight that employees differ in their risk of experiencing techno-stressors. There are employees that are especially prone to experience techno-stressors, whereas other employees are not. Thus, leaders should be aware of these differences, which should also be reflected in their leadership behavior. At this point, a scattergun approach might not be helpful. Instead, the findings allow leaders to specifically focus on employees at risk, which might include individual support provision or the provision of stress management interventions for the risk group.

Third, the findings can be used by software designers for the installation of adaptive enterprise systems. In combination with information from a voluntary personality screening, techno-stressors may be prevented specifically for the employees who are at risk by automatic technological adaptations, e.g. temporary interruption of mail servers for a reduction of incoming mails or the application of wizards [50].

Limitations and Further Research. There are some limitations to the results provided in this study, as illustrated in the following. To begin with, we focused on investigating user's personality traits on the most general level in a way that covers most facets of personality (Big Five) to understand which profiles of personality traits predispose to techno-stressors. However, investigating personality profiles of narrower traits, e.g. IT mindfulness [17], also seems reasonable and could be focus of future research as users can change these personality traits to some degree [17]. Moreover, we focused on techno-stressors as an aggregated construct and did not investigate the predisposition to personality profiles for each techno-stressor separately. Here, future research might study whether each techno-stressor is influenced by different profiles. Finally, it was not specifically investigated how demographic or organizational factors like type of organization or participant's role within the organization influence how personality traits predispose to techno-stressors as this was the first approach to gain an understanding of the depicted connection. The Big Five personality traits are stable across situations and time [51, 52]. Thus, they are rather independent from the influence of organizational factors. However, future research could take a look deeper into each of the six personality profiles and their predisposition to techno-stressors to reveal possible differences based on demographic or organizational factors.

6 Conclusion

The invasion of ICTs at work and daily life is constantly growing, and with it techno-stressors and related financial costs as well as negative health consequences. Therefore, knowledge is needed to detect users who are at risk at an early stage. Using a QCA approach, the study identifies six different profiles of personality traits to predispose to techno-stressors. These findings contribute to existing research by highlighting the importance of personality profiles as a predisposition to techno-stressors and the need to investigate personality traits in profiles. Practitioners may use the research findings to intervene and prevent negative consequences arising from techno-stressors.

Abstract. Recommender Agents (RAs) facilitate consumers' online purchase decisions for complex, multi-attribute products. As not all combinations of attribute levels can be obtained, users are forced into trade-offs. The exposure of trade-offs in a RA has been found to affect consumers' perceptions. However, little is known about how different preference elicitation methods in RAs affect consumers by varying degrees of trade-off exposure. We propose a research model that investigates how different levels of trade-off exposure cognitively and affectively influence consumers' satisfaction with RAs. We operationalize these levels in three different RA types and test our hypotheses in a laboratory experiment with 116 participants. Our results indicate that with increasing trade-off exposure, perceived enjoyment and perceived control follow an inverted U-shaped relationship. Hence, RAs using preference elicitation methods with medium trade-off exposure yield highest consumer satisfaction. This contributes to the understanding of trade-offs in RAs and provides valuable implications to e-commerce practitioners.

1 Introduction

Demand for products customized to individual consumers' preferences (e.g., mass customized or custom-made) has grown hugely in recent years. Concurrently, the range of product variations available on the market has expanded [1]. As a result, consumers are increasingly in need of decision support systems that help them sift through the many variations by providing information transparency on product attributes (e.g., price, quality, performance) and their interrelationships (e.g., price-quality trade-offs). Prior research indicates that navigation aids and decision aids such as recommendation agents (RAs) help consumers understand their preferences and find suitable products [2]. A central aspect within RAs, which is still subject to discussion, are trade-offs.

Trade-offs are mutual dependencies between two attributes, where certain attribute levels become unavailable (e.g. low price) as a result of having selected a specific level of another attribute (e.g. high quality) [3; 4]. How trade-offs are integrated and presented in RAs is an important issue since trade-offs can be difficult to process and imply losses in certain attributes, which tends to make consumers unhappy and frustrated – and in turn reduces their willingness to use the RA [5].

Recommender agents use a number of different strategies to elicit consumer preferences and, hence, present trade-offs differently [6]. Trade-off exposure reflects the degree to which the consumer is forced to recognize and deal with trade-offs. In other words, trade-off exposure refers to how much the user is forced to think about availability and unavailability of product attributes dependent on prior choices in other attributes. For example, when choosing a specific level of quality automatically rules out a variety of choice options (e.g., cheap alternatives), the user is confronted with high trade-off exposure, while an RA with low trade-off exposure hides such consequences. Lower levels of exposure reduce decision difficulty but have the drawback of depriving consumers of important information [7]. In contrast, higher levels of exposure increase recommendation accuracy but tend to be cognitively more challenging for consumers [8].

While traditional RA designs have either hidden trade-offs from users or forced them to explicitly compare attribute levels, recent designs exhibit a medium level of trade-off exposure [5; 9]. While the level of trade-off exposure in an RA may significantly affect users' perceptions (e.g. effort of using or satisfaction with the result), its impact is not yet fully understood. Xu et al. [5] have found that a medium level of trade-off exposure leads to highest usage intentions, however, they have only varied the number of trade-offs while using the same RA in all conditions. Hence, we are investigating the follow research question:

How do preference elicitation methods with different levels of trade-off exposure affect consumers' satisfaction with an RA?

Our study contributes to understanding the role of trade-off exposure by comparing RAs of low, medium and high trade-off exposure in a laboratory experiment with 116 participants. To investigate the influence of trade-off exposure on satisfaction with an RA, we examine cognitive and affective perceptions [10], and how they in turn affect decision quality and decision effort, preceding consumers' satisfaction with the RA.

The results of our study provide valuable contributions to theory and practice. From a theory perspective, we contribute to the understanding of how medium trade-off exposure affects consumer perceptions and, ultimately, how it affects consumers' satisfaction with RAs. From a practitioner's perspective, this study helps RA designers to facilitate consumers' purchase processes. It advances their understanding of how the level of trade-off exposure affects consumers and which level to choose when designing an RA. This in turn can lead to increased sales as consumers find the right products more easily among an extensive range of product variations.

2 Theoretical Background

Recommender agents are virtual assistants which aim to help consumers find, with as little effort as possible, the product that fits their requirements best [11]. The two most common approaches for RAs, collaborative filtering and content-based recommender systems, use information about consumers' past purchases to predict future purchase decisions [12]. However, due to lack of data for new consumers and new products (the so-called cold-start problem), recommendation quality may be quite low [9]. Systems that do not suffer from these problems are based on multi-attribute value theory (MAVT). MAVT-based RAs use consumer-specific value functions and attribute importance weights, estimated at the time of purchase, to provide recommendations [13].

How well an RA is able to support consumer decisions depends, among other factors, on how it deals with trade-offs. Trade-offs are mutual dependencies between two attributes, where certain attribute levels become unavailable as a result of having selected a specific level of another attribute [3; 4]. The trade-offs can be shown explicitly to the consumer or implicitly which is referred to as trade-off exposure. RAs with high trade-off exposure explicitly inform consumers when certain attribute levels become unavailable as a result of having selected a specific level of another attribute. Unavailable attribute combinations are presented to consumers and require consumers to take corrective action. RAs with low trade-off exposure hide consumers from this information, which means unavailable attributes are not shown or attribute selection is decoupled from product presentation. Hence, RAs with high trade-off exposure generally provide users with a more transparent (i.e., users can inspect choice consequences) but also more challenging decision process.

The level of trade-off exposure depends largely on the preference elicitation method implemented in a MAVT-based RA. Common preference elicitation methods are absolute measurement, pairwise comparisons, ordinal judgments, rankings, and matchings [14].

Consumers are forced into explicit trade-offs in preference elicitation methods like pairwise comparisons or rankings. In such explicit trade-off decisions, consumers are made aware of attribute dependencies at each step of the process. When attribute levels become unavailable, consumers can either change the configuration to make a broader range of attribute levels for the other attributes available, or they can accept the unavailability of some attribute levels and choose within the reduced ranges. They cannot continue the recommendation process before a specific attribute conflict is solved [7]. Implicit trade-offs are required in absolute measurement methods. In implicit trade-off decisions, consumers are not made aware of attribute interdependencies: consumers merely indicate their preferred attribute levels or the importance of attributes. If attribute conflicts arise, the RA interface does not point them out and does not ask to resolve the conflicts. Informed consumers may detect low accuracy in the recommendation output as a result [15].

So far, only few studies have examined the role of trade-offs in RAs. Although explicit consideration of trade-offs apparently improves decision accuracy [8], consumers often attempt to avoid considering trade-offs because they do not like the uncomfortable issue of having to accept (perceived) losses in certain attributes [16–18]. Another drawback of explicit trade-offs is the fact that processing trade-off information is cognitively challenging; depending on the number of attributes, levels and products to be compared, it can lead to information overload. Implicit trade-offs reduce decision stress [14] but choices based on explicit trade-offs are perceived to be more consistent and reliable [15; 19]. While Xu et al. [5] have found consumers to prefer a medium level of trade-off exposure, compared to high and low levels, their results were not confirmed in the context of different preference elicitation methods. We aim to improve the understanding of trade-off exposure by explicitly distinguishing low, medium and high trade-off exposure across different preference elicitation methods.

3 Research Model and Hypothesis Development

We investigate how preference elicitation methods with different levels of trade-off exposure affect consumers' satisfaction with an RA. To study the effect of different levels of trade-off exposure on users' satisfaction with an RA, we propose a research model based on cognitive and affective perceptions of an RA. The choice of latent variables and causal mechanisms is based on previous work, incorporating existing theory on the mechanisms driving users' perception [5; 7]. A summary of the research model is presented in Figure 1.

Trade-off exposure is an environmental cue that affects consumers' cognitive and affective reactions [20]. It becomes apparent to users as a visual cue (aside other cues, e.g. colors or layout), being part of the preference elicitation method implemented in a RA. Cognitively, providing information on unavailable options directly facilitates attaining a shopping goal [2], while the interactive nature of its presentation (e.g. moving sliders or crossed out options) can trigger affective reactions [21].

Perceived control and perceived enjoyment reflect the cognitive and affective reactions to the exposed trade-offs. Perceived control reflects the perception of a consumer's impact on an activity or given condition [22]. In the context of an RA, perceived control expresses to which extent consumers feel they can use the RA to accomplish their intended goal of finding a suitable product. Perceived enjoyment is an affective measure of the consumer's perception whether the interaction with the system is interesting and fun or not [23–25].

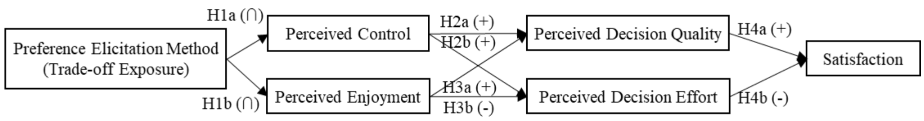

Figure 1. Research Model

Users' final reaction to using the RA is their satisfaction with the recommendation. Prior research has shown that this ultimate response is preceded by perceived decision quality and perceived decision effort [4; 26] – known as the effort-accuracy-framework [27]. Its central idea is that consumers make some compromise between a most accurate decision and the desire to minimize cognitive effort involved. Overall, this research model is based on prior theoretical justification to investigate the role of trade-off exposure as it incorporates both cognitive and affective reactions as well as a rationale for understanding trade-off exposure's effect on consumer satisfaction.

Since preference elicitation methods with low trade-off exposure do not point out attribute conflicts [15], consumers experience discrepancy between current and intended state, leading to lower perceived control [28; 29]. Similarly, the lack of transparency about attribute conflicts may give rise to unrealistic expectations about the decision space, leading to equally unrealistic inputs and in consequence to empty or very small result sets – and in turn, to lower perceived control about the recommendation process.

Trade-offs generally decrease perceived control because they require that "losses" in product attributes, i.e. divergence between current and intended state, are accepted [7; 10]. High trade-off exposure forces the consumer to accept a loss in at least one attribute [16–18] since the consumer cannot continue the recommendation process before a specific attribute conflict is solved. In this case, too, the consumer experiences a discrepancy between current and intended state, resulting in lower perceived control.

A medium level of trade-off exposure makes explicit trade-offs not compulsory but possible. Further, the consumer is informed about changes in attribute level availability after explicitly making a trade-off decision. By giving consumers the choice to only select preferred levels for the attributes of their choice, consumers can apply mitigation strategies. In other words, they can avoid making trade-off decisions between attributes they have little knowledge about and focus on familiar attributes instead. Losses in unfamiliar attributes may be felt less acutely, and the consumer may form more realistic expectations of the decision space. In summary, we expect that:

H1a: Perceived control will follow an inverted U-shape as the level of trade-off exposure increases.

In the context of RAs, the pleasure of using an attractive technology-based tool, as well as the prospect of finding the ideal product, cause enjoyment [30; 31]. An important driver of consumer's perceived enjoyment is the flow state [24]. This concept, central to flow theory, defines a state in which a person is completely focused on an activity, being rewarded just by doing the activity itself, independent of its end result or extrinsic motivation [32].

With respect to enjoyment, low trade-off exposure may leave consumers in a state of underutilizing their knowledge or decision skills. However, "challenges at a level appropriate to one's capacities" are a main antecedent of experiencing a state of flow [32], which drives perceived enjoyment. In contrast to low trade-off exposure, high trade-off exposure may overmatch consumer's cognitive capacity or knowledge, which also prevents flow [32]. RAs with medium trade-off exposure allow consumers to be more active and involved in the process. In addition, consumers can act with a higher degree of self-determination [33] in selecting attributes and proceed in accordance with their capacities. This creates a challenge that matches consumers' existing skills and thereby drives flow [32].

H1b: Perceived enjoyment will follow an inverted U-shape as the level of trade-off exposure increases.

When people perceive high control, they believe that their actions have a higher likelihood of achieving their intended state [28; 29]. In the context of RAs, this translates to the belief that suitable products will be found and suggested by the RA [28]. Consumers who perceive higher control in using the system may expect a higher likelihood of getting a suitable recommendation, hence a higher level of decision quality [34]. When consumers are in full control of the RA, they are able to express the intended state more precisely. They will expect the RA to provide a correspondingly high-quality recommendation [35]. Following these arguments, we propose:

H2a: Higher perceived control leads to increased perceived decision quality.

Higher effort may translate into longer processing times, the need for additional information, or a higher level of energy input (physically and mentally) [36]. At low levels of control, consumers need to find workarounds to bridge the gap between current and intended state, which leads to additional effort [37]. If an RA provides, for instance, insufficient filtering options and consumers are forced to manually search and compare alternatives, they must expend additional effort in terms of both time and cognitive resources. Similarly, the number of iterations required to obtain a satisfactory recommendation affects perceived effort. The more iterations are needed, the more likely it is that consumers must come up with a workaround to produce a state that is different from last iteration and closer to the intended state. This increases cognitive demand since the consumers have to think simultaneously about their actual preferences for the decision task and how to avoid ending up in the same (unsatisfactory) result state as before. Taken together, we suggest that:

H2b: Higher perceived control leads to higher perceived decision effort.

Perceived enjoyment positively affects consumer's future usage intentions [24] as well as their loyalty intentions [38]. In the context of information systems, higher levels of perceived enjoyment are associated with improvements in attitudes and satisfaction with system interfaces [21; 39; 40]. Users who experience higher levels of perceived enjoyment have been found to be more actively involved with the information they process [40]. In terms of a decision task a more active, careful selection of attributes increases the likelihood of ending up with a higher quality product alternative, i.e. higher perceived decision quality. In contrast, not enjoying the decision task leads to being less focused and less careful about the attribute selection and may in turn reduce decision quality perception. Therefore, we expect that:

H3a: Higher perceived enjoyment leads to increased perceived decision quality.

Effort and enjoyment are closely related [41]. For instance, developing software is an effortful task, and software developers are compensated for this effort with wages. However, an astonishingly high number of open source developers are willing to waive such compensation and contribute for free to the open source community [41], motivated by the fun element (i.e. enjoyment) of the task [41]. We expect this effect is observable in decision makers, i.e. they will perceive less effort during a decision, if they enjoy the process. Such perception is related to a flow state where users feel active and creative in contrast to a task experienced as tedious or laborious [42]. Higher perceived enjoyment can also lead consumers to underestimate the difficulty of a task [43]. Consequently, we suggest that:

H3b: Higher perceived enjoyment leads to lower perceived decision effort.

The effort-accuracy framework suggests two main determinants for a positive perception of decision outcome: to increase decision quality and to decrease decision effort [44–46]. This effort-accuracy framework has been widely applied in the research on RAs, for instance to shed light on consumers' intention to reuse RAs [5; 7]. We draw on the same rationale, using satisfaction as a measurement for perception of the decision outcome. Satisfaction has been found to have cognitive [47–49] and affective [50] antecedents [51], which are reflected in perceived decision quality (cognitively) and perceived decision effort (affectively). Harnessing the effort-accuracy framework, we suggest:

H4a: Perceived decision quality positively influences satisfaction.

H4b: Perceived decision effort negatively influences satisfaction.

4 Research Methodology

We conducted a between-subject laboratory experiment to test our research model. The between-subject design was chosen to avoid learning effects and cognitive exhaustion. Participants were randomly assigned to one of three treatments, which were operationalized by different preference elicitation methods with varying levels of trade-off exposure (i.e., low, medium and high). Participants received instructions to use an RA to find the most suitable digital camera they would buy for personal use. We used digital cameras since they are sufficiently complex so that consumers may wish to use an RA [52]. The cameras were composed of 6 attributes with 7 levels each. The product database was identical across treatments. After reading the instructions, participants' attribute preferences were elicited by having them rate and rank 7 random cameras. Subsequently, participants were provided with the respective RA and asked to make a camera purchase decision.

The preference elicitation methods implemented by the RAs were taken from literature, each corresponding in its characteristics to the specifications outlined in section 2 for the respective level of trade-off exposure. Figure 2 illustrates all three preference elicitation methods. In the low trade-off exposure condition, participants were described a situation in which they are stuck between alternatives and asked to assign 100 points to the most important attribute [53]. Participants were then asked to continue with the second most important attribute and assign a lower number of points than to the previous one. This process continued until all attributes had been assigned points.

Trade-off exposure is low because no explicit trade-off between two attributes is supported, and no feedback is given on how the order or the points assigned affect the decision space.

In the high trade-off exposure condition, participants were asked to compare two product alternatives that differed in only two attributes. They were then told to adjust the level of one attribute until both alternatives are equally preferred. This principle is used widely and in many variations [6; 54]. Figure 2 presents the different preference elicitation methods and illustrates high trade-off exposure on the example of zoom and Megapixels (MP).

In the medium trade-off exposure condition, participants were presented with a configuration interface [9] and asked to change attribute levels according to their preferences. The RA determined the price interval for each new configuration and disabled unavailable levels for other attributes. This approach allows for mitigation strategies but enables the participant to perform explicit trade-offs, if required, corresponding to the requirements for a medium level of trade-off exposure.

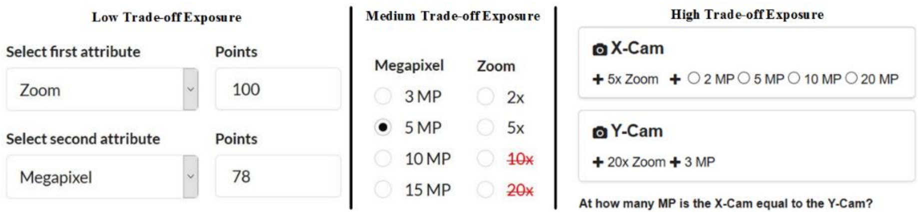

Figure 2. Treatment interfaces

In the questionnaire following the treatment, we collected six variables regarding RA perceptions measured on a 7-point Likert scale. We elicited perceived enjoyment [41; 55], perceived control [55], perceived decision effort [55], perceived decision quality [5; 7; 19] and satisfaction [51]. In addition, participants gave their age, gender and prior experience with RAs and a manipulation check was conducted.

116 students from the University of Passau took part in the laboratory experiment and were assigned randomly to the three treatments (40 participants to low trade-off exposure, 34 to medium trade-off exposure and 42 to high trade-off exposure).

Each participant received a payoff of 10 euros. 36% of the participants were female. Participants' age ranged from 18 to 46 ($\mu = 23$, $\sigma = 5.00$). Familiarity with RAs was average ($\mu = 3.20$, $\sigma = 0.95$). None of the control variables had a significant effect on satisfaction (linear regression results: $p_{age} > 0.1$, $p_{gender} > 0.1$, $p_{experience} > 0.1$).

5 Analysis and Results

We use a two-step analysis approach as previously applied in related studies [5; 7]. First, we examine the influence of trade-off exposure on perceived control and perceived enjoyment (H1a and H1b; Kruskal-Wallis-test and Mann-Whitney-U-tests). Second, we examine the effects of perceived control on effort and quality and how the latter affect satisfaction. (H2-H4; PLS path modelling). We chose Mann-Whitney-U-

tests because Kolmogoroff-Smirnoff tests indicated that our data was not normally distributed ($p_{control} < 0.001$, $p_{enjoyment} < 0.001$) [56].
We first compared perceived control across the three levels of trade-off exposure using a Kruskal-Wallis test, indicating that values of different groups have significantly different distributions ($X^2 = 33.35, p < 0.001$). For perceived enjoyment, we found significant group differences as well ($X^2 = 11.08, p < 0.01$). To shed light on how the values are different across groups, we used pairwise, one-sided Mann-Whitney-U tests between low and medium trade-off exposure and between medium and high trade-off exposure, respectively. Perceived control had its highest mean of 4.87 for medium trade-off exposure: it was significantly higher than in a low trade-off exposure condition ($4.87 > 4.00, p < 0.001$) as well as in high trade-off exposure ($4.87 > 3.52, p < 0.001$), supporting H1a. For perceived enjoyment, the mean in the medium trade-off exposure group was also significantly higher than in low ($4.32 > 3.76,\ p < 0.01$) and high ($4.32 > 3.59,\ p < 0.01$) trade-off exposure groups. This supports the inverted-u shaped relationship proposed in H1b, which is also illustrated in Figure 3.

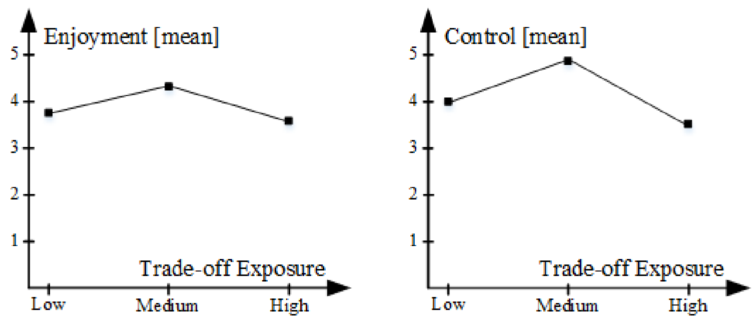

Figure 3. Visualization of U-shaped relationships

Turning to H2-H4, we used a PLS path model to investigate the relationships leading to consumers' satisfaction perception. We analyzed the PLS path model following the two-step process of outer and inner model assessment [57]. This approach is used to ensure reliable results as the analysis of the inner models' paths relies on the reliability and validity of the outer models' constructs [58]. Following Ringle et al. [59]'s call for thorough PLS reporting, we would like to clarify that the analyses were carried out with R 3.1.3, using the plspm library with standard settings.
First, we checked for individual item reliability. Each item should show a substantial correlation with its construct. For reflective items, as solely present in our model, this can be assessed by item loading, i.e. its variance explained by the construct. Loadings should not be lower than 0.7 [60], which is fulfilled in our model. Second, internal consistency was assessed based on item intercorrelations, measured by Cronbach's alpha [61] and composite reliability [62]. Values exceed the recommended threshold of 0.7 for all constructs [63]. Taken together, these results indicate that the measurement model is reliable.
We then assessed convergent validity, i.e. whether all items in a construct's block unidimensionally represent their construct [58]. As recommended by Fornell and Larcker [63] we calculated the average variance extracted (AVE) for every latent

variable. Table 1 shows that AVE is greater than the recommended threshold of 0.5 for every construct [64].
Finally, discriminant validity was examined to confirm that different latent variables actually exhibit significant difference [58]. We checked the Fornell-Larcker criterion [63], stating that the AVE of each latent variable should be greater than its squared correlation with any other variable (which is equal to the AVE's square root being greater than the variables' correlations, which we used for simpler reporting). This is the case, as the values in Table 1 confirm. We also checked the Heterotrait-Monotrait Matrix (HTMT). This criterion has shown superior performance in detecting discriminant validity in a Monte Carlo simulation study compared to cross-loadings analysis and the Fornell-Larcker criterion [65]. The computed HTMT values for our model can be found in Table 1. All values are below 0.85, which satisfies $H_{0.85}$, the HTMT criterion with highest specificity [65]. We conclude that overall measurement model validity has been established.

Table 1. Structural model discriminant validity measures

	Enjoyment	Control	Quality	Effort	Satisfaction
Enjoyment	0.893	0.440	0.373	0.433	0.569
Control	0.397	0.949	0.392	0.421	0.727
Quality	0.346	0.354	0.921	0.320	0.751
Effort	-0.399	-0.383	-0.290	0.876	0.570
Satisfaction	0.509	0.631	0.690	-0.518	0.844
Latent variable correlations		$\sqrt{\text{AVE}}$		HTMT matrix	

Analyzing the structural model next, we focus on perceived control first: We found a significant positive influence on perceived decision quality ($\beta = 0.257$; $p < 0.01$), supporting H2a. Moreover, there was a positive influence of perceived control on perceived decision effort ($\beta = 0.267$; $p < 0.01$) supporting H2b. Higher levels of perceived enjoyment were found to lead to an increase in perceived decision quality ($\beta = 0.245$; $p < 0.01$), while perceived decision effort was reduced ($\beta = -0.293$; $p < 0.01$). Hence, hypotheses H3a and H3b are supported. Turning to the effort-accuracy framework, perceived decision quality had a significant positive effect on satisfaction ($\beta = 0.590$; $p < 0.001$), supporting H4a. Finally, higher perceived decision effort had a significant negative effect on satisfaction ($\beta = -0.347$; $p < 0.001$), which supports H4b.

6 Discussion

Prior research has often made only a dichotomous distinction regarding the level of trade-off exposure, comparing high and low levels while neglecting a medium option. While Xu et al. [5] have showed the possibility for such a medium level, their study did focus on a single preference elicitation method. Our study makes a contribution to the understanding of the relevance of medium trade-off exposure as we investigated how preference elicitation methods with different levels of trade-off exposure affect consumers' satisfaction with an RA. The results support our supposition that medium-level trade-off exposure generates the highest levels of perceived control and perceived enjoyment, compared to low or high trade-off exposure, and that perceived control and perceived enjoyment follow an inverted U-shaped curve as the level of trade-off exposure increases. These findings conform the results of Xu et al. [5], however, in a different research setting and across different preference elicitation methods. Note, however, that preference elicitation methods with low and high trade-off exposure also achieved good levels of perceived enjoyment and control.

The results of our study are consistent with prior research on consumers' perceptions towards RAs, showing that stimuli like trade-off exposure affect cognitive and affective reactions, and those in turn affect the response of the customer. Specifically, our findings show that perceived decision quality was positively influenced by perceived control and perceived enjoyment, while perceived decision effort was affected negatively. In line with the effort-accuracy model, perceived decision quality had a positive effect and perceived decision effort a negative effect on consumer satisfaction. Overall, our results show that a preference elicitation method with a medium level of trade-off exposure creates highest consumer satisfaction with a RA.

6.1 Implications for theory and practice

On a theoretical level, our study contributes to a better understanding of the role of trade-offs in RAs. Specifically, this is the first study to investigate the effect of different levels of trade-off exposure as realized by different preference elicitation methods. The few studies that simultaneously investigated different levels of trade-off exposure mostly focused on high and low levels, neglecting a medium level option. Thus until now, researchers used a linear model for their studies and did not investigate a non-linear coherence of trade-off exposure and the acceptance of it. This study contributes to this knowledge gap by differentiating between high, medium and low trade-off exposure and points out that a medium level has the highest effect on affective and cognitive perceptions.

Our study also contributes to the understanding of the processes that affect satisfaction with an RA. Our research model combines perceived enjoyment and perceived control which each have been part of separate models on consumers' RA perception [5; 7]. Also, in contrast to these models, we have used satisfaction as a more proximate response variable as it is known to be the main determinant of reuse intention [66]. Our model helps to understand consumers' cognitive and affective processes during RA usage and can be used to investigate consumer responses to other RA cues.

Our study also provides practical implications for RA developers. Our results suggest that it is better to avoid using only implicit trade-offs but that forced trade-offs may overburden consumers. Rather, RA developers ought to devise ways of implementing medium trade-off exposure, for instance by using configuration-based preference elicitation methods [5; 9]. The increased influence of consumer actions on the elicitation process in combination with the interactive feedback design can help to leverage the positive effects of a medium level of trade-off exposure.

6.2 Limitations, Future Research

This research is subject to several limitations, to be addressed in future research. First, our experiment was conducted in a laboratory setting. Replicating the study in a field setting would help to establish external validity of our findings. Second, other consumer groups, e.g. older or less technology-savvy consumers, may show different reactions than the student sample used in this study. Further studies with other demographical groups and with other products are required for establishing generalizability of our results. Third, we have focused on trade-off exposure; however, there are multiple other aspects to differing preference elicitation methods. Further studies may try to isolate trade-off exposure or widen the aspects under investigation to provide a more fine-grained understanding of preference elicitation and trade-off exposure.

6.3 Conclusion

This study contributes to the understanding of trade-off exposure in RAs. We compare low, medium and high levels of trade-off exposure operationalized in three distinct preference elicitation methods. The results show that both perceived enjoyment and control follow an inverted u-shape when trade-off exposure increases. While low and high levels also yield good performances, a medium level of trade-off exposure leads to significantly highest results. We further presented a research model that shows how trade-off exposure influences consumers' satisfaction with a RA. While perceived enjoyment and perceived control are directly affected by trade-off exposure, they in turn affect perceived decision effort and perceived decision quality as central determinants of overall satisfaction.

Abstract. The key to an information system's (IS) success is its value experienced by the user. A promising approach to enhance user value is to design for the users' experiential desires. For example, fulfilled experiential desires enhance the users' satisfaction and loyalty. Despite these benefits, few design principles exist for developing IS according to the users' experiential desires. Therefore, the aim of this literature review is to aggregate the current state of knowledge concerning the different theoretical perspectives on utilitarian, hedonic and dual-purposed IS. We build a framework that illustrates the relationship between different theoretical perspectives on IS affordances (i.e., motivational, cognitive, affective, and social) and different technology types (i.e., utilitarian, hedonic, dual-purposed). The presented framework offers a starting point for the development of theory-based design principles for experiential affordances of IS. We conclude with a summary of opportunities for future research to extend our knowledge of experientially fulfilling IS.

Keywords: Motivational affordances, dual-purposed systems, hedonic systems, utilitarian systems.

1 Introduction

The key to an information system's success is its value experienced by the user [1]. Current research mainly distinguishes instrumental and experiential values [2]. Instrumental values contain pragmatic or utilitarian product qualities and are linked to instrumental outcomes such as enhanced productivity or reduced expenditures. Experiential values contain hedonic product qualities and are linked to experiential outcomes such as meaningfulness, engagement, positive emotions or perceived enjoyment [2]. According to their main value and outcome, different technologies can be classified as three different technology types, namely (1) predominantly utilitarian, (2) predominantly hedonic and (3) hybrid or dual-purposed [3]. Utilitarian technologies are mainly used at the workplace or in productivity-oriented contexts of use and provide instrumental value. In contrast, predominantly hedonic technologies are mainly used during leisure time or at home and provide fun and entertainment [4, 5]. Dual-purpose

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

technologies are, however, a hybrid of utilitarian and hedonic technologies [3]. A prominent example of dual-purpose systems are social networking systems which are commonly used for either leisure or work purposes (e.g., Xing).

Since the last decade, especially hedonic and dual-purposed technologies represent an emerging type of IS. Thereby, experiential outcomes are receiving growing attention in research and practice [2, 6]. For example, gamified design elements are used as means of providing experiential value and are already integrated in many products such as internet portals and cars. Here, drivers are for example motivated to improve their fuel economic driving by gamified elements [7, 8]. The interest in the experiential perspective on technology use results from its promising benefits such as enhancing important facets of technology acceptance like for example the users' satisfaction [9], word-of-mouth [10] and behavioral intention [11]. Additionally, experiential values enhance instrumental outcomes such as perceived ease of use which will in turn again enhance outcomes of technology acceptance [9]. Moreover, experiential values enable behavioral change such as reduced energy consumption [12].

In contrast to the expected growth of experiential value [e.g., 6], attempts to design for experiential outcomes fail quite often [e.g., 13]. A prominent example from the organizational context are public leaderboards [14]. For example, managers at DisneyLand tried to motivate their employees with public leaderboards of the most efficient employees. Instead of being motivated and experiencing a gamified competition, the employees mostly felt very uncomfortable with this idea of gamification. Moreover, market analysts discussed gamification trends and strategies and concluded that "80% of current gamified applications will fail to meet business objectives primarily due to poor design" [15]. Furthermore, the MISQ recently published a call for research that stated that "few research and design guidelines exist regarding gamified information systems" and called "to investigate the design and use of gamified information systems from a variety of disciplinary perspectives and theories, including behavioral economics, psychology, social psychology, information systems" [2]. Therefore, we argue that the high failure rate of attempts to design for experiential outcomes is due to the problem that few design principles exist for developing IS according to the users' experiential desires. According to [2], we define design principles as high-level design rules and formulas that should be derived from grounded theory and can support product developers through the whole development process. For example, a design principle in the field of gamification might suggest that gamified IS should include different badges depending on the different user styles and stages. For the creation, application, and evaluation of theory-based design principles that can speak directly to the users' motivation, cognition, affect and social behavior, it is necessary to use suitable theoretical foundations. Therefore, we need to analyze basic research, theories and models from a variety of disciplines like information systems (IS), behavioral economics, human-computer interaction and psychology that can be used to derive experiential affordances. Therefore, the aim of this review is to aggregate the current state of knowledge concerning the different theoretical perspectives on utilitarian, hedonic and dual-purposed IS. We build a framework that illustrates the relationship between different theoretical perspectives on IS affordances (i.e., motivational, cognitive, affective, and social) and technology types (i.e., utilitarian, hedonic, dual-purposed). The presented framework offers a starting point for the development of theory-based design principles for experiential affordances of IS.

Our review is structured as follows: first, we describe the design of our literature review. This includes the selection of appropriate databases, journals and conference proceedings and the coding of the identified relevant papers according to their main theoretical perspective. Second we provide an overview of each theoretical perspective based on our presented concept matrix. Third, we summarize knowledge gaps and opportunities for future research. Finally, our review ends with a conclusion on theoretical and practical implications.

2 Design of the Literature Review

The aim of this paper is to understand and aggregate the current state of knowledge concerning the different theoretical perspectives on utilitarian, hedonic and dual-purposed IS. Thereby, we build a framework that illustrates the relationship between different theoretical perspectives on IS affordances (e.g., motivational theory perspective) and different technology types (i.e., utilitarian, hedonic, dual-purposed). Therefore, we conducted a systematic literature review based on the guidelines of Webster and Watson [16]. We combine research from a variety of disciplines including IS, behavioral economics, human-computer interaction and psychology. An overview of the scope of our review, our search terms and the considered databases can be found in Table 1. In order to decide which papers were relevant for our review, we focused on the following two inclusion criteria: (1) we only included papers that focus on interactive technology because we are interested in designing for outcomes that users derive from the direct interaction with technologies; (2) we only included papers that concentrate on voluntary use of technology because we are interested in the consumer context and not the enterprise software context. Hence, we excluded papers that focused on the organizational context or non-voluntary use of IS in the educational context. In order to identify all relevant papers, we screened the title, abstract and if necessary the whole paper. Finally, including the results of our forward and backward search, 42 papers remained as relevant hits in our review.

Based on Webster and Watson [16] we created a concept matrix to structure our findings. Since our review is meant to provide an overview about the existing theoretical perspectives on utilitarian, hedonic and dual-purposed IS, we structured the relevant papers according to the considered type of technology, namely (1) utilitarian, (2) hedonic, and (3) dual-purposed. Moreover, we tried to find a structure to group different theories into one concept matrix. By filling out our concept matrix, we iteratively refined our columns and finally focused on four main branches of theories, namely (1) motivational, (2) cognitive, (3) affective, and (4) social theoretical perspectives. Motivational theories in the context of technology use [e.g., 17] mainly focus on the interplay of product characteristics and different kinds of human motivations (e.g., intrinsic vs. extrinsic motivation). Cognitive theories mainly focus on the cognitive processing of product characteristics, decision-making processes and product choice scenarios [e.g., 9, 18]. The core element of affective theories is the role of human emotions in the perception, use and evaluation of technologies [e.g., 19].

Finally, social theories mainly concentrate on the influence of social interaction and response patterns on technology use [e.g., 20].

3 Findings

Table 2 illustrates a selection of our concept matrix. In total, 42 papers were clustered according to their main theoretical perspective (i.e., motivational, cognitive, affective, social) and the considered technology type (i.e., utilitarian, hedonic, dual-purposed). Figure 1 illustrates all theories we identified as theoretical basis in the studies that were part of our systematic literature review. In the following paragraphs, we provide an overview of the motivational, cognitive, affective, and social perspective on IS affordances and refer to a selection of the theories listed in Figure 1.

3.1 Motivational Perspective on IS Affordances

In total, we found 20 papers that focused on a motivational perspective on IS affordances. Motivational affordances are defined as the "properties that afford user motivation" [38: p. 274] and are seen as a "key requirement for behavior change" [38: p. 271]. Here, especially Herzberg's [39] Motivator-Hygiene-Theory and Deci's [40] distinction between the two fundamental types of intrinsic and extrinsic motivations are frequently mentioned and applied. While motivators are seen as IS characteristics that provide satisfaction if fulfilled, hygiene factors only cause dissatisfaction if not fulfilled. In the context of intrinsic and extrinsic motivation, user acceptance is seen as either driven by benefits derived from an engaging interaction with the system per se (i.e., intrinsic) or by expected benefits of external rewards (i.e., extrinsic).

Two newer developments within the group of motivational theories are for example the Hedonic-Motivation System Adoption Model (HMSAM) [34] and the Multimotive Information Systems Continuance Model (MISC) [35]. Both models are originally based on the distinction of intrinsic and extrinsic motivators [40]. The HMSAM is meant to improve the understanding of the adoption of hedonic-motivation systems and therefore integrates flow-based cognitive absorption as a mediator of perceived ease of use and behavioral intention. The MISC focuses on the users' expectations and disconfirmations as antecedent of behavioral intention.

Two very concrete examples of applying the motivational perspective are presented by Resatsch [41] and Füller [42]. For example, Resatsch [41] focused on motivating applications in the field of ubiquitous computing in the office, retail and ticketing context and formulated and evaluated design guidelines for NFC-based ubiquitous computing applications. Füller [42] concentrated on designing IT-based customer integration methods and created a framework for positive customer integration experience based on the Motivator-Hygiene-Theory [39].

The motivational perspectives also contain cognitive, social and affective components as for example intrinsic motivators are often conceptualized as emotions like fun, enjoyment, playfulness, pleasure, arousal or dominance [5]. Moreover, motivational needs are often conceptualized as psychological (i.e., autonomy, competence, and relatedness) or social needs (i.e., achievement, affiliation and intimacy, and leadership and followership) [38]. Therefore, the perspectives presented in the following sections are closely related to the paramount motivational perspective.

3.2 Cognitive Perspective on IS Affordances

Most of the identified studies referred to a cognitive or a combined cognitive and affective perspective on IS affordances. Within this category, the Theory of Reasoned Action [43] and the Theory of Planned Behavior [44] are the basis of several models of IS affordances [e.g., 21, 23]. Here, the affective and behavioral reactions towards an IS are seen as the result of cognitive processes including attitudes, subjective norms and perceived behavioral control. Cognitive processes can for example include the semantic and autobiographic elaboration of characteristics and features of IS [19]. The cognitive processing of IS characteristics is especially important for the final product evaluation and choice as well as the justifiability of product choices. For example, recent studies have shown that the processing of pragmatic and hedonic product characteristics results in a cognitive bias. Although users appreciate hedonic product characteristics in terms of positive experiential outcomes, these characteristics are not valued in choice situations because pragmatic choices are easier to justify than hedonic choices [18]. This bias of justifiability is closely related to the construct of cognitive dissonance. For example, cognitive dissonance arises when the context of use rewards external instrumental outcomes, whereas the actual use is motivated intrinsically or results in experiential outcomes [21]. A cognitive strategy to reduce cognitive dissonance is to overlook the pleasurable outcomes and attribute instrumental outcomes to the IS usage. This rational process can be described with the following cognition: "1 am voluntarily spending a lot of time on this and enjoying it, therefore, it must be useful." [21: p. 676].

In general, the cognitive basis of IS affordances highlights that detecting and using IS features creates mental workload. For example, mental workload is created by the comparison of actual IS characteristics with the users' expectations and mental anchors for these characteristics (i.e., Design-Expectation Fit, Anchoring Theory, Expectation-Confirmation Model) [e.g., 35]. Also closely connected to mental workload is the construct of cognitive absorption. Cognitive absorption characterizes a state of total attention, in which lots of cognitive resources are allocated to using a specific IS [e.g., 21]. For example, Lowry et al. [34] integrated the single second-order constructs of the first-order construct cognitive absorption, namely control, curiosity, heightened enjoyment, immersion and temporal dissociation as intrinsic motivators into their HMSAM. This integration helped to further enhance the predictive validity and conceptual understanding of intrinsically motivated IS use.

3.3 Affective Perspective on IS Affordances

In total eleven papers focused on an affective perspective on IS affordances. Affective theories are receiving greater attention since recent studies on IS adoption have shown that emotions are a considerable result of a users' interaction with IS [e.g., 5, 25]. One example of affective reactions to IS usage is provided by Codish and Ravid [25]. The authors implemented cognitive and gamified design principles in the educational context and demonstrated the effect of playfulness as a positive affective response to IS usage.

Another example is provided by Wang and Scheepers [5] in the Model for Hedonic Information System (HIS) Acceptance. Here, the authors identified three overlapping conceptual identities of users of hedonic IS. These identities are described as the computer user, the hedonic consumer and the player. The computer user is associated with the technology acceptance model [45] and the hedonic consumer is associated with the Hedonic Theory [46] from consumer behavior research. The player role is associated with two affective theories, namely the Pleasure-Arousal-Dominance (PAD) Theory [47] and Flow Theory [48]. The PAD Theory is also known as the Three-Factor-Theory of Emotion and states that affective reactions can be described by three main emotions, namely pleasure, arousal and dominance. The Flow Theory describes flow as a state of intense pleasure and involvement in a certain action. Similar to cognitive absorption, flow is associated with attention focus, perceived control, curiosity, and intrinsic interest. Based on their results, the authors even argue that the intrinsic motivators "emotional responses, imaginal responses, and flow experience are three main predictors of HIS acceptance" [5: p. 255].

3.4 Social Perspective on IS Affordances

Only seven of our identified papers considered a social perspective on IS affordances. Social affordances of IS mainly rely on three assumptions, namely (1) that users can personally relate to IS, (2) that users tend to interact with IS in a similar manner as in human-to-human relationships, and (3) that IS can also include the user in collective actions. Here, the IS can serve as a mediator between different users or the system and the user can even work together on a particular task [see 38].

Two examples of applying social affordances to IS are provided by Gnewuch et al. [20] and Oinas-Kukkonen [49]. For example, Oinas-Kukkonen [49] highlighted the importance of considering socio-psychological design principles. In the context of behavioral change support systems, the authors suggested that peoples' behavior can be influenced by persuasive IS through integrated social influence (i.e., social comparison, normative influence, and social learning). Here, for example, health and healthy lifestyles are promising fields of application of behavioral change support systems. The second example was provided by Gnewuch et al. [20] and concentrated on conversational agents for customer service. In this study, the authors turned the cooperative principle of conversation and the central assumptions of the social response theory into design principles.

3.5 Framework of Theories and IS Use Contexts

Figure 2 aggregates the findings described above into one framework that structures the selection of theories according to the IS use context (i.e., utilitarian, dual-purposed, and hedonic). The IS use context can be seen as a continuum that ranges from utilitarian IS to hedonic IS with dual-purposed use a hybrid of these two poles [3]. As explained above, the affordances of utilitarian IS mainly rely on the use of extrinsic motivators and hygiene factors. These factors are for example covered by classical technology acceptance models like the Technology Acceptance Model (i.e., TAM [45]) and the Unified Theory of Acceptance and Use of Technology (i.e., UTAUT [50]) [4]. In the context of hedonic IS, however, these models are no longer sufficient because these models lack the detailed integration of intrinsic motivators and predictors related to experiential and hedonic outcomes. A recent analysis [51] of the applications and extensions of UTAUT has shown that among the many extensions of UTAUT, only two extensions focused on hedonic performance expectancy [52] or hedonic motivation [53]. However, even these UTAUT extensions only regard hedonic components as side effects and do not set the focus on hedonic components [54]. This is why newer models that focus on triggering the user's intrinsic motivation like for example the Hedonic-Motivation System Adoption Model (HMSAM) [34] have to be taken into account in this context. The affordances of dual-purposed systems rely on a combination of the theoretical basis of utilitarian and hedonic IS. For example, the Multimotive Information Systems Continuance Model (MISC) [35] is based on the distinction and combination of intrinsic and extrinsic motivators [40].

4 Discussion, Future Research and Conclusion

This literature review contributes to the understanding of the affordances of utilitarian, hedonic, and dual-purposed IS by providing an overview of theoretical perspectives that can be used for the creation, application, and evaluation of theory-based design principles. Our review highlights that a variety of scientific disciplines including IS,

Technology Type	Theoretical Perspective			
	Motivational	Social	Cognitive	Affective
Utilitarian	27b, 29, 30b, 33	3	13, 14, 17, 24, 25, 35, 37, 38, 40a, 43, 44, 45	13, 14, 17, 24, 25
Dual-Purposed	2, 16, 27, 28, 30, 31, 32	1, 2, 3, 4, 5, 6, 7, 8	5, 10, 12, 13, 14, 17, 21, 24, 25, 34, 35, 36, 37, 38, 39, 40b, 41, 42, 43, 44, 45, 46	9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 21, 22, 23, 24, 25
Hedonic	2, 16, 26, 27a, 28, 30a	1, 2, 4, 8	12, 17, 19, 20, 21, 35, 36, 38, 39, 41, 42, 45, 46	9, 11, 12, 15, 16, 17, 18, 19, 20, 21, 22, 23

Figure 2. Detailed Framework: Classification of theoretical basis according to the context of IS use (*/# = theories that were grouped into more than one theoretical perspective/more than one technology type; numbers refer to the numbers given to the theories in Figure 1)

behavioral economics, human-computer interaction and psychology contain basic research, theories and models that can be used to derive IS affordances. Our findings show that previous research on IS affordances can be grouped according to the four main theoretical perspectives: (1) motivational, (2) cognitive, (3) affective, and (4) social. Among these perspectives, motivational affordances can be seen as higher order affordances that can be translated into IS characteristics and features through cognitive, social and affective affordances. For example, intrinsic motivators are often conceptualized as emotions like fun, enjoyment, playfulness, pleasure, arousal or dominance [5] and motivational needs are often conceptualized as psychological (i.e., autonomy, competence, and relatedness) or social needs (i.e., achievement, affiliation and intimacy, and leadership and followership) [38]. However, the development and application of these theories in the context of IS design reveal some shortcomings which should be addressed in future research (see Figure 3). Our analysis illustrates that we need to learn more about the correct application and modification of existing theories from IS, behavioral economics, human-computer interaction and psychology in the context of motivational, cognitive, affective, and social affordances of future IS. The artefact of this literature review provides a basis to use existing interdisciplinary theories and models systematically to create, apply, and evaluate IS affordances and their impact on users. Before inventing new grounded theory for the affordances of utilitarian, hedonic, and dual-purposed technologies, we need to reinvent existing theories, i.e., extending them among motivational and hedonic components.

The first research gap is that motivational affordances are simply underutilized [38, 57]. Except of some positive examples mentioned above [e.g., 41, 42], there is still a need for more applications and evaluations of motivational affordances. Precisely, "it would be useful as a next research step to prototype and isolate design features that are intended to fit certain task motivations and expectations" [35: p. 539] and thereby isolate single effects and deepen our understanding of the effects of applied motivational affordances. Here, it would be interesting to compare the effects and predictive power of certain extrinsic and intrinsic motivators in distinct usage contexts (i.e., utilitarian vs. hedonic vs. dual-purposed). Furthermore, if applied, most design principles for motivational affordances are very high level, not context-sensitive and not on feature level [e.g., 57]. User experience is, however, very sensitive to the context in which a technology is used [58–60]. Therefore, there is a need for more context-specific evaluation of lower level applications of design principles of motivational affordances.

The second recommendation for future research considers the context of applying and evaluating motivational affordances. Existing applications and evaluations of design principles of motivational affordances can mainly be found in the context of gamification or gamified systems [e.g., 5, 33, 38]. There is, however, a need to study the application of motivational affordances in the context of less hedonic dual-purposed user assistance systems. Dual-purposed user assistance systems are mainly used voluntarily and during leisure time. Their purpose is, however, not only to enhance the users' enjoyment but also enhance their individual instrumental outcomes. Here, it would be interesting to compare the effects of certain motivational affordances in form of intrinsic motivators in this two usage contexts, namely (1) motivational affordances in gaming and gamified systems and (2) motivational affordances in non-gamified systems or rather less hedonic dual-purposed systems. This research agenda would also contribute to the present debate about the effect of gamification in non-gaming applications [61]. For example, in the context of cognitive and behavioral decision theories, it would be interesting, to investigate how the presentation of information (i.e., designed according to motivational affordances vs. purely pragmatic design) influence cognitive processes like decision-making or elaboration.

The third issue this review has identified, concerns the methods used and outcome variables measured to evaluate implementations of motivational affordances. For example, Wu and Lu [3] found that the relevance of different intrinsic and extrinsic motivators varied depending on the considered dependent variable in the research model. Consequently, future studies should always consider multiple outcome variables and pay attention to the possible differences in terms of predictive validity of the considered antecedents. Besides integrating multiple outcome variables, there is a need to combine multiple measures in order to prevent common-method bias [62]. Nearly all identified studies used self-report measures. Focusing on explicit measures exclusively might, however, result in an incomplete picture of the outcomes of motivational affordances. Therefore, implicit or rather unconscious antecedents should be studied. Here, integrating neurophysiological measures (e.g., electroencephalography) is a promising research field [26].

Finally, the fourth research gap concerns the personality of the user. Recent research has demonstrated that applied motivational affordances are perceived differently depending on the personality traits of the user [33, 38]. Different types of users prefer to use different motivating IS. Hence, “[a]pplications designed to accommodate multiple experience tracks for different personality traits could contribute to the sustained use of the application and enable users to better meet their personal goals” [33: p. 82]. A recent example of considering personality in the acceptance of dual-purposed IS was presented by Oettl, Berger, Böhm, Wiesche and Krcmar [63]. The authors classified six archetypes of users of enterprise social networks based on the two dimensions individual openness and perceived task-fit. In the context of motivational affordances in the consumer context, we need similar archetypes based on a combination of personality and motivational affordances.

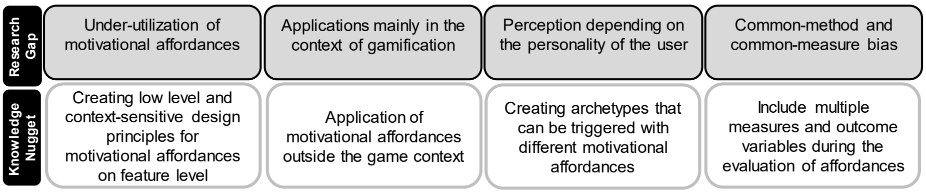

Figure 3. Summary of Identified Research Gaps and Potential Knowledge Nuggets

In sum, although motivational affordances should be a key requirement for IS, many ISs are not based on grounded theories and empirical insights on human motivation, cognition, affective reactions, and social interactions. Our review highlights that there is no need to invent new grounded theory on IS affordances. Instead, we need to rethink existing theories. Therefore, future research should apply and modify the identified theories and models from IS, behavioral economics, human-computer interaction and psychology in order to derive theory-based affordances for IS design. Since past research has mainly focused on the gaming context and gamified elements are more and more used in non-gaming applications, our research agenda focuses on motivational affordances in the context of non-gamified and dual-purposed systems. Here, low level and context-sensitive design principles for motivational affordances on feature level are needed. This is especially important for dual-purposed IS which should combine intrinsic and extrinsic motivators. For the evaluation of these design principles it is important to include multiple measures and outcome variables in order to avoid common-method bias and biases related to a specific outcome variable. Moreover, the interplay of personality traits and motivational affordances should be further studied in order to create archetypes that can be triggered with different motivational affordances. In sum, “taking into account a user’s motivational needs is one of the most crucial (but often neglected) design aspects for IS” [38: p. 271].

Eliciting Customer Preferences for Shopping Companion Apps: A Service Quality Approach

Tobias Wulfert[1], Jan H. Betzing[2], and Jörg Becker[2]

Abstract. Shopping companion apps, which assist customers in product search and buying decisions, are an emerging phenomenon in the context of omnichannel retail. These retailer-provided apps link the digital with the physical servicescape of the store, allowing for new forms of online and at the same time physical service. So far, there is no dominant design for this type of information system. Both academia and practice lack empirical information about what customers expect from this kind of mobile app. Drawing from service quality literature as theoretical foundation, we conducted a qualitative content analysis of 1,448 customer reviews of three major shopping companion apps. The analysis yielded 23 aspects that customers expect from shopping companion apps, and that, in turn, can support establishing high mobile service quality. Our results contribute to the knowledge of m-service in retail and quality-driven app design.

Keywords: Mobile Service, Omnichannel, Service Quality, Customer Reviews.

1 Introduction

The mobile channel is an intimate and direct way for retailers to fulfill their customers' needs [1, 2] since customers nowadays use myriads of mobile devices in all situations of their daily lives including shopping [3, 4]. Customers search for products and services, and shop on the move without temporal or spatial constraints [5]. Customers are already using their smartphones in-store to get product information and compare prices [6]. Brick and Mortar (BaM) retailers respond to this changing customer behavior by introducing what we term *shopping companion apps* [1, 7].

A shopping companion app is conceptualized as retailer-provided software, executed on the customer's smartphone, which complements the personal and e-service of a BaM retailer by an additional mobile channel—manifesting as a digital support to the shopping process within and outside the store. Customers use these apps to access general shopping features such as product search, and immersive, location-based, and personalized functions such as in-store navigation and product recommendations [3, 8]. In contrast to third-party apps, shopping companion apps keep the customer in the retailers' self-contained environments [9] and allow them to create "seamless omni-

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

channel experience[s]" [10, p. 68] that match their overall strategies. Shopping companion apps offer several novel features of hybrid customer interaction [11] and value-added service [7], which are neither usefully realizable just in stationary retail nor in e-commerce [1, 12].

Being an emergent phenomenon, shopping companion apps have not yet received much academic investigation [1], and also instances in practice do not follow a dominant design [13] but rather vary in form and behavior. Developing and designing shopping companion apps that meet or even exceed the customers' expectations is a challenging endeavor [14]. To establish a high-quality shopping companion app as a mobile interface for customer interaction with the retailer, designers must consider smartphone-specific constraints (e.g., display size, mobile Internet) and opportunities (e.g., sensor access, immersion) atop traditional user experience aspects [15, 16].

We draw from Service Quality (SQ) research to identify what makes up a *high-quality* shopping companion app. SQ is concerned with assessing the quality of interactions between a customer and a service provider [17, 18] and is defined as the degree of "discrepancy between customers' expectations and perceptions" [19, p. 111] towards a received or experienced service [20]. SQ assessments have a long and rich history, ranging from person-to-person service (SERVQUAL) [17, 18], over e-service accessed via personal computers (E-S-QUAL) [21], to m-service accessed via mobile devices (M-S-QUAL) [22, 23]. Recent conceptualizations of Mobile App Service Quality (MASQ) now consider the peculiarities of mobile apps such as immersive human-computer interaction, location independence, and potentially far-reaching access to personal information and sensor data through the service provider [24-27]. However, while the literature acknowledges the importance of high-quality in-store service through the mobile channel as a future competitive edge for retailers [28], there is a lack of empirical information about what customers expect, and also–to the best of our knowledge–there is no domain-specific research for shopping companion apps.

Against this background, our research goal is *a set of customer preferences for shopping companion apps* with special consideration on MASQ. To reach this goal, we apply a twofold approach. First, we turn towards SQ literature as the theoretical foundation to understand MASQ. Second, we conduct a Qualitative Content Analysis (QCA) [29] of online customer reviews of three major shopping companion apps to retrieve the individual app users' subjective perceptions of SQ. We follow suggestions from human-computer interaction research to analyze the interaction with mobile apps from a user's point-of-view [16]. From the review corpus, we inductively derive 23 aspects customer prefer for shopping companion apps, which retailers can consider for quality-driven (shopping companion) app design.

The remainder of this paper is as follows: Section 2 introduces MASQ. Section 3 sketches the research approach. Section 4 gives the customer preferences for shopping companion apps, which are discussed in Section 5. We conclude in Section 6.

2 Theoretical Background

2.1 Service Quality

SQ is known to be an important determinant for the success of a company, impacting "business performance, lower costs, customer satisfaction, customer loyalty and profitability" [30, p. 913]. SQ assessments identify the perceived SQ of an individual, which is "a global judgment or attitude" [31, p. 16] comparing the customers' expectations and actual perceptions of a service endeavour. Following the so-called disconfirmation paradigm, high SQ is achieved, when the difference between expectations and perceptions is marginal, or the perceptions exceed the expectations [17]. In contrast, customer satisfaction is "the result of specific service transactions" [32, p. 822]. Existing models of SQ distinguish different sub-dimensions, which further detail the overarching construct. Parasuraman et al. [31], for example, introduced reliability, responsiveness, assurances, and tangibles as dimensions for measuring the quality of interpersonal service. Various technological innovations have led academia to propose adjusted and extended SQ models for different types of information systems, domains, and kinds of service over time. In the context of mobile apps and m-service, adjusted models are subsumed under MASQ. Currently, research on MASQ is sparse [26, 27].

SQ research has created an own literature stream that spreads over the information systems, retail, e-commerce, human-computer-interaction, and marketing domains. To identify the dimensions that may explain high-quality shopping companion apps, we conducted a structured literature review [33] across outlets in these domains, without restricting the search basket to allow for an exhaustive coverage. The search took place on 2017-06-21 using SCOPUS, AISeL, Web of Science, and EBSCOHOST. Table 1 gives the generalized search query, which was adapted to the syntax of the respective search engine.

```

After performing a one-way forward- and backward search, a sample of 34 papers remained, which yields insights on the determinants and dimensions of Electronic Service Quality (ESQ), Mobile Service Quality (MSQ), and MASQ in the B2C area.

2.2 Research Model of Mobile App Service Quality

Figure 1 shows the multidimensional, hierarchical research model of MASQ, adapted from [22]. Synthesized from the identified literature sample, the model comprises the dimensions of SQ, which apply to the case of shopping companion apps.

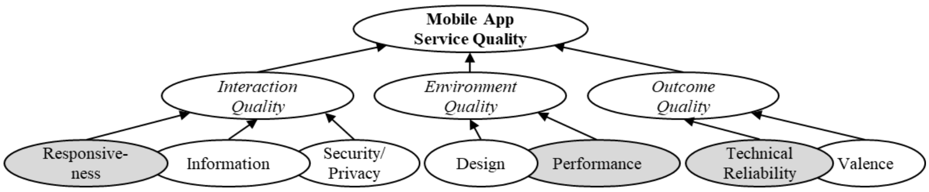

Figure 1. Multidimensional Hierarchical Research Model of MASQ, adapted from [22]

The shaded dimensions are either added to or reframed from the initial model by [22], based on the literature synthesis and initial results of the QCA. The example of the reliability dimension can illustrate this adaption. Initially, this dimension focuses on the reliability of delivery and fulfillment processes [34, 35], which are out-of-scope for shopping companion apps that are used primarily in-store. Reliability in the online customer reviews is often related to technical malfunctions and service dropouts. Hence, this dimension is subsequently denoted as technical reliability. In line with previous hierarchical models [36, 37], the MASQ is comprised of three secondary dimensions, which themselves are comprised by primary dimensions.

The research model in Figure 1 is used as the theoretical lens to analyze and structure the qualitative data in the subsequent QCA. Following the QCA terminology [29], the primary dimensions make up the *content categories*. To allow for a fine-grained analysis, these content categories are further detailed into 22 *characteristics*. Table 2 provides the content categories and characteristics related to MASQ, which have been derived from the literature review.

3 Research Approach

We analyzed customer reviews of three major, shopping companion apps by Walmart (US), Tesco (UK), and Marks & Spencer (M&S) (UK) to elicit customers' preferences for shopping companion apps. Although the selected retailers trade internationally, the apps under consideration are tailored to their respective home countries of operation. We sampled these apps because they are on the market for more than three years, they address a significant proportion of people in their countries of operation, and a vast number of online reviews make these three apps the subject of discussion. Further, these retailers have a long history in BaM operations. Additionally, we focused on grocery retail as industry because these retailers offer a broad spectrum of product categories, and thus, are potentially relevant for the majority of the population, compared to specialist shops that only address a certain focus group. Electronic customer reviews as a form of electronic word-of-mouth are a valuable source for indicating the quality of apps including the users' personal opinions, bug reports, and desired features [38]. We employ the QCA [29] as research design and make use of the methods presented in [39] and [40] to extract and prepare the review sample. The QCA approach is frequently applied to extract information from user-generated content such as reviews [41, 42].

Table 2. Content Categories and Characteristics related to Mobile App Service Quality

Dimension	Description	Support
Interaction quality	"Reflects all the quality characteristics of a customer's interaction with the [...] service provider." [22, p.942]	[22, 36, 37]
Responsiveness	The retailer's ability to promptly and politely solve a customer's issues related with the mobile app. **RES1:** Customer service availability **RES2:** Problem solving ability **RES3:** Politeness and kindness of personnel **RES4:** Guidance and instructions for app usage	[21, 35, 43–45]
Information	"The provision of accurate and precise information" [22, p.943] by the retailer. **INF1:** Information adequacy **INF2:** Information usefulness **INF3:** Information correctness	[22, 34, 35, 46–48]
Security and Privacy	"The protection of system and network resources from any external or internal attack and the protection of users' personal data." [22, p.943] **SEC1:** Information security **SEC2:** Data protection **SEC3:** Data collection	[21, 22, 35, 44, 45, 48]
Environment quality	Reflects "the context in which [mobile apps] are delivered, [and] quality characteristics of the equipment" [22, p.942] that affect the delivery of the mobile apps.	[22, 36, 37]
Design	The aesthetics, features, and layout of the user interface. **DES1:** Visual aesthetics and clarity of layout **DES2:** Quality of multimedia content **DES3:** Ease of use and ease of navigation **DES4:** Search function and filters	[21, 22, 34, 35, 45, 46, 48]
Performance	The performance of the mobile app and its resource requirements. **PERF1:** Processing speed **PERF2**: Device storage usage and mobile network usage **PERF3:** Network connection quality	[21–23, 34, 46, 49]
Outcome quality	Reflects the technical quality of and the customer's satisfaction with the service delivery.	[22, 36, 37]
Technical reliability	The accurate and consistent operation of the mobile app. **REL1:** Mobile app reliability **REL2:** Availability of provided services **REL3:** Continuous operation after updating	[22, 23, 45, 46, 48, 50]
Valence	The customer's ex-post impression of the service delivery. **VAL1:** Overall satisfaction with the provided service **VAL2:** Satisfaction with the scope of provided services	[22, 43, 46, 47, 51, 52]

Following Pagano and Maalej [39], we first extracted review data from Apple's App Store and Google's Play Store using a paid version of the online service *heedzy.com* on 2017-07-03. The raw data contains information on the app name, date, title, and content of the review, the nickname of the customer who created the review, the rating that is provided, and the app version. 10,099 reviews have been extracted in total. This number comprises 6,048 reviews for the Walmart app (1,084 iOS / 4,964 Android), 3,389 reviews for the M&S app (818 iOS / 2,571 Android), and 662 reviews for the Tesco app, where a technical restriction only allowed us to extract reviews from the Apple App Store. Since mobile apps are frequently updated, we only consider reviews written within the last six months, which leaves 8,237 reviews. The review sample was manually pruned by non-informational reviews such as "*Great app!*" and "*Useless!*".

Customer reviews in foreign languages and reviews concerning the retailer's general assortment, delivery quality, and price politics were excluded, which leaves a final sample of 1,448 reviews (795 Walmart, 433 M&S, 220 Tesco) for further investigation.

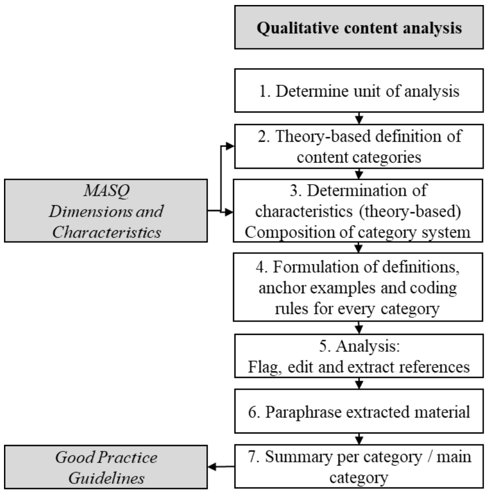

Figure 2. Research Approach, adapted from [29, 33]

Figure 2 shows the QCA process based on its content structuring approach, which supports the deductive assignment of reviews to content categories [29]. The review corpus containing the users' expectations and suggestions was grouped and analyzed for each content category. Anchor examples are used as references to illustrate the elicitation of customer preferences. Since online customer reviews usually contain more than one aspect [39], reviews were sub-classified regarding the characteristics, which results in 1,307 codings. We used *QCAmap.org* to aid the coding process [29].

4 Results

4.1 Relevance of MASQ Dimensions

We assigned the customers' statements to the content categories and characteristics, which allows weighting the relevance of the MASQ dimensions. Table 3 provides the distribution of customer review codings. The amount of codings per characteristic varies between five and 298. In effect, customers emphasize some of the dimensions and characteristics with higher importance than others. For example, *ease of use and ease of navigation* (DES3) as a part of the *design* dimension seems to be more important than attentive customer service (RES3) as a part of the *responsiveness* dimension. Regardless of the provided functionality, customers expect fast response times (PERF1) and reliable service (REL1) and use the review function of the app stores as an outlet to complain when issues arise.

Table 3. Frequency of Characteristics Mentioned in the Online Customer Reviews

Content Category	Σ	Mentions per Characteristic			
Responsiveness	93	RES1: 27	RES2: 52	RES3: 5	RES4: 9
Information	103	INF1: 29	INF2: 28	INF3: 46	
Security and Privacy	67	SEC1: 35	SEC2: 16	SEC3: 16	
Design	452	DES1: 38	DES2: 20	DES3: 298	DES4: 96
Performance	140	PERF1: 119	PERF2: 10	PERF3: 11	
Technical Reliability	394	REL1: 312	REL2: 19	REL3: 63	
Valence	59	VAL1: 45	VAL2: 13		

4.2 Customer Preferences Regarding Shopping Companion Apps

The three shopping companion apps under review provide a similar range of functions: Access to the particular online shop, click & collect, store finder, in-store inventory checking, aisle locator, promotions, loyalty programs, and product scanning. In the following, we focus on the non-functional aspects of app and service delivery. From the review corpus, we found rich hints what customers expect from shopping companion apps and identified 23 aspects that retailers could pick up to improve their m-service offerings. Table 4 lists the aspects, which we have structured by the primary dimensions of the MASQ model (Figure 1).

Customers voiced some preferences that are specific to the context of shopping companion apps. For example, because shopping companion apps enhance the physical servicescape of the store with digital service, customer service should be able to support both the retailer's m-service and issues that arise in-store. Nevertheless, trained customer service—of course—is also relevant to any other m-service. We highlighted the aspects that include such peculiarities regarding shopping companion apps in boldface. However, to provide a complete picture of the customers' preferences, we also include more general aspects in Table 4, which may fit other types m-service too.

Table 4. Customer Preferences for Shopping Companion Apps

#	Aspect	Description
Responsiveness		
01	**Trained customer service**	Customer service should be able to assist the customers knowledgeably and politely with any inquiries related to the retailer's mobile services, app functionality, and in-store issues.
02	**In-app guidance**	The app should include an onboarding process to introduce the retailer's range of provided m-service offerings and should provide a help section with usage instructions.
03	**Omnichannel customer service**	Customer service should be available through all channels the retailer offers and provide personalized service to customers independently of the selected channel.
04	In-app customer service	The app should provide direct access to customer service (e.g., by text, voice or video chat) and display easy to find contact information.
05	Responsive customer service	Customer service should respond timely to customer requests, even during times of high request volumes.
Information		
06	**Real-time information**	Any information shown in the app (e.g., prices, stock information) should be up-to-date, correct, complete, and consistent to information provided by the retailer through other channels.
07	Adequate and clear information	Any information shown in the app should be provided to the customer in a relevant, clear, and intelligible manner.
08	Update descriptions	Customers should receive detailed update and release notes.
Security and Privacy		
09	Request permissions	The customer's personal and payment data should be collected, stored, and processed only after permission for the particular purpose is granted.
10	Restrict permissions	Permissions should only be requested when they are required and appropriate for the app's provided set of functions.
Design		
11	**Limit advertisements**	Although customers expect to receive offers through shopping companion apps, advertisements should be used with moderation and not distract users from fulfilling their current objective.
12	**Accurate product search**	The app should include a product search engine that returns adequate results, which may also take the customer's current in-store context into account.
13	**Convenient product filters**	The app should provide filters to ease digital and physical information and product search processes.
14	High-quality multimedia content	Multimedia content such as product images and videos should be in high-quality and fit to the screen resolution.
15	Clear design and intuitive layout	The app should have a clean and simple design that fosters its Intuitive use.

#	Aspect	Description
16	Short navigation paths	All functions of the app should be easily accessible and not deeply nested.
Performance		
17	Technical responsiveness	The app should start up quickly and react fast to the customer's interactions.
18	Reasonable resource utilization	The app should have a small footprint regarding app and update sizes, local storage occupancy, and (mobile) network traffic.
19	Reduced background activity	The app should keep background activities to a minimum to limit battery drain.
Technical Reliability		
20	Reliable operations	The app should provide its service reliably without crashes or service outages.
21	Sustainable updates	Updates should be non-breaking and sustain existing functions.
Valence		
22	Scope of features and services	A single app should incorporate all m-service offerings that the retailer provides.
23	Continuous improvement	The retailer should use a continuous improvement process to react to ever-changing customer expectations.

Customer reviews frequently contain experiences on service encounters with the service provider. Customer service representatives constitute a direct personal contact within the otherwise human-to-machine context of shopping companion apps. Customers expect service personnel that will respond in a timely fashion when they require assistance, is reachable through the channel of their choice, and can quickly, professional, and politely resolve their issues. We found that customers, among other things, complain about a lack of contact channels and unavailable representatives ("*No one to call no one to email*"), and the quality of employee training ("*The employees are clueless on how to even help you*"). However, they also mention positive service experiences ("*Had problem just called and they had it fixed in 2 mins thanks*").

Especially for shopping companion apps whose information is changing at a fast pace (offers, stock information), users expect correct, current, and complete data that is relevant to their situation ("*Used every day to keep updated with offers and developments*"). Incorrect or useless information discourages users ("*If someone is using the app and looking for the store nearest to them, why would you have a distribution center come up as the closest store and then direct people there?*") and can result in lost sales.

Regarding the app itself, customers expect guidance on the use of the app ("*Can't find instructions on how to use, and there are features that are not all that intuitive*") and want to be informed of changes introduced by app updates ("*When YOU update your app, you need to specify what changed - features, bug fixes, etc. BS like WE MADE IT BETTER is not an update description*").

Similarly, the retailer has to be transparent on the collection and processing of personal data so that customers gain trust and grant the requested permissions ("*Major* *privacy concern I just used the app to make a purchase. Without my knowledge or permission, it stored my credit card information.*"). In effect, permissions and data should only be requested when they are required for the proper provision of the app's service and features ("*Unwarranted permissions - why does it need access to WiFi info, media files and photos, contacts - no, really M&S, and no explanation*").

Design and usability are the most frequently reviewed aspects in our sample (see Table 3). While app designers receive numerous hints of varying relevance from the reviews, we suggest executing a structured usability assessment [53]. Users particularly name aspects such as a clean and simple design ("*Good size text and clear with suitably neutral colours which are pleasing to the eye*"), intuitive navigation ("*The app is far quicker & easier to use than the website*"), high-quality multimedia content ("*doesn't get 5 stars because of the ui and graphics. Low resolution or not optimized for retine screens*"), a reliable search engine, and filtering functions ("*Why doesn't this app allow me to sort my results? Like price high - low?*").

Customers expect well-performing apps ("*Opening app takes a long time*"), which make reasonable use of cellular data ("*Too data intensive. [...] it is taking FOREVER to load [...]*"), on-device storage ("*With storage space at a premium on my phone, I am seriously reconsidering the necessity of having this app*"), and background processing activities ("*It is active in the background to such a degree that it is a constant drain on my battery*"). Although the preferences regarding technical reliability seem obvious and should be taken for granted, customers reported a significant amount of technical issues for the apps under consideration. App developers need to make sure that the range of offered m-services and features is functioning correctly without bugs ("*Nullpointer exception when trying to add anything to the basket*") and continues to work after updating ("*Still can't use scanner...every since November 2016 update*").

The valence dimensions subsume the subjective feelings and perceptions customers have after using the retailer's m-service. We suggest to regularly assess the customers' feelings towards the app, e.g., by using an in-app survey mechanism to identify the individual pain points. Lastly, the apps under review apply two different strategies. Either, all customer-facing m-service offerings of the retailer are bundled in a single app, or there are multiple apps that all fulfill a single purpose. A frequently named ex post evaluation was not to spread features across multiple apps but to follow the first strategy ("*You have so many apps doing different things! [...] Link them for easy use*").

5 Discussion

Informed by extant SQ knowledge and real-world customer reviews of three major shopping companion apps, we provide a set of 23 aspects customer expect from shopping companion apps, structured by a multidimensional hierarchical model on MASQ. Nevertheless, fulfilling these aspects is not a *sufficient* condition for high MASQ *per se*, although they are based on the individual customers' written expectations and perceptions. As with most design decisions, there is no one-size-fits all approach since customers may have different or even contradicting expectations of the same service. Nevertheless, the derived preferences provide a good picture of what the majority of customers desire with regards to shopping companion apps. While these aspects can aid app developers and support quality-driven app design, their implementation might be difficult. Inherent with using customer reviews as data source, we draw from customers' wishful thinking that may conflict with the retailers' economic and business capabilities.

Since the earliest conceptions of SQ, most models are based on the disconfirmation paradigm [18], which states that quality is the result of the comparison between perceived and expected performance [17]. However, a small difference in performance as the indicator for high SQ is subject to critique by some scholars [e.g., 54]. Following the conceptualization, high SQ is achieved as long as the customer's expectations are met or exceeded, even though these expectations might be meager. In our understanding, the SQ is high when the expectations of a large majority of customers are exceeded. Suppose we have a large sample, outliers having particularly low respective particularly high expectations rule themselves out. Consequently, we used a large sample of 1,448 customer reviews to capture a representative set of customer expectations. On a further note, we confirm Knote et al's [40] observation that users' perceptions and evaluations strongly depend on their current situations and previous experiences with other apps, which are taken as a reference point for comparisons.

The elicited customer preferences constitute a snapshot in time that reflects current customers' perceptions and foci. Over time, these foci may change as new technologies and services evolve. For this reason and the subjective nature of SQ, we did not state explicit design guidelines that retailers have to implement to achieve high MASQ.

As with any research, our work comes with some limitations. First, our results may be prone to selection bias because the same set of researchers performed the derivation of content categories and characteristics related to MASQ as well as the subsequent coding of the online customer reviews.

Second, we did not take into account the specific Graphical User Interface (GUI) components and structures defined by the different mobile operating systems. These design conditions may influence both the customers' service expectation prior to the app usage, and their perception when interacting with the shopping companion apps on a smartphone. However, the scope of and interface to the provided functionality of the samples apps only slightly differed between Apple iOS and Google Android.

Third, the sampled apps all focus on grocery retail, which may constrain the generalizability of the derived customer preferences for shopping companion apps that focus on other retail industries such as apparel or sporting goods to some extent.

Fourth, there are inherent limitations when dealing with online customer reviews in general and reviews of mobile apps in particular. As customers can post online reviews anonymously [39], no customer information is available on the analyzed set of reviews. Consequently, we cannot make a detailed statement whether our sample is representative. Further, within the corpus of seemingly authentic online customer reviews published by real customers, there can be spam and misleading reviews [55]. Due to the anonymity of reviewers, we cannot rule out *manipulation* by developers and app providers to praise their product. We have no means to identify fake reviews. However, these reviews usually tend to praise or condemn the app under review without going into detail. Since we are only interested in information on the service delivery, we can quickly discard non-informational reviews such as "Useless rubbish!"—being a fake review or not.

Moreover, the majority of customers only posts a single review, but a small number of customer rates a mobile app several times (up to nine times in our sample). By using the app over a longer period, users become familiar and might identify further aspects worth reviewing. Therefore, we kept those reviews in the corpus. Admittedly, the number of reviews per customers has to be treated carefully because a single customer also can write reviews using multiple nicknames, which biases results in small samples.

Customers tend to report remarkably satisfying or dissatisfying aspects involving exaggerations and generalizations when reviewing products and services [55]. Although we use single anchor examples for clarification, our preferences abstract from single reviews and always summarize the judgments of many customers, in line with [29], so that single exaggerations do not bias our analysis.

We collected the most current 10,099 online customer reviews of the three shopping companion apps across a time span of six months. During this period, the apps have received multiple updates. For simplification, we did not include version numbers in the QCA. Thus, comparisons across app versions are not possible, and changes in the perceived MASQ cannot be traced back to new app releases.

Lastly, the manual coding process follows a strict procedure [29]. However, it may be biased by personal opinions and subjective evaluations. A fully automated process for the QCA, ranging from the extraction of online customer reviews from the app stores to summarizing the results per category using advanced text mining tools or cluster analyses could help to alleviate this issue. Nevertheless, a manual process seems appropriate in the context of subjective online customer reviews that may contain ironic and ambiguous statements, which are hard to identify for automated tools [39, 55].

6 Conclusion and Outlook

M-commerce is a significant growth area for retailers, and mobile shopping companion apps are an emerging phenomenon that has not found much attention in academia so far. To remedy this situation and set the field, this paper first introduced a working definition for shopping companion apps. We built upon kernel theory from SQ and introduced a multidimensional, hierarchical research model of MASQ that comprises the content categories and characteristics relevant to service delivered through mobile apps. From analyzing close to 1,500 real-world customer reviews of three major shopping companion apps, we identified 23 aspects customer expect from this kind of app. Our results can aid service and app designers towards providing mobile service and shopping companion apps that exhibit high MASQ.

We investigated shopping companion apps from a customer's point-of-view. In future work, we will assess the overall service system that spans between retailers and customers and between groups of customers. Special consideration will be put on the interactions between the involved parties and on the co-creation of shopping experiences that are facilitated by m-services and apps. Finally, we follow the dual mission of design science to advance theory while developing and evaluating innovative IT artifacts for practice. The customer preferences elicited in this work will inform our overarching design science research project on m-service in BaM retail.

Abstract. Smart glasses facilitate advanced user interaction and increase workplace efficiency through innovation. Yet, their capabilities rely on user-driven discovery of new software that harnesses its benefits. This study investigates user participation during the discovery of new software, leveraging this emergent technology. We investigate user participation during software product discovery, i.e. during early activities that precede classical development and design activities, through an in-depth longitudinal case study with two representative user organizations. The results suggest an evolutionary perspective toward the benefits of different types of user participation: 1) user as a source of information, 2) user as a co-creator, and 3) user as an innovator. Practitioners benefit from our lessons learned, validation and extension of software discovery toward the emergent technology, and recommendations to apply user-driven software discovery. We distill three lessons: evolving types of user participation, enhancing desirability through user participation, and carefully discovering software products for emergent technologies.

Keywords: Smart Glasses; Software Product; Software Discovery; Augmented Reality; User Participation

1 Introduction

When developing new software products, the literature presents different techniques, processes, and methods such as Scrum, XP or DSDM that help businesses to become more agile and increase development performance [1], [2]. While agile methods provide very little guidance related to early activities prior to programming [3], [4], scholars investigate the extension of these techniques with ideas from user participation practices such as user-centered design [5], [6]. Therefore, we need to better understand the role of user participation in these early activities, also called software product discovery [1]. Given the nature of innovation shifts from mechanical systems toward the software element of such products [7], the discovery of software products is an

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

emergent research field [5]. The associated term of (software) product discovery describes the early activities that precede classical development and design activities. The term originates from the pharmaceutical domain where it is often associated with the discovery of new drugs (e.g. [8]). In other domains, such as new product development, the product discovery phase is described as ideation stage [9]. In innovation management, the terms "fuzzy front-end" and "front-end innovation" have been introduced (cf. [10]). Irrespective of the domain, the objective is to reduce uncertainty at inception of a product development and design project (e.g., [10]). Here, the phase involves users early in order to identify high level needs of the user base and assure the desirability of the solution [11].

The literature presents us with different types of user participation. From a development perspective, we can distinguish three types of user participation [2], [12], [13]. First, and often associated with a traditional waterfall methodology, the user is a source of information [12]. Second, the user can be engaged and co-create the software product with the product team [14], [15]. Third, the user can become an innovating force behind new trends by utilizing toolkits [12]. While some organizations may not decide to involve users at all, other may include them in design reviews or include a user representative as part of the product team [16–18]. However, little is known about the interrelations of different types of user participation.

Smart glasses are an emergent and disruptive technology that can have sustainable impact on society and businesses. The lightweight devices (such as Google Glass or Vuzix M300) are characterized by their high mobility and mobile internet connection [19]. Contrary to other disruptive technologies, such as social media and mobile technology, smart glasses gain faster adoption by businesses than consumers [20]. Businesses see the potential of smart glasses in the way it changes the interaction between the computer and its users [21]. For example, smart glasses used in service and business processes assist employees in conducting tasks through the augmentation of their reality [22], i.e. enriching an individual's reality with further information through digital technology. Particular innovation potential lies with the software and services offered for it [7]. Due to limited experiences with these new devices and the corresponding software, we need to understand the technology's induced changes and influence on users during the discovery of new software products in order to mitigate risks of change requests or unaccepted software products.

This study investigates user participation during the software discovery phase in the context of an emergent technology. Our research objectives are: i) to investigate user participation during software discovery, ii) to understand the interrelations of different types of user participation, and iii) to identify lessons learned from an application of software discovery in a smart glasses project. Consequently, we formulate the following research question: *How can development teams facilitate user participation during the software product discovery for smart glasses?*

Practitioners benefit from our identified activities, lessons learned, and their applicability to software discovery. These can be used as guidelines to instantiate the process of discovering software products for smart glasses [4]. Our theoretical contribution focuses on the investigation of user participation during early activities within software development [5]. First, we adapt existing approaches to discovery by focusing on the participation of users when identifying software products for an emergent technology [1]. Second, we investigate how different forms of user participation benefit the desirability of a product vision during product discovery [23]. Third, we identify the evolutionary nature amongst three types of user participation and suggest a preliminary process model [24].

2 Theoretical Background

2.1 Software Product Discovery

The product discovery process describes the generation of ideas that precedes the development of application functions, leading to a product vision or product discovery plan [5], [1] (Figure 1). The objective of such a vision or plan is to assure the product's feasibility (e.g. [25]), viability (e.g. [9], [26]) and desirability (e.g. [14]). Hence, specific product, user, and team related concerns need to be addressed in five distinct phases. *Initialization* suggests the need for a new development project to assure clearly defined boundaries, the availability of key resources, and key stakeholder commitment [5]. *Product vision building* provides a common understanding of planned software products amongst the development teams [27], [28]. *User engagement* describes integrating the user as early as possible into the discovery process [28], [29]. The participation of users assures gathering actual user goals and user needs and therefore, leads to a desirable solution [1], [28]. *Requirements specification* identifies software needs from their initial idea, to later refined requirements through user feedback [27], [29]. A product backlog will be filled with elements from this requirements specification, the product vision building, and the user engagement [1]. Following, the phase *development and design* of drafts and low-fidelity prototypes simplifies the communication of the vision and helps to gain further insights from users and stakeholders through additional iterations (cf. [29]).

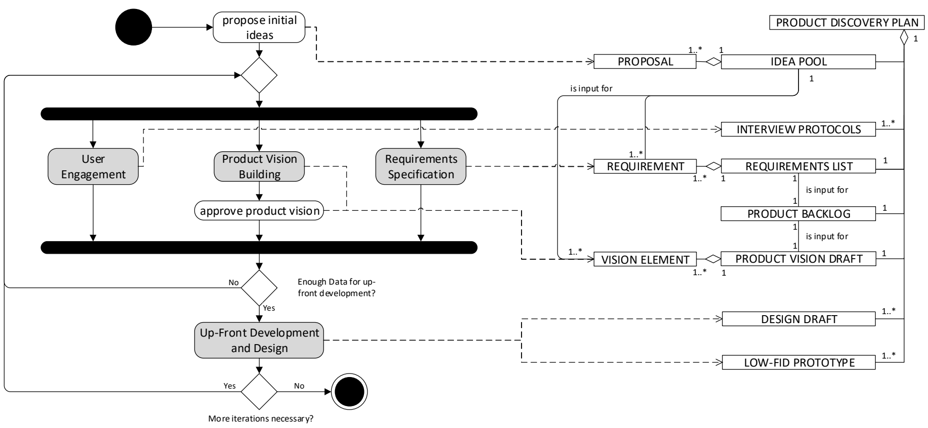

Figure 1. Software Product Discovery (simplified from Werder et al. [1])

2.2 User Participation

User participation has been an important factor in software development for decades [17]. Some of the benefits include quality enhancements, mitigation of unnecessary expenses, higher acceptance, increased use effectiveness, and enhanced development success (e.g. [2], [12]). While the literature presents differences between the concepts of user participation and a closely related concept of user involvement [30], recent studies suggest that scholars use these terms interchangeably most of the times [31], [32]. The positive effect between enabling participation of the user and system success has been empirically demonstrated [32–34]. Yet, system success has been measured in a variety of ways [31].

Prior studies suggest the multidimensionality of user participation [2], [15], [18]. One important dimension relates to the three different types of user participation [2], [12], [13]. First, the user can serve as a source of information. Designs are generated for the user. Second, the user can participate in the creation process as a co-creator. Hence, designs are generated with the user. Third, the user can be the innovating force behind new ideas, when designs are generated by the user. Despite the importance of user participation in software development, the role of user participation in early activities of the product development received little attention [5].

3 Research Method

Given the investigation of a contemporary phenomenon, the study adopts the case study research method [35]. The study presents a longitudinal single case with an embedded design in order to understand the changes in user participation during the discovery of software products for smart glasses. Given the quick adoption of smart glasses in businesses, the study focuses on the use of smart glasses to support employees in the logistics industry, e.g. through information provision or enabling user input during the execution of work-related tasks. The logistics industry is particularly interesting, as workers are confronted with many complex tasks established by manual labor, a field with high potential for technological support [36]. Following prior guidelines, the overall research design, the data collection and data analysis are presented in further depth [37]. Table 1 depicts the different activities and steps incorporating users in the instantiation and first iteration of the software discovery approach, including the duration in which the activities and phases took place. The activities are mapped to the main phases of product discovery (cf. [1], [10]). Since the early activities resulted in the design, development and evaluation of multiple prototypes, the varying timeframes of these iterations were documented in the table as range.

3.1 Research Design

The study follows a longitudinal single case design in order to investigate user participation during the software discovery process. The research context is the logistics industry, where new software for smart glasses is needed to support employees. The discovery phase guides the development of a product vision. Two prospective user organizations that are interested in the software products idea take part in this study. While company ALPHA, a large German logistics handler providing global services, is specialized on contract logistics with a staff of over 12,000 and more than 3,1 billion € annual turnover, company BETA is a German organization mainly offering fashion transport and services with 2,500 employees and more than 250 million € annual turnover. ALPHA's aim of the project is to relieve employees ergonomically and protect them from mistakes in work security. Additionally, ALPHA wants to improve service quality and process time throughout the entire value chain. BETA's goal is to leverage emergent technology in order to create a more attractive and ergonomic workplace. Both seek to implement a software product usable on smart glasses in order to evaluate the innovativeness of the technology in logistics.

Throughout the study, various roles and stakeholders participated. The main activities included researchers from the field of information systems and logistics, domain experts from the two logistics case companies, and software development experts from a software provider focused on logistics solutions. The focus groups were moderated and documented by the participating researchers. Additionally, further domain experts from both case companies were included in an online questionnaire.

3.2 Data Collection

The data collection of this study uses different design techniques and hence, benefits from interaction research design practices [38]. Throughout the project duration, data from multiple sources of evidence was collected, i.e. *expert interviews*, *on-site* *observations through shadowing, focus group sessions, discussions, and an online survey*. An overview of the different design techniques used for data collection during product discovery, and their later use in the analysis is presented in Table 2. The numbers in brackets in the *Data Type* column represents the amount of occurrences (count) of the respective data type. The multiple sources of evidence allow us to triangulate results. Mostly, the literature review and ten discussions in the setting of focus groups lead to the definition of potential system components, collected as idea proposals and vision elements. The collection of data follows the guidelines set by Yin [35], i.e. using multiple sources of evidence, creating a case study database, and maintaining a chain of evidence.

Table 2. Overview of design techniques and their use in data analysis.

Design Techniques	*Data Type (Count)*	*Use in Analysis*
Expert interviews	Interviews with logistics IS experts (2)	- Gather initial ideas for the application of smart glasses in logistics. - Investigate user as an information source.
Focus groups / shadowing	Warehouse observations (4 *together with idea proposal discussions*)	- Examine and gain insights into the usage context.
	Idea proposal discussions (4 *together with warehouse observations*)	- Increase understanding of further potential idea proposals for smart glasses applications. - Investigate collaborative approaches through group discussion.
	Idea cost-benefit discussions (1)	- Construct and analyze cost-benefit based on ideas and product visions.
	Idea proposal consolidation (1)	- Corroborate understanding and consolidate analyzed idea proposals.
	Product vision formulation (1)	- Corroborate understanding and enrich idea proposals with further information and examples.
	Requirements formulation (3)	- Evaluation and formulation of the previously defined ideas and vision elements as requirements from both technical and functional perspectives.
Online questionnaire	Vision survey (1)	- Corroborate product vision benefits with other stakeholders. - Prioritize product vision elements and requirements.
Practical development and design	Design Mockups (3)	- Integrate and crosscheck understanding and findings using design artefacts. - Investigate participatory approaches to user participation.

Design Techniques	*Data Type (Count)*	*Use in Analysis*
	Low-fidelity prototypes (3)	- Integrate feedback and corroborate understanding of design. - Integrate and crosscheck interaction scenarios.
Prototype Evaluation	Focus group discussions (2) Survey (1)	- Review project instantiation through user feedback. - Gain information and feedback on the usage context and acceptability.

The following paragraphs provide a brief description of the applied design techniques embedded in the respective software discovery phases.

Propose Initial Ideas. Initial ideas were identified by conducting expert interviews [39]. As part of the *initialization*, two experts were interviewed, a business system consultant and a business system analyst with experience in logistics. The interviews were each scheduled for two hours and were structured by previously developed guidelines. The interviews helped to understand logistics processes, the respective technical requirements to the technology of smart glasses, and practical development requirements in the domain of smart glasses. Additional usage scenarios were then collected by shadowing employees of both companies according to Myers [40]. Set up as a three-day-observation of workflows and activities relevant for the handling of cargo in goods receipt, storage picking and goods issue, results were documented as field notes and process models.

User Engagement. The *user engagement* phase was started through different focus groups. Eight focus groups were held according to established guidelines [41]. Employees of both companies, researchers with expertise in smart glasses technology and in logistics, and representatives of a software company were present at all focus group meetings. Each focus group was conducted moderated and extensively documented by a team member of the research team. A meeting protocol was sent to all participants, allowing them to make corrections and adjustments to the notes.

Product Vision Building. In order to build the respective *product vision* incorporating the different system components, a catalogue of 36 idea proposals was developed and enriched by descriptions and examples to generate common understanding. These particularized ideas formed vision elements, which were then evaluated using a personalized online survey. In addition to general demographic data and entry-fields for comments and notes, the questionnaire consisted of four questions for each vision (general usefulness, innovativeness, personal usefulness, adoption) using a 7-point Likert scale. 31 participants completed the survey (67% domain experts, 7% software developers, 26% researchers).

Requirements Specification. In order to *specify requirements*, the evaluation results were combined with an additional technical focus group meeting, discussing technical requirements of each vision element. Stemming from this inductive combination, a prioritization of the requirements was conducted in a backlog. Resulting from further focus group discussions with domain experts and software developers, functional and technical requirements were formulated, both for general applicability for smart glasses-based software, and for specific guidance of the respective vision element instantiation.

Up-Front Development and Design. Through the *implementation and design* of three different prototypes, the respective vision elements were instantiated iteratively. Three prototypes were implemented with two different goals aiming at supporting employees from logistics at their daily tasks through different sets of functions (documentation of damages or assembly errors, and process visualization for value-added services). The latter prototype was implemented in two iterations. The implemented systems were evaluated by applying different methods for each system. While the initial prototype was evaluated through a survey with students, the other two instantiations were presented and discussed with domain experts. The various qualitative remarks made by the participants as part of subsequent iterations of the phases *user engagement*, *product vision building,* and *requirements specification* were then included in the next iteration of development and design.

3.3 Data Analysis

The analysis was initiated by applying inductive class formation according to Mayring [42] for each data set, generating idea proposals for potential smart glasses application scenarios on the domain of logistics. Ideas were gathered investigating (a) functional support of a smart glasses application, (b) an implementation of technical requirements in logistics, or (c) a potential or already proven application scenario. Suitable ideas were identified in a subsequent analysis, whereas ideas could be assigned to an already defined idea (subsumption). In case no equivalent idea was previously proposed, a new element was formed inductively based on the specific content [40]. A fundamental challenge in the continuous formulation and aggregation of the idea proposals was the occurrence of partly diverging degrees of abstraction in the description through the different methods. Hence, category formation according to Mayring [42] was applied again, based on the results of the different methodological approaches, in order to subsume the idea proposals gradually. Thereafter, descriptions were derived (including actors, processes, and activities), examples for all scenarios were developed by domain experts of the two case companies, and product vision elements were generated. These artefacts were validated and consolidated in additional focus group meetings and formed the basis for the definition of technical requirements. The line of argumentation for the technical assessment of the requirements was inductively formed. The purpose of this coding step was to consolidate and derive the technical design and create architectural design proposals [42]. Pattern matching and explanation building was applied in order to analyze and synthesize our findings.

4 Findings from a Software Discovery Project

As we seek to investigate the role of user participation during the discovery of software products for smart glasses, the results are presented along the different types of user participation. First, we present findings supporting the participation of users as an information source. Second, we report findings with the user as a co-creator. Third, we present findings concerning the user as an innovator.

4.1 The User as Source of Information

Users were involved as a key source of information through the execution of interviews. This was the first design technique we applied during data collection at an early stage of software discovery. Following the recommendation of gathering idea proposals in software discovery, we identified first ideas, which were then further evaluated. We documented and collected all idea proposals in an idea catalogue. Hence, the idea generation reflects the initialization phase of software discovery, with the catalogue being equivalent to the idea pool. As a result of shadowing and observing users, they provided us with additional insights and information (e.g. at which process steps the user needs both hands). An idea proposal stemming from these activities was a system to support the picking process, by displaying information on which product to pick next, and provide confirmations via barcode scanning.

4.2 The User as Co-Creator

Thereafter, warehouse tours helped to gain more detailed insights and impressions of the needs and processes of different warehouse settings. After two tours at each customer company, followed by in-depth discussions with various stakeholders, most of the previously gathered ideas were validated. Furthermore, new ideas were identified and discussed. The results from our initial user participation activities (i.e., the expert interviews, shadowing, and initial focus groups), formed the first version of our idea pool. Since the focus groups included stakeholders and potential users, the tours and discussions engaged the users as part of the software discovery process.

Throughout the participatory discussion and idea pool evaluation, various ideas were regarded as either too ambiguously defined, or too similar to other ideas. To promote a common understanding across both companies, each company was asked to enrich each element with a detailed description and possible scenarios. This helped us to identify differences between both case companies. As a result, when larger differences were identified, we divided an idea into separate elements (e.g., displaying warnings and safety instructions was separated to a process-based and an object-based warning system idea). Thereafter, we could unify many elements that covered the same area, yet were initially associated with two different idea proposals (e.g., the ideas of identifying objects through QR- and barcodes or RFID were unified to a general object identification). Through this consolidation, the final idea pool was reached for further investigation. The underlying warehouse tours and the focus group discussions were planned in the first iteration and served as main basis for all subsequent steps. Detailed evaluation of the resulting ideas and vision elements was conducted toward the middle and end of the discovery phase. From this type of user participation, more elaborate ideas and vision elements could be derived, such as the documentation of damages by usage of the smart glasses' camera and the transfer of this documentary evidence to damage management. These elements form the product backlog that guided the development, and were later instantiated as a prototype.

4.3 The User as Innovative Force behind Trends

With a well-described and communicated set of system components, a prioritization according to their practical benefit was needed. Hence, an online questionnaire was developed to provide a second evaluation. For both companies, the survey led to a prioritized list of the previously unsorted backlog items. Through this survey, users provided their input and evaluated each component. They were given the means to engage and prioritize backlog items according to the stakeholders' needs. This enabled the user to actively shape the software discovery process, as backlog elements that were deemed as unimportant or not useful for the customer and user could be neglected. This increased the influence of the user, in particular in the area of emergent technologies. The survey counts toward requirements specification, as specific requirements or concerns of different stakeholders and users were highlighted.

Mock-ups as well as prototypes were then designed, developed and evaluated in order to showcase the application of smart glasses in a specific use case (process guidance). Benefitting from early user and stakeholder participation, we were able to document cases in which idea proposals, their detailed formulation as vision elements and development and design artifacts were created by stakeholders or users. For example, the idea to support the process of assembling, equipping and examining promotional displays for groceries was actively developed and matured by a stakeholder and participant of the warehouse tours, and was then chosen as first content for the process guidance prototype. This prototype was then instantiated in two iterations. During both iterations, a close collaboration with the users existed, leading to two maturity stages. The development was conducted toward the end of a product discovery iteration.

5 Toward the Process Model for User Participation

We developed a preliminary process model that seeks to clarify the interrelations of different types of user participation (Figure 2). Through the previously described activities, users and stakeholders were actively involved in the discovery process. Our results suggest that early participation of users and stakeholders is exceedingly important in emergent technologies, as desirability is essential for an intention to use a new system.

The process model starts with the intention to develop a new product idea, serve a new user need, or utilize a new technology. Hence, the development and design team has to learn more about the users' tasks and work context. In this scenario, the users typically act as a source of information for the development team. Building on this knowledge, the users can be invited to co-create, for example through co-creation workshops. Through co-creation design techniques, the users becomes more familiar with essentials of the software development and design processes. Once familiar with different techniques and an understanding of their individual strengths and weaknesses, the users may further contribute. They are now equipped with essential process skills and corresponding tools, which are typically readily available online for easy and quick sketches and prototypes. Building on these skills, the users can develop their own design suggestions and share those with the development and design team. Also, new feature ideas can be integrated into existing screenshots by the users, simplifying the communication between the users and the development team. Therefore, the users can drive further innovation by developing their own ideas. We suggest that the evolution of different user participation types is the result of a knowledge creation process [43], where knowledge about the application domain and knowledge about the technology need to be combined [44]. Through structuring this approach as a sequential and incremental process model with iterations between the subsequent stages (i.e. having one stage of user participation leading to a more mature, more integrated stage including changes to the user's tasks, goals and the environment), we provide an ex-post suggestion on how a software discovery project can be conducted. While the definition of a chronological order of the stages is only one possibility of a respective process model, it provided us with an easy to use and successful guideline throughout the investigated project.

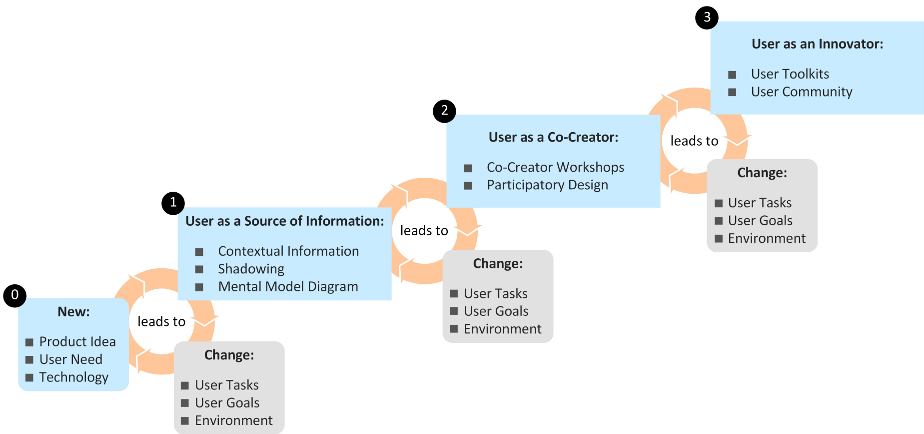

Figure 2. Preliminary process model for the evolution of user participation types

While other researchers, such as Damodaran [2] or Markus and Mao [15], stress the importance of user participation and present detailed role descriptions and research propositions, they do not specify any order or evolution of different types of user participation. As our model focuses on the creation of completely new software in the domain of emergent technology, this temporal link serves as a basis for a holistic approach to user participation. The users are thoroughly guided toward more autonomous roles. We observed that without a chronological order or procedural guidelines, users are quickly overwhelmed by the sheer number of design techniques and design dimensions available and lose track of key objectives, leading to scope creep with ideas and functionality that is out of the scope of the system under development.

6 Lessons Learned

We answer our research question with three lessons learned we identified through the course of the case study. Adhering to and considering these three aspects, practitioners can facilitate user participation when discovering new software.

Consider Evolving Types of User Participation. During the study, multiple iterations of software discovery have been conducted. Through the different iterations, different types of user participation have been observed [13], [16]. The data collection started with interviews, which provided a better understanding of the users' tasks and their environment. Within these interviews, the user served as an information source. Thereafter, on-site observations and focus group discussions were the main source of information. Hence, the user's role evolved, as they were not only the source of information, but also participated in the creation and shaping of designs and prototypes. Lastly, users were engaged as they were given the opportunity to actively influence the design of the software, by generating their own design suggestions. Practitioners should keep these different phases in mind when integrating users to gain the desired information or result.

Enhance Desirability through User Participation. We were able to identify early user and stakeholder participation to be essential for a successful discovery of smart glasses software. The early participation helped to shed light on some concerns and other issues raised by the users and stakeholders. Consequently, these issues and concerns could be addressed from the beginning. Involving users early in the process provides assurance and reduces uncertainty for all people involved [17]. For example, many of the idea proposals resulted from the focus group discussions. Several ideas were related to a tension field (e.g., data privacy). Hence, users had to be reassured that the project aimed at improving processes and ergonomics in their favor without jeopardizing their data privacy. Thus, rushed introductions of technological advancements can have negative effects, whereas comprehensive up-front communication and preparation help to avoid such pitfalls. In the case of emergent technologies, uncertainty or unawareness frequently have to be managed. As different stakeholders, such as users or customers, were not able to imagine the specific use of smart glasses in their work context, hands-on demonstrations were provided in order to specify the technological capabilities of smart glasses within their work environment. Through this course of action in conjunction with the innovative characteristics of smart glasses, different desirable prototypical implementations have been developed. This became apparent as new participants could be regularly included into the focus groups.

Thoroughly Discover Software Products for Emergent Technologies. Through the interaction with users and other stakeholders, prior concerns with the technology became apparent. We wanted to put an emphasis on discovery activities using prototypes and mockups. These artefact-centered means of communication helped to reduce uncertainty by specifying design ideas and concepts. While prior research suggests steps and activities for the discovery of products (e.g. [1], [10]), the case context suggests specific nuances for the application with smart glasses. Given that smart glasses are still an emergent technology, little application examples exist. The role of very early participation of users in order to understand the tasks, goals and work context are important in contrast to application domains with a variety of mature software alternatives fulfilling the same or a similar purpose. Hence, while in an established application domain given instances may swiftly consider co-creation workshops or user participation with a focus on innovative ideas, in our case, technology provider and technology user have to become familiar with each other's domains, as users from all stakeholders issued not being familiar with the technology.

7 Conclusion

The paper investigates the discovery of software products for smart glasses. Key phases and activities for software discovery applied in a case study in the logistics context. As a result, the use of different user participation techniques, depending on the products maturity is suggested. While initially, the user is often seen as a source of information for the developers to understand the task goals and work environment. Subsequently, the user can be engaged as a co-creator. With the use of toolkits, the user can also drive innovative processes by developing own design alternatives and ideas for new product features. While we investigated different sources of information over a longer period of time in order to develop a preliminary process model, the study does not investigate cause-and-effect relations. Hence, future research may investigate the use of different user participation types toward the performance of the discovered product.

The Fluidity of the Self-Concept as a Framework to Explain the Motivation to Play Video Games

Bastian Kordyaka[1], Marius Müller[1], and Björn Niehaves[1]

[1] University of Siegen, Chair of Information Systems, Siegen, Germany
(Bastian.Kordyaka, Marius.Mueller, Bjoern.Niehaves)@uni-siegen.de

Abstract. A better understanding of the motivation to play video games and potential antecedents have a long history in Human Computer Interaction research. Besides different motivational dimensions specific to video games, researchers already used the personality of players to explain the motivation to play and the subsequent video game use. At this juncture, they postulated a rather static self-concept underlying the personality of players. The study at hand tries to resolve this shortcoming and proposes a more holistic perspective on personality following the assumptions of the Social Identity Approach from psychology, which postulates a much more fluid and context-specific salient parts of the self-concept. Specifically, we use findings from consumer research arguing that the dimensional fit between the perception of the self-concept of a player and the corresponding video game holds the potential to explain the motivation to play as well as the subsequent usage of the video game.

Keywords: Video Games, Motivation, Personality Traits, Self-Concept.

1 Introduction

In this day and age, video games can be considered as a specific and especially popular form of socio technical systems [1]. Within the last decade, they experienced an upturn regarding their popularity. In 2017 more than 2.2 billion people worldwide played video games and the industry had an estimated global revenue of $108.9 billion [2]. This indicates that a better understanding of the hedonic motivation to play video games and the subsequent use is a crucial question for academic research and practice.

Information Systems (IS) and Human-Computer Interaction (HCI) research already captured hedonic motivation as a driver for the use of sociotechnical systems (e.g. live streaming, ecommerce) [3, 4]. Additionally, research already explored motivational drivers to play video games. Pioneering work in this regard, identified different clusters of relevant motivations in the context of video games and looked for predictors of motivation [5]. Notable examples used the personality of players as potential predictors of motivation. Surprisingly, the majority of empirical studies postulated a rather static self-concept of personality including demographic or context unspecific personal traits, which limits the explanatory power significantly [5–8].

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

With our study, we aim to address this shortcoming and follow the assumptions of the Social Identity Approach (SIA) from psychology postulating a much more fluid and context dependent self-concept of players [9, 10]. We plan to use existing findings from consumer research and test them for the first time in the context of video games [11–13]. Specifically, we propose the fit between the player's self-concept in the specific domain of a video game as a relevant antecedent for the motivation to play and the subsequent use. Providing a more holistic and relational explanation for video game use promises several important contributions. First, it allows researchers to better understand one contemporary especially meaningful form of technology use and transfer the findings to neighboring IS relevant contexts (e.g. health, learning). Second, it provides the gaming industry with the opportunity to learn more about the design of a game and gain insights into hedonic motivation as a driver for economic success. To ensure the external validity of our findings and explore differences and commonalities between different games, we intend to examine the three most successful games of the year 2017 (League of Legends, Fortnite: Battle Royal, and Overwatch) [14]. Additionally, we want to make use of a multi-level analysis using the levels of single games and aggregate the findings on a higher level of all three games. Therefore, the short paper is guided by the following research question:

RQ: *Can the self-concept of a player explain the motivation to play and the subsequent video game usage?*

2 Related Work

2.1 Game Use

In the specific context of video game use, two different streams of research can be detected. First, negative issues like pathological use and addiction [15, 16], violence [17, 18], and physical correlates [19, 20] are oftentimes dealt with. Second, based on the psychology of action [21, 22], several studies proposed different motivational drivers to play video games [8, 23]. We anchor our study within the second stream since we want to expand the current understanding of the motivation to play video games.

2.2 Gaming Motivations

Looking for potential predictors of video game use different motivational models were already proposed using different theoretical underpinnings. Two noteworthy approaches in this regard are the self-determination theory [24, 25] and the uses and gratifications theory (UGT) from media psychology [26, 27].

We build our study around the UGT since we target to theoretically enrich the existing status-quo of video game motivation, which allows for a flexible approach. The UGT is a widely accepted taxonomy of six main motivations (action, social, mastery, achievement, immersion, and creativity) to play video games [5].

2.3 Predictors of Motivation

According to the UGT, players actively seek to satisfy their needs with their behavior [26]. Therefore, the choice of behavior largely depends on the player's personality consisting of personal traits and the self-concept, which can be understood as UGT components predicting motivation and usage [27].

Personality traits. One of the most established models to categorize personality traits is the five-factor model of personality, which has been used as motivational predictors in several game related studies [6, 28]. The Big Five taxonomy assumes a rather static personality of players and consists of the dimensions openness, conscientiousness, extraversion, agreeableness, and neuroticism [29].

Self-concept. The self-concept can be understood as the totality of the individual's thoughts and feelings referencing to himself/herself as an object [30]. Considering the self-concept from a SIA perspective, it can be characterized by its fluid and context-specific salience [9, 10]. Therefore, we assume that game use largely depends on an individual's own perception of how well a certain game is able to satisfy needs and the corresponding self-concept. The following dimensions are commonly used to describe the self-concept: actual self, ideal self, social self, and the ideal social self [11, 13].

2.4 Relevant Contexts

We intend to examine the three most successful games of the year 2017 *League of Legends*, *Fortnite: Battle Royal*, and *Overwatch*. For comprehensive overviews of the games, we refer to previous literature providing detailed descriptions [31–33].

3 Methodological Approach

3.1 Research Design

We plan on using a cross-sectional approach. Therefore, we will use an online survey to collect self-reported data and covariance based statistics. Additionally, we will make use of a pre-study to develop a measurement (semantic differential) of relevant dimensions related to the games and to have a benchmark to compare them to the different parts of the self-concept. Figure 1 shows our research model and hypotheses.

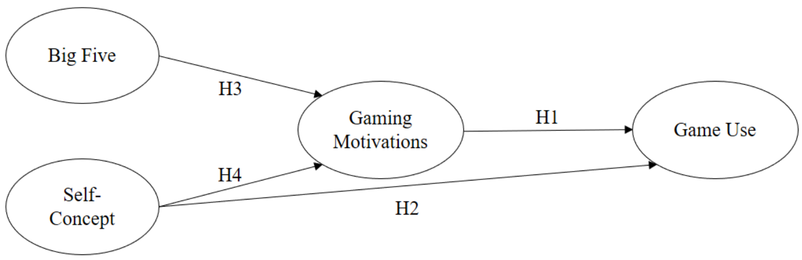

Figure 1. Research Model

3.2 Data Collection

In order to ensure conclusive results, we will survey players of the three games *League of Legends*, *Fortnite: Battle Royal*, and *Overwatch*. We want to consult ordinary players, since the aim of our study is about stereotypical use patterns. In order to acquire a significant amount of respondents (we plan to acquire at least > 200), we will use different channels (e.g. community boards, social media, gatekeepers) to disseminate the link to our survey and promise different forms of incentives (e.g. game currency vouchers) to ensure the motivation of participants in our study.

3.3 Data Analysis

To analyze the data, we aim to make use of different statistical tools. First, we will use co-variance based path modeling to test the hypotheses. Second, we intend to carry out a multilevel analysis to compare findings from the lower level of single games and aggregate them to a higher level.

3.4 Measurements

To measure the variables of our study, we will adapt empirically validated scales to the context of our study (see Table 1). Additionally, we will measure demographic and control variables to have the chance to control our results for potential confounds.

Table 1. Measurements of the study

Type of variable	*Name of variable*	*Exemplary wording of item*	*Source*
Dependent	Game Use	Please indicate your frequency of play? (5 items)	[34]
Mediating	Gaming Motivations	I like chatting with others (12 items).	[35]
Independent	Big Five	I am someone who is full of energy (30 items).	[36]
	Self-Concept	I have respect for myself (35 items).	[37]

4 Outlook

The paper at hand proposes a holistic approach to capture the motivation to play and the subsequent use of different video games. This leads to different implications. First, capturing the effects on different levels of different games indicates the potential for additional insights (e.g. commonalities and differences between games). Second, illustrating the meaningfulness of the self-concept promises fruitful avenues for theory (e.g. a context specific theory to explain video game use) and practice (e.g. demand and economic meaning). Besides the significant insights, the proposed study includes several limitations. First, we will not have the chance to identify causal connections between the constructs because we plan a survey. Nonetheless, on the basis of our results it is possible to conduct experiments to test the causality of relationships. Second, the amount of items is rather high (> 100) which might limit the response rates. To avoid this shortcoming, we plan to use different types of incentives.

Heart over Heels? An Empirical Analysis of the Relationship between Emotions and Review Helpfulness for Experience and Credence Goods

Michelle Müller[1], Dominik Gutt[1]

[1] Paderborn University, Faculty of Business Administration and Economics, Paderborn, Germany
{mmuell15}@mail.uni-paderborn.de, {dominik.gutt}@upb.de

Abstract. According to current scholarly and practitioner thinking, one way of enhancing the perceived helpfulness of reviews is by encouraging the use of emotional language. Yet, studies on review helpfulness have paid little attention to studying this effect as it applies to different product types, namely experience and credence goods. Using data from amazon.com, we conduct an empirical test using a natural language understanding algorithm. Our results suggest that for both experience and credence goods, fear, joy, and sadness are correlated with an increase in review helpfulness, whereas anger is negatively correlated with it. These emotions are perceived as more helpful for experience goods than for credence goods.

Keywords: Helpfulness, Emotions, Experience Attributes, Credence Attributes

1 Introduction

Human-Computer Interaction (HCI) between online shoppers and online review systems has led to the creation of massive amounts of data. Due to the rapidly growing volume of product reviews on review websites, customers often face information overload so that finding particularly helpful reviews can be like searching for a needle in a haystack [1]. To alleviate this problem, online review systems attempt to identify reviews that customers perceive as most helpful [2]. Consequently, research has investigated the features of helpful reviews [3-5], such as emotions conveyed by review texts. One way of eliciting this knowledge is to nudge reviewers towards using particularly helpful emotional language by presenting them with review templates with suggestions on how to craft a helpful review.

Research suggests that emotions expressed in reviews significantly influence perceptions of helpfulness [5, 6]. Emotions are a common and important reason for electronic word of mouth because consumers often write reviews when they are either extremely satisfied or extremely dissatisfied [7]. For instance, if a reviewer expresses lots of joy about a film, this is perceived as very helpful [5], whereas reviews of products like printers are perceived as more helpful when written in a more neutral tone [6]. Existing research on the topic focuses on products that have either search or

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

experience attributes [5, 6]. However, to the best of our knowledge, research has not yet examined the difference between the impact that emotions have on review helpfulness for goods with experience attributes (those that can more easily be assessed after purchase) vs. goods with credence attributes (which are difficult to assess even after purchase). In this paper, we refer to experience (credence) goods, when a good has a high share of experience (credence) attributes. For both of these product types, reviews seem to be particularly valuable because the degree of uncertainty before purchase is high [5]. Hence, we aim to answer the following research questions:

1. *What impact does the degree of emotionality in online reviews for experience and credence goods have on their perceived helpfulness?*
2. *Does the relationship between the emotional content of a review and its perceived helpfulness differ depending upon the type of goods reviewed?*

Our preliminary results suggest that emotional content in reviews is associated with an increase in perceived helpfulness. Counter to our intuition and second hypothesis, this relationship is more pronounced for experience than for credence goods. Our work thus provides research implications, in particular for HCI, and practical implications for online review system designers who can use our results to improve their review templates by suggesting to reviewers to express discrete emotions in their reviews.

2 Related Literature, Theoretical Background, and Hypotheses

An earlier study has employed a latent semantic analysis (LSA) to identify discrete emotions in reviews [8]. This study finds that emotions like hope, happiness, anxiety, and disgust express certainty and have differential implications for a review's helpfulness. Another study employs a bag of words approach to analyze the association between overall emotional content in online reviews for movies and a review's helpfulness [5], finding a positive relationship between overall emotionality and movie review helpfulness. Finally, another study employs a lexicon- and an expert dictionary-based approach to measure a general relationship between discrete emotions and review helpfulness [9], presenting evidence that emotions are conducive to review helpfulness. However, they do not investigate differences in this relationship across product types.

Our study aims to disentangle the relationship between emotions and experience and credence attributes. Experience attributes can only be inspected after purchase, so the consumer must first have bought the product or service, such as a restaurant meal [10]. Credence attributes are characterized by an even higher level of uncertainty, such that the attribute of the product or service can hardly be assessed even after purchase (e.g., the effectiveness of cosmetics or of a medical treatment) [11]. However, reviews of goods whose assessment involves a significant element of either experience or credence attributes can be especially helpful given the high degree of uncertainty prior to purchase (compared to search goods, for example). Finally, in line with prior literature [9], we choose the discrete emotions of anger, disgust, fear, joy, and sadness as the emotions of interest. Expressing emotions has been demonstrated to be conducive to the helpfulness of reviews [5, 9]. Given the high level of uncertainty for experience and credence goods prior to purchase, we expect to find a positive relationship between emotional review content, especially when the emotions are negative [12], and a review's helpfulness. We hypothesize: *Hypothesis 1: Emotions in online reviews for both experience and credence goods are positively associated with a review's perceived helpfulness.*

After consumption, a customer of a credence good is left with more remaining product uncertainty than a customer of an experience good. Thus, when writing a review, a credence good customer can provide less factual information but arguably has to resort to their feeling about the good after consumption. Therefore, to enhance review helpfulness, reviews for credence goods should provide more emotional content, compared to experience goods. Thus, we hypothesize: *Hypothesis 2: The relationship between emotions and perceived helpfulness of a review is moderated by the product type, with emotions in reviews of credence goods being more helpful than in reviews of experience goods.*

3 Research Setup and Empirical Analysis

We obtained a data set from amazon.com containing 53,218 single online reviews of experience goods (video games, digital cameras, in line with [13, 14]) and of credence goods (health- and fitness apps, health and personal care products, in line with [15, 16]). All the reviews had obtained at least one helpfulness vote. They had been collected in July 2014 and contain all reviews since May 1996. To identify expressed emotions in online reviews, we employ the natural language understanding service of IBM Watson. This service can extract features of unstructured content, such as emotions of online reviews. For each review we obtained data related to anger, disgust, fear, joy, and sadness, as well as an overall emotion score.

To test our hypotheses, we conducted a linear regression model with *HELPFUL* as dependent variable. In line with existing literature [3, 4], *HELPFUL* is measured as the proportion of helpful votes out of the total votes a review has received. Review-related *Control Variables* (vector *X*) comprise the rating (1 to 5), squared rating, the average rating, the number of ratings, word count, review age, and the average readability index. The variable $OVERALL\_EMO$ controls for the overall emotional review sentiment and is defined between -1 (negative sentiment) and +1 (positive sentiment). Formally, estimation equation 1 displays our model for review *i* and product *j*:

$$HELPFUL_{ij} = \beta_0 + \beta_1 ANGER_{ij} + \beta_2 DISGUST_{ij} + \beta_3 FEAR_{ij} + \beta_4 JOY_{ij} + \beta_5 SADNESS_{ij} + \beta_6\, OVERALL\_EMO_{ij} + \gamma X_{ij} + \epsilon_{ij} \tag{1}$$

The coefficients for all dimensions of emotions are consistently larger for experience goods than for credence goods (Table 1). Thus, we find support for H1 (emotions are generally conducive to review helpfulness) but we have to reject H2. We tested the statistical significance of coefficients (*Differences*) using the Chow test and find significant differences for all but one coefficient. For robustness, we tested consumer goods and digital goods separately, implemented product fixed effects, and ran Tobit regressions to account for the truncation of *HELPFUL*. Acknowledging that some studies classify digital cameras as a search product [2], we also ran our regressions again without cameras. Our results remain qualitatively unchanged after all these tests.

Table 1. Linear Regression Results

Model *Variable*	*Experience Goods* *HELPFUL*	*Credence Goods* *HELPFUL*	*Differences* *HELPFUL*
ANGER	—0.05***(0.01)	—0.06 (0.04)	χ^2= 8.96***
DISGUST	0.00 (0.01)	—0.05 (0.04)	χ^2=1.07
FEAR	0.13*** (0.01)	0.08** (0.04)	χ^2=4.47**
JOY	0.14*** (0.01)	0.11** (0.03)	χ^2=25.6***
SADNESS	0.23*** (0.01)	0.08** (0.03)	χ^2=41.95***
OVERALL_EMO	0.09*** (0.01)	0.04*** (0.01)	χ^2=30.30***
Control Variables	✓	✓	-
Observations	46,463	6,531	-
R^2	*0.1739*	*0.0854*	-

Note: Robust standard errors are in parentheses. *p < 0.1; ** p < 0.05; *** p < 0.01.

4 Preliminary Conclusions and Future Research

This study provides preliminary indication that discrete emotions, namely, fear, joy, and sadness, are associated with an increase in review helpfulness for both experience and credence goods. More interestingly, our empirical results also show that these emotions are perceived as more helpful for experience goods than for credence goods, indicating that reviews for products with credence attributes should be written in a more neutral tone, compared to reviews of experience goods. Following the call of prior literature [3-5], review systems can use our approach to improve review templates for their customers by suggesting to reviewers that they should express certain discrete emotions or by discouraging them from using certain other emotions (such as anger or disgust). Ultimately, the preliminary insights from this study provide a first step to improving the design of online review systems. Moreover, this work strengthens current scholarly understanding of how to craft a helpful review [2, 3, 4, 13, 17].

Naturally, as our study is based on observational data, it carries limitations which require extended investigation as follows. First, we plan to further validate the identification of emotions by using another natural language understanding algorithm as well as human coders, since text mining techniques such as IBM Watson should always be used with caution. Second, we plan to conduct additional experiments to rule out confounding factors such as reviewer-review self-selection and factors such as the review reader's perception of the review writer's effort. Third, in order to obtain a more holistic picture, we intend to analyze the impact of emotions for digital and non-digital products, as well as for hedonic and utilitarian goods.

Unfolding Concerns about Augmented Reality Technologies: A Qualitative Analysis of User Perceptions

David Harborth

Chair of Mobile Business and Multilateral Security, Goethe University Frankfurt, Frankfurt am Main, Germany
david.harborth@m-chair.de

Abstract. Augmented reality (AR) greatly diffused into the public consciousness in the last years, especially due to the success of mobile applications like Pokémon Go. However, only few people experienced different forms of augmented reality like head-mounted displays (HMDs). Thus, people have only a limited actual experience with AR and form attitudes and perceptions towards this technology only partially based on actual use experiences, but mainly based on hearsay and narratives of others, like the media or friends. Thus, it is highly difficult for developers and product managers of AR solutions to address the needs of potential users. Therefore, we disentangle the perceptions of individuals with a focus on their concerns about AR. Perceived concerns are an important factor for the acceptance of new technologies. We address this research topic based on twelve intensive interviews with laymen as well as AR experts and analyze them with a qualitative research method.

Keywords: Augmented reality, qualitative user study, privacy concerns, security concerns, social consequences.

1 Introduction

Augmented reality (AR) gained much attention in the public in the last years, especially due to the success of mobile applications like Pokémon Go [1]. Since the origins of AR technologies in 1968 [2], there was a consistent technical development of AR hard- and software. However, the technical development of AR lacks accompanying research about user perceptions, attitudes and behaviors. Already in 2005, Swan and Gabbard [3] postulated the need to further develop AR systems from a technology-centric medium to a user-centric medium and demanded user-based experimentation. Comparable results are found by Harborth [4], who finds that the majority of research on AR deals with technical aspects and developments and only few user studies and evaluations are conducted. In addition, Dey et al. [5] report on ten years of user studies published in AR outlets. They find that most of these studies are formal user studies, with little field testing and almost no heuristic evaluations. The majority of existing

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

studies on augmented reality focuses on the behavior of users interacting with the technology, especially in laboratory environments.

Besides the prevailing gap in current research on AR, it is important to investigate this technology due to its potential impact on all aspects of individuals' daily lives. Tim Cook, CEO of Apple, states that *"[...] it will happen in a big way, and we will wonder when it does, how we ever lived without it. Like we wonder how we lived without our phone today"* [6]. This opinion is substantiated by an increasing activity in the mergers and acquisitions (M&A) market, where large technology companies like Apple or Snapchat are buying small specialized AR firms [7, 8]. Furthermore, AR is experiencing an increasing relevance in the B2B sector by providing substantial efficiency gains [9]. Thus, it is relevant to investigate the interaction with AR and the implications of using AR as early as possible. In summary, the current state of research and the importance of AR as an innovation make it necessary to conduct more user studies on AR in order to analyze users' needs and concerns. In contrast to quantitative research, a qualitative method makes it possible to investigate a wider horizon of possible perceptions and attitudes of individuals that previous research did not consider. Therefore, we investigate the perceived concerns of users with regard to AR technologies based on a qualitative method, called grounded theory method (GTM) [10]. The results can serve as a starting point to evaluate and foster market adoption as well as future developments of AR technologies.

The remainder of this paper is structured as follows. We review related work in Section 2. The methodology is described in Section 3. The results are presented in Section 4. Section 5 contains a discussion of the results. We conclude with Section 6.

2 Literature Review

Past and current research on AR is mainly technical. Comparable research investigating the potential and actual users of AR is relatively rare [3–5]. Most of the existing user studies follow a quantitative research method and investigate one specific case of an AR technology using known theoretical models and construct operationalizations like technology acceptance models or privacy concerns (e.g. [11–17]). Partially, studies complemented quantitative approaches with qualitative methods. For example, Grubert et al. [18] investigate user reviews for AR browser, focusing on negative comments and clustering these comments with regard to certain application features. Olsson and Salo [14] mix open questions with numerical evaluations in an online user survey to investigate general acceptance issues and user experiences with respect to mobile AR. Haugstvedt and Krogstie [13] investigate acceptance factors of a mobile AR application for cultural and historic information in cities. First, they employ a quantitative approach based on a technology acceptance model for hedonic information systems to test their adapted model. Second, they complement this analysis with qualitative interviews with users who actually interact with the application. Besides these mixed-method studies, we could only identify three studies that employ a pure qualitative research method. Ross and Harrison [19] assess technology acceptance factors of a specific AR application based on face-to-face focus groups. Olsson et al. [20] use contextual interviews (i.e. in the natural environment of the research object, in this case shopping centers) to investigate their expectations and requirements for mobile AR applications. The only study which applies a GTM is the one by Anuar [21] who investigates mobile AR apps for tourism and how such apps influence the experiences of users. Since our research does not focus on one specific application, it provides a higher level of analysis, indicating that the results hold for a variety of different AR technologies. In addition, perceived concerns of AR users are seldomly included in existing analyses. We identified only two articles dealing with one dimension of concerns for the case of Pokémon Go, namely privacy concerns. First, Harborth and Pape [11] specifically focus on the privacy concerns of actual players of the game. They find that although privacy concerns are relatively high, people are still playing the game. This indicates that benefits potentially outweigh the concerns. Therefore, as long as developers can address current concerns with regard to a missing added value of AR, it is possible that users will still adopt AR technologies in light of privacy concerns. The results by Rauschnabel et al. [22] indicate similar conclusions. They find that privacy risks have no significant effect on the attitude towards playing Pokémon Go. Besides these articles, other analyses of the different concerns could not be found.

3 Methodology

Our qualitative research approach relies partially on techniques of the GTM [10]. The GTM constitutes an inductive and comparative methodology for the development of theory grounded in systematic data collection and analysis. The theory involves an iterative process, moving back and forth between data gathering and data analysis; hence, it constitutes focused data gathering and makes the analysis more theoretical. At the center of grounded theory lies the constant comparative method, that is, new data is constantly compared with previous data to draw conclusions from similarities and differences within the data. We apply techniques from the constructivist grounded theory by Charmaz [23]. Constructivism assumes the existence of multiple social realities constructed by the research subject and the researcher and aims to interpret and understand the meaning of the constructed reality [8]. Since we think that interaction effects between researcher and interviewee are important to account for, we lean towards the constructivist GTM by Charmaz [23] in our research. GTM is a commonly used approach in the Information Systems (IS) domain for conducting qualitative research [24]. In a recent article, Wiesche et al. [24] provide a classification of 43 articles using GTM in the major IS outlets. The GTM is mainly supposed to generate a theory for a certain phenomenon under investigation. However, another purpose of GTM is to create a rich description of a phenomenon, in our case the possible concerns of individuals with respect to AR technologies. Since the GTM makes it possible to understand a certain problem from a variety of different perspectives, it is well suited for analyzing user perceptions about AR to generate specific recommendations for AR hardware and software developers to address these issues. We provide an overview of the single steps in the following sections.

3.1 Research Problem

As described earlier, the research objective of this paper is to analyze the individuals' concerns about AR technologies. For that purpose, we gathered data through intensive interviewing and created a semi-structured interview guide for conducting the interviews. Our interview guide is characterized by open questions and a high level of flexibility. This means, that we changed the interview guide according to new insights from already conducted interviews, e.g. by including interesting questions which came up in prior interviews. During the first interviews, our questions were rather generic. We asked interviewees about their personal experiences with AR, their beliefs about why AR is used, which application areas are favorable and how these use cases change in the future. Furthermore, we wanted to know the interviewees' assessments with regard to these future developments. When participants mentioned certain issues, barriers for adoption or concerns with regard to AR, we followed up on statements and investigated different dimensions of the statements in an explorative manner. The highly flexible approach with respect to the interview guide allowed for this procedure. Consequently, our questions were more guided during the last interviews when we focused on assessing whether our categories are saturated and whether they were covering the relevant sub-dimensions.

3.2 Data Collection Procedure

The requirements for including participants in the sample are the following. As the AR technology constitutes a new concept that is hard to compare with prior user experiences, the most important aspect for the initial sampling is that participants could answer certain questions correctly and, by that, showed either a certain degree of knowledge or actual experience with AR. Thus, we distributed questionnaires to potential interviewees to test this knowledge. We included interviewees in the sample when we could observe that this knowledge was sufficient. One of the interviewees is an expert in the field of AR with long-term experience in the field (interviewee 3).
After we conducted the first interview, the audio file was immediately transcribed and coded, and memos are written to reflect the discovered patterns and processes. Consequently, more data is gathered which focuses on the identified categories and their properties. This strategy is called theoretical sampling. Theoretical sampling aims to define the categories and their properties [23]. Our initial interviews include participants who exhibit diverse characteristics, including variation in age, gender, jobs, and distinct relations to AR, which we tested in the preliminary questionnaire. Our aim was not to create a sample that represents society, but to increase the potential variation within the data. We selected the participants according to two different strategies. The first strategy is to elaborate the new properties and dimensions of existing concepts based on participants who are similar to earlier interviewees (minimal comparison). The second strategy addresses the development of new categories and properties based on interviewees with different attributes (maximal comparison). The resulting categories, which are successively differentiated and enriched, thus control the further sampling process. The sampling process can stop when no new categories arise and the

properties of the identified categories are saturated. Saturated categories imply that gathering new similar and contrasting data does not lead to any new findings. Therefore, sample size is not the most important criterion when conducting a grounded theory research. For example, Bowen [25] states that a sample of 10 interviews done by a skilled interviewer could lead to more powerful insights than 50 interviews done by a novice. In this study, we conducted new interviews until no new categories or properties of categories emerged. This process led to a total of twelve analyzed interviews with a minimum length of 42 minutes up to 56 minutes (cf. Table 1).

Table 1. Demographics of the Interviewees

Interviewee	*Age*	*Gender*	*Education*	*Sector*
1	25-29	male	Bachelor	Consulting
2	30-34	male	Diploma	Consulting
3	45-49	male	Master	AR Industry
4	20-24	male	A Levels	Logistics
5	20-24	male	A Levels	Technical Services
6	25-29	male	Bachelor	Car Engineering
7	50-54	male	Diploma	Teaching
8	25-29	female	Bachelor	Information Mgt.
9	30-34	male	Master	Machine Construction
10	15-19	female	A Levels	Industrial Engineering
11	25-29	female	A Levels	Law
12	25-29	female	Bachelor	Managerial Economics

3.3 Initial and Focused Coding

In order to gain insights, to raise the analytical level of these insights and to construct theory from the gathered data, it is important to stop and analyze what has been found during the interviews. Analytic questions are asked to direct and further shape the following data gathering and to structure the data in a way that enables constructing theory. This step is called coding: Pieces of data are labeled to summarize and categorize the available data. Coding provides a tool to sort, structure and analyze a huge amount of data. For coding the data, we used the software package MAXQDA12. Grounded theory uses at least two phases for the data analysis, namely initial coding, in which the gathered data is analyzed line-by-line and segment-by-segment (initial codes fits the data closely); and focused coding, in which the most important and recurring initial codes are structured, integrated and arranged to gain analytical in-depth insights [23]. We used the most frequent initial codes that appear promising to reveal insights about concerns as focused codes. Where it was possible and provided analytic value, we aggregated different initial codes into a focused code that has a broader and more abstract view on the actions and their underlying patterns. After we defined a focused code, we compared it with previous and additional data to refine this code and to identify properties that can provide more insight.

3.4 Memo-Writing, Generation of Categories and Integration of Results

By applying the coding techniques, the data reveals certain structures and details. However, a link between the analysis of data in the coding phase and the creation of a theory or rich description that underlies the actions that have been identified remains absent. Memo-writing provides this intermediate tool and builds the bridge between the collection of data and a potential theory [23]. We used memos to summarize the statements of the interviewees, compare the statements made by participants to other statements in the same and prior interviews, structure patterns and processes of multiple interviews and to raise focused codes to conceptual categories.

The identified categories are the different dimensions of concerns. They represent the highest abstraction level of our analysis. They are defined by the mostly named codes which form the different sub-dimensions of this category (cf. Figure 1). As described earlier, these codes are closely linked to the data.

4 Results

An overview of the results is presented in Figure 1. The figure illustrates the abstraction process that emerged from applying the method described in the previous section. Categories represent the highest level of abstraction. We find that there are four dimensions of concerns of individuals with regard to AR technologies, which constitute the categories in our results. The dimensions are concerns about social consequences due to the use of AR, concerns about privacy, security and concerns about the missing added value AR might generate for the users. Figure 1 also shows the number of initial codes which form a sub-dimension (first number in parentheses). In addition, the second number shows how many different interviewees mentioned these codes. We will discuss each of the category in this chapter in more detail and provide exemplary statements from the interviews in Table 2.

4.1 Concerns about Social Consequences

This category is one of the most complex concepts due to the nature of AR, especially when considering HMDs. The first sub-dimension is the ***potential misuse of AR*** technologies. This focused code is closely linked to privacy concerns, but still different. The interviewees are not only concerned about the increasing possibility to gather data through the high pervasiveness of AR devices, but also about the potential consequences in their social life like a job loss. It is striking that the big benefits of AR, like constant analyses of the real environment, basically cause the concern about misuse scenarios. A strong ***involuntary exposure to ads ("Receiving Ads involuntarily")*** through AR devices is mentioned regularly amongst the interviewees. This concern is specific for HMDs considering the statement of interviewee 4. The other interviewees stated similar concerns about a constant flow of influencing advertisements. Considering the current state of internet marketing with an already high degree of ad exposure, it will be interesting to see how the relevant AR platform or device providers for HMDs deal with this situation.

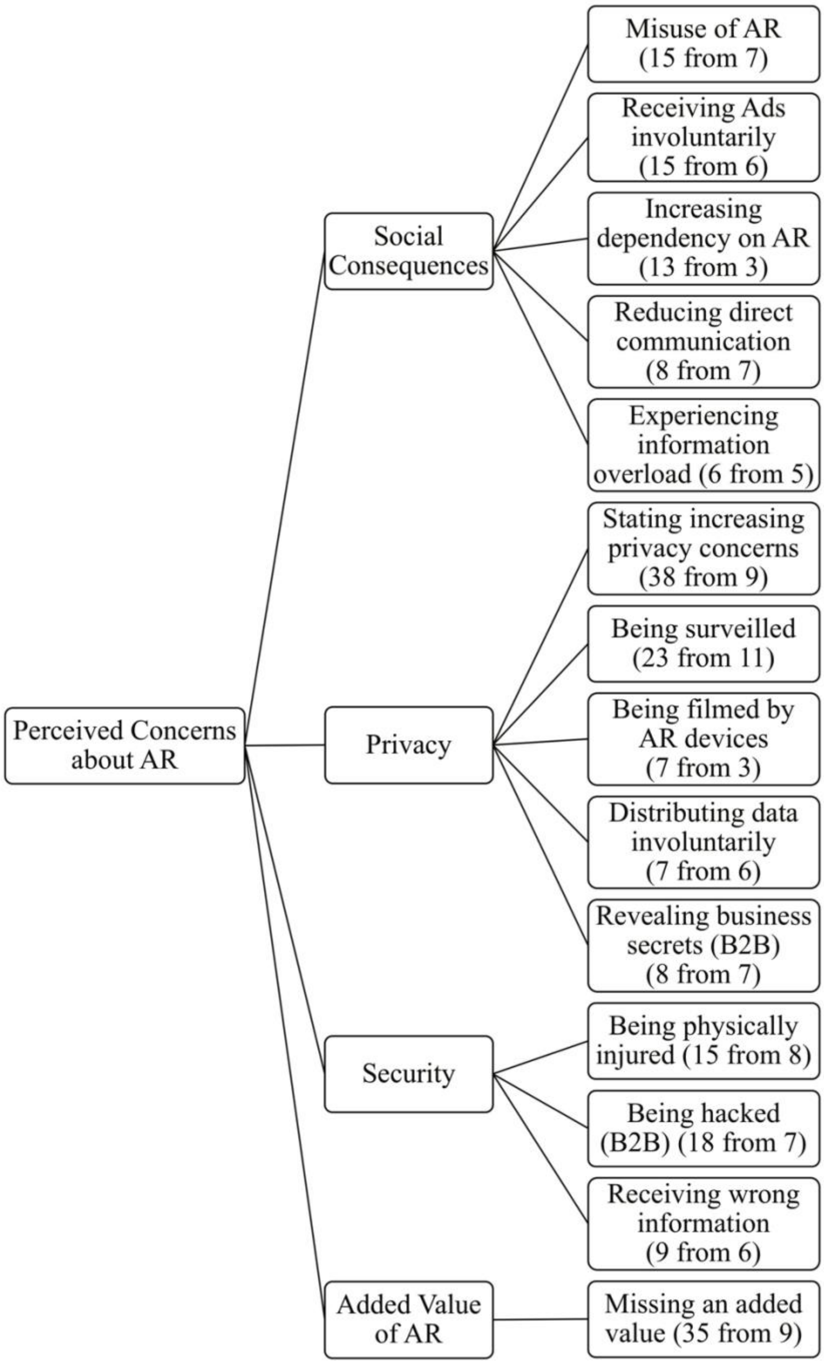

Figure 1. Results of the qualitative analysis process. The parentheses show the number of initial codes from different interviewees (e.g. the sub-dimension "being surveilled" is formed by 23 different initial codes, mentioned by eleven different interviewees)

It is promising to think about that form of advertisement from an economic point of view since users can be confronted with ads at the right place at the right time [26]. The third sub-dimension is about the ***increasing dependency on AR***. Our analysis reveals that the interviewees oftentimes refer to the smartphone when making certain judgements. Here, the exemplary statement also shows this comparison. Interviewee 7 sees a problem in a technology-dependent individual. For AR these concerns are apparently worse than for the smartphone. The next sub-dimension is related to the previous one. It emerges out of several interviewees saying that AR is most likely to ***reduce personal communication ("Reducing direct communication")*** amongst individuals even more than it happens already with the smartphone. This sub-dimension as well as the previous one are difficult to influence by AR developers or managers since they are problems inherent to several forms of AR devices like HMDs. The last sub-dimension is about concerns about ***experiencing an information overload*** when using AR. Information overload is a well-known problem in the digital sphere [27], encapsulated by the quote of Nobel laureate Herbert Simon when he said that "[...] a wealth of information creates of poverty of attention". Our analysis shows that individuals are rather not concerned about the sheer amount of data that is shown to them, but rather about the quality of information. Too much ”bad” information causes an information overflow since it is hard to differentiate which information is useful and which is not. This concern can be addressed by a well thought out information supply. Lastly, concerns about wearing HMDs in the social environment are not prevalent in this analysis. This is interesting since the media reported about incidents where people with the Google Glass were attacked by other people in their environment [28].

4.2 Concerns about Privacy

The literature provides several definitions of privacy and it can be said that Privacy is a concept in disarray. Nobody can articulate what it means [29]. In the context of this paper, a useful privacy definition is the one by Culnan, who states that privacy is the ability of an individual to control the access others have to personal information [30]. Our analysis of the privacy concerns matches the importance of control over personal information for individuals for several dimensions. The category privacy concerns is mainly about five sub-dimensions of concerns. First, interviewees perceive ***increasing concerns due to AR compared previous technologies*** like the smartphone. As interviewee 10 points out, this is mainly due to the perception that AR captures a larger amount and diversity of data. Closely linked to this, is the fear of ***being surveilled*** by government or other able parties. In contrast to this perspective, we find that interviewees also express concerns about the case where individuals ***being filmed*** (as bystanders) by an AR device worn by someone else. The next sub-dimension is about the ***involuntary data distribution ("Distributing data involuntarily")*** due to using AR. Besides following the prevalent law of the country, AR companies should provide transparency to show people what is being filmed, analyzed and stored to overcome these concerns. The last sub-dimension shows a different perspective by clearly focusing on business secrets. ***Being able to keep company information safe ("Revealing business secrets (B2B)")*** is apparently a prerequisite for a wide adoption of AR technologies in the business environment and need to be considered carefully when designing AR software and hardware.

4.3 Concerns about Security

Our analysis shows that security concerns can be divided into some kind of safety concerns, concerns about getting hacked (mainly mentioned in the B2B context) and concerns about receiving wrong information in the devices. Concerns about ***physical injuries ("Being physically injured")*** also came up in research articles and the press during first months after the appearance of Pokémon Go [31]. In our sample, interviewee 3 mentions potential long-term eye injuries due to the used technology. ***Concerns about hacks ("Being hacked (B2B)")*** are immanent when discussing security. The same holds for the possibility of ***receiving wrong information***. This is possible through malfunctions in the corresponding systems which can possibly lead to damaging exertions of influence.

4.4 Concerns about the Added Value of AR

The last category about the added value of using AR is not as fine-grained as the others. The only focused code we could identify is ***"missing an added value"***. However, it is a reoccurring theme across the interviewees that AR currently provides not enough added value because the technology is not mature enough. This evaluation of the interviewees is shared amongst several experts in the field of new technologies and AR. For example, Tim Cook, CEO of Apple, stated that "AR is going to take a while, because there are some really hard technology challenges there. But it will happen, it will happen in a big way, and we will wonder when it does, how we ever lived without it. Like we wonder how we lived without our phone today" [6]. Our results combined with such evaluations show that AR (especially in the form of HMDs) certainly needs more time and technical maturity to become a technology that is accepted in the end consumer market. In addition, the importance of showing a clear benefit of a certain AR technology to the customer has to be considered. Especially many mobile AR applications are rather designed to show the new possibilities of overlaying information over the real environment. However, only few of them provide a level of utility high enough in the users' daily lives so that they could represent more than just a shenanigan to once use for a few hours.

Table 2. Exemplary Quotes for the Sub-Dimensions from the Interviewees

Sub-Dimensions	Exemplary Statements
Misuse of AR (Section 4.1)	*And that [the data gathered through AR devices] could eventually be used against me sometime. If I say, I worked for my job. But then I was somewhere else and I used augmented reality to look something up, then it could actually be somehow used against me.* (interview 8) *Yes, so it could be [...] that my video recordings or my audio recordings or my behavior in principle by the use of augmented reality gets unlocked*

	for individuals or companies, where I usually do not really want, that they get this data. Be it any advertisers who use this data to send me personalized advertising or insurance, for example, who knows if I drive a little bit too fast in my car now and the augmented reality glasses will pass this data on to my insurer, who will then think about whether or not he will charge me the more expensive premium. (interview 1)
Receiving Ads involuntarily (Section 4.1)	*I would not want to be penetrated every day with any ads that I have to see. I mean, by that, I'm also influenced. That means, that the consumer is permanently influenced in the end.* (interview 4) *So that it now collects data about me, for example, what kind of clothes I normally wear, and when I walk past C&A, it then sends the data to me ah here you like to wear jeans or shirts and we just have shirts here on sale or something. So that would be where I would say, I do not want to see any ads unless I want them explicitly, but I cannot imagine that for my case.* (interview 2)
Increasing dependency on AR (Section 4.1)	*[...] the same positive and negative effects that had the smartphone, only reinforced. Even less self-responsibility, even more is transmitted, even more is automated, even less thinking [required by the individuals] in the negative sense.* (interview 7) *That somehow this [AR] manages this balancing act to have a noticeable advantage for me without that I feel so dependent on it.* (interview 8)
Reducing direct communication (Section 4.1)	*With them [smartphones] the social problems have increased. Social contacts are focusing a lot on the digital world and that social life, which normally exists, has already declined to a certain extent. And I also think Augmented Reality will reinforce that because it's not really necessary to meet friends, if you can see them in a live broadcast over the glasses, or yes, you can communicate directly via all possible communication media. And also has the feeling that you are sitting directly opposite a person.* (interview 12) *So everything that makes everyday life easier, you can clearly assume that that the society is getting lazy, more and more cumbersome. You can already see that. Um less communicates with each other, but more relies on devices. This is increasingly becoming a problem. So, you rely more and more on mechanics, more and more on technology and um, the trend is likely to continue.* (interview 4)
Experiencing information overload (Section 4.1)	*On the one hand, the data must come in smoothly, there must be no great delays, the data must be adapted, there must not be a flood of information, which is useless.* (interview 7) *Simple, that so to speak, that the reality gets into the background and just this information, this added information umm gets the upper hand and uh distracts you from possible events.* (interview 1)
Stating increasing privacy	*Now many see privacy as their private messages or at home private rooms, and through augmented reality you would be potentially recorded in these private rooms. And then perhaps, privacy is defined only for individual rooms, individual conversations or one has to say, that one is*

concerns (Section 4.2)	*private, if no one wears these glasses or so. Because I think that one already gives up parts of his privacy for it. Not that it might be unintentional or something, because we also use cell phones in our private rooms, but I think you could intervene in a different way [with AR devices]. Yes.* (interview 10) *And if you are in some kind of private sphere where you do not want visual or auditory information to leak out. I would probably still resign from it [using AR technologies] in this area until I am really sure that there prevails a sufficient privacy protection.* (interview 9)
Being surveilled (Section 4.2)	*[...] but most devices film the environment all the time, which is usually not recognizable for the surrounding people. And because of that, it would theoretically be possible to gather all the data and make a large-scale surveillance possible.* (interview 6) *Although we already have a lot of camera surveillance, you would also appear in the data of other people. So, by the fact that everyone could be monitored by anyone or just filmed.* (interview 10)
Being filmed by AR devices (Section 4.2)	*[...] if the technology would come to use in everyday life and [...] video material, for example, from different people walking around would be collected, then this would of course limit the privacy of the people according to current law* (interview 1) *For example, in my home I would not want a camera to permanently record my, yes my, apartment or my surroundings. My yes, my living situation or even if I am in the bathroom or something similar, that I am permanently filmed there.* (interview 12)
Distributing data involuntarily (Section 4.2)	*[...] what is recorded, is it recorded at all, how is it processed, where is it stored. I think that would be all the questions I would ask myself if I have such a device in my hand, because I'm very interested in the question, who can still see what I see?* (interview 5) *[...] I will probably never be able to control what it [the AR device] transmits, that is, which areas of my field of vision and whether it cuts out certain areas of my visual field so that people I see are not transmitted. I do not think we will have such options for an end user device. Basically, I would like to have a variety of granular options, for example, I want to say, I do not want data about other people to be transmitted or I do not want conversations with other people to be shared.* (interview 7)
Revealing business secrets (B2B) (Section 4.2)	*[...] um, because that's what the company lives on, that it's the only one who knows this information. That's why the problem is that you give the augmented reality application information so that it can process them furthermore, but this information must not be allowed to go outside. That's why I think companies need to establish a specific regulation where augmented reality can and cannot be used.* (interview 11)
Being physically injured (Section 4.3)	*Of course, there is much discussion with the glasses. What impact will this have on the eyes in the future? Umhm, above all new topics like light field technology, projections in the eyes and so on. Does it leave any damage in the long term?* (interview 3)

	There were also some cases in which you were so deepened in that [MAR applications] so you may also provoke accidents in the real world, because you do not see, for example, a lamp post, because somehow it is covered by other things. (interview 10)
Being hacked (B2B) (Section 4.3)	*Um, like all technical devices or even software, it is of course hackable, vulnerable.* (interview 2) *But in itself we would have the same concerns [as for smartphone and laptop use and storing data in data clouds] that our data could be passed on to third parties or these glasses could be hacked and this is currently also the case.* (interview 10)
Receiving wrong information (Section 4.3)	*[...] a set of algorithms behind it that can make mistakes, have wrong data, or possibly deliberately push in the wrong direction in the sense of propaganda. This is of course also possible if you are now really sitting at a data source and a large part of the people uses data similar to Google. That you can put your political mark on it, too.* (interview 7) *[...] gaps or IT-security deficits can be exploited very quickly and I think, examples would be the insertion of false information [...]* (interview 5)
Missing an added value (Section 4.4)	*So, if I refer it to myself now, [...] I think, as I said earlier, that it is not mature enough at the moment to really bring much benefit to me or change or facilitate my life drastically now, or so.* (interview 11) *[...] and above all, the question is what does it really bring me now? So, does it make sense now to buy a license for one hundred thousand euros to save a [previously used] device, but in the end it [AR glasses] shows me exactly the same information, but in a different form.* (interview 2)

5 Discussion

Our analysis provides a rich description of the different concerns expressed by the interviewees. We find that the main dimensions are concerns about social consequences, privacy, security and the missing added value through using AR. The results have practical implications for hardware and software developers as well as managers in AR companies with respect to specific design decisions that may weaken these concerns and foster future market adoption. As an example, our results indicate that the application of AR in the B2B context has to be accompanied with a well-thought policy on where the technology is allowed to be used and where it is forbidden. In the B2C context, AR products should be specified in a transparent way with respect to data gathering and processing. Furthermore, our research confirms the problem of the privacy of bystanders of AR users which is also found in the literature [32, 33]. Researchers, practitioners and governments have to find solutions to deal with this kind problem affecting the public sphere.

We contribute to the literature twofold. First, in contrast to the majority of earlier work on AR, we do not focus on technical issues of the technology, but solely on perceptions and concerns of potential users of it. Second, we show that individuals associate multi-faceted concerns with AR. These concerns are partially comparable to related findings about concerns with respect to smartphones. However, several sub-dimensions show AR-specific issues which have to be considered and investigated by researchers in order to overcome the concerns of potential users.

Since we applied the constructivist grounded theory approach by Charmaz [3], certain limitations arise. The method assumes a mutual construction of the reality by the researcher and the interviewee and it considers the researchers experience and view on reality. On the one hand, we choose the constructivist approach on purpose, because it supports our underpinnings and view on the world. On the other hand, we aim to minimize the personal influences on data collection to base our analysis in as much data as possible. However, our findings represent one possible version of the results which we analyzed based on our interactions with participants and the data. In addition, we did not set out to develop a model of how these concerns interrelate with each other and affect other variables like attitudes towards AR. Thus, this work only provides a rich description of the concerns related to AR as a first step to understand the perceptions of users in more detail.

Future work can build on our results to further investigate the most important concerns associated with AR technologies. A next logical step would be an extensive quantitative analysis of the influence of the different categories and dimensions of concerns on the intention to use AR, and if possible, on the actual use behavior. In addition, we could show that a qualitative approach is very useful for investigating innovative technologies like AR since most of the individuals are highly heterogenous with respect to their knowledge, perceptions and attitudes towards new technologies like AR. Thus, we recommend researchers to consider qualitative research methodologies for future user studies and evaluations to gain deeper insights into the users' perceptions and attitudes.

6 Conclusion

In this article, we identified four major categories of concerns about AR technologies. For every category, we disentangled the different sub-dimensions (if existent) and partly provided suggestions for how to deal with these concerns in order to increase the possibility of successful market entries of AR technologies in the future. Our analysis focused on AR technology in general and is therefore a first step towards a more granular understanding of concerns. Thus, the specific concerns can be more or less pronounced when looking at the specific type of AR technology. In addition, some of the sub-dimensions are not directly addressable by developers or managers (e.g. concerns about reducing direct communication or increasing dependency on AR) since they are, although very important, rather an object of a philosophical discourse that has to be conducted in the society itself.

To (Psychologically) Own Data is to Protect Data: How Psychological Ownership Determines Protective Behavior in a Work and Private Context

Margareta Heidt[1], Christian Michael Olt[1], Peter Buxmann[1]

[1] Technische Universität Darmstadt, Information Systems, Darmstadt, Germany
{heidt,olt,buxmann}@is.tu-darmstadt.de

Abstract. The ever rising rates of data generation entail new opportunities for business and society but also an increasing risk of data breaches. Apart from technical measures, approaches like password authentication to ensure data protection revolve around the end-user as the human element in information security. Drawing on organizational research which argues that the sole feeling of ownership towards an intangible target like data can lead to heightened levels of the individual's responsibility, we investigate whether and to what extent this ownership feeling differs between personal files and data accessed in the work context. To this end, we draw on data derived through a two-phase questionnaire among a representative group of 209 employees. Consequently, we find evidence that psychological ownership shows stronger effects on protection motivation among participants in a private context. Furthermore, results indicate that employees partly relinquish their responsibility regarding security responses to protect data in their work context.

Keywords: password security, psychological ownership, employee, home user, protection motivation theory

1 Introduction

According to the latest estimations in 2012, 2.7 million terabytes existed in the digital universe with roughly 35 zettabytes of data generated annually by 2020 [1]. Data generation is further fueled through the acceleration of the Internet of Things and the growth of worldwide internet users to 4 billion in 2018 [2].

Unsurprisingly, the age of big data promises new opportunities for business and everyday life but entails new flip sides as evidenced by the ever increasing frequency and amount of damage of data breaches committed by cyber criminals. Verizon's annual report estimates that 81 percent of data breaches that occurred since 2014 were caused by stolen or weak passwords [3]. An estimation particularly striking given that the most prevalent approach to both access and protect private and business data remains through password authentication. Passwords can thus be considered a particular vulnerability as they are especially intertwined with the human element in information systems – the end-user. Since end-users have been continuously identified

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

as the "weakest link" within the security chain, behavioral information security research emerged as an important subfield of information systems (IS) [4, 5].

Research on human behavior in IS security has been drawing on psychology, criminology, or health science and various adapted frameworks and models have been applied within the end-user context, examining either employee or individual private user behavior [5-7]. These models show that factors such as the certainty of sanctions, the risk appraisal of a cyber threat or perceived behavioral control are strong indicators leading to the behavioral intention to perform certain protective actions [8, 9]. However, extant studies have only identified and analyzed the effectiveness of these factors on security in *either* a work environment *or* in the context of private use [10]. Thus, it remains unclear if certain factors affect the intention to behave in a more secure way in order to protect – one's own or the company's – data even though the context-sensitivity of findings has recently received increased attention among IS scholars [11].

In this regard, existing studies [e.g., 12, 13] have suggested that the sole feeling of possession or "being psychologically tied to an object" [14, p. 299] might lead to heightened levels of individual responsibility and engagement in IS security behavior. This feeling is referred to as "*psychological ownership*", a concept that describes the self-derived perception of ownership opposed to the actual legal ownership which is backed by the perception of others and the legal system. Psychological ownership (PO) is rooted within the innate human need to experience possession of either tangible or intangible targets [15] and the sense of regarding this target as extension of one's self [16]. In turn, human desire to experience control and accountability over the target differs according to the level of PO an individual experiences [14, 17].

However, IS studies thus far have either focused on feelings of ownership towards the targets 'internet' and 'one's computer' among home-users [12] *or* towards the target 'information' in a generic work-based scenario [13]. Whereas the first study argues for a direct influence of PO on intention to protect the target of ownership, the latter theorizes how PO affects the protection motivation, i.e., antecedents of intention to protect information. Due to the dearth of research on the influence of PO on security behavior, both aforementioned studies call for future research with Anderson and Agarwal specifically recommending additional studies that "explore the differences in behavior between employees and home users" [12, p. A15]. Nevertheless, other IS studies that integrated PO into the privacy calculus [18] or explored PO of IT [19] have only examined the role of PO in one single context and have not questioned yet how levels of PO might differ according to situational differences in contexts. But do individuals really experience the same degree of PO regarding, for example, their own electronic device or one provided through their company? Or do individuals experience higher levels of PO regarding their personal data as opposed to PO regarding the data they work with – and are supposed to protect through appropriate security measures – in their professional environment?

Against this backdrop, we seek to (1) extend prior IS research on individuals' protection motivation of data by highlighting the distinct role of PO both in a work and a private context. Furthermore, our study is the first to our knowledge that actually (2) compares protection motivation based on a repeated measures study design and one distinct sample in both contexts.

The remainder of this article is structured as follows: the theoretical background of both Protection Motivation Theory and psychological ownership is presented and serves as the foundation of our hypotheses which are integrated into a research model and tested in both a work and private setting. Subsequently, the results of our study are demonstrated and discussed before implications for theory and practice are derived.

2 Theoretical Background and Hypotheses Development

The following section provides an overview of the current state of behavioral IS security research in both work and private contexts along with the basics of the aforementioned concept of psychological ownership and how it has been accounted for thus far in IS security literature. Based on the theoretical background, hypotheses are developed and integrated into our research model which draws on Protection Motivation Theory (PMT).

2.1 Information Security Research

IS research has a long-standing tradition of analyzing security-related issues on an organizational and individual level [20, 21]. In an organizational context, researchers continue to advance technical approaches to prevent intrusion or to detect attacks [22, 23], however behavioral information security research has gained considerable momentum during the last two decades by focusing on human, and in particular, end-user behavior in work and private use contexts.

Within behavioral information security research, users in a work context can generally be divided into two subgroups: users that exhibit deviant behavior, i.e., compromising information security through espionage, theft, or sabotage, and those users who misbehave without the intent to cause damage [24]. By means of example, the latter group's misbehavior can manifest itself through defiance of security policy aspects such as using corporate devices to access non-work related websites or utilizing weak, repetitive and thus easy-to-compromise passwords for important work accounts [25]. In order to understand the driving factors of such "unintended" misbehavior or to identify aspects that encourage the use of safeguarding practices, IS researchers have heavily relied on behavioral theories that originate in behavioral psychology, organizational science, criminology, or health research [6-9, 12].

Protection Motivation Theory has been widely used to analyze "any threat for which there is an effective recommended response that can be carried out by the individual" [26, p. 409] and thus serves as a widespread theory in IS security research due to its applicability to security threats such as violating security compliances [27] or losing data due to irregular backups or weak passwords [28]. At the core of PMT, attitudes of individuals are assessed through two cognitive processes which lead to an increased intention to protect oneself against a potential threat: namely, *threat* and *coping appraisal*.

Threat appraisal comprises the perception and assessment of threat severity as well as the personal vulnerability to a threat. In our security context, perceived severity of a data breach and one's own vulnerability to fall prey to such an event will affect the protection motivation regarding data. As both perceived severity and vulnerability are positively correlated with the response behavior to protect one's data, which in our case will be through strong passwords, we hypothesize:

H1a *Perceived vulnerability will have a positive effect on an end-user's intention to protect (work and private) data.*
H1b *Perceived severity will have a positive effect on an end-user's intention to protect (work and private) data.*

Once the threat is assessed, e.g., the potential severity of data loss or theft and one's susceptibility or likeliness to experience such an incident, individuals will evaluate a potential behavioral response to the threat during the so-called coping appraisal.

Coping appraisal includes the concepts response efficacy and the associated response costs of the planned coping response necessary to protect oneself from the specific threat, as well as one's perceived self-efficacy in performing the response. If self-efficacy and response efficacy outweigh response costs, an individual yields a positive coping appraisal, i.e., individuals will install anti-virus software despite the associated costs in terms of purchase price or time to install because they feel capable of performing the installation and also deem the software to be effective in averting viruses and malware [12, 28]. More precisely, response efficacy in PMT refers to the belief that a certain response performed by the individual actually leads to a reduction or elimination of the considered threat.

Regarding IS security, end-users might wonder if strong passwords actually increase the security of their own or their company's data. If this specific response is considered effective in actually decreasing the threat (such as potential misuse of data caused by unauthorized access) an individual will be more inclined towards actually using strong passwords. However, this response also entails the cognitive effort of remembering several complex passwords. The concept of response costs thus assesses all efforts and expenditures associated with the coping behavior which will have a negative impact on the intention of actually performing the response in question. We thus hypothesize:

H1c *Response efficacy will have a positive effect on an end-user's intention to protect (work and private) data.*
H1d *Response costs will have a negative effect on an end-user's intention to protect (work and private) data.*

The core nomology of PMT additionally includes the concept of self-efficacy which has also been applied in various other theories to assess IS security behavior, often as part of the construct perceived behavioral control (PBC) [8, 29, 30]. On the one hand, self-efficacy relates to the confidence of individuals in their own skill, knowledge and ability to perform the response. On the other hand, controllability, as the second aspect of PBC, describes how much of the performance is actually up to the individual [30, 31]. One example would be that employees might be hindered to implement a security measure due to missing administrator rights on their work computers. Similar to other PMT-based studies which extended their research model with elements of the models originating from Theory of Planned Behavior, we also integrate the complete concept of PBC into our model as it could serve as a differentiator between the work and private context [12, 32].

In an IS security context, end-users who are confident in their ability to perform an appropriate security measure like backing up data at home or at their workplace, will be more inclined to progress with that chosen coping mechanism. However, controllability might differ across contexts, because employees might not express the same extent of assumed controllability regarding their actions if they cannot implement a security measure due to missing administrator rights – even if they had the skill and knowledge in doing so. As a result, they might shift the responsibility to their IT department or employer. Nevertheless, if employees just like private end-user ascribe responsibility to themselves, i.e., perceive higher degrees of controllability regarding the coping mechanism, they will be more proactive in taking appropriate security measures [32]. Hence, we expect that:

H1e *Self-efficacy will have a positive effect on an end-user's intention to protect (work and private) data.*
H1f *Controllability will have a positive effect on an end-user's intention to protect (work and private) data.*

2.2 Psychological Ownership

The following examples serve as an introduction to the general concept of PO: 1) Alice and Bob, both three-year-old toddlers, erupt in a fight over a doll in a physician's practice: both children claim the doll belongs to them and attempt to protect it from the other claimant by shouting "It is MINE!" – Although, technically, the doll is legally owned by the physician. 2) Alice's mother is a project manager. She lovingly calls one of her recent projects her 'baby' and takes many project-related tasks home to continue working after hours instead of delegating tasks because she feels a high sense of commitment and ownership towards this particular project. These scenarios depict how individuals behave when they feel that they possess an ownership stake in a physical or intangible object – a phenomenon called psychological ownership.

The term PO stems from psychology and describes the sense of ownership of a target like the aforementioned doll or project, but can also be felt towards a concept, another person, or an entire organization or community. The target is seen as an extension of the self [33], i.e., the owners regard the target as an expression of themselves or feel a strong sense of belongingness towards the target – as evidenced for example by football supporters who feel strong ownership towards their football club [14, 16]. Although related, PO is distinct from legal ownership which is recognized by society and protected by legislation – whereas PO is a "condition of which one is aware through intellectual perception […] coupled with an emotional or affective sensation" [34, p. 86]. The resulting effects of PO have been analyzed and categorized into positive outcomes – such as citizenship, personal sacrifice and assumption of risk, or experienced responsibility and stewardship – and negative effects like territoriality and other defiant behavior, or personal maladies like stress or frustration if the target is subject to any form of alteration [34, 36].

The roots of PO or the reason why this cognitive-affective state exists is best explained by an innate need of having a place or belongingness to the target [15], a sense of symbolic expression though the target or self-identity [16], and the desire to experience causal efficacy through control and accountability over the target [14, 17]. Due to the versatility of the PO concept, it has found extensive application especially in management and organizational research. More recently, studies in an IS context have started to introduce PO and demonstrated its impact on system usage and appreciation of IT [19, 35], willingness to disclose data [18], or intentions to perform security-related behavior [12, 13]. However, only the latter two studies examine the role of PO as antecedent of the threat and coping appraisal or its direct effect on intention in a behavioral security context [12,13]. In line with their reasoning and to further explicate how PO possibly affects the coping and threat appraisal, we present a third example: 3) Bob's father uses a CRM application on a daily basis at work which is accessed through password authentication. He is fully aware of the criticality of customer and business data stored in the application and has an intimate knowledge of many entries since he found and recorded a lot of the information himself. The data is not simply his company's data but also his own in his perception and a loss thereof would hurt him personally. Thus, threats to the target can be regarded as threats to oneself because the target represents an extension of one's self-concept or identity. In our context, higher levels of PO will lead to heightened perceptions of severity and vulnerability when faced with the prospect of losing one's data. This will more likely occur in the context of private data as opposed to data in a work context. Hence, we assume that risk appraisal will be influenced through psychological ownership as follows:

H2a *PO of (work and private) data will increase perceptions of threat vulnerability. This effect will be more pronounced in a private context.*
H2b *PO of (work and private) data will increase perceptions of threat severity. This effect will be more pronounced in a private context.*

Intimate knowledge or a deep understanding and familiarity of an object will lead to higher degrees of association with the object [37]. This is evidenced by individuals' statements of preferring own targets to comparable others, simply because one knows them better, e.g., the favorite spot in the canteen. Acquiring knowledge about a target is also linked to investment of the self into the target which represents the third route to PO. Investing time, effort, or energy into the creation or development of a target, e.g., in a mentor-mentee relationship or into do-it-yourself-projects, facilitates feelings of PO by seeing one's own reflection in the target [34]. In organizational studies, employees who feel PO toward their company are shown to express higher levels of organizational commitment, organizational-based self-esteem, and job performance [36, 38, 39]. Subsequently, Pierce and colleagues argue that pronounced feelings of PO will influence the degree of its effects – both positive and negative [38]. In line with Menard and colleagues, we also expect that PO will exert influence on the coping appraisal considering the use of diverse and strong passwords in both the private and work context [13], and thus hypothesize:

H2c *PO of (work and private) data will increase perceptions of response efficacy. This effect will be more pronounced in a private context.*
H2d *PO of (work and private) data will decrease perceptions of response costs. This effect will be more pronounced in a private context.*

Apart from intimate knowledge of the target, and investment of the self, Pierce and colleagues also argue that perceived control is closely tied to feelings of PO [14]. Numerous studies prove that control is a core feature of ownership as objects that are habitually used or can even be manipulated by an individual become more assimilated into the user's self-concept [17]. According to Avey and colleagues, individuals will be "feeling more efficacious about working with the target, feeling more accountable for what happens with respect to the target" [39, p. 24] when they feel psychologically tied to the target. In our context, PO regarding their data will thus facilitate feelings of responsibility and as a result lead to heightened levels of willingness and confidence in their ability to carry out a protective response against the IS security threat [40].

H2e *PO of (work and private) data will increase perceptions of self-efficacy. This effect will be more pronounced in a private context.*
H2f *PO of (work and private) data will increase perceptions of controllability. This effect will be more pronounced in a private context.*

3 Research Model and Methodology

Our research model draws primarily on the approach of Menard and colleagues [12] which examines how psychological ownership affects the protection motivation based on PMT. We further extend the model with the additional construct of controllability in order to include and examine another important but yet often overlooked aspect of perceived behavioral control. In both contexts, we examine how the behavioral intention to use strong passwords in order to protect data is influenced by both the classic determinants of PMT and how these are in turn influenced by PO in our two contexts.

3.1 Data Collection Procedure

In order to investigate our research questions, we conducted an online survey among employees in Germany who use electronic devices to access software applications or websites and are interacting with company data in their professional environment on an everyday basis. Since comparing work and private contexts involves repeated measures for our research model, certain biases have to be considered and countered. In order to avoid that participants remember their answers from the first context (i.e., work) and aspire to repeat the same answer in the second context (i.e., private) to ensure self-consistency [42], we decided not to survey both contexts (work vs. private) in one single questionnaire. Furthermore, we chose to survey the same panel of respondents (cohorts) for both contexts. This enables us to investigate differences in an individual's perception handling work-related data as well as private data.

As threat scenario we chose the misuse of data caused by insecure passwords. Consequently, the coping strategy depicted the usage of strong passwords which are distinct between different user accounts. Both questionnaires were distributed online in August 2018 in two waves with the help of a market research institute. Seven days upon completion, the same cohort was invited to participate in a second survey assessing their password behavior within their private context. This timespan was chosen in order to avoid manipulating risk appraisal and coping appraisal between both conditions through unforeseen incidents or factors (work vs. private context) and is comparable to other IS studies using a repeated measures design [41, 42]. Using an even longer time-span entails the risk of external influences (security incidents and other message cues) to bias the respondents' perceptions compared to the first wave. Both surveys commenced with a welcome page which ensured the participants' anonymity and that there are no "wrong" answers in order to counteract common method and social desirability biases [13,43].

Only those participants who completed both survey questionnaires were included in the data analyses (N = 217). Since eight participants failed our attention check during the second wave, their answers were deemed unreliable resulting in a final sample size of 209. The effective response rate after the second wave – and the elimination of unreliable responses and attention checks – amounted to 70.37 percent, an acceptable rate for questionnaires considering security-related behavior [e.g., 28, 44].

The sample was evenly distributed in terms of gender (51.2 % female; 48.8 % male) and age (mean = 44.9; min = 19; max = 65) through quotas mirroring the percentage of the overall population in Germany and thus providing an adequate snapshot of reality of German employees. We report a more detailed sample statistic in the online appendix (Table A1).

3.2 Operationalization of Research Variables and Instruments

All measurements to operationalize our research variables are based on previously validated operationalization and have been adapted to the context of our study as we report in the online appendix (Table A2). The items for all threat related PMT constructs (vulnerability [VULN], severity [SEV]) were adopted from Johnston and Warkentin [45]. Items for response efficacy [RE] have been extracted from Witte [46] whereas response costs [RC] as well as self-efficacy [SE] were adapted from Milne at al. [41]. Controllability [CON] was measured using the scale from Kraft and colleagues [47]. Our dependent variable behavioral intention [INT] has been operationalized using items from Herath and Rao [25] whereas psychological ownership [PO] has been adopted from van Dyne and Pierce [38].

4 Data Analysis and Results

Our data set contains 209 responses for each context based on the same respondent cohort. Therefore, we distinguish between two contexts: the work versus the private context. In the following, the hypothesized relationships between variables are analyzed relying on the PLS algorithm as implemented in SmartPLS in order to simultaneously validate the measurement model and the conceptual path model [48].

Measurement Model Testing. We begin by assessing convergent validity of all our variables for each condition (work and private). Internal consistency can be assumed for constructs if Cronbach's alpha (Cr α) as well as composite reliability (CR) are at least 0.7 [49]. To establish convergent validity, the average variance extracted (AVE) should exceed 0.5 [50]. In addition, item loadings are assessed against a threshold of 0.65 or higher [51]. We find minimum loadings of 0.707 / 0.840 in the work and private context respectively. Therefore, we conclude that convergent validity is ensured.

Table 1. Measurement Model Validation

	Work Context

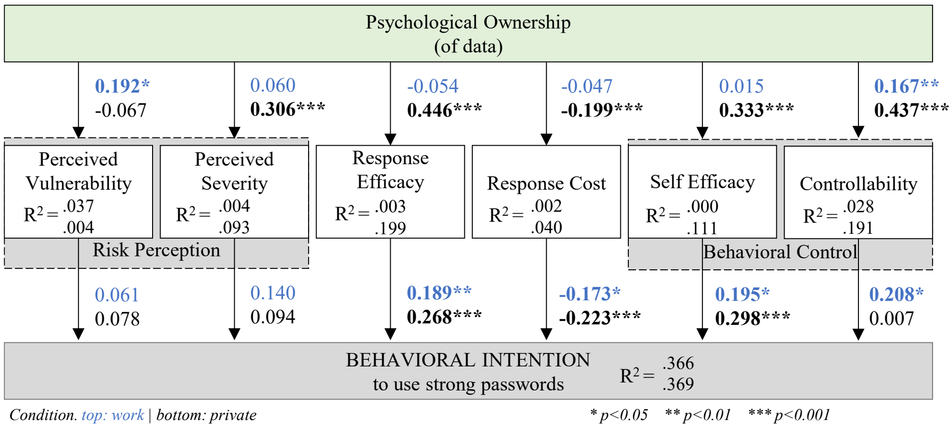
	Private Context										
	Cr α	CR	AVE	CON	INT	PO	RE	RC	SE	SEV	VULN
CON	.937	.954	.840	**.916**							
INT	.930	.955	.876	.366	**.936**						
PO	.888	.931	.818	.437	.297	**.904**					
RC	.949	.963	.867	.582	.364	.446	**.898**				
RE	.881	.926	.807	-.354	-.446	-.199	-.070	**.931**			
SE	.881	.927	.810	.399	.514	.333	.189	-.746	**.900**		
SEV	.929	.950	.825	.252	.260	.306	.364	-.080	.137	**.909**	
VULN	.898	.928	.762	-.235	-.102	-.067	-.171	.356	-.209	.095	**.873**

For acceptable discriminant validity, we rely on the criteria suggested by Fornell and Larcker [52]. Accordingly, the square-root of AVE (**bold** numbers in Table 1) needs to be greater than the correlations to all other constructs. Since this holds true for all constructs within both conditions, we assume our measurement model to be accurate as further evidenced by cross loadings reported in the online appendix (Table A3).

Structural Model Testing. Continuing with the validated measurement model, we assess the overall model fit of our conceptual models. The standardized root mean square residual (SRMR) is 0.066 resp. 0.046 (work resp. private) which is well below the cutoff-point of 0.08 recommended by Hu and Bentler, indicating a good model fit [53]. The amount of variance explained within our dependent variables (R^2) are presented in Figure 1. We use a bootstrapping procedure with 5,000 subsamples to test for statistical significance of path coefficient estimates which results are also reported.

Figure 1. Results of the PLS Model Estimation



Work context. In the work context, all hypotheses based on PMT (H1c, d, e, f) except for risk perception, i.e., perceived vulnerability and severity, are supported. Furthermore, psychological ownership of data shows only significant influences on the variables perceived vulnerability (H2a) and controllability (H2f).

Private context. The results show that risk perception has no significant influence on behavioral intention to use strong passwords in the private context. Nevertheless, response efficacy, response costs and self-efficacy significantly influence behavioral intention to use strong passwords and thus support H1c, d, e. The expected effect of controllability on behavioral intention is not supported. However, PO has a strong influence on the majority of PMT related constructs (H2b, c, d, e, f supported) whereas the effect on perceived vulnerability could not be supported in the private context (H2a rejected).

Multi Group Analysis. As an extended analysis of the differences between the two contexts, we conducted a multi group analysis. Due to space limitations we report hypotheses which ultimately show significant differences in their path-coefficients only in our online appendix (Table A4). Hereby, the context shows a mediating effect on H1f and H2a as the effects are stronger in the work context compared to the private context. The context furthermore mediates all other relations from psychological ownership. Hence, the effect of psychological ownership is stronger in the private context compared to the work context for H2b, c, d, e, f.

5 Discussion and Contributions

With this study, we contribute to a better understanding of PMT according to the situational context and via an extension through PO. By using a repeated measures design, we are able to demonstrate varying mechanisms leading to the intention to protect either private or work data through strong passwords. Specifically, our results demonstrate that risk appraisal through perceived severity and vulnerability does not significantly affect the intention to use a security measures such as strong passwords which is in line with some recent findings of other researchers [8, 13].

Furthermore, we find significant differences regarding the effect of controllability across contexts: whereas a significant effect of controllability on the intention to use strong passwords indicates that employees feel accountable for their choice, this effect could not be shown among private end-users. This might indicate that they do not even perceive an opportunity to shift control, and thus accountability, to some third party such as the employer. Therefore, we find evidence that individuals in the private context are aware of their sole accountability when responding to security threats. Otherwise, we found the influence of coping appraisal to be generally stronger in a private context.

Similarly, but opposed to the study of Menard and colleagues, we could demonstrate lesser and mostly insignificant effects of PO on PMT antecedents in a work context [13]. PO effects are mostly only significant in a private context apart from the hypothesized influence on perceived vulnerability – which, in turn, is only evident in a work context – and with controllability which is significant in both contexts. Additionally, a post-hoc performed paired t-test ($t(208) = -20.36$; $p < 0.001$) of PO according to the condition work ($M = 3.07$; $SD = 2.77$) or private context ($M = 5.89$; $SD = 1.34$) showed significant differences. Accordingly, we can subsume that PO is more pronounced considering the protection of private data and, as individuals tend to evaluate a target more favorably when they own it, feelings of accountability, responsibility, and investment of the self in the target are stronger [34, 38, 39]. This leads to several potential implications for both theory and practice.

Theoretical Contributions. From a research point of view, our approach is the first to our knowledge that is based on a repeated measures design which enables the comparison of PMT's explanatory power in a work and private context based on the same safeguarding behavior, i.e., the use of strong passwords. Our study contributes to an improved understanding of the relationships within the theory and shows varying support of the general concepts of risk and coping appraisal. Risk perception in isolation does not promote safeguarding measures in any context, whereas the inclusion of controllability could contribute to more thorough understanding of employee intention regarding the use of strong passwords. Additionally, our findings contribute to the still scarce literature on psychological ownership in IS security. IS research and studies on information security in particular, have incorporated PO very rarely and diversely in terms of context and the mode of influence which calls for replication studies as called for by Menard et al. or Anderson and Agarwal [12, 13]. In this regard, we could demonstrate that PO significantly influences several PMT antecedents only in a private context and barely affects the protection motivation among employees.

Practical Implications. As such, our study informs IS scholars but also practitioners about how a sense of ownership can regulate protection motivation and thus lead to the actual use of safeguarding mechanisms like strong passwords. Practitioners in particular should stimulate feelings of PO regarding company data in order to increase protection motivation. PO can, for example, be increased and stimulated by tapping into its antecedents, e.g., through more intimate knowledge of the target, in our case data. Also if employees invest more time and effort into understanding how data can be protected, employees will develop a feeling of freedom of choice and more accountability which in turn increases PO and thus exert a positive effect on safeguarding mechanisms [19].

6 Conclusion, Limitations, and Future Research

Despite taking all necessary measures to ensure qualitative results, our study is not without limitations. In this regard, a typical limitation of behavioral IS theories is the measurement of intention rather than actual behavior. Although intention is widely regarded to be a very robust predictor of actual behavior [29, 54], future research could build onto our findings with an experimental design that observes the influence of PO on actual behavior. Similarly, previous research has identified several other influencing factors like culture or personal characteristics which had to be omitted due to duration constrains but could enhance our understanding about the modes of action of PO in an organizational and individual security context. Especially, since culture has been shown to have an effect of the level of PO expressed, our results could be culturally constrained to Western, more individualistic, cultures [13]. From a methodological point of view, the rather short timeframe of our two surveys might add to the general finding that humans strive for a consistent manner of self-representation which might result in memory effects or so-called experimenter demand effects [42, 43]. However, an extension of the time frame might be affected by unidentifiable external influences due to unforeseen incidents or other biases that arise during the survey period.

An avenue for future research could be the analysis of PO antecedents through an action research design measuring whether increased feelings of PO also lead to improved actual security behavior in both a work and a private context. Our study thus serves as an important stepping stone which first compared the behavior of individuals in these contexts in a repeated measures design revealing varying degrees of effect sizes in well-established PMT and newly hypothesized PO relationships. Furthermore, future research could develop a new operationalization of PO for the IS context, as current measures are often based on physical, tangible targets. A different approach could be the use of an Implicit Association Test which can detect underlying attitudes of users or consumers particularly when subjects are unaware or unwilling to identify sources of influence – like PO in our context [55]. This could prove to be particularly interesting since an additional estimated PLS model including a path from PO to intention showed that no direct influence on intention was found in both contexts as opposed to the previous studies. This could be related to the differences in targets as one's own device might elicit more pronounced feelings of PO compared to intangible data or the operationalization of PO through scenario manipulation and represents another possible avenue for future research [11].

7 Acknowledgments

This research project was funded by “Hessisches Ministerium des Innern und für Sport”. We express our gratitude to everybody involved in enabling us with the conduct of this study – in particular to Henrik Schlünkes and Zhengchao Wu.

Understanding Data Protection Regulations from a Data Management Perspective: A Capability-Based Approach to EU-GDPR

Clément Labadie[1], Christine Legner[1]

[1] Faculty of Business and Economics (HEC), University of Lausanne, Switzerland
{clement.labadie, christine.legner}@unil.ch

Abstract. The European General Data Protection Regulation (EU-GDPR) has entered into force in May 2018. Its emphasis on individual control and organizational accountability constitutes a new paradigm that requires changes in the way organizations manage personal data. However, organizations face difficulties when implementing EU-GDPR due to a lack of common ground between legal and data management domains. Anchored in the resource-based view theory (RBV), this paper argues that the regulation requires companies to build a dedicated data management capability. It presents a capability model that was developed in an iterative design science process, integrating both interpretation of legal texts and practical insights from focus groups with more than 30 experts and from 3 EU-GDPR projects. The paper advances the regulatory compliance management literature by translating legal data protection concepts for the IS community. It also contributes to practice by enabling organization to set-up systematic approaches towards EU-GDPR compliance.

Keywords: EU-GDPR, Data Protection, Regulations, Compliance, Capabilities.

1 Introduction

In 2017, The Economist published an article entitled "The world's most valuable resource is no longer oil, but data" [1], mirroring the transformation of our modern economies, in which massive data collection and analysis have become a key competitive advantage. This transformation had led the European Union (EU) to start a major reform of its data protection framework, which resulted in the adoption of the General Data Protection Regulation (EU-GDPR) in 2016, and its enforcement in May 2018. The EU-GDPR constitutes a paradigm shift in data protection, towards greater choice and sovereignty for individuals, and more accountability for organizations [2]. For organizations, it comes with the burden of proof related to whether, how and how well they protect personal data and increased fines for noncompliance. This requires them to fundamentally rethink the way they store and process personal data on an

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

enterprise-wide level. Despite the past deadline, most companies have not yet reached full EU-GDPR compliance. A study conducted in April 2018 among more than 1000 European and US companies reported that 40% of respondent organizations would not comply on May 25th, 2018. And even if companies have started to address GDPR, only 23% of US-based companies and 31% of EU-based companies stated that they were confident with their ability to comply [3].

The difficulties in implementing EU-GDPR highlight the general lack of common ground between legal and IS in both research and practice. From the research side, legal aspects of information privacy were not among the "topic areas closer to the interests of most IS researchers" [4], and the few IS studies on EU-GDPR have a very restricted scope. Similarly, in most companies, data protection topics have traditionally been addressed by legal departments by adapting contracts and general conditions, but without directly influencing data management practices. However, the new regulation does not allow for such a restricted approach, and companies see data processing related issues as the most challenging topics in EU-GDPR. In fact, preparing for data breach notification, operationalizing data portability, operationalizing the right to be forgotten and conducting data inventory/mapping were cited as "most difficult GDPR obligations to comply with" [3]. Furthermore, our interactions with practitioners indicate that the regulation is very generic, and that there is a need to translate it into data management concepts and practices. This "translation" would help analyze compliance requirements and options, before deciding on concrete (technical) implementations.

Anchored in the resource-based view theory (RBV), this paper argues for utilizing capabilities as an interface between abstract compliance requirements and their concretization. It aims at addressing the following research question: what data management capabilities need to be built in order to address EU-GDPR's requirements? Following a design science research approach, we propose a capability model for EU-GDPR that integrates both interpretation of legal texts and practical insights from focus groups with experts from 22 companies as well as 3 EU-GDPR related projects. The resulting capability model comprises organizational and system capabilities from a data management perspective. In contrast with the few existing research papers on EU-GDPR that treat selected aspects of the regulation, such as data breach notification or data portability, our study thereby provides an integrated perspective on enterprise-wide data management practices. The resulting capability model may also act as a classification framework for those studies that investigate specific aspects of the regulation.

The remainder of this paper is structured as follows: we first introduce the EU-GDPR as well as an overview of current research on the topic and on regulatory compliance in general. After outlining the research methodology and process, we motivate the capability perspective and present the capability model. We conclude by summarizing our contribution and discussing future research.

2 Background and related research

2.1 The European General Data Protection Regulation (EU-GDPR)

In January 2012, the European Commission published a proposal for an overhaul of data protection law within the European Union, which would become EU-GDPR[2]. It thereby addressed the need to remedy the fragmented implementations of the preceding Data Protection Directive (95/56/EC), as well as to account for the significant changes introduced by the internet and digital services [5], [6]. As a result, EU-GDPR directly applies in every EU member state. Moreover, any organization that processes personal data of EU-citizen must comply with it, regardless of the geographical location of their operations. If it fails to do so, fines with significantly heightened amounts will apply (i.e., up to 20 million euros or 4% of an organization's global revenues, whereas previous regulations averaged at ca. 500 000 euros). EU-GDPR reinforces existing concepts, and introduces new ones. Most notably, existing transparency mandates have been strengthened – organizations must now inform individuals about data processing in clear language and separately from general conditions, and are also required to present more granular consent options [5]. One of the major additions is the concept of accountability, which implies that organizations must be able to demonstrate compliance with the regulation. They must also appoint data protection officers (DPOs) and announce data breaches to both authorities and individuals (data breach notification). Privacy-by-design principles (i.e., implementing privacy from the ground up in systems and offerings) also appear in the regulation, along with new individual rights, such as data portability as well as a right to oppose automated decision making [5]. All of these evolutions constitute a paradigm shift in data protection, towards greater choice and sovereignty for individuals, and more accountability for organizations [2], [6], [7].

2.2 EU-GDPR and Data Protection in IS Literature

Although EU-GDPR was finalized in 2016 and presents a major paradigm shift in data protection, it has attracted relatively little attention in IS literature so far. A query with the keyword "GDPR" returns 27 results on the AIS Electronic Library, as the time of writing (September 2018). The majority of these papers simply mention EU-GDPR, but only seven studies treat it as key topic. From Table 1, we see that existing EU-GDPR studies fall in the domains of information privacy practices (5 studies) and information privacy technologies and tools (2 studies), in [4]'s taxonomy of topic areas. However, with the exception of [14], all studies exclusively focus on one of EU-GDPR's requirements. There are two shortcomings in this approach: First, none of them is aimed at analyzing the entire regulation and its implication from an enterprise-wide perspective. Second, these papers do take the compliance requirements for granted and directly look into specific practices. Hence, we are still lacking a broader understanding

[2] Regulation (EU) 2016/679. Recitals (R.) and articles (art.) mentioned throughout the text refer to EU-GDPR unless otherwise specified.

of the challenges faced by companies in implementing EU-GDPR. [14] addresses this topic by proposing a Digital-Privacy Transformation "Gap-Map" that measures the organization's propensity for change. However, it exclusively takes a change management perspective, without investigating the compliance requirements and their implications on enterprise-wide data management practices.

Table 1. Summary of EU-GDPR-Related Studies in IS Literature

	Study type	EU-GDPR aspects	Topic area based on [4]	Level of analysis	Research focus
[9]	Empirical	Data breach notification	Information privacy practices	Orga-nisation	Applying data breach notification to past infringements
[10]	Conceptual	Data breach notification	Inf. privacy practices	Orga-nisation	Information security / incident management
[11]	Conceptual	Data portability	Information privacy impact	Market	Impacts of data portability right on competition dynamics
[12]	Conceptual	Privacy-by-design	Technologies and tools	Indivi–dual	Privacy label for GDPR
[13]	Conceptual	Tran-sparency	Technologies and tools	Orga–nisation	Guidelines for com-pliant privacy notices
[14]	Conceptual	Entire regulation	Impact / Inf. privacy practices*	Orga–nisation	Transformation framework for digital privacy
[8]	Empirical	Account-ability	Inf. privacy practices	Market	Review of third-party data processors
** scope beyond [4], covering organizational and individual readiness and transformation*					

2.3 Regulatory Compliance Management (RCM)

So far, the academic discussion on EU-GDPR has not linked up to the regulatory compliance management (RCM) research domain, although the latter could inform how to analyze regulations and their influence on business practice. RCM is defined as "ensuring that enterprises are structured and behave in accordance with the regulations that apply, i.e., with the guidelines specified in the regulations" [15]. RCM introduces useful background definitions to delimit relevant legal concepts. In his overview paper, [15] distinguishes between regulations (i.e., binding document), regulatory guidelines and compliance requirements, as provided in the legal text. Following interpretation, this ultimately results in concretized compliance requirements as implementation.

Two review papers from 2009 have analyzed the coverage of RCM in IS research. [16] conducted a literature analysis through the lens of enterprise architecture, and isolated 26 relevant papers. They found that while some aspects of RCM have been prominently studied (e.g. organizational and behavioral impacts of regulations, compliance supporting IT solutions), others had been neglected. Specifically, they found no contributions on the operationalization of compliance objectives. [17]'s literature analysis on RCM, revolves around the approaches (i.e., explanatory or solution) and context (i.e., region, type and domain) of the considered contributions. From the 45 papers, the majority focused on North America, whereas only 3 of them focused on European issues. Related to data protection, they identified 2 papers that study Fair Information Practices, and only one on the European Data Protection Directive (95/46 EC), even though it had been enforced for 15 years. Furthermore, all identified contributions offered either preventive or detective solutions, but no corrective solutions. The authors hypothesize that corrective solutions are an outcome of legal analysis, which is why they were not addressed by the IS community.

Hence, there is a lack of RCM-related contributions that address data protection regulations, focus on regions other that North America [17] and provide guidance to concretize strategic compliance objectives [16]. This last call is echoed by our literature review on EU-GDPR – although contributions exist around the topic, they all focus on specific aspects of the regulation, and lack a single integrating framework.

3 Research method

Given our stated goal to support companies in achieving EU-GDPR compliance, we adopt design science research (DSR) to develop a capability model, as an artefact "to solve identified organizational problems" [18]. Table 2 depicts the research steps, following the iterative process suggested by [19] and outlines the close interactions between academics and practitioners, comprising 5 focus group meetings with 33 data management experts from 22 companies and insights from 3 EU-GDPR projects.

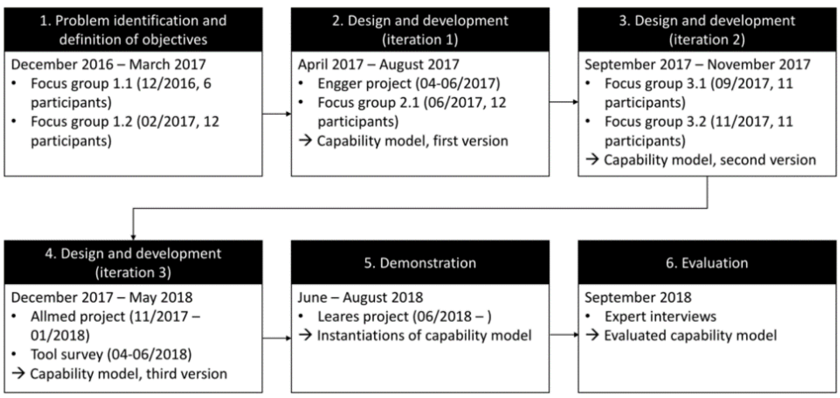

Figure 1. Research process (based on DSRM)

The **first phase** was meant to understand the problem at hand and specify the objectives of the solution to be developed. It was conducted between November 2016 and March 2017 based on an initial review of the regulation, with the objective of isolating requirements relevant for data management. We started by extracting and analyzing EU-GDPR's compliance requirements according to foundational data protection principles in legal literature (i.e. personal data, informational self-determination, accountability and transparency). To that end, we selected reference text books that provide a comprehensive analysis of data protection foundations and applications – they integrate legal texts and their related preparatory works, as well as insights from case law and legal doctrine [20–22]. Early results of this analysis were discussed with practitioners through focus groups 1.1 and 1.2, allowing them to reflect on the regulation's impacts on their organizations and implementation challenges. These discussions led to an in-depth understanding of the issues in implementing EU-GDPR enterprise-wide and the subsequent decision to design a capability model.

The next phases (2, 3 and 4) were **iterative design cycles**, involving insights from field projects and internal research activities to design the capability model, as well as focus groups for collecting feedback. Internal research activities included a continuous analysis of EU-GDPR-specific legal literature [2], [5–7], [20], [22], [23], guidelines from official authorities [24–26] as well as interpretations from the private sector, including consortia (e.g. [27–30]) and industry stakeholders (e.g. [31]).

Phase 2, the first design iteration phase, comprised a project at Engger[3], a global engineering company, and resulted in the initial version of the capability model. It had just started a multi-project around EU-GDPR-compliant personal data aiming at harmonizing business partner data management in a highly distributed landscape, i.e., with around 500 systems in different countries and subsidiaries. This project helped understanding issues and define capabilities related to collection and distribution of personal data and consent. It ultimately led to the first version of the capability model that was presented to and discussed with data management experts in focus group 2.1.

During **phase 3**, the discussions in the two focus group meetings 3.1 and 3.2 revolved around the scope of the model. Feedback from focus group 3.1 indicated that security is usually a distinct function, and supported the need for a data management-centric perspective. From an academic perspective, information security is a well-research field and the existing concepts may be translated to EU-GDPR, whereas there is little coverage of data management practices in regulatory compliance with data protection regulations. It was decided to set aside all security-related considerations from the capability model and focus exclusively on data management capabilities.

Phase 4 comprised a project around consent management at Allmed, a global pharmaceutical company. Its technical team had designed an MVP solution, which we analyzed based on the second version of the capability model. Insights from the project resulted in the capability model's third and final version. Afterwards, we analyzed software tools from major vendors claiming to support EU-GDPR compliance – to that end, we designed a taxonomy of desired functionalities based on the capability model (following the methodology proposed by [32]) and used it to classify 23 tools from major vendors. This analysis allowed us to validate the system capabilities.

Phases 5 and 6 included a demonstration with the EU-GDPR activities at Leares, a small consulting firm. The capability model proofed to be applicable and useful for assessing the current capabilities, identifying the required capabilities and prioritizing compliance activities. Additional expert interviews confirmed utility of the artefact.

[3] All company names have been anonymized.

4 Data Management Capabilities for EU-GDPR

4.1 Problem Formulation and Definition of Objectives

Discussions held in focus groups 1.1 and 1.2 revealed two main challenges with regards to GDPR compliance. First, participants recognized a lack of understanding of the regulation itself, while anticipating significant changes to the current way of storing and processing personal data on an enterprise-wide level. Second, they cited a lack of common ground with legal departments. In their organizations, discussions around data protection and privacy regulations are often cut short due to a lack of common approaches and vocabularies, which blocks the identification of feasible and compliant solutions and hinders progress. This led to the research objective of defining a capability model for EU-GDPR that assists data management professionals to understand and implement the regulation, as well as collaborate with legal colleagues.

4.2 Capabilities as a Link Towards Concretized Compliance Requirements

As theoretical foundation, we chose to rely on the RBV, as regulatory compliance is a component of firm performance, and contributes to an organization's control objectives (as defined by [33]). Building on [34]'s definition of an IT capability, we define data management capabilities for regulatory compliance as a firm's ability to acquire, deploy, and leverage its data resources in combination with other resources and capabilities in order to achieve an organization's compliance objectives.

Table 2. Positioning capabilities within RCM concepts

RCM concept	**Definition (based on [15])**	**Illustration in EU-GDPR**
Regulatory guideline	Stipulates a set of obligation to comply to.	Art. 6 – "Lawfulness of processing": enumerates conditions in which data processing is legal.
Compliance requirement (CR)	Pieces of text extracted from the regulatory guideline specifying an expected behavior / a specific condition to fulfill.	Extraction of requirements bearing data management relevance. E.g. art. 6 § 1 a and art. 7 § 1 require that data be processed according to individuals expressed consent.
Capability	*Result of the interpretation of CRs in terms of capabilities that are to be implemented or improved.*	*Manage consent and sub-capabilities: implement consent items, collect consent instances, distribute consent, enforce consent-based processing.*
Concretized compliance requirement (CCR)	Implementation of a CR in an enterprise model, fulfilling its legal specification.	A concrete measure implemented in a specific organization to operationalize CRs. E.g. "In company X, consent data should be first recorded in system 1 and pushed to other systems every 12 hours".

The capability model complements RCM concepts [15] and acts as an abstraction layer between the normative aspects of the regulation, i.e. the regulatory guidelines and compliance requirements (CR), and the concretized compliance requirements (CCR), i.e. the concrete implementation of a CR. Introducing capabilities allows describing what organizations should do, as opposed to how they should do it, i.e. how the specific implementation should be carried out. Table 2 depicts this articulation.

4.3 Capability Model: Structure and Overview

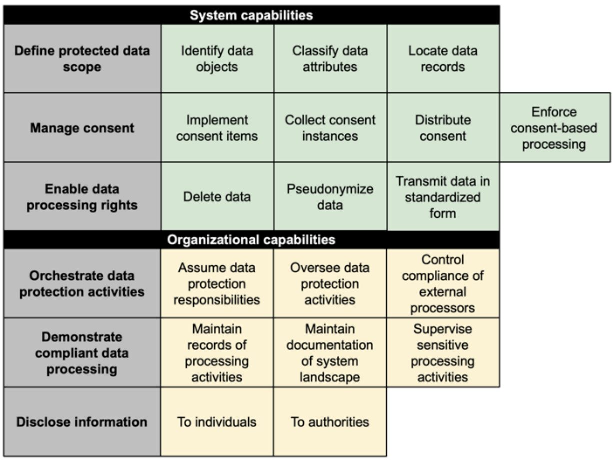

Figure 2. Capability model for data management in EU-GDPR

Art. 24 § 1 states the overall responsibility of organizations with regards to the regulation as the implementation of "appropriate technical and organizational measures to ensure and be able to demonstrate that processing is performed in accordance with this Regulation". We thus derived our two main capability groups, i.e., system and organizational capabilities (see Figure 2), reflecting their predominant aspect[4]. Correspondingly, **system capabilities** are mainly enabled by data-processing systems, while **organizational capabilities** rely on data protection processes and responsibilities. Capabilities were derived from EU-GDPR's underlying principles, as described by legal literature, and reflect the "pillars" of the regulation. Sub-capabilities are the result of the analysis and express compliance requirements. In the following sections, we present each of the suggested capabilities, along with its justification, the empirical evidence and the sub-capabilities.

Define Protected Data Scope. This capability is based on art. 1 § 1 and 4 § 1 and denotes the ability to clearly identify, classify and locate personal data. Personal data is defined as "data enabling direct or indirect identification of a single physical person,

[4] In the RBV, capabilities "involve complex patterns of coordination between people and between people and other resources" [35]. Authors relying on the RBV in the IS literature usually demarcate technological and organizational aspects that underpin IS capabilities [36, 37].

data that is specific to a single physical person without enabling identification, data that can be linked to a physical person, data regarding which anonymization techniques cannot completely mitigate the risk of re-identification” [21].

Focus groups 1.1 and 1.2 indicated that companies generally had no overview on the personal data collected and used during processes, especially in terms of storage location. A participant of focus group 3.2 asked: “How do you identify personal data in a heterogeneous IT-System landscape?” Follow-up questions revolved around means to identify personal data. The project at Engger provided significant insight regarding this capability group. One of its main objectives was making sure that personal data was consistently kept up-to-date within all systems, which proved difficult due to multiple overlapping systems managed in independent subsidiaries. Overall, companies faced two main challenges: determining what kind of personal data they were processing, and where such data was stored. The resulting capability may be best summarized by [20], stating that “organizations must have perfect knowledge of personal data”. Practitioner reports also fall in line with this statement – [29] recommend two actions that mirror these issues (e.g. data discovery and system mapping) and suggest that personal data should not only be identified, but also classified. This is required as EU-GDPR prescribes higher protection levels for data that is considered sensitive (R. 51). The resulting sub-capabilities are:

- **Identify data objects:** identify data domains and related data objects that fall within EU-GDPR’s scope of applicability.
- **Classify data attributes:** assign levels of sensitivity to data attributes contained within personal data objects.
- **Locate data records:** identify all storage instances of personal data objects and have the ability to access and retrieve them.

Manage Consent. This capability comprises the prerequisites for collecting consent and ensuring consent-based processing of information. The principle of consent [5], [20, pp. 12, 94], [22, p. 93] is arguably one of the pivotal concepts of EU-GDPR and an expression of the right to informational self-determination. It can be defined as ability for each individual to determine whether and to what ends information about themselves can be processed [6]. The related concepts of conditionality, granularity and specificity are the most challenging for data management [24]. Conditionality (art. 7 § 4) means that consent for processing activities cannot be bundled in general conditions, and that a difference should be made between necessary and optional processing activities for a given purpose. Granularity (R. 43) implies that each processing activity and related consent item must be presented separately. Specificity prescribes a 1:1 relationship between processing types and consent items (i.e. yes/no question that relates to a personal data processing activity). This is a departure from practices before GDPR, when consent was mostly obtained through the bulk acceptance of general conditions.

Consent management found a significant echo in our focus groups. During focus group 3.1, none of the participants reported solutions either in final stages nor operational. During focus group 3.2, more questions were asked regarding consent management than all other capabilities combined. The Allmed project goal was making consent information accessible and readable by all systems, which mirror capabilities "distribute consent" and "enforce consent-based processing". However, difficulties arouse in two areas. First, the system would need to be connected to every system storing and processing personal data – identification of such systems proved difficult and the existing system landscape documentation was deemed insufficient (see the capability "define protected data scope"). Second, the team struggled to identify consent items, as they were usually contained in unstructured form (e.g. within general conditions, contracts, webpages). A specific sub-capability was added to reflect this issue, and is a prerequisite to all other consent-related capabilities. The resulting sub-capabilities are:

- **Implement consent items:** define and implement consent items that mirror data processing activities performed throughout business processes.
- **Record consent instances:** collect and record consent expressed by individuals.
- **Distribute consent:** ensure consent items updates in all affected processing systems.
- **Enforce consent-based processing:** ensure that data processing activities are performed in accordance with consent expressed by individuals.

Enable Data Processing Rights. This capability denotes the ability to process data according to EU-GDPR's data rights and principles. It was derived from the principle of accountability (art. 24 § 1), but covers only the technical aspects to reach compliance, document them, and provide proof of compliance [5], [20, p. 12], [22, pp. 31, 38].
Art. 17 provisions a "right of erasure", according to which individuals can request that organizations delete their personal data (provided that they have no other obligation to keep said data). From a technical perspective, enterprise systems usually prevent users from deleting data and practitioners expressed a difficulty in that regard. When asked about it, none of the participants of focus group 3.1 reported that they had operational deletion processes or mechanisms. Focus group 3.2 also expressed a lack of well-established solutions at this level, and our tool study identified only 2 solutions supporting this capability. Art. 25 mandates privacy by design / by default approaches, including the principle of minimization [22, p. 90], i.e. processing as little personal data as possible. One way of operationalizing it is pseudonymization, which is a rare occurrence of EU-GDPR mentioning a specific technological approach (R. 28-29). This can be seen as an alternative to deletion, as pseudonymized data exits EU-GDPR's scope of applicability, and was thus added as second order capability. Art. 20 introduces a "right do data portability" – organizations are required to transmit personal data records "in a structured, commonly used and machine-readable format" to individuals, and, in some cases, directly to other organizations. During focus group 3.1, only a quarter of respondents declared that the provision of data in standardized formats was mature, and none of them reported working communication channels. We have identified only two solutions in our tool study, both of which are marketed as "Customer Identity and Access Management Systems" (CIAM). The resulting sub-capabilities are:

- **Delete data:** permanently remove data records from their systems.
- **Pseudonymize data:** use pseudonymization techniques in order to adhere to the principle of minimization.

- **Transmit data in standardized form:** transmit personal data to external parties using standard formats and set up communication channels with other organizations.

Orchestrate Data Protection Activities. This capability denotes the organizational ability to coordinate and execute data protection activities, involving different roles and responsibilities. It was derived from the organizational component of the principle of accountability [5], [20, p. 12], [22, pp. 31, 53, 71]. As stated, focus group feedback indicated that data managers often are at a loss as of who to consult when faced with data protection inquiries. This became particularly clear during the Allmed project – when the team needed to obtain information regarding data protection matters, they did not have a clearly designated contact person. On several occasions, responsibilities (e.g., for defining consent items) were not clearly defined. Art. 37-39 requires that organizations of a certain size appoint a "Data Protection Officer" (DPO). The DPOs should monitor compliance by acquiring an overview of processing activities, serve as advisory contact person [25], oversee record keeping and cooperation with authorities. We designed related capabilities for data protection oversight.

EU-GDPR also makes a distinction between data controllers and processors, and art. 28 orders the former to control compliance of the latter. This distinction is relevant to organizations when they outsource data processing to third party companies – the use of cloud services also falls into this situation, as merely storing data is considered processing. This became apparent during the Allmed project (cloud CRM) and especially in the case of Leares, which exclusively relies on cloud services (e.g. CRM, content management, websites) for the storage and processing of data. A corresponding capability was therefore added. The resulting sub-capabilities are:

- **Assume data protection responsibilities:** responsibilities for data protection-related tasks in all business functions that routinely process personal data.
- **Oversee data protection activities:** a leading role should oversee, organize, control and coordinate data protection activities.
- **Control compliance of external processors:** monitor that data processing conducted by third parties for EU-GDPR compliance.

Demonstrate Compliant Data Processing. This capability comprises the ability to record and evaluate sensitive processing activities, as well as to document system landscapes. It was derived from the documentation component of the principle of accountability [5], [22, p. 44]. Art. 30 orders organizations to "maintain a record of processing activities under its responsibility" and details the contents of such documentation. It was identified as a significant difficulty by [30], and all participants of focus group 3.2 acknowledged that documentation represented a significant effort. Maintaining system landscape documentation was identified as another sub-capability, as focus groups indicate that most organizations have difficulties locating data – this was the very motivation for the Engger project, and one significant roadblock for Allmed's solution implementation. Art. 35-36 further require organizations to conduct and document in-depth data protection impact assessments (DPIA) when performing sensitive processing activities. The resulting sub-capabilities are:

- **Maintain records of processing activities:** inventory and document personal data-related activities performed throughout business processes.
- **Maintain documentation of system landscape:** inventory and document systems that store and process personal data on a regular basis.
- **Supervise sensitive processing activities:** identify and evaluate sensitive data processing activities.

Disclose Information. This capability involves the ability to disclose information to individuals (R. 58) and authorities (art. 31). It was derived from the principle of trans–parency, which requests data protection measures to be clearly exposed [5], [20, p. 17].

Transparency requirements apply in two cases [26]. First, at the point of data collection, organizations must present related information separately, in a manner (e.g., language, illustrations) that can be easily comprehended. This would include, for instance, a clear description of each consent item. Transparency also refers to communications with individuals after data is collected, when organizations are faced with right-related requests (e.g., access, rectification, deletion). Art. 31 specifies that organizations "shall cooperate, on request, with the supervisory authority in the performance of its tasks". This implies that organizations set up a contact person for authorities (usually the DPO), and the ability to present relevant information / documentation as proof of compliance.

These capabilities may be seen as the operationalization of the principle of accountability, which is materialized by documentation. Since such documentation should contain all relevant information regarding an organization's data protection practices, these capabilities are about presenting that information to the interested parties (i.e. individuals and authorities). The resulting sub-capabilities are:

- **Disclose information to individuals:** provide individuals with complete and understandable information regarding the processing of their personal data and respond to their data protection-related requests.
- **Disclose information to authorities:** collaborate with designated data protection authorities and communicate relevant information upon request.

4.4 Demonstration

The main purpose of the capability model is to guide organizations in implementing EU-GDPR's requirements into their existing practices. To demonstrate its applicability and usefulness in EU-GDPR initiatives, we present how it was applied to assess the situation of Leares, a small-sized consulting firm that had started to draft a GDPR "action plan". A lengthy to-do list compiled the most visible and pressing compliance issues (e.g. adapting web forms, newsletters and contracts) in order achieve what was considered a "minimum" level of compliance. There were significant shortcomings with this approach. First, there was no indication of why certain actions were necessary, or what compliance issue they were meant to fix. Second, actions were presented as isolated, one-time efforts – there was no indication as to what extent GDPR compliance was actually achieved, or how it would be maintained in the future. Third, and most notably, these action items focused mostly on technical issues, with no documentation mechanisms or compliance processes put in place.

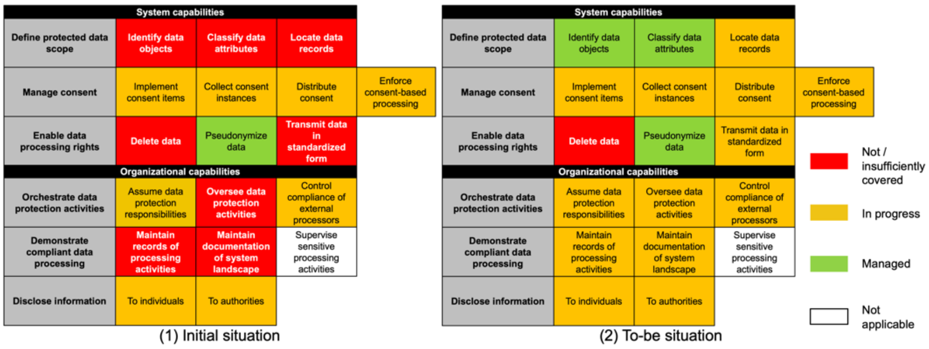

Figure 3. Evaluation of Leares' compliance level

Using the capability model contributed to alleviate these issues and helped Leares in identifying compliance gaps as well as defining and prioritizing actions. Going through the model, we were able to assign each check-list activity to capabilities, and assess to what extent they contributed to achieving compliance. When capabilities were partially covered by those activities, the model provided guidance to refine them. The capability model also helped identifying capabilities that Leares had not considered at all, such as defining the protected data scope. In these cases, new measures had to be defined. The instantiations depicted in Figure 3 show how the model was used to assess existing practices in the initial situation, along with a realistic target situation to be achieved within the next months. As a result of using the capability model, Leares was able to devise a structured action plan, covering all aspects of its data management practices.

5 Conclusion and Outlook

This paper introduces a data management perspective to EU-GDPR and argues that the regulation requires companies to build a dedicated data management capability. The suggested capability model was developed in an iterative design science process, integrating both interpretation of legal texts and practical insights from focus groups with more than 30 experts and from 3 EU-GDPR projects. By translating compliance requirements into organizational and system capabilities, it contributes to (1) building common ground between legal and data management domains and (2) assisting organizations in assessing practices, identifying and deciding on implementation options for achieving compliance with EU-GDPR. From a research perspective, our capability model complements the emerging body of research on EU-GDPR, that mostly investigates selected information privacy practices. The capability model may be used to classify and integrate these focused research efforts into an enterprise-wide perspective. Furthermore, it complements IS security research by focusing on non-security aspects of information privacy. For practice, the capability model supports companies in developing a systematic approach towards achieving EU-GDPR compliance and monitoring progress, instead of “fire-fighting”. As outlook for future research, our focus group discussions reveal that implementing EU-GDPR is not a one-time effort, but an ongoing process. The suggested capability model may serve as a basis for studying how the capabilities are being built and how they can be assessed. As it is supposed to contribute to reaching a firm’s control objective, a potential lead for further research would be to propose indicators of compliance goals and measure them.

On the Difficulties of Incentivizing Online Privacy through Transparency: A Qualitative Survey of the German Health Insurance Market

Max Maass[1], Nicolas Walter[1], Dominik Herrmann[2], and Matthias Hollick[1]

Abstract. Today, online privacy is the domain of regulatory measures and privacy-enhancing technologies. Transparency in the form of external and public assessments has been proposed for improving privacy and security because it exposes otherwise hidden deficiencies. Previous work has studied privacy attitudes and behavior of consumers. However, little is known on how organizations react to measures that employ public "naming and shaming" as an incentive for improvement. We performed the first study on this aspect by conducting a qualitative survey with 152 German health insurers. We scanned their websites with PrivacyScore.org to generate a public ranking and confronted the insurers with the results. We obtained a response rate of 27%. Responses ranged from positive feedback to legal threats. Only 12% of the sites – mostly non-responders – improved during our study. Our results show that insurers struggle due to unawareness, reluctance, and incapability, and demonstrate the general difficulties of transparency-based approaches.

Keywords: privacy, web security, transparency, quasi-experiment, e-mail survey

1 Introduction

Privacy plays an increasingly important role for consumers, regulators, and companies, especially on the internet. A growing number of companies provide services in the areas of online advertising, web analytics, and user profiling. Users and regulators have responded by deploying tracking blockers and passing stronger privacy laws, e.g., the European General Data Protection Regulation (GDPR).

So far, most research has focused on user perceptions of information privacy [1–4] and models for firms' data sharing gathering [5–7] and sharing behavior [8]. However, there is a lack of research on how to incentivize companies to reduce their use of tracking services, which are disliked by many users [9]. The study presented in this paper investigates the role of *transparency* as an incentive mechanism. Our scope is not limited to *privacy* (represented by online tracking services); we also consider the

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

connected area of *security* (e.g., transport encryption of web and mail traffic), as they affect user privacy against malicious actors like criminals and intelligence agencies.

Existing website scanners like the Qualys SSL Test (ssllabs.com) and Webbkoll [10] allow to assess security and privacy features of single sites. However, these scanners communicate the result only to the particular user who commissioned a scan. Therefore, there is little incentive for site operators to improve their rating. In contrast, we consider a scenario in which the scan results for multiple competing organizations are published openly on the internet in a ranking. This combination of publicity and comparability creates more transparency for consumers, which may increase the pressure on site operators to improve. Therefore, we pose the following research questions:

- **RQ1**: How do website operators react when they are notified that their website has been rated in terms of privacy and security aspects and the results are publicly available online?
- **RQ2**: Does telling them about being in a *public ranking* change their reaction?

We seek to answer these questions by contacting 152 German health insurance providers in a qualitative study, confronting them with and asking their comment on the current state of information privacy on their websites as determined by the PrivacyScore platform [11]. PrivacyScore.org is a public web service that automatically analyzes websites for security and privacy issues. Since its inception in June 2017, it has performed over 1 million scans and is being used by activists, data protection officers, and the general public. To the best of our knowledge, our study is the first to investigate how the competitive nature of public privacy and security rankings affects website operators, using the ranking functionality offered by PrivacyScore.

2 Related Work

The majority of IS privacy research focuses on individual privacy [6]. One of the central questions in this area is how privacy concerns affect the way individuals behave and their willingness to disclose personal information [1]. A frequently discussed aspect in this context refers to the decisions that individuals make regarding privacy and a trade-off between risk and benefit [3], which is informed by many factors, including company culture, legal environment, and the industry of the information-gathering company [4].

In contrast, there is less research on the question of how privacy issues are perceived from the **organization perspective**, i.e., by companies who work with personal data of their consumers. This field concerns itself with the interests and attitudes and motivations that companies have towards privacy [1, 5–8]. Greenaway and Chan argue that companies can behave in a reactive or proactive manner in regard to privacy and thus influence the perception of customers, and that their behavior can be explained using two models [5]. The *Institutional Approach* (IA) considers firms behavior as a search for legitimacy in the face of external pressures, and distinguishes an *acquiescent* (compliance with law, imitation of peers) and a *proactive approach* (exceeding minimum requirements and using clear communication to achieve leadership without falling out of line). The *Resource-based View* (RbV) posits that firms seek a sustainable competitive advantage using either an *information-* (through superior data analysis) or a *customer focus* (through superior customer trust).

To the best of our knowledge, the role of **competition** in promoting privacy has not received significant attention so far, although individual companies like Apple[1] or DuckDuckGo[2] have started marketing themselves as privacy champions. Like the RbV, Ohlhausen and Okuliar view privacy as a factor in competition [12]. Kerber reverses the argument and posits that a lack of competition may be partially responsible for the lack of privacy offerings from online companies [13].

Another reason may be that the privacy behavior of companies is often invisible from the outside. Thus, consumers find it hard to check whether companies are living up to their claims, for instance by following accepted best practices that ensure the privacy and security of their customers. **Transparency** can make these invisible practices of companies visible, enabling customers to easily verify claims and compare the practices of competing companies. The IS transparency literature has so far been focused on transparency strategies for companies [14], but has not yet considered transparency provided by external actors in the field of information privacy. Such external transparency has been shown to improve outcomes in areas such as Corporate Social Responsibility [15] and corporate ethics [16], among others, making it a promising avenue for more research.

3 Technical Background

We use the platform PrivacyScore.org [11] to investigate how operators of websites react when they are confronted with the fact that a third party is creating transparency about the privacy and security practices exhibited by their websites.

PrivacyScore.org[3] is an automated website scanner that allows anyone to investigate websites regarding privacy and security issues. Compared to other website scanners like Qualys SSL Scan and Webbkoll, the scans conducted by PrivacyScore are more comprehensive, including both security and privacy aspects. Currently, PrivacyScore performs more than 60 checks in four groups: *Tracking and Privacy* checks if a website includes third-party trackers. *Website Encryption* checks if a web server offers state-of-the-art secure connections, whether it redirects users to the secure version of the site, and whether it sets the HTTP Strict Transport Security (HSTS)[4] header, which prevents certain classes of attacks. *Mail Encryption* checks whether the mail servers of a website support state-of-the-art encryption, and *Web Security* checks if a website leaks internal information [17] and whether it protects users against client-side attacks.

Detailed results of each scan are published on the website and retained in a database to facilitate longitudinal studies. While it is possible to scan individual websites with

[4] https://tools.ietf.org/html/rfc6797 (accessed 2018-11-19)

PrivacyScore, it is primarily intended to be used to scan lists of related websites (e.g., all pharmacies with an online shop in a specific country). Scanning a list generates a public ranking with all sites that belong to a list. Rankings put the individual scan results into context and allow consumers, data protection authorities, and site operators to assess how a particular site compares with its competitors. At the time of writing PrivacyScore hosts over 200 scan lists and has conducted more than 1 million scans.

A noteworthy limitation of PrivacyScore is that it conducts scans automatically without human oversight. As a result, the assessment is limited to aspects that can be reliably verified programmatically from the outside by visiting the website with an instrumented web browser. In particular, PrivacyScore cannot verify whether statements in the privacy policy are adequate and whether the site actually adheres to them. Moreover, PrivacyScore conducts only benign checks. For instance, it does not actively attempt to find and exploit vulnerabilities in the website under test.

Finally, PrivacyScore attempts to find a fair balance between satisfying the desire for transparency of consumers and operational interests of site operators. To this end, all scans are conducted instantaneously, i.e., without asking operators for permission. Website operators can have their website excluded from future scans. For reasons of transparency, this fact is published next to the scan results. Moreover, the last successful scan result before the complaint is shown for the respective site.

4 Study Design

As proposed by Greenaway and Chan [5], we use a mixed method [18] approach by combining a classical open question survey with a quasi-experimental setup based on the PrivacyScore platform. We follow a qualitative research process consisting of planning, data gathering, preparation of analysis, and analysis and summarization [19].

4.1 Gathering Websites and Scan Results

Our focus is on the health insurance sector within Germany, as visitors of health insurance websites may disclose sensitive information (e.g., by looking up information about specific illnesses and treatments). We obtained the homepage addresses (domain names) of all public and private health insurers in Germany from Wikipedia,[5] uploaded the URLs to PrivacyScore and added them to the newly created scan list “Deutsche Krankenkassen und Krankenversicherungen” (privacyscore.org/list/15). In December 2017 (T1) we saved a local copy of the scan result for each website as well as its rank within the aforementioned list. We performed two additional scans at later points in time (February and August 2018; T2 and T3) to determine whether the insurers had changed security and privacy properties of their sites.

4.2 Group Allocation

Seeking to answer RQ2 we use a quasi-experimental setup, which is common in organizational research [20]. We split the insurers into two groups A and B, introducing the variable *competition*. We prepared two kinds of solicitation emails. Insurers in Group A were only informed about the overall scan results for their site in terms of the four areas that are published on the PrivacyScore website: "Tracking and Privacy", "Website Encryption", "Mail Encryption", and "Web Security". Insurers in Group B were additionally confronted with the rank of their site in our "Deutsche Krankenkassen und Krankenversicherungen" scan list. All solicitation emails started out with a brief description of PrivacyScore and ended with a request to participate in our study by answering the following two open questions: *What do you think about this kind of an assessment from a company's point of view? Would you consider making changes to your website in order to improve its privacy properties?*

The group allocation was not randomized but based on the ranking of the websites on PrivacyScore. This was done to ensure that both groups are homogenous in terms of the distribution of the ranks as given by the scan list. To this end, we assigned the numbers from 1 to 152 to the insurers in the order of the PrivacyScore ranking. The companies with odd numbers were put into Group A, those with even numbers into Group B. This procedure was guaranteed to result in two groups of the same size and allowed us to handle cases of ties in a deterministic fashion. Note that our allocation resulted in an uneven distribution in terms of the *type of insurer*: Group A contained 61 public and 15 private insurers, whereas Group B contained 51 and 25, respectively. This heterogeneity will be taken into account during the analysis.

4.3 Sending of Solicitation Mails

We obtained an email address for every insurer by visiting each website and manually searching for a suitable contact address in the privacy policy, the contact section, and the imprint of the site. If available, we preferred data protection-specific addresses such as "datenschutz@" to general-purpose addresses like "service@" or "info@".

On 8 December 2017, we sent out solicitation emails to all 152 insurers, using a university mail account not affiliated with the PrivacyScore project. As most insurers had not replied with a definitive response after four weeks, we sent out reminders to 135 insurers on 11 January 2018. The majority of responses was received in January and February 2018. After we had received all responses (March 2018) we iterated over them multiple times for open coding. As two of the authors are part of the PrivacyScore team, we were also in the position to receive any complaints directed towards the platform (which was not communicated to the recipients).

5 Results

In this section, we report the results of the initial scan of the websites and how site operators responded to our solicitation mails. Afterwards we discuss the three primary response types, i.e., positive responses, complaints, and other responses, in more detail.

5.1 Initial State of Websites

At the beginning of the study (T1), 26% (39) of the websites did not use any third-party tracking. 67% (102) of the websites used a well-configured Transport Layer Security (TLS) setup (defined as automatically forwarding users to the encrypted version of the website, offering TLS 1.2 and not offering the outdated and insecure protocol versions SSLv2 and SSLv3), and only 26% (39) of the websites set a HTTP Strict Transport Security (HSTS) header. Mail server TLS scans exhibited a failure rate of 6.5% (15), likely due to spam protection techniques like tarpitting. Still, 78% (119) websites had a well-configured mail server TLS setup (with TLS 1.2 and without SSLv2 and SSLv3).

5.2 Contacts and Respondents

In total, we received responses from 41 insurers (response rate: 27%). We found that sending a reminder message greatly increased the response rate, with more than half of the responses (23 of 41) reaching us only after the reminder. We had contacted 97 data protection (DP) contacts (64% of 152 insurers; A=45, B=52) and 55 general-purpose contacts (A=31, B=24). The overall response rates of Group A and B are similar (A=26%, B=28%), with data protection contacts showing a slightly higher rate (A=29%, B=31%) than general-purpose contacts (A=23%, B=21%).

We also observed many instances of messages being forwarded inside the companies, with different departments responding to our inquiries. An overview is given in Table 1. In Group A, our messages were frequently answered by marketing and data protection or IT teams (40% and 35%, respectively). Members of the board of directors (20%) and other departments (5%) sent the remaining 25% of responses.

In Group B, we observed a markedly different behavior. The majority of the responses were written by data protection and IT specialists (71%), while the remainder was evenly split between marketing, board members, and others. This deviation can only partially be explained by the larger number of DP contacts in Group B (A=45, B=52): The fraction of data protection and IT responses is higher in Group B for both messages sent directly to a DP contact (A=35%, B=75%) and for messages sent to a general-purpose contact (A=14%, B=60%).

5.3 Types of Responses

Overall, the responses fall into one of the following three categories: Firstly, there are *positive responses*, e.g., statements of gratefulness, expressions of interest in the study, and very detailed discussions of the scan results. Secondly, there are *complaints* criticizing the nature of the unsolicited scans and the publication of the scan results. Thirdly, there are *other responses*, ranging from acknowledgements of the receipt of our message to explicit expressions of indifference. The heat map in Fig. 1 provides a summary of the results by breaking down the responses according to their response type. It also indicates the relationship between response type and changes to the website, which we will analyze in Sect. 5.4 in more detail. All direct quotes in this paper are our translations of German replies.

Table 1. Recipients and Respondents

Group A			*Group B*		
Sent to	*Response From*	*Count*	*Sent to*	*Response From*	*Count*
General	DPO / IT	1	General	DPO / IT	4
	Marketing	3		Marketing	1
	Board Member	1			
	Other	2			
DPO	DPO / IT	6	DPO	DPO / IT	12
	Marketing	5		Marketing	1
	Board Member	1		Board Member	2
	Other	1		Other	1

Positive Responses. In total, we received 16 positive responses (A=9, B=7). In Group A, most responses came from the marketing (5) and data protection / IT departments (3), with a single response from a board member. In Group B, the responses came almost exclusively from data protection or IT departments (6), with only a single response from a marketing department. The responses varied widely in length and level of detail, ranging from single-sentence responses thanking us for the information and noting that the IT department would be investigating the report further, to differentiated technical and economic analyses of the trade-offs between user privacy and economic success for their company. For example, B_{58} explained that while they used tracking services on their websites, they were disabled in sensitive areas, and noted that "*tracking is above all about the care with which data is handled. The mere collection of data does not necessarily lead to better business success.*" A_{33} noted that while they did not forward users to the secure version of their website by default, all sensitive data (login information, payment details) were transmitted over a secure connection.

Two respondents claimed that they would be making changes based on the results of the scan: A_{67} gave a detailed response, referring to many individual test results in detail, and demonstrated that they had already reacted by implementing some changes, like enabling the Referrer-Policy[6] HTTP header. They also noted that some parameters related to the mail server were outside of their control, as they were managed by a third-party appliance. A_{63} responded that internal tests had confirmed the findings of PrivacyScore and mentioned nonspecific changes that were made to the website as a result. They also noted that "*the results helped us protect the privacy of the users of our website [and provided] valuable support for the implementation of changes based on an easier analysis and identification of weak points.*" In contrast, A_{35} noted the beta-status of PrivacyScore, but claimed that they would be performing their own checks to confirm the results, and act upon them, if necessary.

[6] https://www.w3.org/TR/referrer-policy/ (accessed 2018-11-19)

Response Type	Total	Insurer Type: Public	Insurer Type: Private	Group: Group A	Group: Group B	Website improved?: yes	Website improved?: no
Positive	11 %	7 %	3 %	6 %	5 %	1 %	10 %
Neutral	11 %	9 %	2 %	5 %	5 %	0 %	11 %
Complaint	6 %	6 %	0 %	2 %	4 %	0 %	1 %*
None	73 %	52 %	21 %	37 %	36 %	11 %	66 %
Sum	100 %**	74 %	26 %	50 %	50 %	12 %	88 %

*No scan results for 8 insurers that opted to be excluded from further scans. **Deviation due to rounding error.

Figure 1. Breakdown of responses according to response type

Finally, A_{91} provided a highly detailed response, going into some detail on the trade-offs between user privacy and economic success in online tracking. They noted that online tracking was required to evaluate the effectiveness of their online affiliate marketing campaigns. An additional concern was the analysis of the needs of potential customers, noting that "*we determine the needs of new and existing customers through market research studies. However, [...] their results are only of limited significance. This can be seen in the fact that statements determined by market research and actual user behavior partially contradict each other.*" Another concern was personalization, with the respondent noting that "*both market research and measurements show that personalized content [...] is used much more intensively by users and is increasingly expected, [which] can only be fulfilled by tracking tools and marketing automation. [...] Of course, users also have a high interest in sufficient protection of their privacy. However, we are convinced that the data protection regulations in force in Germany [...] cover the expectations of most users.*"

Several respondents noted that they were already using external scanners to validate the security of their websites and that they commissioned professional security audits for their websites. Almost all respondents (A=7, B=5) forwarded the report to their IT departments for further analysis. There were also cases of respondents not being aware of alternatives to the privacy-invasive technologies they were using, with one respondent showing surprise when being informed about privacy-enhancing alternatives to their current practices.

Complaints. We received nine complaints, all of them from public insurers. As Group A contains a higher ratio of public insurers, we would have expected more complaints from this group. However, the majority of complaints came from Group B (A=3, B=6). Most complaints came from companies whose site had a poor rank in the initial scan (min 25, mean 80, median 87, max 123 of 125). Four of the nine complaints (A=1, B=3) were raised directly with the PrivacyScore team, i.e., not by replying to our solicitation mail. In one case, we received a positive reply to our solicitation email, while the PrivacyScore team received a complaint two days later. Eight of the nine companies requested to be excluded from future scans.

In the following, we will give an overview of the concerns raised in the complaints. We observed that the tone of the responses was generally more terse in Group B. Five of the six complaints from Group B explicitly referenced the ranking. One of the three complaints from Group A explicitly referenced the fact that the results were publicly available. One frequently raised point was that the scan was performed (B=2) and published (A=1, B=2) without asking for permission in advance. Three companies (A=1, B=2) claimed to be investigating if the scan constituted an illegal attack on their infrastructure, B_{150} alleged a violation of competition law, and A_{109} argued that the scan violated their copyright. In contrast, legal scholars concluded that PrivacyScore is fully compliant with German law [21].

Of particular interest is the complaint by B_{150}, which we will discuss in more detail here. After obtaining a low rank in the initial scan, their information security officer contacted the PrivacyScore team, asking to exclude the website from future scans. Almost two months later another response reached the PrivacyScore team, this time from the chief legal officer, stating that the legal department of the company had analyzed the case and had raised a number of issues with how the results were being displayed. In particular, they objected to a perceived incomprehensibility on how the rankings were computed and how old results from excluded websites were maintained. They claimed that this could be "*damaging to their company*", and may be illegal under the law against unfair competition. At the same time, they acknowledged that they were open to critical analysis of their website. In a subsequent phone call, the company explicitly mentioned the competitive and privacy-sensitive nature of the public health insurance market and the disadvantages a company could experience from a low rank in such a privacy ranking. A constructive discussion resulted in several changes to PrivacyScore being proposed and implemented, adding various clarifications to the results pages to make it easier for visitors to understand what they (do not) imply. In return, the insurance company started work to improve some of the security and privacy properties of its website. However, they still declined to be added back to the ranking.

Other Responses. We received 16 neutral reactions (A=8, B=8). Six organizations (A=4, B=2) explicitly stated that they were not interested in participating in the study. Five others (A=1, B=4) replied that our message had been forwarded internally, but we did not receive another response from them. Organization A_{153} declined participation, citing insufficient capacity, and B_{40} stated that responding would entail a work order to an external service provider. A_{51} stated that they could not give any information on the topic of privacy. B_{94} states that they did not understand the provided information. Finally, A_{95} simply stated that they would not be making any changes to their website.

5.4 Changes to the Websites

To evaluate how websites changed over the course of the study, we performed measurements before sending our messages (T1) and repeated them at the end of the study (T2), skipping insurers that had asked to be excluded from future scans.

Twelve companies had stated that they were open to changing their website (A=6, B=6). However, at T2, only 4 (A=4) had actually made changes to one of the parameters measured by PrivacyScore. The total number of embedded third-party trackers (TPTs) increased over the course of the study period, from 411 to 439, which can be explained by a general inflation of the number of service providers in the market for behavioral advertising. We observe 12 (A=7, B=5) cases of at least one TPT being removed, and 13 (A=7, B=6) cases of at least one TPT being added.[7] Most of these websites belong to companies that did not respond to our messages. A_{63}, who had responded positively and promised to make changes, only replaced one TPT with a different one. A_{91}, who had provided us with a differentiated view of the trade-offs between privacy and economic success, appears to have briefly removed a number of third parties, but has since added them again. A_{133} had stated their willingness to adapt their website – and indeed, they have removed all trackers, leaving only a cookie consent script hosted by a third party. Conversely, A_{74} responded positively to our message, but only discussed the security aspects of the PrivacyScore evaluation, without regard to the privacy ratings. Their website added four additional trackers over the course of the study.

Several companies also made changes to the security of their systems by changing the configuration of their TLS setups. Four companies (A=3, B=1) disabled the outdated and insecure protocol version TLS 1.0, and two of them (A=1, B=1) also disabled TLS 1.1, leaving only the latest available version TLS 1.2 active. Five companies (A=3, B=2) enabled HTTP Strict Transport Security, while one (B=1) disabled it. However, none of them had responded to our message, so it is unknown if this happened as a reaction to our messages, or due to other, unrelated reasons. Similarly, 10 companies (A=6, B=4) started automatically forwarding all visitors to the secure version of their websites. Closer investigation revealed that while none of them had responded to our messages, five are maintained by the web design agency maintaining the website of B_{128}, who had asked to be excluded from future scans and threatened legal action. A manual visit of their website revealed that they, too, now forwarded all visitors to the secure version of their website. Thus, it is plausible that our messages were at least partially responsible for this agency-wide change.

Our observations indicate that insurers are willing to deploy changes that benefit the privacy interest of users without impacting the economic interests of the insurer (e.g., enabling a more recent TLS versions). If privacy and company interests are in conflict, companies are more reluctant to make a change (cf. the smaller number of insurers that removed third-party trackers from their site).

To put our results into context we compare the impact of our solicitation mails with the effect of regulatory changes (cf. Fig. 2). For this purpose, we scanned the websites once more in August 2018 (T3). Besides the introduction of the GDPR in May 2018, the timeframe also included new PCI DSS rules coming into effect in June 2018,[8] requiring websites that process credit card payments to update their TLS configuration.

Due to technical issues with PrivacyScore, scans for 10 sites reproducibly failed and had to be excluded in T3. Moreover, we observed significantly higher failure rates for the mail server TLS scans in T3 than in T1 and T2, precluding a meaningful comparison in this area. Cursory investigations indicate that the failures are due to the increasing prevalence of spam defense mechanisms deployed by mail server operators.

[7] We consider individual third parties, not the total number. Thus, if a website removes one third party and adds a different one, it will be counted in both groups.

[8] https://blog.pcisecuritystandards.org/are-you-ready-for-30-june-2018-sayin-goodbye-to-ssl-early-tls (accessed 2018-09-11)

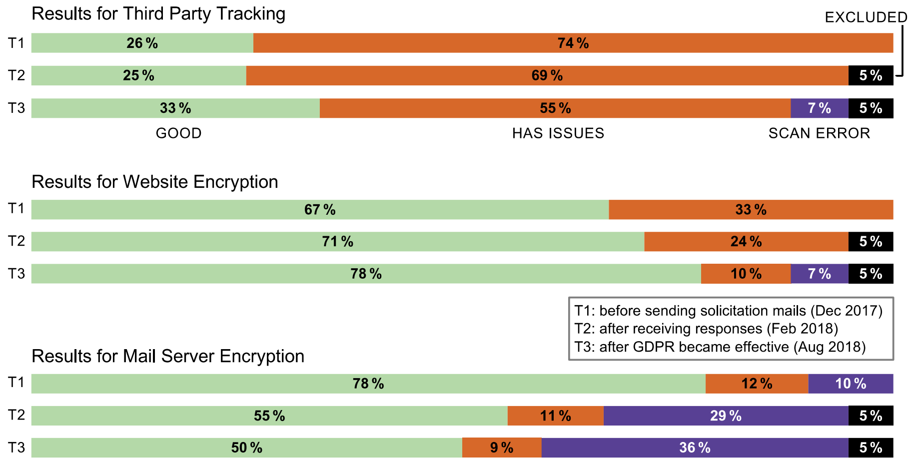

Figure 2. Scan results of health insurer websites at different points in time

As expected, the changes between T2 and T3 are substantial. 19 sites[9] removed all third parties, while 4 sites reintroduced trackers (compared to 2 and 1, respectively, in our study). 16 improved their TLS configuration (compared to 11 in our study), with 6 adding and 1 removing HSTS (5 additions and 1 removal in our study).[10]

Even though the time between T2 and T3 is much longer than between T1 and T2, it is unlikely that the observed differences are only due to the different durations given the changes to two regulatory frameworks. While we cannot infer what reasons served as an incentive for insurers to improve security and privacy features of their websites between T2 and T3, the combination of the passage of time and new regulatory requirements has a higher impact than our solicitation messages. This is to be expected, as the GDPR and PCI DSS changes were important and widely publicized, with strong incentives for compliance. While regulation has a large effect, transparency can still remain a valuable tool in affecting changes, as regulatory changes are infrequent events. Furthermore, regulation only establishes a lower bound of acceptable behavior, without incentives for exceeding the minimum requirements. Since the minimum requirements still permit many privacy-invasive techniques, transparency can serve as an incentive to exceed these requirements, which is vital for improving the state of online privacy.

6 Discussion

In this section, we discuss our results and their implications. The goal of our research was to investigate how health insurance companies react to transparency through public

[9] This includes 10 websites operated by the same association of insurers, whose websites are centrally managed. Thus, the number of distinct organizations making changes is at most 10.

[10] The difference with the changes visible in Figure 2 is due to some websites moving to the *excluded* or *failed* category

security and privacy ratings of their websites (RQ1) and if knowledge about the results being displayed in a ranking changes their response (RQ2).

We found that the responses varied greatly in the level of detail and content, ranging from detailed analyses of the trade-offs between user privacy and economic success to terse legal threats seeking removal from the public ranking. The responses cited a variety of reasons for the current state of their websites, ranging from conscious trade-offs between user privacy and the economic success of their company to technical limitations, e.g., third-party appliances whose configuration cannot be changed. One respondent also identified tension between the users' expectations of personalized content, which necessitates tracking, and user privacy.

6.1 Rankings Create Antagonism

We observed that public health insurers are more likely to complain than private insurance companies. Multiple complaints cited the privacy-sensitive nature of the health insurance market, and the potential competitive disadvantages caused by a bad privacy result. This led to a number of companies asking to be excluded from future scans, often under the threat of legal action based on questionable legal bases, including copyright, competition law, and cybercrime legislation [21].

We also observed a higher proportion of complaints from Group B (A=3, B=6), which was explicitly informed that their website was part of a ranking. This seems to indicate that the public ranking led to a higher probability of complaints being made. This theory is supported by the fact that five of the six complaints from Group B explicitly referenced the ranking in their complaints.

The complaints also have in common that all of them passed through the data protection and/or IT department of the companies, either as the initial point of contact for our study, or through company-internal forwarding. Thus, at first sight, a competing explanation for the higher ratio of complaints from Group B may be that the data protection and IT departments generally have a higher likelihood to complain. Coincidentally, we sent a higher fraction of our mails directly to data protection contacts in Group B (A=59%, B=68%), which corroborates the competing explanation. However, there are two arguments that challenge its validity: Firstly, several responders explicitly referenced the ranking in their complaints, and secondly, the complaint rate is still higher for Group B if only messages passing through data protection and/or IT departments are considered (A=21%, B=30%). Thus, we give more credence to our initial theory, which confirms RQ2.

6.2 Reasons for the Reluctance to Change

Our scans indicate that the websites under study are in permanent flux, with a general trend towards increasing the number of third-party trackers. As many of the insurers whose website changed during our study did not respond to our messages, the effect of our study on the websites is hard to quantify. Based on the received responses, we can attribute four changes directly to our messages, including one company that stopped using third-party trackers altogether, and assume that six more changes are at least partially the result of our messages. While these changes improve the privacy and security of website visitors, the low number of overall changes shows that the effectiveness of the messages was limited, indicating that at least in its current state, transparency and rankings through PrivacyScore do not significantly influence the willingness of most website operators to change their websites.

Many responses matched the *acquiescent approach* proposed in the IA [5], stating that they were in full compliance with applicable laws without giving additional details. A small number of companies moved towards the *proactive* approach by elaborating more on their internal processes, stating that tracking was disabled in critical areas, or citing frequent security audits of their websites.

We distil three reasons for the current state of insurance company websites: Conflicting value propositions, missing awareness, and negligence. Firstly, companies operate in a field of tension between their own economic goals (e.g., evaluating the effectiveness of their marketing campaigns), their reputation, and (sometimes conflicting) customer expectations like privacy and personalization. If not all expectations can be fulfilled, a trade-off needs to be found, leading companies to evaluate the costs of each solution. Stated in terms of the RbV [5], by gathering customer data (*intellectual resource*), companies can satisfy their own goals and some of the user expectations (e.g., personalization). As the use of web tracking is ubiquitous, it incurs almost no reputational cost and thus has low potential for differentiation (*relational resource*), leading most companies to pursue a *knowledge focus* and value their own economic goals higher than the privacy interests of their customers. This also explains their observed reluctance to be included in a ranking, making them favor an intentionally intransparent strategy, as proposed by Gerlach *et al.* [7].

Secondly, website operators may not be aware of alternative solutions that allow them to maintain the utility of their current solutions while decreasing their impact of the privacy of their users. Such alternative solutions include self-hosted tracking software like Matomo (matomo.org) that keeps the data under the control of the company, or two-click social media buttons (github.com/heiseonline/shariff) that do not disclose information to social networks on every page view.

Lastly, website operators may have been negligent and forgotten to configure their website correctly to respect the privacy of their users. This could manifest as the failure to enable the IP anonymization feature of Google Analytics (which is mandatory in Germany), or not forwarding visitors to the encrypted version of the website.

Problems caused by negligence can in many cases be remediated by a notification to the website operators, although such notifications have been shown to not always be reliable [17]. Raising awareness for privacy-preserving alternatives cannot easily be done at scale. In addition, awareness alone is not sufficient, as deciders need to be convinced that the benefits of switching to a privacy-preserving solution are worth the required effort and potential costs of changing the website, leading back to the issue of conflicting value propositions. These can only be influenced by changing the costs associated with the different options, which is easiest in the area of reputational costs. In the context of online privacy this means that privacy-invasive techniques have to become reputationally "expensive", which would turn forgoing their use into a relational resource, allowing differentiation through the *proactive approach*. This idea is at the center of the PrivacyScore project. However, our evaluation has shown that at the moment, the effect of transparency through PrivacyScore is not sufficient to cause large-scale changes. It is unclear if this is a general result or an artefact of the relatively unknown PrivacyScore platform. After all, companies may be more inclined to perform changes if a well-known consumer group or news outlet published a privacy ranking.

Finally, the behavior of companies can also be influenced by legislation and regulatory oversight. This was confirmed by our post-GDPR scan, which showed changes in a larger number of websites. Thus, the upcoming European ePrivacy regulation is a promising avenue for affecting further changes at scale.

7 Limitations, Future Research and Conclusion

Our study is subject to limitations. Firstly, we only investigate a single, privacy-sensitive sector – health insurance – in a single country. Extending and replicating the study with different sectors and in different countries could shed additional light on the general applicability of the results. Secondly, the number of respondents does not allow us to draw statistically significant conclusions. Our analysis also only considers two fixed dates when evaluating changes to the websites of the included companies, and we do not investigate if improvements are sustained over time or reverted.

Another limitation is the permeability of the group assignments. While we did not inform members of Group A about the ranking feature of PrivacyScore, the scan results page contains a (non-prominently presented) link to the ranking. Thus, members of Group A might have learned about it on their own. Nevertheless, we observed notable differences between Group A and B, which indicates that many members of Group A have not taken notice. The last limitation is the nature of PrivacyScore. As a relatively new platform, the publicity provided by it may present less of an incentive for change than a more popular and well-known platform or publication would have provided.

In conclusion, our results show that transparency – in the form of public assessments – can improve privacy features of websites. However, such efforts can also result in complaints and legal threats. A major factor limiting the willingness to change is the conflict between user privacy and the perceived need for privacy-invasive analytics for economic success: our solicitation mails led to much larger changes in areas where company and user interests are aligned, like website connection security. Another factor contributing to the current state appears to be a lack of awareness about privacy-preserving alternatives to common tracking services. While our study provided some initial insights on these difficulties, evaluating the effects of transparency on privacy remains a promising avenue for future work, for instance when publishing assessments in more widely disseminated channels like newspaper articles.

What is Your Selfie Worth? A Field Study on Individuals' Valuation of Personal Data

Nora Wessels[1], Amina Wagner[1], Jayesh Prakash Sarswat[1,2], and Peter Buxmann[1]

Abstract. Referred to as the new oil, undoubtedly personal data is a valuable resource for organizations. Contrary, it is still blurred, to what extent individuals value their data even though, in a digitized world, users are requested to exchange their data for adequate services. Former research on individuals' valuation of personal data result in scattered, partly contradictious values, depending on the data type, context, and the measurement method. In this study, we aimed to facilitate the valuation for individuals by applying a new and promising measurement methodology: the participants of our field experiment had the chance to sell their selfies in a name-your-own-price auction with repeated bidding and feedback loops. As a result, 39% of our participants were willing to donate or sell their selfies with a median of 5€. Additionally, bidding clusters were identified. Implications for research on the valuation of personal data in terms of privacy are discussed.

Keywords: Value of Personal Data, Privacy, Willingness-to-Sell, Willingness-to-Accept, Name-Your-Own-Price Auction

1 Introduction

There is no question that we live in a period of time where personal information as a resource is becoming increasingly important. Discussions about personal data as the new oil, gold, or fuel are ubiquitous [1, 2] and the successes of data-driven companies like Google outcompetes traditional business models [3]. Notably, five of the top six companies according to their market value in the world are data-driven companies [4, 5]. Thus, personal information is a valuable asset for organizations and they already compete for profiting from it [6].

In contrast, taking the perspective of individuals, the benefits they get from releasing personal data is blurred as they typically do not receive a monetary compensation. Obviously, users benefit from using online services based on personal data, but still privacy concerns about the disclosure of personal information have increased, inherited with the feeling of being unfairly treated [7-9]. Indeed, a study in the Netherlands shows that individuals perceive that they are not getting enough value for their data, as 89% state that the industry benefits the most from data economy [10]. Thus, individuals seem to become more aware of the fact that their data is valuable, at least at an abstract level.

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

However, to assess the current data handling processes and regulation approaches, individuals need to know the value of their data more precisely in order to be able to compare the costs of potential privacy losses in terms of data disclosure with the benefits of data usage [11]. In an attempt to investigate individuals' valuation of personal data, recent research measured either users' willingness-to-pay (WTP) for an enhanced privacy level or their willingness-to-sell (WTS) personal information [e.g., 12, 13, 14]. Yet, resulting valuations are scattered between studies depending on the type of data, the context in which the studies are conducted, and the research methodology [15]. So, it seems that individuals' valuation of personal data is not trivial.

Although personal data is reminiscent of traditional valuable resources, it is unlike these previous resources because of its infinity and the fact that it does not consume itself [16]. Further, personal data cannot be compared with ordinary goods for which individuals can set up a price more easily, as data can be sensitive and may make the disclosing person identifiable [17]. This makes it even more complicated for individuals to put a price tag on it. Therefore, research in the field of valuation of personal data requires carefully selected study designs and in turn measurement methods that can handle individuals' potentially vague awareness of the valuation of personal data due to its specificity and minor experience of its monetarization. In this vein, we have conducted a study to measure individuals' valuation of personal data with a new and promising methodology, which is already applied in other contexts for the pricing of 'opaque' goods [18]: a name-your-own-price (NYOP) auction. This methodology can identify the bidders' unique, lowest price for personal data separately for every individual, as it does not require synchronous bids [18-20]. Further, NYOP auctions can be implemented with a repeated bidding option that give individuals the chance to receive feedback if the bids are too high in order to state re-considered bids. This can facilitate individuals' establishment of the price, using the feedback as a source of information and as a trigger to reveal the lowest price [21, 22].

By strengthening the external validity of measuring individuals' value of personal information with a new methodology, we are aiming to answer the following research question: *What monetary value do users assign to their personal information, when being able to state several values after receiving feedback in a name-your-own-price auction with repeated bidding?*

In order to investigate this, we conducted a field experiment where participants could sell personal information in form of selfies in a name-your-own-price (NYOP) auction. We included a repeated bidding option, to make participants feel more comfortable with the situation as they could bid again after receiving feedback about the valuation and thus, can use the haggling process to overcome a lack of information due to low experience with monetized personal data [22]. Indeed, the results indicate that participants used their chances to bid several times, leading to a median final selling price of 5€. Analysis of the provided bids further show different clusters of bidders, indicating that the valuation of personal data is still very individual.

The paper is structured as follows: First, we summarize the theoretical background regarding the valuation of personal information in terms of privacy. In the subsequent chapter, the field study is presented with its methodology and results, before we close the paper with the implications, limitations, and future research directions.

2 Valuation of Personal Information

With the rise of data-driven business models, research and practice are concerned about the valuation of personal data from an individual perspective. Specifically, they are interested in individuals' valuation of privacy in order to understand their data disclosure decisions. In these attempts, scholars were either investigating individuals' willingness-to-sell (WTS) data [e.g., 23, 24] or their willingness-to-pay (WTP) for protecting their personal data [e.g., 12, 25] in order to measure the monetary value of data. However, former research studies are scattered and discordant [15]. Table 1 gives an overview of former studies investigating individuals' valuation of personal data along with their results, type of data under investigation as well as the applied measurement method.

Table 1. Overview of prior valuation of personal data studies
(foreign currencies are translated into € based on the exchange rate in November 2018)

Reference	WTS/ WTP	Type of Data	Research Method	Results (median or mean)
Danezis et al. (2005)	WTS	Location data	Vickrey Auction	11.42€ for research & 22.85€ for commercial purposes (median)
Cvrcek et al. (2006)	WTS	Location data	Vickrey Auction	43€ (median) for research & two-fold for commercial purpose
Brush et al. (2009)	WTS	Location data	Vickrey Auction	88.71€ for academic and commercial purposes (median)
Barak et al. (2012)	WTS	Location data	Close-ended questions	8€ (median)
Benndorf & Normann (2014)	WTS	Contact details & preferences on social networking sites (SNS)	Becker-DeGroot-Marschak method (BDM) & close-ended questions	**BDM** (mean): 8.32€ for preferences 14.88€ for contact details **Close-ended questions:** 24/24 accepted 5€ for preferences 35/42 accepted 5€ for contact details
Huberman et al. (2005)	WTS	Weight & age	Vickrey Auction	Age: 51.22€ (mean) Weight: 65.90€ (mean)
Grossklags & Acquisti (2007)	WTS & WTP	Weight	Surveys: close-ended & open-ended questions	**Open-ended Questions:** 12/12 accepted 0.22€ WTS-offers 12/14 accepted 0.89€ WTS-offers 1/7 accepted 0.22€ WTP-offers 1/14 accepted 0.89€ WTP-offers **Close-ended questions:** Min. WTS: 28.30€ (mean) Max. WTP: 0.71€ (mean)
Bauer et al. (2012)	WTP	SNS	BDM	0€ (mean)

Table 1. (continued) Overview of prior valuation of personal data studies

Reference	WTS/ WTP	Type of Data	Research Method	Results (median or mean)
Spiekermann & Korunovska (2017)	WTP & WTS	SNS	Contingent valuation method (CVM)	**WTP:** No market awareness: 0€ (median) Market awareness: 5€ (median) **WTS:** 49% WTS=0€ 23% 0€ < WTS < 4006€ 28% WTS > 4006€
Krasnova et al. (2009)	WTP	SNS	Conjoint Analysis	Between 14.14€ and 17.24€ a year
Schreiner & Hess (2015)	WTP	SNS	BDM	0.63€ (mean)

As shown in Table 1, the valuations for location data for instance vary between 11€ to 88€ even for the same measurement method of a reverse Vickrey auction due to different samples and variations in the study design [13, 26, 27]. By applying a survey with close-ended questions, Barak et al. identified a valuation of only 8€ [24] enlarging the range of results for location data even further. Supplementary, Benndorf & Normann found evidence that the measurement method can have a remarkable impact on the valuation, as the results for selling SNS details vary up to 10€ between Becker–DeGroot–Marschak mechanism (BDM) and close-ended questions for the same sample [28]. Similarly, Grossklags and Acquisti, ascertain that individuals requested a minimum price of 28€ for selling their weight information when being asked openly, while in the same study, individuals also accepted offers for even 0.22€ [14]. To spread the results even more, weight information was sold for a minimum WTS of 65€ in an auction study by Huberman et al. [23].

Grossklags and Acquisti also investigated individuals' willingness-to-pay for protecting their weight information and found a valuation of 0.71€ conforming a general gap between WTS and WTP [14]. The tendency that individuals demand more money for an object compared to the amount of money they are willing to pay for it, is widely known in research [29] and seems to hold for personal data as well [14]. Indeed, most WTP-studies report rather low values, however, also with variations within the prices. While Bauer et al. and Spiekermann & Korunovska for example found that individuals are not willing to pay a single Euro for their SNS details, the median increased to 5€ when data will be traded [6, 30]. Other studies, like the conjoint analysis by Krasnova et al. show that a user would be ready to pay 14€-17€ per year if no demographic information is used for personalized advertising, while Schreiner & Hess' BDM-participants reported to be willing to pay only 0.63€ for privacy control features within a Facebook premium version [12, 25].

To sum up, investigations on the valuation of personal information from an individual perspective is context-specific and depending on a variety of factors like the measurement method. The high discrepancies of individuals' valuation limit its implications for decision makers and theory. However, it also demonstrates that individuals have difficulties in assessing a stable and confident monetary value associated with personal information. This was also clearly confirmed by Brush et al. who reported that several of their participants found it challenging to value data and some even tried to ask for hints about what other participants had bid [27]. In our study we address the difficulties in assessing a value of personal information by relying on a novel measurement method. We chose a NYOP auction, because it facilitates individuals' valuation as they receive feedback. Further, it is not subject to a hypothetical bias as individuals were incentivized. In order to be transparent and unambiguous, we clearly explained how the data will be used and by which party.

3 Experimental Study

3.1 Methodology of the Experimental Study

In order to investigate individuals' valuation of personal data in an auspicious new way, we conducted a field experiment using a name-your-own-price auction with repeated bidding options where individuals could sell their selfies. In the following we will describe the experimental setting, the NYOP mechanism, and the study realization.

Experimental Setting. Following the call by Dinev et al. for more realistic study scenarios capturing actual behavior, we were aiming to provide an experimental design for our willingness-to-sell study, where participants perceive the disclosure of personal information as a natural and comprehensive task that leads to an actual sale [31]. As our natural environment is the university, it seems appropriate to develop a scenario that fits into this environment. Thus, students were the target group. We developed a fictional campaign, that our chair is looking for the "faces of our university" to advertise our institution among interested pupils and potential new students. Therefore, the alleged aim of this campaign was to collect selfies of students for marketing purposes in order to promote the university in an authentic and sympathetic way with the slogan "from students for students". For the purpose of this campaign, we implemented a website containing a detailed description of the presented purpose as well as the NYOP auction, with which the students could allegedly sell their selfies to us. We decided to focus on selfies as personal information, as selfies always depict the subjects' faces which turns a picture into personal information compared to ordinary photos. Furthermore, selfies are fashionable and omnipresent and thus, assures familiarity of young students and reduces the risk of misunderstanding [32].

Name-Your-Own-Price (NYOP) Auction with Repeated Bidding. This type of auction is based on an interactive pricing process between buyer and seller, in which both parties are actively involved in finding the price [33, 34]. It is referred to as a haggling process where no average or market price is disclosed [18, 35]. Traditionally, NYOP auctions are initiated by the product sellers to investigate buyers' willingness-to-pay without disclosing the lowest price [e.g., 35]. However, likewise studies building on other auctions [e.g., 13, 23, 26], NYOP auctions are also applicable to investigate individuals' willingness-to-sell. In doing so, the buyer sets a maximum price (also referred to as the treshold) at which he or she is willing to buy the good, but does not provide any information about it [19, 36]. The potential seller can then initate the first offer and if it meets or undershots the threshold, the sale is made in the amount of the value offered by the seller [19, 37]. However, if the bid is above the limit, it is rejected, but the seller has again the chance to repeat his or her bidding [18].

We opted for a NYOP auction for the following reasons: First, it is applicable for 'opaque' goods where the price is non-transparent [18]. Second, NYOP is used to elicit the lowest price of the bidder and thus, reflects individuals' actual willingness-to-sell transferrable to real-life situations [18]. Besides, in contrast to a "one price for all" strategy, it identifies individuals' unique selling price [19]. Fourth, depending on the design adjustments of the auction, the initiator of the auction can allow several bids in chronological order until the threshold is undershot (repeated bidding) [38]. Thus, individuals receive feedback if the bids are too high, which can serve as valuable information within the haggling process [22, 39], and therefore makes the method appropriate for individuals' vague awareness of the valuation of personal information. Indeed, former research has shown, that individuals' loose statement of a price without any reference information is associated with cognitive effort and therefore they prefer an alternative in which they can select a price or receive information about the valuation, for example by given reference price ranges [35]. However, this would go along with an impeding of the accuracy of the valuation [35] and a biasing in the direction of the external provided reference information [40]. In contrast, the feedback provided by a NYOP auction with repeated bidding option gives individuals something to go on in a subtler way without anchoring them too much as no initial value which then needs to be adjusted [41] is given. A fifth reason is that compared to reverse Vickrey auction often applied in studies investigating individuals' valuation of personal data [e.g., 23, 42], NYOP auctions do not only award one bidder [37]. So not only one participant has the chance to sell his or her personal information, but all who bid accordingly. Indeed, with NYOP there is no need to receive the bids at the same time, as asynchronously arriving bids can be accepted or rejected immediately if the threshold is set before [20].

Due to the design decision on repeated bids, we had to fix the threshold at a low value, because a higher value would have entailed the risk of losing information about a low willingness-to-sell. Thus, we decided to set the threshold to 1€.

We further decided to limit the amount of bids to three, as previous studies on the design of NYOP auctions are based on the assumption that sellers include frictional costs in their choice of bids [38]. Frictional costs are referred to mental efforts for navigating through the website, typing in the selected bids, as well as occuring from the waiting time until the bid is accepted or rejected [38, 39]. In order to prevent these frictional costs from taking on too much importance, we limited the number of bids to three. This also has the advantage of better comparability of the results of all participants in our study. Figure 1 summarizes the mechanism of our NYOP auction.

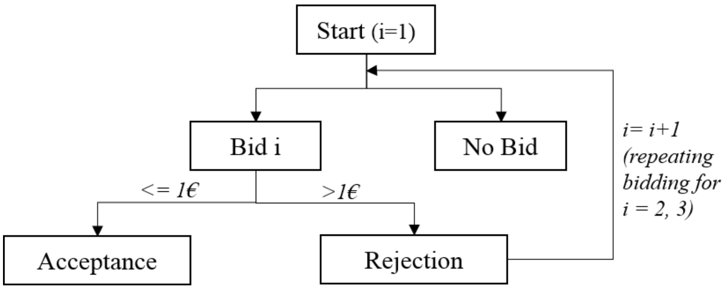

Figure 1. NYOP mechanism of our field experiment, adapted from [38]

Study Realization. We implemented a website for our NYOP auction. When entering the website, the participants were informed about our proposal of buying selfies for the chair's campaign, but we did not provide any price information. In addition to the NYOP mechanism, participants also had the opportunity to donate their selfies for the same presented purpose. This was even possible after making an offer. To meet the challenge that interested sellers might not have an appropriate selfie ready, we provided the chance to bid immediately, but upload the selfie later. However, we clearly stated that the money will only be paid off when the selfie is uploaded. For this purpose, we provided a separate link.

In order to distribute the website to students in our university, the field experiments' website was integrated into a cover online survey. Thus, the participants did not know the real intention of the study. For our cover study, we decided to emphasize on advertisement as a topic as it is omnipresent and therefore interesting for students. To provide students with an additional incentive to participate in the survey, they received 3€ in cash for responding to the online cover survey. The cover study consisted of different parts: After an introductory page providing all GDPR-relevant information, age and gender demographics were collected. Subsequently, different scales investigating participants' perception of advertising were presented. After finishing the cover study, we informed the participants about our current campaign where we are looking for the 'faces of our university' and that they have the chance to gain additional money by participating. By clicking on the next-button, all participants of the former cover study were forwarded to our NYOP website where a detailed description of the auction was given and interested participants could directly type in their bids or donate their selfies as presented above. The participants who were not interested in bidding or donating a selfie at all, were able to return to the initial cover survey by clicking on a "no interest"-button where we informed about the real purpose of the fictive campaign.

We advertised the cover study by distributing flyers on the campus and by setting up a post on our chairs' Facebook profile. From the 186 responses, we had to remove 15 due to bad data quality (incomplete or invalid data), leading to 171 complete data sets. The final sample consisted of 44 females (26%), 125 males (73%), and two unspecified genders (1%). The male quota is representing the gender distribution of our technology-focused university. With a share of 75%, the majority of the participants were between 18 and 25 years as expected due to our targeting on students. Further, 22% of the participants were between 26 and 35, 2% were between 36 and 45, and 1% was older than 46 years. From the 171 participants, 67 individuals bid or donated, while the other 104 directly returned to the cover survey.

To analyze the data and present the distribution of the bids, we followed former studies on valuation of personal data applying reverse Vickrey auctions [11, 13, 43]. Additionally, we conducted a Wilcoxon signed-rank test and cluster analyses.

3.2 Results of the Experimental Study

The results of our field experiment are presented in the following sections, divided into insights about participants' willingness-to-sell selfies for the advertised campaign and their willingness-to-donate selfies.

Willingness-to-Sell Selfies. In total, 54 participants of our study (32%) bid. The bidders were on average 23.76 years old (SD = 3.77) and consisted of 20% women, 78% men, and 2% unspecified genders. While 40 participants made full use of the possibility to bid three times, seven individuals provided only two offers, and other seven stated just one value. Following the assumption that the last bid provided in a NYOP auction bid series represents the participant's actual willingness-to-sell, the final bid is of most interest. We further assume, that those who bid two values, have already reached their lowest, unique willingness-to-sell within the second offered value, thus, this is their last bid. Analogous, those who eventually provided only one value seem to have such a clear valuation in mind that they only want to express their lowest, unique value in one bid. Thus, we have allocated all of these bids under *final bids*. The mean of these final bids is 29.24€, with bids ranging from 997€ to 1 Cent. The median of these final bids is 5€. The big difference between mean and median and the relatively high standard deviation of 135.24 indicates that there are some very high valuations shifting the mean, which will be analyzed later on. In total, the threshold of 1€ was met or undershot 14 times leading to successful "sales" of selfies. Table 2 summarizes the statistics of the final bids together with the first and second bid.

Table 2. Statistics of the starting bids, second bids, and final bids (in €)

	First / Starting bid	Second bid	Third / Final bid
Mean (SD)	93.28 (221.91)	50.95 (154.93)	29.24 (135.24)
Median	25	10	5
N	40	47	54
[Max; Min]	[999.99; 2]	[998; 1.1]	[997;0.01]

Looking at the first and second bids, it is striking that the participants successively decreased the values of each bid. For analyzing the differences between the three bids, we conducted pairwise Wilcoxon signed-rank tests as our data was not normally distributed. This test is equivalent to a one-sample t-test conducted at signed ranks substituting the differences and is used for comparing the equality of medians of two samples [44, 45]. We compared the first bids with the second and the final bids as well as the second bids with the final bids. Since we were interested in differences between two bids, we had to exclude seven values from the test which only provided one bid. The participants who provided two bids are analyzed within the comparison of the second and final bids. The test statistics summarized in Table 3 show that all bids are significantly different from each other with a large effect size (r) based on Cohen's indexes [46, 47]. Based on the medians reported in Table 2, the first bids' median is 25€, while the second bid decreases by 40% leading to a median of 10€. The decrease from the second to the final bid is even higher with 50%.

Table 3. Wilcoxon signed-rank test statistics

	z	p-value	N	r
First bid – Second bid	-5.514	.000	40	.87
Second bid – Final bid	-5.912	.000	47	.86
First bid – Final bid	-5.513	.000	40	.87

We further investigated the distribution of the bid series in more detail. As some of the bid series were appreciably higher than others, we conducted hierarchical cluster analyses (with median clustering, single linkage, and ward methods) for testing whether there are different bidder groups [48, 49]. For these analyses we imputed the missing values in the bid series where only one or two values were named by filling the absent bids with their only stated (or in the case where only one bid is missing with the second stated) bid. This is again in line with our assumption that the participants specified their valuation within their *final bid* which was for seven participants the only stated value.

Surprisingly, the analyses revealed no clear clustering as the very high values were so scattered that it would lead to clusters with very few values. In a second step, we excluded the nine very high values from further analyses that were identified by the single linkage cluster analysis in addition to a z-based outlier-analysis. However, these bidders should not be seen as outliers in a traditional sense, as these are no measurement errors, but show the respondents' extraordinary high value proposition of personal data in terms of privacy. These might be therefore seen as a group of *privacy protectors*.

A re-iteration of the cluster analyses could identify three different clusters. Figure 2 depicts the scatterplot of these bid series as well as the allocation of them to the clusters.

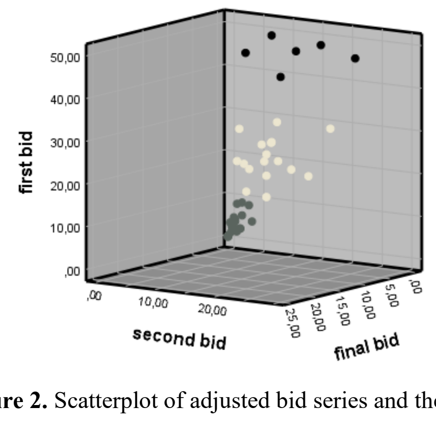

Figure 2. Scatterplot of adjusted bid series and their clusters

The first cluster, colored in black (Figure 2) is characterized by the fact that all bidders start with 50€ as first bids. The second bid is around 20€ and the final one about 10€ as depicted in Table 4. We call this cluster *striding out bidders* as the steps between the bids are with absolute decreases of 30€ and 10€ wider compared to those from the subsequent clusters. While the bidders in the white cluster show a similar final bid as the black cluster, their starting bid was only 25€ in median. Hence, their absolute steps between the bids were smaller compared with the former cluster. Thus, we name them *moderate bidders*. Finally, the bidders allocated to the grey cluster bid relatively low in all three bids. The median of the final bid in this *low bidders'* cluster meets our threshold of 1€.

Table 4. Statistics of the hierarchical cluster analysis (ward method) in €

Cluster (n)		First bid	Second bid	Final bid
Black (n=6)	**Mean**	50	20.83	11.20
Striding out bidders	**Median**	50	20	10
White (n=17)	**Mean**	24.16	15.41	10.01
Moderate bidders	**Median**	25	15	10
Grey (n=22)	**Mean**	4.36	2.91	1.84
Low bidders	**Median**	4.25	2	1

Table 5 summarizes the demographics of the three bidder groups identified by the clusters analyses as well as the *privacy protectors*. However, an ANOVA test could not identify significant statistical differences between the groups with regard to age or gender of the participants.

Table 5. Demographics of the bidder groups

Bidder group	Mean age (in years)	Women	Men	Others
Privacy protectors	25.44 (SD = 4.79)	11.11%	77.78%	11.11%
Striding out bidders	21.17 (SD = 1.34)	16.67%	83.33%	0%
Moderate bidders	23.71 (SD = 3.59)	17.65%	82.35%	0%
Low bidders	23.82 (SD = 3.46)	27.27%	72.73%	0%

Willingness-to-Donate Selfies. Additionally, participants had the chance to donate their selfies for the stated purpose. In total, 13 participants chose this option. From these, 38% were female, 62% male. The average age was 24.69 years (SD = 3.07). Three of these donators started to bid values in advance: One person bid 15€ before deciding to donate, another individual tried a 3€-bid first, and the third person bid 3€ and even 1€ so that the offer would be accepted if not donated. All results are discussed and implications are provided in the following.

4 Discussion

Within this study, we investigated individuals' valuation of personal data by conducting a NYOP auction with repeated bidding and feedback loops. In the following the implications as well as limitations and future research suggestions are discussed and a conclusion is given.

4.1 Implications of the Study

Our study adds to research in several ways. First, our main *theoretical contribution* is the investigation of the value individuals assign to their personal information in a realistic, highly accessible, and comprehensive fashion. In this vein, we relied on a new and promising method, a NYOP auction with repeated bidding revealing individuals' lowest, unique selling price [18, 19]. Due to the opportunity to bid several times after receiving feedback, individuals feel more comfortable by stating their valuation as they can use the haggling process as a source of information [22] and re-think their valuation with each bid. However, bidders are not anchored as no initial price as a starting point is presented [41]. In contrast to other auctions, sellers in NYOP auctions with a repeated bidding option can strategically start with a higher, internal generated value and then sequentially approach their own lowest bid based on feedback [39], revealing individuals' actual WTS.

Further analyses reveal subsequent implications. Thereby, it is striking that except for seven participants stating one value, most of the bidders took the chance to bid twice or three times. The three bids were significantly different from each other, decreasing by 40% from the first to the second and 50% from the second to the final bid. Looking deeper into the distribution of the bid series itself, we can observe some scattered, high bid series, referred to as the group of *privacy protectors* and three clusters of bidders with similar valuations. We could see very low bids of 1€ in median within the *low bidders'* cluster. These make up 41% of the bid series. Another two groups of bid series, the *moderate bidders* (31% of the bidders) and the *striding out bidders* (11%), end up both at a final bid of about 10€ in median, but differentiate by their bidding strategies: While the bid series in the first cluster start with a higher bid of 50€, the bid series in the second cluster are more temperate, starting with 25€ in median.

Lastly, the results show that 39% of the participants were willing to sell or donate a selfie. The 13 donations indicate that these participants seem to believe in the good cause of our campaign and a monetary compensation is not required. We further hypothesize that the three individuals that first bid and then decided to donate, perceived the threshold as "not worth" and then rather wanted to support the campaign by a donation.

Beyond that, we show that our study participants would sell their selfie for 5€ in median. This monetary value seems convincing as current photo-selling platforms offer about 5€ to their users for one picture. For example, *Candidly Images* and *Foap* provide marketplaces where normal hobby photographers can sell their photos to interested parties [50, 51]. The photos are sold for around 10$ whereby the seller receives 5$

(about 4.39 € based on exchange rate in August 2018) as a reward. Thus, it is indeed a price where demand and offer come about.

To conclude, we found participants' willingness-to-sell personal data in this field study to be realistic, but due to the scattered high values and the three different clusters, still to be very individual as well. This implies that valuation of personal information in terms of privacy is very sensitive, context-specific, and individual. As a result, it is not generalizable across humans.

Beyond theoretical implications, our research also provides *practical contributions.* Not only since the German Chancellor Angela Merkel proposed to tax the sale of personal data, the investigation of individuals' valuation of personal data is becoming an important issue [52]. Already in 2014 Jentzsch indicated that a truthful valuation of personal data is an important matter in this time, as an increasing number of online platforms allow the sale of personal data to companies [42]. Indeed, more and more platforms appear (e.g., Datacoup, Data Fairplay, Datum) on which users can actively sell their personal data they are willing to disclose to interested companies and are therefore monetary compensated [53]. In this vein, our research contributes to practice by providing a mechanism that fosters the measurement of individuals' unique, lowest valuation of personal data which can also help providers of data-selling platforms to evaluate their prices and assess their business chances.

Secondly, when individuals use social networking sites (SNS) like Facebook or Instagram, they are agreeing to the term that the provider receives the license to use all shared images [54, 55]. Thus, individuals are using an apparent free service but they are paying with their personal information in terms of their photos and user behavior in general. In this vein, one could argue that SNS users do not value their photos as they give it up for free. However, our results provide evidence that Internet users indeed value their photos beyond free services in return.

4.2 Conclusion, Limitations, and Future Research Suggestions

Personal information has its value for organizations and users, at least at an abstract level. Whereby organizations trade personal information like an asset, individuals take a rather passive role in this process. In order to be able to assess current data handling approaches, individuals are requested to assign a value to their personal data. However, former research investigating users' valuation of personal data is scattered. Against this background, we conducted an experimental study with a NYOP auction allowing repeated bids and therefore feedback loops aiming to facilitate the valuation. In total, 39% of our participants were willing to sell or donate their selfies to the university for advertising purposes with a median price of 5€. The applied method can reveal individuals' actual, lowest, and unique valuation and can therefore help Internet users to pave the way from a 'passive spectator' to an 'active beneficiary'.

However, our study comes not without limitations. First, the sample of our experimental study consisted of more male than female participants due to the gender distribution of our technology-focused university. Although we saw in the data a tendency that women were more willing-to-donate, this tendency was not significant. Further, we relied on a German sample which could limit the generalizability of our study results for other cultures. Thus, we call for a deeper investigation of gender differences with a more balanced, international sample.

Further, as shown by the literature review, studies on the valuation of personal information are very context sensitive, meaning that the willingness-to-sell personal information and the actual requested value depends strongly on the circumstances under which the study was conducted [15]. Thus, we were aiming to optimize these circumstances by stating in an easy understandable manner who is buying, what data, for which purpose. Further, in our scenario, there were no complex partner structures involved, as the university was the only buying party which seems applicable as several willingness-to-sell studies were already successfully providing an experimental setup in the university environment [e.g., 13, 24, 26]. However, it might be interesting to conduct a NYOP auction with a repeated bidding option in another context in order to improve the transferability of our results.

Abstract. Online mass surveillance by governmental organizations is omnipresent. Even though this results in a loss of privacy and further negative outcomes for individuals, a majority is justifying mass surveillance. Understanding, why this is the case is among others important for individuals, who want to decrease justification of mass surveillance. Therefore, this study aims to uncover the factors that drive this justification. Drawing on system justification theory we consider mass surveillance to be a political arrangement. Five factors were identified that potentially drive individuals' justification of mass surveillance which are among others, perceived privacy control or perceived security. A quantitative study was carried out and the results support most of our hypotheses. With our results, we contribute to the privacy-related area in the domain of IS, by indicating that individuals consider mass surveillance not necessarily to be bad and by giving advice on how to alter the level of justification.

Keywords: mass surveillance, system justification theory, privacy, nothing to hide, justification

1 Introduction

Governmental organizations have created a system of online mass surveillance. That means, these organizations analyze a vast size of information sent over the Internet without suspicion [1]. The result of this mass surveillance is that a majority of individuals thinks they are having almost no privacy anymore [2]. This reduced privacy results in disadvantages such as profiling, manipulation [3] or chilling effects [4]. For example, among others, individuals do not search online for certain issues such as 'terrorism' anymore because they are afraid becoming a target of governmental organizations [4]. To protect one's own privacy, one might thus assume that individuals reject mass surveillance e.g. by protesting against it.

However, although individuals rate their privacy as very important [2], surveys indicate that more individuals are justifying, i.e. defending and warranting, mass

14th International Conference on Wirtschaftsinformatik,
February 24-27, 2019, Siegen, Germany

surveillance rather than rejecting it [5, 6], e.g. by protesting against it [7]. What is good for governmental organizations, who have an interest to keep mass surveillance [8], is bad for individuals' privacy [9].

Therefore, both parties – individuals and governmental organizations – need to understand what factors drive individuals' justification of mass surveillance. Then both might have the chance to either change these factors to change the level of justification or to keep these factors to keep the level of justification. Either way, for both parties it is necessary to understand:

What factors drive individuals to justify mass surveillance?

To answer the research question we rely on the one hand on previous research on mass surveillance [6, 10–13]. There, perceived security has been suggested as one of the main factors determining justification of mass surveillance [10, 11, 13]. Yet, this factor has only been suggested and has not been supported scientifically. On the other hand, mass surveillance is a method that is used to monitor a population of individuals, approved and ordered by governmental organizations [14]. Although also companies from the private sector can use mass surveillance technologies, we focus on mass surveillance being a political arrangement as an ordinance by the government. To find out why individuals justify mass surveillance, typical theories from information system (IS) research in the privacy domain cannot be applied [15]. This is because these theories usually focus on an actual IS. In this study, it is more about mass surveillance as a political arrangement. That is why in this research study we refer to system justification theory (SJT) [16–18].

Thus, in the following, we will provide information on SJT as well as mass surveillance and discuss both research streams together to understand mass surveillance justification. A quantitative study is then carried out, using workers from Amazon Mechanical Turk (mTurk). Based on the results, we then contribute to theory by providing factors that are important in a mass surveillance context.

2 Theoretical Background

We next provide information on the system justification theory (SJT) [16, 17]. We continue with research on mass surveillance before carving out the research gap.

2.1 System Justification Theory

System justification: The justification of a system means that individuals defend, bolster or warrant a system [18]. A system is defined as existing social, economic, and political institutions and arrangements. It can range from small-scale systems, such as a nuclear family up to an entire nation [19]. System justification is therefore defined as defending, bolstering or warranting existing social, economic, and political institutions and arrangements.

SJT is a theory to explain why individuals justify a system [17]. Thereby, alternatives of the status quo are degraded. Individuals do so because they have social and psychological needs to consider a system as being legitimate and as being good, fair, natural, desirable, and inevitable [16–18]. They also want to reduce anxiety, guilt, dissonance, discomfort and uncertainty [17].

Prior privacy-research in the domain of IS has not been using SJT in their research studies [15]. In other research domains, SJT has been used to explain justification of different systems including political systems [17], financial work systems [18] or economic systems such as meritocracies [20]. Three factors mainly influence system justification: the perceived powerlessness, the perceived need for order and stability and the perceived dangerousness of the world.

Perceived powerlessness: Power refers to having asymmetric control over particular resources [21]. Individuals, who are in a status of power, are able to process information and to make decision, with the goal to maintain the current position in the system. The more powerful an individual is the more she has access to resources to control her own position [21]. Previous research on SJT has especially researched on individuals who are in a status of perceived powerlessness, i.e. on those individuals who do not have control over particular resources because of living in a particular system [18]. SJT thereby indicates that powerless individuals still justify the system and sometimes even more justify it than powerful individuals, although it is the system, that reduces their power. For example, individuals, who are financially deprived by the current system nevertheless believe in meritocracies [20].

Perceived need for order and stability*:* Individuals, who have a perceived need for order and stability, have the perception that the environment they live in should be orderly, well-structured and unambiguous. If decisions are made they have a desire to stick with these decisions [17].

Perceived dangerousness of the world: Individuals, who think that they live in a dangerous world, have the perception that life is fiercely competitive and ultimately believe that others are constantly threatening to harm them [22]. These individuals have a heightened sensitivity to potential dangers in the social environment, including threats of violence, and terrorism, and have permanent concerns about being in danger [17].

To theorize the relation between system justification theory and mass surveillance, we provide detailed information on mass surveillance in the following section.

2.2 Related Work on Mass Surveillance and Research Gaps

Mass surveillance is generally defined as any method, that collects information of a population, without any attempts to limit the surveillance to a particular individual, but rather to monitor an entire group of individuals [14]. Mass surveillance in an online context has become a major topic in society[1], through revelations proving evidence on how the National Security Agency (NSA) of the USA conduct mass surveillance. Yet, also governmental organizations of other countries conduct mass surveillance on individuals worldwide. It is known that governmental organizations worldwide,

[1] Several EU projects have been conducted to better understand the issue of mass surveillance (please see http://www.projectpact.eu/; http://surprise-project.eu/ and https://cordis.europa.eu/project/rcn/102282_de.html).

essentially store and examine a vast amount of information, which is sent over the Internet, without suspicion [1].

Mass surveillance thereby violates individuals' privacy, whereas privacy is a multi-facet concept [23]. However, in IS research, privacy is usually defined as the amount of control an individual has over her personal information [24], expressed by privacy control [25]. Since mass surveillance takes place by examining information, individuals have often lost control over their information, and thus also over their privacy.

Through mass surveillance, individuals suffer from several disadvantages. For example, individuals search less for delicate issues such as 'terrorists' on the Internet because they are afraid of becoming a target of governmental organizations [4]. Also, discrimination, profiling or manipulation can occur through mass surveillance [3]. Still, it is indicated that more individuals justify mass surveillance rather than oppose it [5], e.g. by protesting against it.

To find out, in how far previous literature has been researching on the topic of mass surveillance justification, we conducted a literature review[2], and identified several articles [6, 10–13, 26–29]. The studies cover topics such as coping with mass surveillance or factors leading to the disapproval of mass surveillance. Still, although covering different issues, all articles commonly suggest two factors that need to be considered when researching on mass surveillance:

Perceived security: Several studies have indicated that increased security in everyday life through mass surveillance might be an important factor why individuals justify mass surveillance. Thereby, it is about the perception of individuals that security is enhanced through mass surveillance [10, 11, 13, 28, 29]. This is in line with governmental organizations which state that through mass surveillance, objective security, such as less terrorist activities, is increased [8].

Nothing to hide: Several studies introduce the concept of 'I have nothing to hide'. This refers to individuals, who state that they have no problem with governmental organizations examining their information, because they think have no information to conceal [10, 11, 27]. Rather they think that only criminals would have something to hide, which would then justify it to spy on it [10].

Research gap: In sum, scholars have already researched on individuals' attitude towards mass surveillance and have therefore strengthened our understanding on this topic. They have particularly indicated that perceived security and the concept of 'nothing to hide' could be important factors in the context of mass surveillance [10, 11, 13, 28, 29]. However, there is scarcity on how these or other factors of the SJT lead to the justification of mass surveillance. We therefore theorize on justification of mass surveillance based on the SJT and the mentioned research on mass surveillance.

3 Theorizing on Justification of Mass Surveillance

In this research study, we use SJT to find out what determines an individual to justify mass surveillance. However, when using a rather general theory in a more particular

[2] The literature review covered the AIS basket of eight, ICIS, HICSS, ECIS and WI proceedings, alongside with a general search on Google Scholar.

context, it is usually inevitable to adapt the theory to the particular context [30]. Therefore, when using SJT to explain mass surveillance, we will on the one hand adapt the existing concepts when necessary. On the other hand, we will add two concepts that are suggested by previous literature on mass surveillance [6, 10–13, 26–29] to better explain the dependent variable.

Thereby, we consider mass surveillance to be a system in the sense of the SJT. That means we consider mass surveillance as an existing political arrangement. Individuals, using the Internet, live in the system of mass surveillance, because through mass surveillance as a political arrangement, they are monitored while using the Internet. Therefore, in light of SJT, justification of a system refers to **justification of mass surveillance**. Based on previous research on SJT and mass surveillance, we define it as the motivation of individuals to defend, bolster or warrant existing political arrangements, allowing mass surveillance, conducted by governmental organizations such as intelligence agencies [16, 29].

Furthermore, we include powerlessness of individuals, which needs to be adapted to the particular context [30]. For example, an individual who is smart but has no physical strength, is powerful on the resource 'information' but powerless on the resource 'strength'. In this study, we research in the context of mass surveillance and privacy of individuals. Privacy of individuals is defined as having control over ones' own personal information, expressed by privacy control [24, 25]. Mass surveillance – the system in this study – is reducing privacy and thus the amount of control over privacy. In SJT, powerlessness refers to the power individuals have but that is reduced by the system. Therefore, in this study, since mass surveillance reduces the power over one's own privacy, we conceptualize powerlessness as the **perceived loss of privacy control.**

We also include both perceptions **perceived need for order and stability** as well as the **perceived dangerousness of the world**. Both perceptions do not need to be adapted to a particular context as they are independent of the situation [17].

Besides the components of the SJT, previous research on mass surveillance suggests two factors, that need to be considered when conducting research on mass surveillance: On the one hand, many individuals think that mass surveillance increases security [28, 29]. This could have an influence on individuals' justification of mass surveillance [13]. We therefore include the component **perceived security** and define it as the perception of an individual that through the conduction of mass surveillance there will be increased security, e.g. less crime or terrorist activities [28, 29]. On the other hand, the argument of many people that they have **nothing to hide** is also suggested to be an important concept in the context of mass surveillance [10, 11]. We therefore include the concept of nothing to hide, and define it as the perception of an individual that she has no information to conceal in front of governmental organizations [10, 11].

Based on these concepts, we build our research model. The research model also includes **prior disclosure** as a control variable. This concept is defined as the amount of information, individuals have disclosed in the past on the Internet [31]. With this variable, we aim to control for, in how the participants have disclosed information on the Internet at all, to account for in how far mass surveillance is even an issue for them. In case they have not disclosed information on the Internet before, it might influence their justification of mass surveillance. Furthermore, as has also been done by previous privacy research [e.g., 31] we also controlled for gender and age. This is because previous research has shown that gender [32] as well as age [24] are variables which often influence attitudes of individuals in a privacy context. Therefore, it is recommended to generally control for them. Hypotheses for the research model are explicated in the following.

Individuals, who are high on perceived loss of privacy control have the perception that they are not able to govern their own personal information. Mass surveillance is a factor, which decreases privacy control [26, 29], because a vast amount of information is captured, stored and examined by governmental organizations, without the control of the individual [1, 29]. Previous research has shown that individuals, who do not have access to needed resources and who are therefore powerless, paradoxically more justify the system, which causes their powerlessness [18]. Individuals, who are high on perceived loss of privacy control, i.e. who are in a less powerful state, will therefore also more justify mass surveillance, which causes their powerlessness. They do so to better maintain a positive image about their situation even if it is not positive at all [18]. We hypothesize:

H1: Perceived loss of privacy control increases justification of mass surveillance.

Having a high need for order and stability means that these individuals want to maintain their status quo [17]. Mass surveillance is considered to be the system, which represents the current status quo. Individuals do not want mass surveillance to stop, because then the status quo is changed, they might need to adapt, and uncertainty arises [33]. This is because one does not know what would happen after mass surveillance has stopped. For example, less security or publishing the results of mass surveillance, would all change the current status quo. Continuing mass surveillance as it is, would at least maintain the status quo even at the expense of decreased privacy. Hence, individuals who have a high need for order and stability, more justify mass surveillance. This is also aligned with the SJT [17] and previous research, suggesting that the need for social order can result in the justification of mass surveillance [28, 29]. We hypothesize:

H2: Perceived need for order and stability increases justification of mass surveillance.

Individuals, who think that they are living in a dangerous world, do see the world as threatening. They think that through certain events, they are under severe danger causing harm. For example, crime activities or terrorist attacks are those events, which increase the perception of severe danger to those individuals [34]. Individuals, who think that they live in a dangerous world, do have that perception across different situations. However, they welcome practices which would reduce their perception, and which fights against that dangerous world. Mass surveillance is said to fight against the dangerous world [26]. This will make them more likely to justify it, which is also aligned with basic premises of the SJT [17]. We hypothesize:

H3: Perceived dangerousness of the world increases justification of mass surveillance.

If individuals think, that there will be more security through mass surveillance, they will also be more likely to justify mass surveillance. This is because increased security is seen as one of the main benefits out of mass surveillance [13]. For example, it is said that through mass surveillance, crime or terrorist activities are reduced, by identifying subjects and forestalling potential crime or terrorist activities [8]. To gain that benefit, individuals will be more likely to justify mass surveillance, which is also suggested by previous research [10, 11, 13, 28, 29]. We hypothesize:

H4: Perceived security increases justification of mass surveillance.

Individuals, who have something to hide, do not want their information to be read by others, e.g., governmental organizations [10, 11]. Therefore, they value their privacy in terms of that they want to control their information. Mass surveillance is against individuals, who have something to hide, because mass surveillance allows governmental organizations to jeopardize individuals' privacy, and to read their private information [10, 11, 27]. Hence, individuals, who have something to hide, will be less likely to justify mass surveillance. The other way around, individuals, who state they have nothing to hide, will therefore be more likely to justify mass surveillance. They see less disadvantages from mass surveillance, and rather think that as long as they do not do something wrong, governmental organizations should be allowed to examine information sent over the Internet [10]. We hypothesize:

H5: Nothing to hide increases justification of mass surveillance.

To evaluate our research model (see Figure 2) we conducted a quantitative study. The methodology therefor is explained in the following section.

4 Methodology

We aim to research on why individuals justify mass surveillance. To do so we conducted a quantitative survey. The used items are depicted in Table 1. To conduct the survey, we used Amazon Mechanical Turk (MTurk) because it is considered to be equivalent to similar data collection methods [35] and it has also been successfully used in a privacy context [36]. We followed the guidelines of previous research to conduct the survey, e.g., by only letting participants take part which have a very high number of already completed tasks. We told workers of MTurk that the maximum time for completing the task will be 12 minutes. Payment was $0.25 for each worker. 141 participants took party in our survey, whereas only these participants who provided answers to at least 90 percent of the questions were kept. All others were removed. After cleaning the data, we ended up with 135 participants in total. Participants were

30.88 years old on average, with a standard deviation of 9.64 years. 38 female participants and 97 male participants took part in our survey.

Table 1. Items and Loadings

Construct	Item	Loadings
Justification of mass surveillance [13]	Intelligence agencies needs to have access to individual bank accounts.	0.840
	Intelligence agencies need wiretapping authority.	0.923
	Intelligence agencies needs to have authority to use high tech surveillance tools for Internet eavesdropping.	0.909
Perceived loss of privacy control [25]	I do not have control over who can get access to my personal information I provided on the Internet.	0.727
	I do not have control over how personal information is used by other parties on the Internet.	0.991
	I do not have control over my personal information provided on the Internet.	0.816
Need for order and stability [37]	I enjoy having a clear and structured mode of life.	0.868
	I like to have a place for everything and everything in its place.	0.871
	I find that a consistent routine enables me to enjoy life more.	0.789
Perceived dangerousness of the world [34]	Every day as society becomes more lawless and bestial, a person's chances of being robbed, assaulted, and even murdered go up and up.	0.907
	It seems that every year there are fewer and fewer truly respectable people, and more and more persons with no morals at all who threaten everyone else.	0.900
	My knowledge and experience tell me that the social world we live in is basically a dangerous and unpredictable place, in which good, decent, and moral people's values and way of life are threatened and disrupted by bad people.	0.844
Perceived security [38, 39]	Mass surveillance by intelligence agencies is good for protecting our country.	0.918
	When conducting mass surveillance, our country is more likely to be protected.	0.951
	Continuous mass surveillance by intelligence agencies lessens the chances of terrorist attacks.	0.902
Nothing to hide [40] Last item was self-developed	People who obey the law have nothing to fear from mass surveillance.	0.945
	Only criminals have any reason to be afraid of mass surveillance.	0.920
	I do not have anything to hide when it comes to mass surveillance by intelligence agencies.	0.678 (dropped)

For the analysis of the survey, we used SmartPLS 3.2.6. The reason is that we also asked for negative perceptions such as loss of privacy control which can skew results [41]. Details and results are given in the following section.

5 Results

To test our research model, we first accounted for common method bias (CMB) followed by the evaluation of the measurement model and the structural model.

Common method bias: We first conducted the Harman's Single-Factor Test, which indicates that 30.46 percent is explained by one factor which shows no indication of CMB [42]. We also accounted for the Unmeasured Latent Marker Construct techniques. The average R^2 with the CMB factor is 0.0027 higher than without the CMB factor. As the R^2 excluding the CMB factor is 0.79135, the ratio is 1:293. Therefore, CMB seems to be no issue [43].

Measurement model: To account for a valid measurement model, we checked on the following criteria: 1) *Indicator reliability*. The threshold of each indicator should be 0.707 to account for at least 50 percent of the variance of the latent variable [44]. As shown in Table 1, this was the case except for one item of 'Nothing to hide' which was dropped in the further evaluation. 2) *Composite reliability (CR)* and *average variance extracted (AVE)*. CR should be above 0.7 and AVE should be above 0.5 [45] which is both the case as one can see in Table 2. 3) *Discriminant validity*. To make sure that all constructs differ from each other, the square root of AVE needs to be greater than the correlation between the constructs [45, 46]. This is also the case as depicted in Table 2. We also computed the heterotrait-monotrait ratio [HTMT, 47]. When using the most conservative approach $HTMT_{0.85,}$ we see no signs of discriminant validity since the highest value is between perceived security and 'Nothing to hide' with 0.742. As all requirements are fulfilled, we conclude that our measurement model is valid.

Table 2. AVE, CR and bivariate correlations

	Mean	St.d.	AVE	CR	1	2	3	4	5	6	7	8	9
1 Justification of mass surveillance	3.48	1.89	0.794	0.920	**0.891**								
2 Perceived loss of privacy control	4.98	1.63	0.725	0.886	-0.138	**0.852**							
3 Need for order and stability	5.07	1.33	0.712	0.881	0.250	-0.004	**0.844**						
4 Perceived dangerousness of the world	4.19	1.53	0.782	0.915	0.478	-0.060	0.289	**0.884**					
5 Perceived security	4.37	1.73	0.854	0.946	0.728	-0.125	0.099	0.475	**0.924**				
6 Nothing to hide	4.22	2.03	0.908	0.952	0.601	-0.089	0.125	0.450	0.742	**0.953**			
7 Prior disclosure	3.96	1.74	0.790	0.919	0.187	0.096	-0.031	0.248	0.290	0.161	**0.889**		
8 Age	30.88	9.64	n/a	n/a	-0.010	0.122	0.007	0.098	0.119	0.163	-0.099	**n/a**	
9 Gender (1=male, 2 = female)	1.28	0.45	n/a	n/a	0.090	-0.025	0.122	-0.003	0.079	0.026	0.109	0.048	**n/a**

The diagonal bold values represent the square root of the AVE of the corresponding constructs.
n/a cannot be computed because these are single-item constructs

Structural model: To evaluate the structural model, we checked on the variance extracted (R^2) of the dependent variable as well as the significance level of each path coefficient. Please see Figure 1 for an overview.

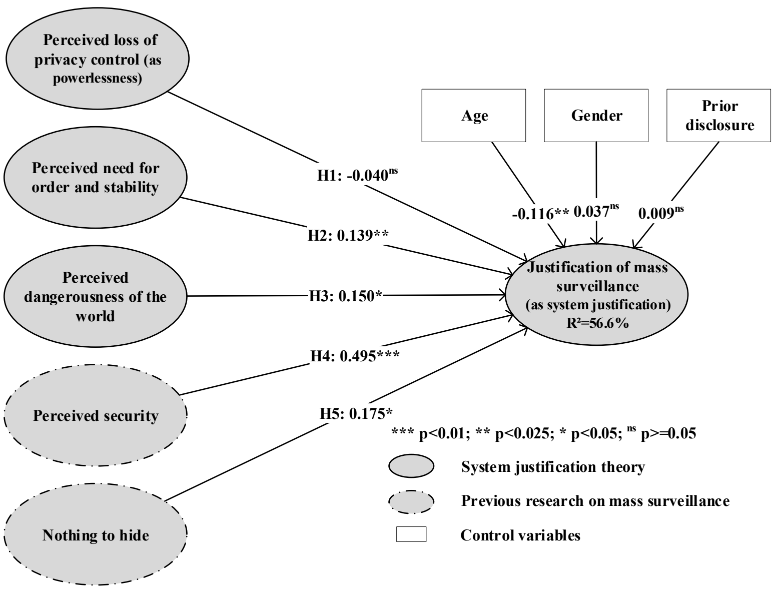

Figure 1. Structural model

The results reveal that 56.6 percent of the variance of justification of mass surveillance is explained. H1 is not supported as the path coefficient is not significant.

Besides, the results support all other remaining hypotheses, i.e. H2, H3, H4 as well as H5. Moreover, the results indicate that gender and prior disclosure as control variables, do not significantly influence justification of mass surveillance. However, age as a control variable has a significant, negative impact. This means that the older the individual, the less likely the justification of mass surveillance.

These results have implications for both, theory and practice, which will be discussed in the following section.

6 Discussion

A majority of individuals is justifying mass surveillance by governmental organizations [5, 6] despite a reduce in one's own privacy [2]. This can lead to further challenges to the individual such as profiling, manipulation [3] or chilling effects [4]. Finding out, why individuals justify mass surveillance, is important for the individuals themselves, in case they want to change their attitude on mass surveillance. Also, for governmental institutions who have an interest in keeping mass surveillance, the results can be important. Scholars have thus already put some research on mass surveillance [10–13]. Yet, research on justification of mass surveillance is rather scarce [15].
